A stronger reading of the concept of creolization, closest to the way the concept is used in linguistics, proposes ways of identifying the cultural logic which provides answers to the following questions: What changes and what does not, and under which conditions? What is the nature and the pace of the change? If culture is practice, how does change affect the practice of identity? If culture is text, is every aspect of culture affected in the same manner and to the same extent? If culture is grammar, are there parameters and constraints for change? What makes the change acceptable? This version of creolization rests on a set of assumptions: (a) that moral–existential aspects of culture can be differentiated from instrumental aspects; (b) that the latter change at a faster pace than the former; (c) that, with regards to the pace of change, they can be compared with the syntax and lexicon of a language respectively. In situations of creolization, local instrumental aspects of culture are often replaced, along with their attending symbols and meanings, with those from another source. The moral–existential aspects of culture are now sustained by new symbols, and may be given slightly different meanings, but will still be perceived as essential to the group's definition of identity. The bridewealth payment mentioned above is essential to the father's standing in one of his networks (here his lineage) and justifies his traveling back to the home village to collect it. All participants in the transaction agree that the meaning of such bridewealth is now very different from what it used to be, and that the amount is inflated. Yet bridewealth has to be paid, even against the wishes of the parish priest, because this form of exchange is essential to the integration of lineages, and therefore to the father's identity as a member of the group. As with any form of social process, creolization rests on people's agency and ability to engage the

world, and is associated with a reconfiguration of self and of the practice of identity. Undoubtedly, there is a distinct advantage in identifying the processes that lead to a redefinition of people's practice of identity, even if, initially, this identification may start with an analysis of the features and elements that are being transferred across cultures, with or without attendant localization.

3. *Essentialism*

Contra critics have argued that creolization theory is essentialist because it presupposes the existence of pristine cultures that will subsequently join, mix, overlap, and be reshaped; proponents of creolization reject this notion, and point to culture as a locus of permanent change, made even more spectacular at particular times in the history of societies. They also point to the shortcomings of a conception of culture as a bounded pristine entity.

If creolization were an essentialist theory, the concept of cultural loss would be integral to its definition. Yet, it is not, for the simple reason that talking about loss in connection with social change implies a move away from the ideal, but unreal, pristine state of tradition. Loss belongs to a theoretical framework in which cultures are seen as essential wholes, neatly bounded self-reproducing structures, impervious to the passage of time and deriving legitimacy from a primal pristine state. Cultures are not less authentic because they are creolizing. The new cultural practices, and the new cultural forms, that have emerged out of the creolization process are not any more authentic or spurious than the ones they are derived from, or more spurious or authentic than societies that have changed in other ways. They simply exist. What is revealed by the creolization concept is the endless negotiation of meaning that takes place when groups and individuals engage in social relations within societies. The pace and scope of these cultural negotiations are more important in situations of rapid social change. The strength of creolization theory is that it points to (or foregrounds) elements that are not easily captured by other models: heterogeneity rather than homogeneity, process rather than stasis, fragmentation rather than integration, multiple rather than singular identities, and above all at the domain of culture as contested ground rather than public space.

4. *The World System and Globalization*

Typically, but not exclusively (see Hannerz 1996) the creolization concept has been applied to the analysis of social change in the so called Third and Fourth World societies, in colonial and postcolonial situations. Colonial, postcolonial and hegemonical contact relations are particular in the type and speed of the sociocultural change they provoke and are best suited to be studied with the paradigm of creolization that holds the speed of change as a defining element. Critics have argued that the quasi-exclusive application of creolization theory to these societies disempowers them and reinforces the *fait accompli* of colonization by strengthening stereotypes. The argument is usually framed in relation to the World System theory and to the concepts of core and periphery. There may be a reason for this affinity: the very sociocultural formations and ideologies that have fostered the development of creole languages have reappeared under a new guise, that of the World System, economic and cultural, which creates even more pressures for change in these societies than anywhere else at the same moment. These types of contact-induced ideological and experiential pressures resemble the superstrate and substrate influences at work in the formation of creole languages in that they juxtapose and confront practices and meanings that are produced by different social systems and ideologies. This raises the question of the relationship of creolization to globalization. Creolization shares with globalization an increase in available modes of social organization and cultural representation (Pieterse 1995), both offer more options. Both are associated with more culture and not less, even if, on the surface, things look different. But with globalization residing in a movement of ideas, as much as in people's engagement with new sets of ideologies and practices, one could identity, as Hannerz does in Stockholm (1996), creolizing formations in nontypical creolization sites.

5. *Urbanization*

It is in cities that creolization is the most obvious, if only because of the rate and scope of change. As cultural market places, cities are the loci of very fast sociocultural mutations that lead some observers to talk of deculturation, and not only of adaptation to an urban way of life. Creolization is neither. When full-fledged towns and cities develop over mere 40 years, as is the case in many parts of the Third World, in places where there is no local tradition of urbanization, for instance, it requires on the part of urbanites a reassessment of the parameters of their identity (as with the father's behavior at the time of his daughter's wedding) and subsequent engagement in new types of social relations of the type and scale that is not found in other forms of sociocultural change. What is typical of cities is the ebullition of cultural creativity. Only a close study of the superstrate and substrate influences could reveal why, despite the onslaught of a generic cultural and economic World System (the superstrate) onto local traditions (the substrate), the cultural formations of urban Nigeria (Hannerz 1987) Solomon Islands (Jourdan 1985), and Guyana (Drummond 1980) are similar in very many ways, and yet very different from

one another. This begs the question of the specificity of creolized societies: are they any different from other types of societies, given the fact that all societies are changing, and that many contemporary non-Third World societies have, at some point in their history, lived in situations of colonization, invasion or hegemony? May be they are, if only because of the speed and the depth of change that characterize them, and give the impression of a permanent flux. The lifespan of creolization is also a subject of debate: is creolization a transitional period in the life of societies, at particular moments of their history, or is it a permanent state of affairs? One has to ask whether anthropology will be better served by using creolization as a universal synonym for fast cultural change associated with globalization, or whether the concept is not more useful when applied to some social contexts of change and not to others.

Crime and Class

Does social class affect criminal behavior? If so, why has the relationship been so difficult to document in self-report crime surveys? If not, why are prisoners drawn almost exclusively from the ranks of the poor? These questions are important for stratification researchers as well as those studying law, criminology, and deviance. Criminologists are interested in class because it is a fundamental indicator of social position. If crime is related to social class, then social structural factors such as inequality, poverty, and labor markets are likely to be important causes of crime. If not, criminologists must look to factors that may cut more evenly across class lines, such as individual pathology or dysfunctional family processes. Stratification researchers are becoming interested in crime for analogous reasons. Individual-level evidence suggests that crime and the societal reaction to crime can disrupt individual attainment (Hagan 1993), while macro level studies show that crime and punishment may alter unemployment rates and economic performance (Western and Beckett 1999). This article first reviews empirical generalizations about class and crime, and the conceptual and methodological tools used to interpret them. It then outlines recent theoretical and empirical developments and diverse research strategies to further elaborate the relationship, concluding that the relation between criminal behavior and social class is likely to be reciprocal or endogenous.

1. Measurement

1.1 Measurement of Crime

The relationship observed between crime and class is sensitive to the measurement of each concept. There are three primary sources of crime data: the offenders, the official enforcement agencies, and the victims. Self-report studies, typically based on samples of high-school students, generally report very weak relationships between social class and delinquency (Tittle et al. 1978). However, social class is a strong and significant predictor of official law violation, as measured by arrest and punishment, all over the world (Braithwaite 1981). Surveys of prison inmates show that they are educationally and economically disadvantaged relative to the general population. Prior to their most recent arrest, only two-thirds of inmates in the USA had completed high-school, one-third were not employed, and less than half reported annual income greater than $10,000 (US Department of Justice 1993). The relation between social class and criminal victimization depends on the type of crime under consideration. In 1998, in the USA, the violent victimization rate among households reporting annual income greater than $35,000 was only half the violent victimization rate of households earning less than $7,500. For property crimes such as theft, however, the highest victimization rate occurs among households earning $50,000 or more per year (US Department of Justice 1999).

It has proven difficult to reconcile the conflicting pictures of the class–crime relationship provided by self-report, official, and victimization data. Some argue that the discrepancy arises because self-reports generally capture a different domain of behavior than official data. When self-reports are compared with police records, the results show high rates of congru-

ence for white, in-school youths, but less agreement for black males with an official history of delinquency (Hindelang et al. 1981). Some attribute these discrepancies to under-reporting by black males, while others point to race biases in arrest records that overstate the arrests of blacks relative to whites. Most agree that greater police attention to lower-class areas exacerbates class (and race) discrepancies in self-report and official data.

The nonsignificance of class in self-report surveys may also be a product of the compressed frequency and severity range of offending typically recorded in self-report surveys (Elliott and Ageton 1980). In support of the argument that self-reports and official data tap different domains of criminal behavior, some investigations find that middle-class and upper-class delinquency is less serious than delinquency by less advantaged youth. Nevertheless, the strong negative relation between social class and official delinquency and the far smaller class differences in self-report delinquency are well-founded empirical generalizations.

Any discussion of class and criminal behavior would be incomplete without noting that social class is one of the defining characteristics of white-collar crime, or 'crime committed by a person of respectability and high social status in the course of his occupation' (Sutherland 1983, p. 7). By definition, this conceptualization assumes that some degree of power and influence is necessary to commit crimes such as bank embezzlement or insider trading. Because the structure of opportunity to commit such crimes is bound up with social position, however, it is difficult to identify meaningful comparison groups to determine whether white-collar, occupational, or corporate criminals are any more or less deviant than the general population.

Finally, most self-report studies have been conducted on youth, often in school settings. Unfortunately, we know comparatively little about the class distribution of self-reported adult offending in the general population. Class differences in the longitudinal sequence or criminal careers of individual offenders have rarely been explored, although lower-class offenders may have higher crime frequency and participation rates, earlier ages of onset, and longer career durations (Janson and Wikström 1995). With the aforementioned caveats regarding occupational and adult offending, however, the results of self-report studies are generally consistent, reporting weak negative relations between social class and crime. Much of the remaining variation among these studies can be attributed to differences in the conceptualization and measurement of social class.

1.2 Measurement of Class

The effects of social class on self-reported crime depend on whether researchers use gradational or relational class measures. Researchers using continuous gradational measures, such as socioeconomic status (SES), generally find little association between SES and crime. Investigations that operationalize class as a relational measure, based on Marxian ownership or Weberian authority generally report somewhat stronger associations (Brownfield 1986) (see *Class and Law*). One problem with many class indicators, however, is that they omit the most disadvantaged individuals and families—the underclass or surplus population. Theories of crime such as Merton's (1938) anomie model point to the importance of sustained poverty and limited opportunity within a cultural context of common success symbols. Along these lines, some research suggests that parental unemployment is a positive predictor of self-reported delinquency (Farnworth et al. 1994).

Most of the research considered so far actually considers social class origins rather than the social positions or interests of the offenders themselves (Stark 1979). In part, this is because the peak age of offending for many crimes occurs in the mid-to-late-teens, preceding the transition to full-time employment in many societies. To the extent that the social class positions of adolescents have been considered in the delinquency literature, schools are generally the primary (if not exclusive) setting. Nevertheless, many adolescents and young adults have established independent class positions outside the educational arena, particularly those who have left home and school. Research on homeless youth that assesses class in terms of unemployment, hunger, and lack of shelter, reports strong 'foreground' class effects on street crime (Hagan and McCarthy 1997).

In summary, the strongest relations between social class and crime have been observed in studies that use relational rather than gradational class measures. In fact, the most important class distinction is likely between the most disadvantaged and everybody else. Though some specifications of the 'underclass' concept blur the distinction between class and criminal behavior by including law violation (in the form of violence, drug use, or other crime) among its many manifestations, such tautological reasoning is unnecessary to establish the relationship. Sustained parental unemployment in an individual's background or more immediate and extreme material deprivation places persons at greater risk of offending.

2. Sampling, Units of Analysis, and Analytic Approaches

2.1 Sampling

As the preceding discussion suggests, class effects on criminal behavior are unlikely to be observed unless the research methodology ensures an adequate rep-

resentation of extremely disadvantaged respondents and a meaningful comparison group. 'Street criminology' differs from 'school criminology' (Hagan and McCarthy 1997) in both theoretical and analytic orientation. In particular, each approach implies a different domain of criminal behavior and a correspondingly different sampling strategy. Student samples can yield elegant tests of theory among nationally representative samples, although results may not generalize to more extreme law violation. Street samples are more difficult to obtain, in part because complete sampling frames are rarely available. Nevertheless, the latter approach is best suited to identifying respondents from truly disadvantaged class origins and more marginalized current class positions.

2.2 Units of Analysis

Studies conducted at the aggregate rather than the individual level of analysis have generally shown stronger relationships between social class and crime. Housing costs affect the population composition of a neighborhood, which, in turn, influences the distribution of social groups with differential risks for offending (Janson and Wikström 1995). At the community level, the studies of Shaw and McKay (1942) showing delinquency rates in Chicago by neighborhood economic status remain among the most powerful statements in this line of research. At least part of the individual-level discrepancy between self-reported and official crime and delinquency is thus explained by greater police attention to lower-class areas (Sampson 1986).

Emerging multilevel methods are beginning to shed light on the intervening mechanism connecting class with neighborhood crime rates. Research merging individual-level data with neighborhood characteristics shows that the effect of poverty and unemployment rates on violent crime is mediated in large part by 'collective efficacy,' or a community's capacity for informal social control and mutual trust (Sampson et al. 1997). Finally, national-level research on class structure and crime suggests that inequality (Braithwaite 1979), state welfare spending (Messner and Rosenfeld 1997), and unemployment (Archer and Gartner 1984) bear some relation to official crime rates.

2.3 Qualitative and Quantitative Analytic Approaches

Many qualitative researchers take the association between class and crime for granted, focusing their efforts on gangs or individuals in extremely marginalized circumstances. Increasingly, however, such work also includes a comparative dimension. Mercer Sullivan (1989) for example, shows how early criminal behavior can disrupt adolescent education and employment, which in turn increases adult criminal behavior. By examining cliques of boys from similar class positions but different neighborhoods and ethnicities, Sullivan identifies contingencies such as local job networks and illegal markets that mediate the relation between class origins and crime. Other ethnographic work illustrates how street crime is woven into the everyday lives of some individuals and neighborhoods (Venkatesh 1997), identifying the critical turning points in their criminal histories. Because such insights are difficult to glean from the quantitative analysis of survey data, several prominent quantitative criminologists have added a qualitative element to their investigations (Hagan and McCarthy 1997, Sampson and Laub 1993).

3. Promising Avenues for Research

3.1 Reciprocal Relations

The reciprocal relationship between attainment and deviance that Sullivan (1989) noted among disadvantaged adolescents has been explored in a number of important quantitative studies. Analyzing a cohort of London boys born in the 1950s, Hagan (1993) finds that adolescent criminal 'embeddedness,' measured by delinquent activities, friends, and parental criminal convictions, has a strong effect on unemployment in young adulthood. Similarly, in a sample of American delinquent and non delinquent boys born in the 1920s, Sampson and Laub (1993) report that early juvenile incarceration decreases later job stability, which, in turn, exacerbates adult criminal behavior. Thus, social class and crime are likely to be reciprocally determined.

The type and severity of offending however, remains important in determining crime effects on class. Substance use and minor delinquency have little effect on the life outcomes of a predominantly middle-class sample, partly because they are likely to receive numerous 'second chances' (Jessor et al. 1993). Similarly, Hagan (1991) finds that identifying with a subculture of delinquency reduced occupational attainment among working-class boys, but identifying with a 'party subculture' had a small positive effect on attainment among non-working-class boys. In such cases, the type and severity of offending determine the sign as well as the magnitude of the effects of crime on social position.

3.2 Elaborating the Relationship

Criminological researchers have elaborated the relationship between class and crime by specifying and

testing interactions between social class and other factors and by seeking the intervening factors that interpret the relation. With regard to interaction, the relationship between social class and crime may be conditional on background characteristics, such as race, sex, or other characteristics. Power-control theory, for example, posits that social class interacts with gender to affect common delinquency, receiving mixed empirical support (Hagan et al. 1987) (see *Crime and Gender*; *Crime and Ethnicity (Including Race)*).

Regarding intervening factors, Wright et al. report both positive and negative social-psychological paths connecting socioeconomic status and delinquency, characterizing the relationship as 'causation but not correlation' (1999, p. 179). High SES increases delinquency by increasing risk taking and social power and by decreasing conventional values, but reduces delinquency by diminishing alienation and economic strain, and increasing aspirations (Wright et al. 1999). Other research suggests that class effects on crime and deviance are largely mediated by family factors and school performance (Hagan and McCarthy 1997).

Even if the bivariate relationship between class and crime is close to zero, as some self-report research suggests, further research on interactions is necessary to explain how we get to zero—to specify the positive and negative paths linking social class and criminal behavior. Where the bivariate relationship between class and crime is stronger, as in studies using parental unemployment or official crime data, further research is needed to identify the catalysts that transfer class origins into criminal outcomes.

3.3 Cross-national and Comparative Work

A great deal of the research discussed above has been conducted on English-speaking samples, such as Hagan's work on British (1993) and Canadian (1991) data, the Wright et al. (1999) piece on New Zealanders, and the many American studies reviewed by Tittle et al. (1978). Nevertheless, Braithwaite's comprehensive international review suggests that patterns observed in these nations are replicated across the world with a 'degree of consistency which is unusual in social science' (1981, p. 38). To date, however, few truly cross-national or comparative efforts have been undertaken. Most studies have taken nation states as the level of analysis, identifying the structural-level correlates of homicide rates (e.g., Archer and Gartner 1984). One individual-level effort, comparing working-class males in London and Stockholm, found remarkable similarity in the criminal career patterns of the two groups (Farrington and Wikström 1994).

It is difficult to locate the comparable samples and indicators necessary to test the stability of individual-level class effects across national contexts. Nevertheless, such research will be necessary to generalize knowledge of class and crime and to begin to disentangle the relation between social structure and criminal behavior in varying cultural settings.

4. Taking Stock

The concepts of class and crime are fundamental to understanding social position and social order and disorder. Not surprisingly, their relationship is complex and multifaceted. Social class is a strong predictor of official law violation by all measures and a weaker but consistent predictor of self-reported law violation by gradational measures. Researchers are elaborating the relationship by specifying the interactions and the intervening mechanisms connecting class and crime. In particular, it has become increasingly clear that criminal behavior and social class are likely to be reciprocally related throughout the life course.

C. Uggen

Crime and Delinquency, Prevention of

Juvenile delinquency and crime are legal definitions rather than specific behavioral or psychiatric syndromes. Since common law is based on theological law, society has historically responded to juvenile delinquency and crime based on moral and religious beliefs regarding the age at which juveniles are criminally responsible rather than from scientific knowledge regarding the developmental course of delinquency and crime. Historically, the age at which children are criminally responsible has been subject to much debate and has varied significantly both within and between nations (Rutter et al. 1998). Moreover, this debate and variability has led to ongoing tension within society and its institutions between a focus on punishment or treatment and rehabilitation. However, since the early 1970s scientists and interventionists in the fields of criminology, sociology, and psychology, who have focused on the prevention of juvenile delinquency and crime, have made significant methodological and theoretical progress. This progress has included identifying specific antecedents and mediators and their developmental sequencing, and the development of precise interventions (see Stoff et al. 1997). Society and its institutions will need to use this accumulated scientific knowledge as the foundation for developing policy and interventions that are intended to prevent delinquency and crime.

1. Historical Background in the Prevention of Delinquency and Crime

Since the rise of delinquency as a social problem during the industrial revolution, the prevention of delinquency and crime has had a history of swinging between two philosophical poles: punishment and rehabilitation (Bernard 1993). Advocates of punishment have relied on the intellectual power of classical theory, whereas advocates of rehabilitation have relied on learning and attachment theories. Classical theory and its criminological offspring, social control and strain theory (Gottfredson and Hirschi 1990), posits that individuals are responsible for their own behavior and are motivated by cognitive appraisals of the potential costs and benefits of delinquent or criminal acts. Attachment and learning theories and their most recent progeny, social interactional or social developmental theory (Patterson et al. 1992), posit that the probability of performing a delinquent or criminal act is highly related to a child's history of reinforcement for certain behaviors within a family and early associations with negative peers. That is, complex but observable reinforcement contingences are responsible for the initiation and then maintenance of chronic antisocial behavior.

Currently, social control theory appears to be most influential among the public and politicians both in the USA and in other Western countries (Howell 1997, Rutter et al. 1998). However, in the scientific literature social developmental theory appears to have more empirical support. Policy and intervention implications of a reliance on social control theory (i.e., harsher punishments such as training schools, juvenile jails, reprimanding juveniles into adult courts and jails,

mandatory sentencing, etc.) have been shown to be neither in the best financial interests of society nor to have reduced rates of juvenile delinquency and crime. Whereas, recent cost–benefit analyses of interventions based on social developmental theories suggest cost effectiveness, particularly in the long run (Howell 1997). Therefore, there has been a re-emergence of social developmental theoretical models of delinquency and crime. These models emphasize the importance of interactional contingencies operating within family, peer groups, schools, neighborhoods, and communities in the development and maintenance of antisocial behavior (e.g., Patterson et al. 1992) versus theoretical models of delinquency and crime based on economic opportunity (e.g., Gottfredson and Hirschi 1990).

2. *The Problem of Chronic Offenders*

Recent research has shown that a small percentage of children with antisocial behavior, including those who are arrested as juveniles, account for a large proportion (50–75 percent) of juvenile crime (Huizinga et al. 1995). Researchers have also found similar percentages in adult samples. Because this smaller proportion of criminals accounts for a large percentage of crime, it has been suggested that communities often waste their limited resources on noncareer juvenile delinquents who are unlikely to commit further offenses. By the time these noncareer criminals are arrested and/or targeted for intervention, they are often at the end of their short offending span. However, it is also argued that intervention may be easier and more likely to work with the non-chronic group. Some researchers have also suggested that the youth in the chronic group account for a disproportionate share of mental and physical health problems, divorce, domestic violence, and drug and alcohol problems in their age cohorts.

It has become clear that it is rare for a persistently delinquent youth to become a chronic offender without moving through an increasingly well-validated developmental sequence (i.e., early childhood noncompliance, antisocial or aggressive behavior in childhood including covert antisocial behavior, and early arrest, Stoff et al. 1997, Chap. 20). For example, Patterson and his colleagues at the Oregon Social Learning Center have developed two models, an early-onset and a late-onset model, that may account for differences between life-course persistent and transient offenders. In the Oregon Youth Study sample Patterson found that boys with the highest rates of antisocial acts in childhood are at the greatest risk of being arrested before the age of 14. In addition, Huizinga et al. (1995) reported that from 39–62 percent of chronic violent offenders self-report committing their first act of violence at or before age 9. Patterson has also found early arrest (before age 14) is associated with the increased probability of being a chronic offender and, in turn, being a chronic offender is positively correlated with both violent offending and being arrested as an adult (Howell 1997, Rutter et al. 1998).

3. *Prediction and Stability of Antisocial Behavior*

Since the early 1970s there has been increasing agreement among researchers that, to a great extent, externalizing conduct disorders in childhood precede chronic delinquency (Patterson et al. 1992), and chronic delinquency precedes serious and violent juvenile crime and adult criminality (Loeber and Farrington 1998). In addition, there is impressive international evidence that antisocial behavior, including criminal behavior, is relatively stable across stages of the life course (Rutter et al. 1998). The stability of delinquent behavior is particularly strong when antisocial behavior begins early in the life course. Researchers have also found that the development of childhood antisocial behavior and juvenile delinquency leading to adult criminality is multiply determined and involves the convergence of many risk factors (Howell 1997, Loeber and Farrington 1998, Patterson et al. 1992, Rutter et al. 1998). However, recent strides have been made in identifying specific risk factors for the initiation and maintenance of antisocial behavior and perhaps most important the developmental sequencing of their influences.

4. *Developmental Sequencing*

Several well-designed prospective longitudinal studies (e.g., Huizinga et al. 1995, Patterson et al. 1992) have shown that levels of common parenting practices starting early in a child's life and continuing through adolescence are associated with the reduced probability of delinquent behavior. These parenting practices include appropriate discipline (e.g., application of mildly aversive consequences for problem behaviors, structuring, reinforcement of prosocial behaviors, and lack of abusive tactics such as humiliation and hitting), supervision (e.g., monitoring children's behavior and peer affiliations in school and community environments), and developing a positive relationship with a child (e.g., having reasonable levels of positive reinforcement for prosocial behavior, involvement in positive leisure activities). These longitudinal studies along with other recent research (Dishion et al. 1999) have shown that delinquent peers become a significant factor in the development and maintenance of delinquency, and this effect is most significant during adolescence.

In addition, researchers have found an array of complex individual, psychosocial, and society-wide influences that are related to externalizing behavior

problems, offending rates, and a variety of antisocial and delinquent behaviors. These influences include genetic influences, obstetric complications, cognitive abilities, temperament, peer relationships, biased cognitive processing, autonomic reactivity, serotonin metabolism, teenage parenting, large family size, broken homes, abuse and neglect, coercion and hostility, ineffective parenting and supervision, peer groups, poverty and social disadvantage, mass media, school effects, and accessibility of guns and drugs (Rutter et al. 1998, Stoff et al. 1997). Although most of these influences have been shown to have robust associations with delinquent behavior, their individual influences on rates of delinquency are often small (i.e., often accounting for less than 10 percent of the variance in delinquency and crime).

What is significant about the individual influences is that most have been shown to increase in importance as they accumulate for any one child. Longitudinal research also suggests that individual influences are most important if they interact negatively with parent, peer, school, and community relationships. Contingent interactions (many of which have been shown to be bidirectional, Patterson 1982) that occur in these settings have been implicated in the emergence and subsequent maintenance of chronic childhood antisocial behavior, delinquency, and crime. For example, recent research strongly suggests that parent–child interaction patterns starting in early childhood that take place in the context of typical parenting tasks are associated with positive and negative child development outcomes (Patterson et al.1992). It has also been hypothesized that biological and genetic variables play a role in the development of problematic parent–child interaction patterns (Rutter et al. 1998). That is, infants with difficult temperaments and/or hyperactivity are harder to parent, and when matched with low-skilled parents, they have been shown to have more negative developmental outcomes such as higher levels of noncompliance and parental rejection. It is also interesting that, studies by Werner (1989) and others have shown that difficult infants raised by reasonably skilled parents are not at particular risk for negative developmental outcomes.

Many of the individual contextual influences that have been historically associated with rates of delinquency and crime (e.g., poverty, high crime neighborhoods, parental antisocial behavior and psychopathology), in large part, have been shown to be mediated to children through their disruptive effect on parenting practices and family functioning (e.g., parental depressed mood, poor parental discipline, marital conflict) (e.g., Patterson et al. 1992, Sampson and Laub 1994). Some theorists even postulate that economic downturns increase both the number of difficult-to-raise infants (because of increases in infant health problems) and the number of low-skilled parents (through the complex effects of transitions and mobility). These low-skilled parents then drift into disorganized neighborhoods (where rents and costs are lower) and where there are high crime rates and low levels of social support that create further isolation and stress (Sampson 1992). Patterson has suggested that further research on the relationship between economic downturns and density of difficult-to-raise infants and low-skilled parents may solve an embarrassing problem for most current theories of delinquency: that these theories have been unable to account for significant variance in societal rates of juvenile offending.

5. *Prevention and Intervention*

The outcome of three decades of intense research has been a general agreement that prevention of delinquency and crime needs to involve multiple components that target multiple risk factors, and that no single-component intervention will have enough strength to alter the course of seriously antisocial or delinquent behavior. Because many of the early risk factors directly or indirectly involve parent–child interactions, early prevention efforts are increasingly targeting parenting and other contextual variables that indirectly or directly affect parenting. As the children age, their interactions with adults and peers in schools, neighborhoods, and the larger community also become important in the further development and maintenance of antisocial and delinquent behavior (Stoff et al. 1997, Chap. 20). Therefore, all serious current prevention and intervention models for antisocial and delinquent behavior target multiple variables (e.g., family interactions, school success, peer group affiliations, social support, graduated sanctions) in multiple settings (e.g., home, school, neighborhoods, and communities) (Loeber and Farrington 1998).

5.1 *Gender*

International research has shown that young males commit a higher proportion (up to 80 percent) of officially reported juvenile crime. This ratio is somewhat lower when self-report data is used to document criminal acts. It is also known that these ratios are falling at the end of the twentieth century and the disparity between male and female delinquency was less than a third of what it was even 40 years before (Rutter et al. 1998). There is argument about why there is an increase in officially reported and self-reported female antisocial behavior (see Stoff et al. 1997). Regardless of why increases in female antisocial behavior are being reported, the long-term detrimental effects of such behaviors are well-documented (Sampson and Laub 1994). In particular, female antisocial behavior, especially delinquency, has been linked to the development of later psychiatric, educational, and

employment/occupational problems, substance abuse, early pregnancy, the selection of antisocial partners, early marriage, and early death.

However, because developmental research in the area of delinquency and crime has primarily involved boys (particularly prospective longitudinal studies), very little is currently known about the development of juvenile offending and criminality in female populations. The existing literature, however, does suggest that there are different effects for parenting, sibling, and peer relations on antisocial behavior in boys and girls. It also shows that the developmental histories of delinquent boys and girls differ in other respects such as levels of abuse, neglect, and trauma (Stoff et al. 1997, Chap. 46). Researchers also have proposed that the same predictors and mechanisms may not explain these gender variations. Further, even though females contribute proportionally less than males to delinquency and crime rates, some theorists believe it is critically important to increase the study of girls. Not only are antisocial or delinquent young women at grave risk for a plethora of negative developmental outcomes, they also may play a key role in the intergenerational transmission of criminality through pairing with antisocial boys, early pregnancy, and low parenting skills (Rutter et al. 1998).

6. *Future Directions*

Continued use of multiple measures and multiple methods within passive and experimental longitudinal studies will further identify malleable variables and validated intervention technologies at all levels of delinquency and crime prevention (i.e., primary, secondary, and tertiary) (Loeber and Farrington 1998). Studies will also focus on the further development and validation of gender-specific predictive and prevention models. These models will likely lead to the development of screening criteria that can identify the small percentage of youths who account for the most delinquency and crime and those youths most likely to be involved in the transgenerational transfer of delinquency and crime. These improved screening measures will reduce to acceptable levels the current high false-positive rates associated with previous attempts to develop screening tools for early identification of children at risk of persistent delinquency and crime. However, until this scientific task is accomplished, results from programmatic longitudinal research using causal modeling suggests that targeting children and families who have both biological and socioenvironmental risk factors will be most cost effective. Although the Gluecks and their colleagues argued for this approach many years ago (Glueck and Glueck 1972), accomplishing it appears possible at the beginning of the twenty-first century, given recent improvements in measurement theory, research design and analysis, and intervention technology.

In addition, future theoretical and methodological advances will include an increase in research on the interaction between biological/genetic variables and social environments (both naturally occurring and therapeutically designed) and the results of this interaction on antisocial developmental trajectories and rates of delinquency and crime (Stoff et al. 1997). Also, empirically validated prevention interventions targeting delinquency and crime will be developed for all ages and levels of seriousness. Furthermore, any intervention used by society will be seen as potentially a preventive intervention if it has a positive effect on the developmental trajectory of antisocial behavior once it has begun (Stoff et al. 1997, Chap. 32). Finally, long-term solutions to the problem of delinquency and crime will lie in the scientifically informed cost–benefit balance between prevention, rehabilitation, and graduated sanctions (Howell 1997, Loeber and Farrington 1998, Rutter et al. 1998).

Crime and Ethnicity (Including Race)

This article explores research regarding race, ethnicity, and crime. It focuses on the disproportionately high incidence of racial and ethnic minorities caught up in the justice systems of Western countries and on the reasons behind these disparities.

1. Race, Ethnicity, and Crime and the Limitations on Research

The term 'race' once referred to the 'major biological divisions of mankind' (Caucasoid, Negroid, and Mongoloid), as characterized by skin color, hair texture, and other physical features (Walker et al. 1996). This notion has fallen into disrepute for lack of scientific validation. Race is now recognized as a social construct used by groups seeking to delineate themselves from others. Ethnicity is a similar concept that principally refers to the countries from which an individual's heritage can be traced (e.g., 'Hispanic' refers to those with Spanish ancestry), although it is also associated with language, religion, cultural practices, and self-perception. The meanings of these terms continue to be debated, and usage is not consistent internationally. In Germany, for instance, the term *Ausländer* (foreigner) includes ethnic and racial differences in its vague and elastic scope. In England and Wales, researchers consider Blacks to be ethnic minorities, but offenses against them are sometimes referred to as being 'racially' motivated.

Crime typically is defined as 'a social harm that the law makes punishable' (Garner 1999). Examples of crime range from white-collar crimes and organized crime, to murder and hate crimes. This article will focus on conduct often referred to as 'street crime' (also known in the US as Index Crime: murder and nonnegligent manslaughter, forcible rape, robbery, burglary, aggravated assault, larceny-theft, motor vehicle theft, and arson), because current records provide the best data for analysis of variation in offending and victimization by race and ethnicity.

Analysis is constrained by the difficulty in obtaining reliable crime statistics. Such data are collected regularly in Western countries; however, even where crime data is available, the race and ethnicity of victims or offenders are rarely recorded. Only the US officially records and publishes data regarding an individual's race beginning at arrest and continuing to incarceration, and even there data has reliability problems (see the subsection entitled *The Quality of Criminal Justice Data on Race and Ethnicity*, in Walker et al. 1996). Lawmakers in many countries have chosen not to record racial and ethnic identification data for ethical reasons. Though the reluctance of Europeans to compile data regarding the ethnicity of offenders and victims is hardly surprising, given the legacy of Nazi Germany, the decision to forgo collection is equally problematic. Comparing existing data cross-nationally can be difficult because each country has different laws and processes, research traditions, and immigration histories, but these concerns are not insurmountable.

1.1 Racial and Ethnic Disproportion in Justice Systems

Tonry (1997) notes that 'members of *some* disadvantaged minority groups in every Western country are disproportionately likely to be arrested, convicted, and imprisoned for violent, property, and drug crimes.' Whether or not this is a more universal phenomenon is as yet unknown, as research has largely been limited to English-speaking and European countries. Regardless, what is now known is disturbing enough. Racial disparities in arrest and incarceration have historically been of particular concern to researchers in the US, and it is with that data that this investigation begins.

Table 1
Proportion of arrestees for FBI index crimes by racial category (percent of general population in parenthesis)

	Whites	Blacks	American Indian or Alaska Native	Asian or Pacific Islander
1976	72.3% (88.3)	25.3% (11.5)	1.4% (n.a.)	0.09% (n.a.)(a)
1986	71.3% (84.7)	27% (12.2)	1.0% (b)	0.7%
1996	66.9% (82.8)	30.7% (12.6)	1.3% (c)	1.2%

Source: Bureau of Justice Statistics: Source book of Criminal Justice Statistics: 1978, 1987, and 1997
(a) Chinese and Japanese only (b) Other racial categories comprised 3.1 percent in 1986 (c) Other racial categories comprised 4.5 percent in 1996

The Federal Bureau of Investigation (FBI) has collected crime data since 1930 and annually produces the Uniform Crime Report (UCR). The UCR details arrest data for four racial groups (White, Black, Native American, and Asian), but it does *not* include ethnicity. These data are necessarily incomplete, as they only reflect crimes reported to the police, yet they reveal the stubborn stability of racial disproportion in US arrestees for Index crimes (Table 1).

Clearly, White Americans are the most numerous arrestees, but African Americans are arrested at rates that greatly exceed their representation in the population (about 12 percent). Though the data in Table 1 are aggregated, the racial disparity holds in each Index crime category. In 1996, African Americans were arrested at a rate disproportionate to their representation in the general population ranging from 1.9 times for arson to 4.6 times for robbery.

Research indicates racial and ethnic disparities in US jail and prison populations as well. In 1990, 14 percent of jail inmates were Hispanics, who composed only 9 percent of the general population. More notable is the fact that in 1992, 27 percent of federal prison inmates were Hispanic. US jail and prison data revealed that in 1990, 47 and 51 percent of each population was African American, respectively; the percentage of African American prison inmates has exhibited an upward trend since the 1920s. In 1997, 1,083 of every 100,000 American Indians were in jail—the highest rate for any race.

The US is not alone in exhibiting racial and ethnic disparity in arrests and imprisonment. Australian records, for example, indicate disparity in the arrest of Aborigines—considered a racial minority in that country. Aborigines were almost 8 times more likely to be arrested than non-Aborigines in 1990; the rate increased to 9.2 by 1994. Additional data show that Aboriginal juveniles particularly are likely to be arrested or detained. Data from 1993 reveal ethnic or racial disparities in the prisons of England, Wales, and Canada. Blacks (people of West Indian, Guyanese, and African origin) represented 11 percent of the male English and Welsh prison population, while comprising only 1.8 percent of the young adult males in the general population. Aggregating across all Canadian provinces, researchers found that in 1993–1994, when about 3.7 percent of the Canadian general population was Aboriginal, Aborigines composed 17 percent of provincial prison admittees. Blacks are also overrepresented. Data from Ontario correctional facilities reveal a prison admission rate of 705 per 100,000 for whites, 1,992 per 100,000 for Aboriginals, and 3,686 per 100,000 for Blacks.

Notably, while *some* minorities are overrepresented in various criminal justice systems, others are underrepresented, either in the aggregate or in arrest rates for specific offenses. In England, the rates of imprisonment among Indians, Pakistanis, and Bangladeshis are generally *lower* than that of whites, despite their generally poorer economic position. Likewise, a 1992 profile of US prison populations showed that Asians were underrepresented. Asians comprised 3 percent of the general population, yet they made up only about half of one percent of state inmates and just over 1 percent of federal inmates.

Thus, minorities are over and underrepresented in Western justice systems—usually the former. Why?

3. *Reasons for Racial and Ethnic Disproportion in Justice Systems*

The debate concerning minority overrepresentation in justice system processing has largely centered around two questions. Are racial and ethnic disparities the result of discrimination by criminal justice system actors? Or are they the result of disproportionate offending? Current research strongly suggests that racial and ethnic disproportionate representation in international justice systems results from both factors.

3.1 *Evidence of Discrimination*

The evidence does *not* suggest that bias is systematic: it does not afflict Western justice systems at all levels, in all cases, and at all times. Rather, it suggests that in certain cases, places, and times, minorities are more likely than majority members to face discrimination in interactions with justice system components. Four arenas evidencing bias are worth discussing briefly: 'Neutral' processes, police practices, drug law enforcement, and the death penalty.

3.1.1 'Neutral' processes. Research has confirmed that two practices, designed to be 'race neutral' in implementation, operate to the disadvantage of minorities on a regular basis: pretrial detention, and plea-bargaining. Though it seems logical to hold before trial those most likely to flee, international scholars have discovered that the characteristics associated with flight risk are more likely to be present in the minority population than in the majority, which results in racial disparities in pretrial detention. Similarly, minorities are less likely to plead guilty. Research indicates that this tendency is shaped by and contributes to the beliefs many minorities have about justice system bias.

3.1.2 Police practices. The first experience many minorities have with the criminal justice system comes through contact with the police (see *Policing*). The police function entails vast enforcement discretion, so the possibility of abuse of authority is ever-present. In the countries in which minorities are

overrepresented in the justice system, there is also minority dissatisfaction with police practices. Reports of brutality and unnecessary stops, searches, and arrests fuel these views. In a 1994 US study, 47 percent of African Americans surveyed reported having been harassed by police, while only 10 percent of Whites reported harassment. Researchers in Maryland found that African Americans were the subject of 77 percent of vehicle searches conducted by state troopers in 1995; no contraband was found in 67 percent of the cases. Similarly, the police forces of Glasgow, London, Ottawa, and Toronto are among those who have come under scrutiny recently.

It is possible that police practices impacting primarily minorities also affect the opinions of the police held by the majority population. In a survey conducted in 1981 and 1990 in 20 countries, only a minority of *all* citizens polled, ranging from a high of about 40 percent in Britain to a low nearing 5 percent in Argentina, expressed 'a great deal' of confidence in their nation's police; in all but four of these countries the percentage had *declined* by 1990.

3.1.3 Drug law enforcement. Since the 1980s, the problem of race, ethnicity, and crime in the US and elsewhere has been driven by drug laws and policies that have resulted in the rapid rise in the incarceration rate of minorities. The increase in the Black prison population in the US, England, and Wales is obviously tied to drug law violations. In these countries minorities tend to be convicted of relatively low-level drug offenses at rates much higher than those of the majority of individuals. Scholars have concluded that the stark racial disparities in arrests and incarceration resulting from drug law enforcement are difficult to justify given the small gains in crime control from these policies (Tonry 1995, Meares 1998).

3.1.4 The death penalty. This issue is of particular concern to scholars in the US, as it is the only Western democracy still imposing this sentence. Examination of sentencing practices indicates that the *victim*'s race, not the offender's, most often determines whether or not the defendant will receive the death penalty. Those who murder Whites are more likely to receive the death penalty than those who murder Blacks. African American defendants charged with murdering Whites are most likely to receive the ultimate sanction.

Despite this evidence, the US Supreme Court has refused to void the death penalty, finding in *McCleskey v. Kemp* (1987) that defendants must demonstrate, in addition to discriminatory effect, that the prosecutor's decision to pursue the death penalty in a particular case was the result of racial animus. Today, US death rows are still predominantly minority. Not one death row defendant has yet been able to demonstrate the evidentiary requirements stipulated by *McCleskey* (see *Death Penalty*).

Figure 1

3.2 Evidence from Victimization Studies

To determine the extent of discrimination in international justice systems, some scholars have looked to victimization surveys, reasoning that if arrest data matches victimization reports, the racial disparities evidenced in arrests could be explained by disproportionate offending rather than by bias.

Among Western countries, only the US, England, Canada, and The Netherlands conduct long-term national victimization studies. US data shows that minorities fall victim to violent crime at a rate that exceeds their representation in the population (Fig. 1). US data also shows that violent crime is largely an intraracial event. From 1976 to 1996, 94 percent of cases involving Black murder victims involved a Black offender. The corresponding percentage was 85.6 for Whites.

The victimization data largely points away from invidiously or blatantly discriminatory targeting of offenders by the justice system. Instead, the data suggests that differential rates of offending by racial and ethnic groups contribute a great deal to the disparity in the US justice system. Hindelang's (1978) classic study shows significant correspondence between the distribution of the perceived race of offenders from victimization survey results and the distribution of arrestees by race from official statistics. While there are well-documented limitations to this approach, existing research has prompted Tonry (1997) to conclude that 'in countries in which research has been conducted on the causes of racial and ethnic disparities in imprisonment, group differences in offending, not invidious bias, appear to be the principle cause.'

4. Why do Minorities Disproportionately Offend?

Minority groups overrepresented in justice systems tend to be economically and socially disadvantaged, especially compared to the majority. In many cases this is the result of historical discrimination, or is tied to the group's recent immigration to their new national home. Often racial and ethnic minority groups are segregated geographically from other groups. *Social disorganization theory* postulates that the geographical concentration of poverty, along with factors such as joblessness and family disruption, negatively impacts the ability of community-level institutions to mediate crime (Shaw et al. 1929, Sampson 1989). This theory helps to explain why some disproportionately minority areas—especially urban ones—exhibit high crime rates. But it does not explain why particular individuals do or do not engage in crime. It is primarily for this reason that attempts to incorporate the notion of 'rotten social background' as a legal excuse for crime commission have been unsuccessful.

Other explanations for minority involvement in the criminal justice system emphasize power and social relationships over economic disadvantage. *Conflict theory* suggests that discriminatory justice practices are simply another expression of the disproportionate power distribution in society. The dominant group can and does use available means to maintain its grip on power (Liska 1992). *Cultural conflict theory* maintains that heterogeneous societies tend toward disparate values and are thus more vulnerable to crime (Sellin 1938). This theory suggests that some minority groups, for various reasons, do not accept majority values, increasing the likelihood of criminal behavior. Finally, *social strain theory* sees increased criminality as one of several responses to the tension inherent in a society in which many lack the means to obtain dominant goals in the generally agreed upon manner (Merton 1957). Rebellion and retreatism (e.g., through drug use) are among the other reactions to this type of societal stress. While each of these theories has certain merits, none does a particularly good job of explaining why some disadvantaged minorities are disproportionately *underrepresented* in criminal justice systems.

5. Conclusion

Racial and ethnic disparities apparent in Western justice systems will increase rather than decrease, at least in the short term, as a result of increasing rates of immigration to Western countries by racial and ethnic minorities and the worldwide trend toward urbanization. This problem is not confined to the Western countries emphasized here. One need only consider the social landscape of South Africa (and the ongoing conflict between Israel and the Palestinian Liberation Organization) to see this. The main impediment to exploration of these issues worldwide is the profound lack of data. Thus, the challenge of promulgating useful crime policy without unnecessarily impacting racial and ethnic minorities will continue to be considerable without good data to help determine the scope and substance of the problem.

Crime and Gender

One of the most consistent and strong findings in criminology is that females commit much less crime and juvenile delinquency than males. This gender gap in law-violation is found using data on arrests, convictions, self-reported crime, and victims' reports about offenders. It also appears to exist across nations and over time.

Yet, until the 1980s, gender differences in crime received scant attention. In the 1970s, feminist critiques of criminology called attention to the neglect of females (e.g., Smart 1976). Since that time, there has been a trend toward taking more seriously the issue of female offending and the gender gap in crime and delinquency.

This article summarizes the research on gender and crime that has been conducted since these critiques. It first identifies some of the major issues that have emerged in this research, and identifies three typical approaches to the study of gender and crime. It then discusses key findings and arguments in research taking each of these approaches. Note that space limitations restrict the scope of this essay to research on the causes of gender differences in offending; it does not address the literatures on gender and victimization, or gender and criminal justice processing. For a review of this literature, see Kruttschnitt (1996).

1. *Approaches to Studying Gender, Crime, and Delinquency*

A major issue in research on gender and offending centers on the level of analysis. One line of research focuses on the *macro-level* of analysis, emphasizing patterns of crime over time and space, and seeking to explain these as the outcomes of broad social patterns. Specifically, this line of research examines changes in the gender gap in crime over time, and reports some convergence between female and male crime rates since the 1950s and 1960s in various nations, including England and Wales, Canada, and the United States (Box and Hale 1983, Fox and Hartnagel 1979, Steffensmeier 1993). At some times during this period, the increase in female crime rates has exceeded the increase in male rates; at other times, male crime rates have declined more than have female rates. Both of these patterns have resulted in some narrowing of the gender gap in crime, although male offending exceeds female offending throughout the period. This pattern holds for most types of serious crime, except murder (Heimer 2000); however, it is more pronounced during some periods for certain property crimes, such as larceny and fraud (Steffensmeier 1993). Almost all existing research on changes in the gender gap uses annual arrest or conviction rates, aggregated to the national level. The typical explanations offered for the changes include women's liberation and economic circumstances.

Another line of research on gender differences in offending uses individual-level data and proposes *social–psychological* explanations. This research typically is based on quantitative data from self-report surveys administered to large samples. These surveys show that males are more likely than females to commit minor, as well as serious, law violations. However, the gender gap is most pronounced for the most serious offenses (see Smith and Visher 1980). Individual-level research has focused on how social–psychological factors—such as family processes, beliefs, and attitudes—contribute to the gender gap in law-violation.

A second major issue in the study of gender and crime is the type of methodology employed. Whereas the two lines of research discussed above rely mostly on *quantitative* methods, a third line of research uses *qualitative* methods, such as the analysis of open-ended interviews and ethnographic techniques. This research most often focuses on either male or female offenders, and thus addresses differences in crime among groups of females or groups of males rather than the comparison of offending across gender.

The remainder of this essay briefly reviews the three lines of research identified above. It then, discusses attempts to bridge the macro- and individual-levels of analysis. Finally, it suggests that fruitful avenues for future research are continuing to bridge levels of analysis, and moving toward greater synthesis of quantitative and qualitative research findings.

2. *Research on the Narrowing of the Gender Gap Over Time*

Research on the narrowing of the gender gap in crime rates over time proposes three explanations—women's liberation, economic marginalization, and the decline in chivalry. The *liberation hypothesis* argues that women's crime rates increased during the 1960s and 1970s because women gained increased economic and social independence from men. One variant proposes that a convergence in gender roles led to a convergence in the gender gap in all types of crime (Adler and Adler 1975). Another variant proposes that women's increased labor-force participation created new opportunities for crime in the workplace (Simon 1975). Both variants have been criticized for assuming that labor-force participation and improved economic

conditions increase crime by females, whereas these conditions reduce crime by males (Chesney-Lind 1997). Moreover, the narrowing of the gender gap is most pronounced for crimes that are consistent with women's preliberation roles—including larceny (theft), fraud, and forgery (see Steffensmeier 1993). Perhaps not surprisingly, therefore, empirical research provides little evidence that women's labor-force participation increases their crime (e.g., Box and Hale 1983; for review, see Steffensmeier and Allan 1996).

Consequently, contemporary studies often focus on the *economic marginalization hypothesis*, which proposes that the increased financial hardship of women relative to men has contributed to the narrowing gender gap in crime (Box 1987, Steffensmeier 1993). Very few studies have assessed this hypothesis empirically, and existing studies use restricted measures of economic marginalization. A review of these studies argues that future research needs to address the interplay between the specific elements of women's poverty that affect their crime rates, including increasing rates of single motherhood, persistent gender inequality in wages, and changes in social welfare policies (Heimer 2000).

A third explanation of the narrowing of the gender gap in crime is the *decline of chivalry hypothesis*, which proposes that the observed changes are due in part to changing attitudes among law enforcement personnel. Specifically, the gender gap in arrest rates reflects the chivalry of law enforcement personnel toward women (e.g., hesitation to arrest women), and the narrowing of the gap reflects a decline in this attitude over the years (Steffensmeier 1993). Empirical evidence suggests that the decline of chivalry likely has had some effect on changes in the gender gap in crime, although economic factors are at least as important (Box and Hale 1983, Steffensmeier and Allan 1996). However, there remains debate over the veracity of the chivalry hypothesis, with some researchers arguing that females are treated more harshly than males for some types of offenses (Chesney-Lind 1997).

3. *Qualitative Research on Women's Offending*

Consistent with the economic marginalization hypothesis, most ethnographic and qualitative studies of women's crime highlight structural disadvantages. These studies typically focus on women offenders only and do not address directly the gender gap in offending. Instead, they conduct an in-depth analysis of the factors that are associated with chronic offending among women. As a group, these studies suggest that poverty, unemployment, and single motherhood combine to create conditions of extreme economic hardship, which in turn are associated with events and conditions of women's lives that increase the chances of a life of crime (Miller 1986, Carlen 1988, Daly 1994, Maher 1997, Baskin and Sommers 1998). For instance, several studies emphasize the connections between abuse during childhood, economic hardships, and criminal careers among women (Daly 1994, Maher 1997). Other studies show how living in a marginalized community facilitates entry into criminal networks and peer groups, which play an important role in initiating women into lives of crime and sustaining these lifestyles in the future (Miller 1986, Baskin and Sommers 1998). Finally, several studies suggest that turning to crime is a rational attempt to support children and other family members when confronted with severe economic hardship (e.g., Miller 1986, Carlen 1988). These studies offer rich insight into the social world of female chronic offenders and, as we note in Sect. 5, open the door for the development of theories that can address macro-level as well as social–psychological processes.

4. *Self-Report Research on Gender and Juvenile Delinquency*

Most research based on self-report surveys focuses on juvenile delinquency, especially common and less serious forms of delinquency. The emphasis is on understanding the social–psychological mechanisms that contribute to the gender gap in delinquency. Recent research on these mechanisms suggests that the gender gap reflects both gender differences in *exposure* to factors that make law violation more likely, as well as gender differences in the *impact* of these factors.

The social–psychological mechanisms that have received the most attention in research on gender and delinquency occur within the family. Specifically, some research shows that part of the gender gap in delinquency is explained by the greater exposure of girls than boys both to direct parental controls, such as supervision and monitoring, and to indirect controls, such as emotional bonding (e.g., Jensen and Eve 1979, Hagan et al. 1985, 1987). Other research shows that the gender gap is not the simple outcome of girls being subject to higher levels of familial controls, but also reflects the differential impact of these controls on girls versus boys. For instance, even though girls are more closely supervised, boys' delinquency appears to be influenced more strongly by supervision and monitoring; by contrast, girls' delinquency is influenced more strongly by emotional bonds to their families (Heimer and De Coster 1999; see also Hagan 1989). In short, it may be that parents control girls' misbehavior through subtle, covert control mechanisms (e.g., emotional bonding), whereas controlling boys' misbehavior requires more direct, overt strategies (e.g., supervision).

Another individual-level factor that has received attention is gender roles. The argument, related to the liberation thesis discussed above, is that feminine roles restrain delinquency more than masculine roles do (e.g., Shover and Norland 1979). Many studies of

gender roles and delinquency appeared in the late 1970s. However, the empirical research was inconsistent, perhaps because gender roles were operationalized in diverse ways across studies, often including traits, attitudes, and familial controls as well as behavioral expectations or roles.

The more recent trend has been to focus on cultural definitions of gender or hegemonic gender definitions, which are widely-accepted beliefs and attitudes that support the subordination of females to males under patriarchy. Hegemonic gender definitions depict a feminine ideal that includes a high capacity for nurturance, passivity, connectedness to others, and physical weakness; by contrast, the masculine ideal emphasizes competitiveness, aggressiveness, independence, and strength. Definitions of femininity thus are more inconsistent than definitions of masculinity with victimizing others physically or taking their property. Some empirical research shows that acceptance of these gender definitions is an important contributor to the gender gap in law violation (Simpson and Elis 1995, Heimer and De Coster 1999). Other research suggests that boys who have internalized hegemonic definitions of masculinity are more likely to engage in crime and violence (Messerschmidt 2000).

A third individual-level factor that has received attention in the literature on gender and delinquency is attitudes toward risk-taking. The hypothesis here is that youths who develop a taste for risk will be more likely than others to engage in thrill-seeking behavior, including delinquency. The power–control theory of gender and delinquency, discussed below, proposes that one reason males are more likely than females to be delinquent is that males are socialized to prefer risk-taking (Hagan 1989).

5. *Bridging Levels of Explanation*

To date, most research on gender and criminal offending has focused on either the macro-level or social–psychological explanations discussed above, and rarely has pursued links between the two. One notable exception is Hagan's power–control theory, which argues that parents' positions in the workplace shape their parenting practices, including their supervision of children, emotional bonding with children, and the inculcation of taste for risk in children (Hagan et al. 1985, 1987). More specifically, when fathers have more power than mothers in their work or professional lives, mothers experience paternalistic control within the family. They then reproduce this arrangement with their children by subjecting their daughters to higher levels of control and by encouraging taste for risk more among their sons. When parents have more equal power in their work lives, female and male children are treated more equally. Thus the gender gap in delinquency will be smaller in the latter type of family. Research supports many of these arguments, although there is some debate over some of the specific predictions (e.g., Jensen and Thompson 1990, Morash and Chesney-Lind 1991).

Another emerging perspective on gender and crime with the potential to bridge levels of analysis is the work of Messerschmidt (e.g., 1993, 2000). He argues that males may attempt to display masculinity through crime and violence when legitimate channels for claiming their gender are blocked by structural barriers, such as unemployment and poverty (Messerschmidt 1993). Messerschmidt (2000) further explores links between structural barriers and social–psychological mechanisms in his analysis of boys' violence. He argues that much of this violence is a result of the interplay between patriarchal structures, social class, and social–psychological processes, such as alienation at school, victimization, body image, and hegemonic masculine ideals. Although this line of work does not address female offending, it moves toward bridging levels in analyzing masculinity and crime, and suggests a pathway for a similar analysis addressing femininity and crime.

Some of the qualitative research discussed in Sect. 3 also could serve as a springboard for the development of theories that bridge the macro- and social–psychological levels of analysis. Many of these studies examine how economic hardship and cultural contexts influence individuals' perceptions and decisions about crime (e.g., Miller 1986, Maher 1997, Baskin and Sommers 1998). The next step would be to account for these findings by specifying a theory of the links between the macro- and individual-level mechanisms leading to women's crime, and then broaden this explanation to address gender differences in crime.

6. *Directions for Future Research*

Up to the end of the twentieth century the strands of research discussed above have remained relatively isolated from one another. In addition, research has been aimed more at uncovering empirical relationships than at building comprehensive theories of gender, crime, and delinquency. Future research will need to develop rigorous theoretical arguments that link levels of analysis, drawing links between the mechanisms identified by macro-level research on changes in the gender gap and individual-level survey research. Moreover, research must bridge the divide between quantitative and qualitative research, combining findings from both to generate more complete explanations of gender, crime, and delinquency.

Crime, Geography of

Crime is a form of deviance that involves the infringement of rules or laws that a specific society has created; both the act of a crime and the behavior of the criminal are therefore socially defined. The geographic study of crime draws a distinction between the geography of offences, where crimes are committed, and the geography of offenders, where criminals live. Different offences have different geographies. The places where shoplifting, robbery, and residential burglary occur are all different: the teenage mugger is likely to come from a different kind of neighborhood than the tax fraud. This diversity has stimulated study of the geography of crime at a variety of scales. Environmental criminology, with its focus on the places at which crimes occur, offers one organizing framework; the problematic concept of the 'crime area' another.

1. Origins

The origins of the geography of crime are found in early nineteenth century interest in cartographic criminology. A French statistician, Guerry (1833), produced maps showing the regional concentrations of crime. His observation that crimes of violence were disproportionately represented in the south of France led him to link criminal behavior and climate. In England, the social reformers such as Mayhew (1861-62) noted the strong clusters of crimes and criminals in specific areas of cities. Mayhew described the 'rookeries' of London where children were 'born and bred to the business of crime.' The Chicago studies of Shaw and McKay (1942) established a social science basis perspective on crime or delinquency areas, urban spatial patterns, and gradients and a set of 'theories' that underpinned the ecology of crime in the city. The basic premises were that crime had a spatial order; it was not distributed randomly but showed strong and persistent trends to cluster in poorer, disadvantaged environments. Subsequent studies have shown a remarkable persistence of these basic qualities of a geog-

raphy of crime and, further, have demonstrated that spatial order, clustering, and a link with 'place' typify related aspects of the criminal justice system such as sentencing patterns.

2. Information Bases

The geography of crime shares with criminology the problematic nature of the available data. Official crime statistics are suspect because the police record a relatively small minority of offences that actually occur and apprehend an even smaller number of criminals. Approximately 80 percent of offences that occur never enter police records. This 'dark area' varies by type of offence. It is very high for offences such as shoplifting or vandalism and low for car theft or homicide and arises from the unwillingness of the public, as victims or observers, to report crime to the police. Reasons for under-reporting range from embarrassment to fear of reprisal to apathy. Police themselves actually observe few criminal events and therefore rely on the public, broadly defined, to notify them when offences occur. Even the remaining 20 percent is further diminished by offences not proceeded with. This under-recording of crime may mean that official data contains biases and deficiencies. Does it over-record offences by disadvantaged youths? Does it under-record white-collar crime? Official crime statistics may reveal more about those who define criminality and administer the criminal justice system than about the actual incidence and seriousness of crime.

The official 'antidote' to these concerns about criminal statistics has been the introduction of national crime surveys. Dating in the main from the 1980s, these build upon an older *ad hoc* tradition of self-report studies and take the form of sample surveys of victimization experience and related attitudes towards crime, justice, law, and order. National crime surveys have confirmed under-recording and have qualified statements on rising crime rates, which may reflect differential recording practice rather than actual changes in crime. They have also augmented our knowledge of topics such as fear of crime. Whereas national crime surveys have not remedied the deficiencies of official criminal statistics, they have allowed their interpretation in more refined and constructive ways. For geographers, official statistics and national crime surveys are useful for studies of national and regional variations, but many geographies of crime focus on neighborhood variations and 'crime areas' within cities.

3. Theoretical Bases

The geography of crime draws upon the generic theories of criminology and social science and its own disciplinary concepts. Criminology has nurtured many theories and a significant lack of consensus. Most embrace a 'multifactor' explanation, which, despite diffuseness, is probably correct. There is no single causal explanation for criminality but a 'package' of inter-related conditions of varying applicability. Structural theories see criminal behavior as the inevitable outcome of societies that create inequalities. Yet these macrotheories fail to account for the fact that some individuals who suffer from inequality will react criminally, whereas others will not. Geographers have favored those criminological theories that lend themselves to analyses that allow a focus on place. Social disorganization is one such theory. Originating in the Chicago studies of the 1920s and 1930s, this theory linked crime with areas that lacked social order, established values, leaders, and social networks. Comparisons were made with residential areas that did possess these qualities, were 'socially organized' and experienced low rates of crime. Subcultural theory, proposing that crime may be prevalent because it is part of the normal behavior pattern within specific groups, can be found in embryo form in Mayhew's study of London's rookeries. Although now argued most consistently in relation to social groups, subcultural theory can be articulated in terms of areas or neighborhoods. Social control theory shares common strands with social disorganization and subculture, emphasizing the positive impacts of social control mechanisms in reducing the incidence of criminal behavior. The mechanism may be good parental supervision, an effective school or teacher, or the effects of voluntary organizations or community groups. It is again a theory that can be adapted to a focus on place and has a central concern with the offenders and where they live.

Environmental criminology offers the closest approximation to a geographical 'theory' of crime. It emphasises the criminal act and the location at which it occurs, the 'where' rather than the 'why' of crime (Bottoms 1994). Place is central to an approach that acknowledges that each offence leaves a new point on the map and is a clue to the activity space of the offender. The approach draws in considerations of the routine spatial activities of offenders and victims, the concept of journey to crime, and related ideas of territoriality and surveillance. At the present time environmental criminology is more a methodology than a theory. As such it draws heavily on basic geographical concepts such as space and place, and lends itself to detailed spatial analysis through geographical information systems. Conceptual issues include the problem of attaching any independent significance to space and understanding the full range of meanings attached to place.

4. Approaches to the Geography of Crime

Studies that merit the description of a geography of crime have changed along with broader paradigm shifts within the social sciences. Cartographic crimi-

nology, basically concerned with the mapping of criminal statistics and the representation of spatial patterns, has evolved to reflect wider use of statistical methods including the sophisticated technology of geographical information systems (GIS). Police forces recognize the value of GIS as a part of crime data analysis and the geocoding of criminal events for computer storage has become standard practice. There are clear advantages in the rapid portrayal of crime patterns and the related ability both to measure the features of the spatial pattern and to explore correlation with other environmental indicators. One police analysis of 79 crimes involving a single serial rapist was reported as involving 790,000 calculations using probabilities of journey to crime to link all points on a grid to the known crime sites (Grescoe 1996). Research into the statistical correlates of area crime rates has progressed through a wide range of single and multivariate analyses. The areal units used in such analyses include nations, police force areas, urban car beats, and census tracts; each raises methodological issues of data reliability and measurement. Scale effects, the modifiable areal unit problem, and 'ecological fallacy' continue to qualify exercises of this kind. Broadly, the outcomes of these analyses show a high level of consistency revealing strong correlations with indicators of a poor residential environment. Measures such as high unemployment rate, low income, substandard housing, and low educational attainment recur and, less frequently, indicators such as lone-parent families and broken homes. Correlates of this kind have been interpreted as indicative of some more general condition such as social disorganization or weak social control, and particular significance is often attached to single measures such as high unemployment. For the most part, however, the results of this type of analysis remain descriptive; they have value in identifying groups and areas from which offenders are likely to come but are in effect markers of some more general social condition as is the crime rate itself.

Statistical analyses have also been used as a first stage in the study of crime or delinquency areas. After identifying clusters of offenders and the conditions under which they live, the research task then is to probe more deeply with different research methodologies into the nature of the 'crime area.' One approach has identified particular neighborhood characteristics that might predispose residents to criminology. Herbert (1976) compared 'crime' and 'noncrime' areas in a city, controlling for sociodemographic profiles, and found a consistent difference in terms of sets of values and forms of behavior between the two types of area. In the 'crime' areas, parents adopted different approaches to control, had a clear tendency to accept some forms of misbehavior, and the children were lower achievers educationally. Other neighborhood studies have focussed on specific issues such as lack of parental supervision. More recently, what might be termed 'crime area' studies have taken a known problem area and sought to unravel both its origins and present form. In the United Kingdom, the so-called 'problem housing estates' lend themselves to this kind of analysis. Such estates often originated as local housing managers 'dumped' known problem families or relocated a slum clearance population to a specific estate. Early episodes of misbehavior reinforced labeling and reputations that have persisted. The Meadowell Study (Barke and Turnbull 1992) demonstrated a life-style that was permeated by welfare dependency, drug-trading, petty crime, and vandalism. Often self-selection of tenants who opt for this kind of lifestyle builds the area profile.

Understanding why criminal events occur where they do requires different approaches. Criminals respond to opportunities or targets in the environment and the task is to identify these 'cues.' A large majority of such crimes are opportunist and involve minimal planning; a minority is 'professional,' involving experienced criminals who may spend significant amounts of time preparing for a single criminal event. It is the former that lends itself to analyses based on opportunism and environmental cues. What makes some areas or residential units more vulnerable to crime? First, areas that offer more obvious or lucrative targets for a crime such as burglary are not likely to experience most offences. In part this is a function of security, wealthier neighborhoods are able to defend themselves with security devices and forms of control such as block or neighborhood watch. Research also shows that burglars tend not to travel far to commit an offence (Herbert and Hyde 1985). The offender–residence hypothesis suggests that vulnerable areas are either the areas or are close to areas where offenders live. Neighborhoods have 'cores' and 'borders' and the border-zone hypothesis suggests that the borders are more vulnerable. The local social control hypothesis suggests that ordered, well-organized neighborhoods with a strong sense of community identity experience less crime; the area variability hypothesis suggests that 'mixed' areas experience more. Hypotheses of these kinds, focusing on the places at which criminal events occur, blend into the general approach of environmental criminology. So too do studies of incivilities or signs of disorder in the urban environment (Herbert 1993) and the idea that these may indicate a deteriorating situation in neighborhoods. The concept of a 'community career' suggests that some localities move through a form of life cycle with highs and lows of criminal activity (Bottoms et al. 1992).

As criminals react to cues in the environment so do potential victims. Fear of crime arises from the perception that parts of the city, types of individuals or groups, and times of the day, are dangerous. People will modify their behavior to cope with fear and to achieve feelings of community safety. Early studies identified residents' perceived stress areas and showed that these were avoided in everyday routines. Fear of

crime is known to be high among old people and women with young children (Valentine 1997). Such groups experience less crime than youths but adopt avoidance strategies to reduce risk. Police have responded with initiatives such as 'do not speak to strangers' to protect children, but part of the problem may lie in the design of city environments and conventional attitudes towards time and place.

The step from environmental criminology to 'designing out crime' and crime prevention has proved a short one. In his thesis on 'defensible space,' Newman (1972) argued that places became more vulnerable if they had bad design features, lacked a sense of territoriality, had poor surveillance, and were stigmatized by their externalities. If design could incorporate the positive qualities, it could create defensible space and become less vulnerable to crime. The most comprehensive test of defensible space principles was provided by Coleman's (1985) study of housing projects in inner London. She developed a 'disadvantagement' score that was made up of measures on a range of indices from presence or absence of overload walkways to alignments of doors and windows. Coleman demonstrated close correlations of disadvantagement with crime and argued that less disadvantagement meant less crime. Although criticized for neglect of social dimensions, this work had a high impact on policy and on perceived community safety and quality of life. More restricted research designs, such as those to assess the impact of improved street lighting or CCTV camera surveillance, have produced similar positive results. The caveat with such measures is that instead of reducing crime they can simply displace it to other less well-protected areas. The ultimate in designing out crime is evident in rich suburban enclaves where high technology surveillance devices, walls, gates, and guards are used to protect residents. Davis (1990) wrote of fortress Los Angeles, divided between the protected enclaves of the very rich and the territories of the criminalized poor. Geographical research on social conditions also translates easily into crime prevention policies. Block or neighborhood watch is a direct transfer of ideas on community, surveillance, and social control.

The geography of crime has extended to consideration of policing, sentencing, and the criminal justice system. Early studies showed that sentencing was harsher in certain states and localities: where one committed a crime affected the sentence received. At international scale there are clear differences; Islamic law, for example, punishes an offence differently from European law. Within the United States, Florida tends to have more prisoners on death row and more executions (Harries and Brunn 1978). Studies show that jury composition affects verdicts (Herbert 1994). Magistrates drawn from one class judge offenders from another. Policing as an activity has strong spatial connotations. Police carry images of the city, derived from their experience and passed-on wisdom; these influence the ways in which they police the city. As police patrol areas, they need a detailed understanding of those places; the distributions in space of offenders and offences are key considerations for them. The police often focus their resources on specific areas and/or crimes for limited periods both in terms of community policing initiatives and crime prevention or target hardening. Geographers have studied policing initiatives such as police consultative committees and the ways in which they are constructed. Studies of the so-called 'victimless crimes' of prostitution (Shumsky and Springer 1981) suggest that policing practice and the variable workings of the criminal justice system shape their geographies. Beyond policing and the courts is the penal system, and as prison populations rise, their distribution and access are significant.

5. *Future Directions*

The geography of crime started from a few simple observations of spatial distributions and extended to a variety of applications of basic disciplinary concepts of space, place, and environment. Current thrusts involve developing pattern analysis through sophisticated information technologies, focusing on the meanings and relevance of place, and examining the interfaces between crime, criminals, and the criminal justice system.

Crime: Knowledge about and Prevalence

Systematic knowledge about crime and its prevalence relies largely on legal definitions of crime, which—like commonsense definitions—are socially constructed. After describing sources of information on crime, this article summarizes what is known about its historical and social distribution, and how this distribution has been explained.

1. *Defining Crime*

In popular discourse, crime is behavior that violates fundamental moral precepts and deserves to be denounced and punished. This commonsense definition implies that certain behaviors are inherently criminal and necessarily invite sanctions. Because moral precepts, as well as responses to their violation, vary substantially over time and place, commonsense definitions of crime cannot denote a fixed and natural category of behaviors.

In legal discourse, crime is behavior which leads to particular legal procedures and for which the law permits imposition of criminal penalties. Here crime is constituted by legal reactions, not by characteristics inherent in behaviors. Legal definitions of crime appear to be both more precise and more objective than commonsense definitions: crime is what the law defines and treats as such. Because legal systems are products of particular historical epochs, and legal definitions are created and applied through social and political processes, crime in this definition is both historically and socially constructed.

Social and behavioral scientists who study crime typically rely on legal definitions, and restrict their attention to acts defined as violations of the criminal law. They differ, however, on the questions they ask about crime. Some are interested primarily in behaviors defined as crime and people who engage in them, whereas others are interested in the processes through which particular behaviors and people are defined as criminal.

Determining how much crime occurs and explaining why people commit it have traditionally been the principal concerns of those who study crime. Because there is no common behavioral attribute that ties all crimes together, the task of explanation becomes quite complex. How, for example, can one account for behaviors as diverse as possession of heroin, price fixing, vandalism, bribery of public officials, and spouse assault? Each of these violates the criminal law of many countries.

The difficulty of explaining crime as behavior suggests why other researchers direct their attention to the social and political processes whereby acts and people are criminalized. Here, crime is both a product of, and a discourse used in struggles over how social order is defined and achieved; its lack of any essential attribute highlights its ideological character (van Swaaningen 1997). This approach, however, 'implies a virtually unlimited legislative power to create crimes without regard to any restraining principles' (Hughes 1983, p. 301) and neglects the near-universal criminalization of certain behaviors, such as murder, assault, theft, and arson.

Notwithstanding the conceptual challenges of defining crime, the combination of two elements is ordinarily recognized as critical: human behavior, and a state-sanctioned response to it. Crimes of greatest concern in most societies also involve a third element: *intention* to harm or wrong another. The more serious of these crimes—what are called *mala in se* (acts wrong in themselves)—are the target of substantial measurement efforts designed to answer questions about their prevalence, distribution, and causes.

2. *Measuring Crime*

Efforts to measure crime are usually guided by legal definitions within the jurisdiction of interest and rely on crime reports of legal officials. Most nations compile annual reports on the number of crimes known to police and the number of persons proceeded against. There are two principal difficulties with this approach to measuring crime. First, while legal definitions and official statistics provide a reliable guide to what is designated as criminal behavior *within* a given society, they may not measure accurately differences *across* societies in similar types of behavior. This is because legal definitions of even relatively serious crimes vary across societies.

The second difficulty is that, for a number of reasons, official statistics do not measure accurately

levels of crime, even within a single society. Characteristics of official agencies that collect information on crime, such as the police, inevitably influence how these acts are interpreted and recorded. Some acts that fit legal definitions of crime may be subject only infrequently to criminal enforcement, such as many white-collar or corporate crimes. Since the public is the primary means by which officials learn about crime, popular views on crime and the agencies that deal with it also influence which acts are reported to legal officials. So, for example, well under a half of all physical and sexual assaults are reported to police in most nations (Mayhew and van Dijk 1997). As a result, official statistics on crime do not reflect its true prevalence.

Unofficial sources of crime data, such as surveys of the general population, avoid some of these problems and shed light on the 'dark figure of crime'—that is, crimes that do not come to the attention of legal officials. Victimization and self-report surveys, which ask people about their criminal victimization, or offending, over a specified period of time, yield higher estimates of the prevalence of crime than do official statistics. Victimization surveys also show that the likelihood that a crime will become known to officials depends in part on the characteristics of the victim, the offender, and their relationship; and that the more serious the crime, the more likely it is to be reported to officials. But because they rely on the honesty, memory, and perceptions of respondents, such surveys have their own limitations and biases.

All efforts to measure crime inevitably confront the problem of *defining* a crime: someone—a victim, a police officer, a witness, or a researcher—must apply a legal definition to a complex set of circumstances and human relationships. The difficulties in measuring crime, then, are not simply technical or statistical, but conceptual—and unavoidable. Consequently, it is impossible to determine the total amount of crime in any jurisdiction at any time. One can, however, count and describe with some accuracy events which are crimes according to the law, and which come to the attention of legal officials, as well as criminal events which people report to survey researchers. These estimates form the basis of knowledge about the prevalence and distribution of crime over time, place, and persons.

3. *The Distribution of Crime*

Is there more crime now than in the past? For reasons outlined above, this question has no simple answer. To the extent that contemporary criminal law defines a wider range of behaviors as criminal, there is likely to be more crime. The most reliable historical evidence pertains to serious violent crimes, such as homicide, robbery, and serious assault, in Western Europe and North America. Their trends over the last six or seven centuries have undoubtedly been downward, albeit punctuated by short-term waves of violent crime after wars and other major social dislocations (Gurr 1989).

This long-term decline reversed somewhat in the late twentieth century. In the early 1970s, rates of serious violent crime rose and then plateaued in most Western nations but in many Eastern European nations, violent crime rates appear to have increased dramatically since the late 1980s. Nevertheless, violent predation has become a much less customary part of daily life over the long term. Whether the same can be said of property crime is unclear, because reliable historical data do not exist. But the best evidence suggests that, as societies developed, property crime rates increased, in part because consumer goods were more available and more portable.

Are some societies more crime-prone than others? Cautious comparisons can be made of direct-contact, predatory crimes by individuals using data from international victimization surveys (Mayhew and van Dijk 1997), and public health statistics on homicides (World Health Organization 1997). According to these data, rates of serious violent crime vary greatly, even across relatively similar societies. At the end of the twentieth century, for example, homicide rates were four times higher in the USA than in Canada, three times higher in Finland than in Norway, and four times higher in Venezuela than in Chile. Among advanced capitalist nations, homicide rates are higher in the New World countries (the USA, Canada, and Australia). Countries in North Africa and the Middle East tend to have relatively low rates of serious violent crime, as do many Asian countries (Heiland et al. 1992).

Homicides and other serious violent crimes make up only a small part of the total crime rate, however. In all nations, most crimes are crimes against property; national differences are much less pronounced for property crimes than for serious, violent crimes, especially in advanced capitalist countries. While the property crime rate is not necessarily a good predictor of the violent crime rate, nations with high rates of property crime are unlikely to have low rates of violent crime. Although there is little research and almost no systematic data on national differences in white-collar, corporate, and political crimes—for example, theft by corporations, environmental destruction, or illicit violence by state agencies—these appear to be more common in developing countries. In part, this results from lax enforcement and the ability of offenders to avoid prosecution. For similar reasons, activities of criminal organizations, such as trafficking in drugs, people, and weapons, money laundering, and cross-border terrorism, may also be more prevalent in countries with emerging or transitional economies.

As this suggests, the economic and political organization of a nation produces particular patterns of crime. For example, although the pre-1990s socialist countries of Eastern Europe had low rates of violent

and predatory street crimes, other behaviors—worker sabotage, theft of nationalized property, bribery, and black market activity—were relatively widespread. Violent crime rates are higher in nations with greater inequalities in income and wealth, and in nations with fewer restrictions on the ownership and use of firearms. Nations that go to war more often also tend to have higher homicide rates during peacetime.

Many of the social processes, conditions, or policies commonly thought to affect crime rates often do not do so, or affect only some types of crime. Urbanization and unemployment, for example, typically are not accompanied by higher rates of violent crime, although they are associated with higher rates of property crime (see *Crime and Class*). Conversely, some social policies that are intended to decrease crime in fact do not. For example, there is little evidence that the death penalty deters homicides (see *Death Penalty*). During the twenty-first century, the social process likely to have the greatest impact on crime—from street crimes to crimes of transnational corporations—is globalization. 'Globalization,' according to Findlay (1999, pp. 1–2), 'creates new and favourable contexts for crime' and enables 'the transformation of crime beyond people, places and even identifiable victims.'

Are some people more likely to engage in crime than others? Once again, the heterogeneity of the acts comprising crime demands a cautious answer. Serious, direct-contact, predatory crimes are the domain of young, economically disadvantaged males in virtually all nations. White-collar, corporate, and political crimes are also male-dominated, though these are, for obvious reasons, rarely the preserve of the young and the poor. It is largely for victimless crimes, such as prostitution, gambling, or drug use, that women's involvement at times rises to the level of men's (see *Crime and Gender*).

4. *Explaining the Distribution of Crime*

Most explanations for the distribution of crime feature one of three mechanisms: motivations, controls, or opportunities.

Motivational explanations focus on social conditions or processes that generate criminal tendencies in societies, groups, or individuals. Criminal motivations have their roots in both social structure—institutional patterns and processes that organize interactions and relationships—and in culture—accumulated traditions and shared experiences that shape the values of a society or group. Economic inequality is a structural factor thought to increase motivations for crime by fostering alienation and hopelessness (Hagan and Peterson 1995). Norms that advocate criminal acts under certain conditions are a cultural factor that may motivate criminal behavior.

Control explanations focus on social conditions and processes that weaken internal and external, informal and formal controls on crime. Both structural and cultural factors can affect social control (Sampson and Raudenbush 1999). Crime tends to be lower in societies with stable families and integrated community networks because these strengthen controls on criminal behavior. Crime tends to be higher where group norms excuse crimes against certain victims (e.g., against spouses, organizations, sexual minorities, etc.) because these cultural features weaken controls.

While motivational and control perspectives are concerned primarily with potential offenders, opportunity explanations focus on the circumstances in which crimes occur. Situations in which a motivated offender encounters a suitable target in the absence of capable guardians create opportunities for crime (Cohen and Felson 1979). Patterns of routine daily activity that take people away from home foster opportunities for burglary, mugging, and vehicle theft. Criminal opportunities are also greater where small consumer items are mass-produced.

No general theory of the distribution of crime has been tested adequately enough to command widespread support. Indeed, there is still considerable debate over whether a general explanation of crime is possible or even desirable, given the heterogeneity of crime. Nevertheless, some generalizations about the sociocultural contexts that appear to discourage direct-contact, predatory crimes can be drawn. These are characterized by: (a) strong systems of informal social control reinforced by highly consensual normative systems, (b) strong networks of communal obligation and mutual interdependence, and (c) cultural orientations that discourage interpersonal aggression. Societies with these characteristics tend to be organized around collectivist rather than individualistic principles, which are reflected in their political, economic, and legal ideologies and practices (Pampel and Gartner 1995).

These generalizations are limited by their grounding in research on a restricted range of criminal behaviors. Too little is known to be able to develop similar generalizations about many types of crime, such as those perpetrated by transnational corporations and national governments. Crimes that cross national borders have also been neglected by researchers, although this is changing. New forms of crime emerging in some societies—cyber-crimes, for example—also need to be studied. Until documentation of these crimes is taken seriously, understanding of the prevalence and distribution of crime will be incomplete.

Crime: Organized

Relative to other kinds of crime groups (e.g., a burglary crew), law enforcement practitioners and social scientists typically define an organized crime group as follows: (a) it has some manner of formalized structure whose primary objective is to obtain money through illegal activities; (b) it has continuity over time; (c) it maintains its position through use of violence or threat of violence, corruption of public officials, and extortion. Additional important elements may include: (d) its operations tend to be interjurisdictional; (e) key members are bufffered by forms of organizational structuring and by the use of 'fronts' and nonmember associates; and (f) long-term goals stress the maximization of profit and power through monopolization, or cartelization, of criminal enterprises and markets, as well as control over legitimate (noncriminal) businesses and sectors of the economy (Lupsha 1995).

Organized crime groups may perpetrate almost any kind of swindle, theft, or illicit activity imaginable. But the two main types of activities involve the provision of illicit goods and services like illicit drugs and gambling, and the infiltration of legitimate business (including the illegal manipulation of labor unions).

Most organized crime is never detected and so its costs to society are unknown. It generally is recognized, however, that the costs of organized crime in terms of illicit profits, unpaid taxes, disruption of legitimate business, and political and commercial corruption far exceed the costs incurred from conventional crime and street crimes.

1. Scope and Structure of Organized Crime Groups

The size, structure, and cohesion of criminal organizations has been the subject of much debate. At one end of the spectrum, organized crime is described in terms of large hierarchical organizations that are structured rather like traditional corporations. At the other end, organized crime is described in terms of small, fluid networks that are rather amorphous in structure and are characterized by considerable opportunism.

This dichotomy is unnecessary, however. Organized crime as a concept is a matter of degree, not a matter of kind. Criminal organizations fall along a continuum from large to small and from formal hierarchical (even bureaucratic) structure to fluid network organizations (Steffensmeier 1995). Criminal organizations falling at either end of the continuum may be equally adaptable to the exigencies of the illicit marketplace. Groups may combine elements of a formal structure at certain levels, with more amorphous and flexible networks at the lower levels. The Colombian cartels and the US Mafia, for example, have demonstrated remarkable adaptability in spite of their large size and organizational sophistication.

In addition to size and degree of formal structure, criminal organizations can be identified and compared relative to their scope of criminal activities. Some groups are highly specialized and focus on one kind of activity, such as prostitution or drugs. Other groups engage in a broader range of criminal activities such as gambling, extortion, drug trafficking, financial scams, and infiltration of legitimate businesses.

Criminal organizations or networks also vary in terms of their geographic scope—local, national, or transnational. A powerful transformation is occurring whereby organized crime increasingly is becoming transnational in character. Less and less are the criminal activities of criminal organizations constrained by national borders. Further, organized crime groups which are still predominantly domestic in scope can be expected in the future to increase their exploitation of global opportunities.

A final dimension concerns the level or scale of impact on the citizenry and on the political and economic structure of a nation. The US Mafia and the

major transnational crime organizations represent what has been termed large-scale organized crime, to refer to those powerful criminal groups 'able to engage in political and economic activity both through legitimate official structures and by illegal means, and which can adversely affect whole areas of productive, social and institutional life' (Arlacchi 1986, p. 213).

2. *Organized Crime Groups/Networks in the USA*

The bulk of research and theory about organized crime has centered on the USA, where four main forms of organized crime networks now exist: the US Mafia, emerging or previously ignored crime groups, local racketeering syndicates, and transnational criminal organizations (Steffensmeier 1995). These forms are analytically distinct but in practice may merge one into another.

2.1 *The US Mafia*

Italians are but one in a long succession of groups to become involved in organized crime in the USA. The Irish were the first group to become involved on a large scale, followed by Eastern European Jews, and then by Italians. In recent years Hispanic and Chinese immigrants have made a place for themselves in organized crime. But Italian–American organized crime, of which Cosa Nostra is the archetype, has achieved broader dominance over a wider range of criminal activities than that of any other ethnic group, and for a longer period of time.

At the beginning of the twenty-first century, about two dozen Cosa Nostra families are centered in urban areas with relatively large Italian–American populations, such as New York and Chicago. The networks of these families are expansive, moreover, so that localized Mafia groups and Mafia-connected criminal activities exist in a substantial number of US cities. Legislation used to counter organized crime, notably the Racketeer Influenced Corrupt Organizations (RICO) Act, was designed with Cosa Nostra in mind and has enabled law enforcement to develop cases against Mafia groups and other crime organizations as criminal enterprises (Jacobs 1994). Until about the 1970s, 'Cosa Nostra' and 'organized crime' were considered to be synonymous terms by many law enforcement authorities.

Newer evidence confirms and refines the picture of Cosa Nostra provided by earlier sources (see Cressey 1969). Cosa Nostra exists; possesses a hierarchical chain of command; is self-perpetuating and has an overarching structure which is independent of criminal activity; and becoming a 'made' member involves initiation rites and pledges of loyalty, secrecy, and violence. A Cosa Nostra 'family' operates autonomously in many US cities, but individual groups are joined together in a crime confederation in which a limited amount of authority has been ceded to a governing national commission. The commission regulates interfamily conflicts but does not attempt to run the day-to-day operations of the syndicates.

The bureaucratic analogy sometimes applied to Cosa Nostra, however, has been overstated. Its structure is looser and more decentralized than the organizational charts imply (Abadinsky 1999). Day-to-day operations of organized crime are often quite haphazard, both because of inadequate managerial skills on the part of many participants and because of the need for secrecy—which sets limits on managerial control. Relationships between family hierarchy and members, as well as associations with other family groups, are flexible and fluid. Individual members have sufficient autonomy to build their own power bases and connections. They make their own deals with other criminals, businesses, labor leaders, and government officials based on potential profits or services required.

It appears that the criminality and influence of a number of Cosa Nostra families is less at the beginning of the twenty-first century than it was in the early 1990s. Factors contributing to this decline include intense federal enforcement efforts directed at the Mafia; changing illicit markets (especially drugs); advancing age and attrition in membership; the decline of ethnic communities in urban areas; the shift of political power from cities to the federal government, including the decline in the local 'political machine'; and the decline of unions. These together have reduced three main historical assets of the Mafia—centralized corruption of police and local officials, a disciplined workforce, and reputation (Reuter 1994). However, some recent prosecutions and law enforcement reports indicate that the increased law enforcement activity has had a tremendous impact on the hierarchy of the families but little effect on Mafia-related activity (Kelly 1999, Pennsylvania Crime Commission 1991).

2.2 *Previously Ignored and Emerging Crime Groups*

Besides traditional Italian organized crime, it is widely recognized that there exists in many US metropolitan areas a collage of groups—Asians, bikers, Blacks, Colombians, Dominicans, Jamaicans, Mexicans, Syrians, Lebanese, and Russians—involved in organized crime, notably in the drug trade (Pennsylvania Crime Commission 1991, Steffensmeier 1995). Recent immigration to the USA, in particular, has spawned ethnic crime groups who often direct much of their criminal activity against members of their own ethnic group and maintain ties to criminal groups in their homelands. Some of the nontraditional groups are highly organized, while others are not. While many of

these groups are considered 'new' or 'emerging' in that they have become active in recent years, other groups are 'new' in the sense that they have only recently been recognized as crime groups. The outlaw motorcycle gangs, for example, have been operating for many years in organized crime activities and are now well established.

2.3 Local Racketeering 'Syndicates'

As far back as 1951, the US Senate's Kefauver Committee concluded that much organized crime is localized and indigenous to the community in which it exists. A largely unrecognized but important dimension of the organized crime phenomenon is the significant and longstanding presence of local racketeering groups which dominate extortion and vice activities in many localities and cities throughout the USA, doing so both through legitimate official structures and by illegal means (Pennsylvania Crime Commission 1991, Steffensmeier 1995). Core 'membership' in these racketeering groups includes not only mafioso and professional criminals but also business people (e.g., car dealers, contractors, restaurant owners), police and city officials, attorneys, and other individuals from 'respectable' society who are influential in local politics.

These local crime syndicates generally represent distinct entities, although they often overlap and may even be fragments of a large-scale crime organization such as Cosa Nostra. The syndicates tend to be dominated by a handful of entrepreneurs in which the illegal activities of individual racketeers are carried out through a network of individuals associated with them in that activity. With this type of operation, it frequently is the activity rather than the particular people that fosters the relationship. A number of substantive criminal relationships or 'partnerships' may develop, linking joint criminal operations within a network and across other crime networks dominated by other local criminal figures. Overlapping partnerships for specific illegal ventures are stitched together through opportunistic and fluid alliances. In some instances there may be a central racketeering figure, but more likely there is shared power and a shifting power structure depending, in particular, on who at the time is most influential with local law enforcement and city officials (Steffensmeier 1986).

3. Transnational Crime Organizations (TCOs)

Criminal organizations, particularly in the USA and other rich countries, are increasingly engaging in activities that cross national borders (Martens 1991, National Research Council 1999, Williams 1999). Factors contributing to this development include the globalization of the economy and financial markets; the rise in the numbers and heterogeneity of immigrants, who bring with them social and commercial networks that make law enforcement more difficult and that facilitate conspiracy; improved communications technology, which makes borders more permeable and criminal activities less conspicuous; the end of the Cold War and triumph of capitalism, which have increased the porosity of national boundaries and created new markets for both licit and illicit commodities.

The term 'transnational' refers to the movement of information, money, physical objects, people, or other tangible or intangible items across national boundaries (Williams 1999). 'Transnational organized crime,' in turn, refers to large-scale crime organizations or networks that operate across national borders or that have a home base in one nation but that operate in other nations or states where there are favorable market opportunities. Their principal activities at the turn of the twenty-first century include: smuggling—in commodities, drugs, and protected species; contraband such as stolen cars and tobacco products; and services—in immigrants, prostitution, indentured servitude, and money laundering (see Kelly 1986, National Research Council 1999).

Transnational crime organizations (TCOs) vary considerably in the structure, geographic scope, and scale of their operations. Some are organized hierarchically, while others are fluid in structure. The TCOs typically operate out of 'national sanctuaries'—in areas where there is uneven justice and limited law enforcement capacities, and where they are relatively immune to law enforcement efforts. By acting transnationally, the groups gain access to lucrative markets for illicit commodities or services where the profits are very high and then channel the proceeds from illicit activities through the global financial system.

The most widely recognized transnational groups are: Chinese triads, Colombian cartels, Japanese yakuza, Sicilian Mafia, and some Russian criminal organizations (which vary greatly in organizational structure and sophistication). The Asian gangs and the Sicilian Mafia have long traditions as compared to the Colombian cartels and Russian gangs, which are relatively young.

The Sicilian Mafia, the most global and perhaps the most complex of the transnational organizations, actually refers to four distinct, often overlapping, groups. The most important of these groups is the Sicilian Mafia or Cosa Nostra, followed in order by the Neapolitan Camorra (a group of predominantly local organizations), the Calabrian N'drangheta (a federation of families involved in illegal drugs, contraband tobacco, kidnaping, and extortion), and the 'Sacra Corona Unita' in Apulia (based on breakaway factions from the Camorra and N'drangheta). Like the US Mafia, these groups entail a relatively simple hierarchical structure and are based on close associations that are partly functional, partly personal and

familial, and partly based on fear (Arlacchi 1986, Paoli 1999). Recent trials both in the USA and Italy (e.g., the 'Pizza Connection' case in 1986) have revealed the scope of the Sicilian Mafia's involvement in international drug trafficking (especially heroin and cocaine) and the considerable extent to which its members associate and interact in criminal activity with the US Mafia. Although its power base remains in Sicily and southern Italy, the Sicilian Mafia has increasingly become a transnational enterprise and its Mafia groups can now be found in virtually every country where there resides a moderately sized population from Sicily (Savona 1993, Sterling 1990).

The Colombian cartels are foremost in the drug business, in contrast to the Sicilian Mafia and most other transnational criminal organizations which engage in a range of illegal activity. The cartels—and particularly the Cali cartel that has become the predominant group in the cocaine industry—have also amalgamated corporate and criminal cultures more than any other group (Williams 1994). They resemble modern legitimate firms in utilizing business management principles such as elaborate staffing and division of labor, administrative oversight, strategic planning, and meticulous accounting procedures. The cartels have developed a very specialized cell structure to carry out activities such as logistics, marketing, and money exchange; the cell stucture also provides protection by disbursing information on a need-to-know basis (see Pennsylvania Crime Commission 1991).

The recent rise and expansion of major international crime networks represent the most important and threatening development in organized crime at the turn of the twenty-first century. First, very large fortunes have been amassed by some TCOs—reflecting both the extraordinarily large profits obtainable in the illegal economy and the ease with which money can be laundered or 'cleaned.' Second, the expanding demand for criminal labor generated by the increased scale of activities has fostered integrative links between the international mafias on the one hand with common and juvenile crime on the other (Arlacchi 1986). The changes toward an older profile and adult involvement in youth gangs in many US cities reflect this development. Third, the most powerful criminal groups (e.g., in Colombia, Russia, Sicily) have shown that they can influence society and economic processes to a greater extent than they are determined by them (Arlacchi 1986).

Fourth, the large-scale criminal organizations—through their huge economic resources and by means of private violence—are able to impose their power and to manipulate large sectors of the political system and the state apparatus. These groups not only arouse general fear and anxiety in many countries but also threaten the governability of individual countries and the world order more generally. The threat to democratic institutions and the erosion of government's ability in many parts of the world 'to govern, to provide even the basics of civil peace, economic opportunity, or justice' (Olson 1994, p. 1) are probably the most detrimental repercussions of the transnational criminal organizations.

4. *Roots of Organized Crime*

At least four main factors, singly or in combination, contribute to the rise and persistence of organized crime. First is a certain level of social-cultural disorganization (Arlacchi 1986). Important here are the consequences of (a) the industrialization and urbanization that have taken place over the last two centuries in countries in the West; (b) the so-called 'modernization' that is presently taking place in certain large Asian, Latin American, and African nations; and (c) the spreading democratization and free-market capitalism in the Eastern European nations. Their effects—growing social injustice, poverty, and violence—are a seedbed in particular for the recent emergence of large-scale criminal organizations at the global level.

A second factor is 'weak' government. Criminal organizations are more likely to emerge and flourish where the government is lacking in legitimacy or is not fully in control of the territory under their jurisdiction. Organized crime in many countries, as in Sicily, has been generated by despotic governments which give rise to groups formed for self-protection and for providing quasi-governmental services. These conditions also help to foster an ethos of cultural underpinnings for organized crime (Cressey 1969, Pennsylvania Crime Commission 1991, Steffensmeier 1995). Main tenets include distrust of outsiders and government, clannishness, proclivity for sanctioned violence and private revenge, a sense of how to coopt the law and achieve immunity by corrupting influential persons, and savvy to cultivate the goodwill of local residents while simultaneously exploiting them for personal advantage.

Third, organized crime arises because it is 'functional'—either to the community or large subgroups in the society (Cressey 1969). These functions are varied, but may range from providing desired but illicit goods and services, social control and protection (e.g., against certain predatory crimes) in areas where government or official agencies have failed, opportunities for political and economic participation, and welfare-type assistance (e.g., in finding employment, short-term loans to prop up precarious small businesses).

Fourth, there is an easy affinity between organized crime and market-based economies. Organized crime is about the exploitation of business or market opportunities. The necessity to maintain and extend one's share of the market governs entrepreneurship in organized crime as it also does in the legitimate market (Cressey 1969, Smith 1980).

By their very nature, many organized crime activities, especially financial crimes, require the tacit or open cooperation of legitimate organizations and actors. In the abstract, organizations could be perceived as either legitimate groups that commit no crime or as criminal groups with purely criminal purposes. In the real world, however, the activities of many organizations, both legitimate and criminal, fall between these extremes (Steffensmeier 1986, National Research Council 1999).

These factors together suggest that the organized crime phenomenon is primarily economic and institutional, rather than criminal (see Arlacchi 1986, Cressey 1969). Control strategies most likely to be effective will target the real structures and seats of power of organized crime—governmental weakness and official corruption, financial markets and accumulated capital, and the institutional degeneration that allows the problems to continue and grow worse.

5. *Ethnicity and Organized Crime*

Ethnicity affects organized crime in three related ways (Pennsylvania Crime Commission 1991, Steffensmeier 1995). First, organized crime is a multiethnic phenomenon in the sense that a wide variety of ethnic groups are involved. Second, ethnicity typically plays an important role in the formation and function of organized crime groups. Ethnicity contributes to the organization of crime, a feeling of camaraderie built on blood ties, a common cultural base, insularity, mutual trust, a distrust of government, and an exclusivity that reinforces bonds and secrecy within the organization. Third, in both the USA and other rich countries, foreign and immigrant criminal groups have become principal figures in transnational organized crime.

5.1 *Alien Conspiracy vs. Ethnic Succession*

The role of ethnicity in shaping a country's organized crime problem has been the subject of some dispute. The alien conspiracy view holds that organized crime doesn't so much emerge out of a country's culture or economic realities and politics, but is thrust upon it by particular ethnic, immigrant groups who bring forms of organized crime with them. In the USA, for example, the theory holds that a secret organization originating in Sicily made its way into the USA during the period of massive Italian immigration around the start of the twentieth century. Popular in the 1950s and early 1960s, the Mafia conspiracy view has since been widely rejected. In 1969 organized crime expert Donald Cressey stated that while 'the similarities between the two organizations are direct and too great to be ignored, the American Mafia is not merely the Sicilian Mafia transplanted' (Cressey 1969, p. 8).

A contrasting view characterizes organized crime not as a foreign import but as an expedient avenue for social mobility that is an integral part of a country's social and economic system (Ianni 1972). Ethnic succession refers to the process by which different ethnic immigrant groups have used, and continue to use, organized criminality as a means of assimilation and advancement. Using their illegal gains and as more legitimate opportunities opened, legitimate advances with all their advantages were pursued as alternatives to criminal activities.

The process of ethnic succession adequately describes the Irish, the Germans, and the Jews (who preceded the Italian migration into the USA), as well as some of the recent ethnically based crime groups both in the USA and elsewhere. But the persistence of the Italians in organized crime is at odds with ethnic succession.

6. *Alternative Models of Organized Crime Groups*

Recent writings on organized crime distinguish among three main paradigms of organized crime (Albanese 1998).

In the *hierarchical structure model*, organized crime is a more or less government-like structure with graded ranks of power or authority; organized illegal activities are conducted with the blessing of higher-ups, illicit activities are 'protected' through the influence of the hierarchy, and profits or 'tribute' are funneled to superiors (Cressey 1969).

An alternative approach has been to describe organized crime as a *network of patron–client relationships* wherein people's connections provide them with access to a particular illicit activity (Albini 1971, Ianni 1972). Relationships develop around a central figure, or patron, and the recipients of his favors who are dependent upon him for contacts, protection, and resources. In return, these clients offer loyalty and allegiance.

The *enterprise model* constitutes a third paradigm of organized crime. Organized crime is a 'business' activity that represents a deviant variation on legitimate activity (Smith 1980). The focus is on the 'enterprise' and its functional needs, such as revenue and investment requirements, rather than the group undertaking it. Notably, the size and structure of an organized crime group is basically determined by the activity in which it is involved (i.e., function determines structure).

These models are analytically distinct and offer competing pictures of reality, but are better seen as complementary. All organized crime is entrepreneurial and is shaped by market forces; moreover, both patron–client and kinship relations are typically key features of hierarchical crime organizations. One key difference is that the enterprise model focuses more on how organized crime activities are organized (e.g., a

drug smuggling operation, a bookmaking business), whereas the hierarchical model focuses more on how crime groups are organized.

7. *Success and Survival of Organized Crime Groups*

Five factors help explain why some crime networks, like the Cosa Nostra or Japanese yakuza groups, succeed and survive for a lengthy period of time (see Reuter 1994, Steffensmeier 1995). The first is historical circumstance—e.g., Italian mobsters arrived on the US scene at a critical time (i.e., Prohibition) and were able to entrench themselves in the rackets of urban USA. Once in place, they warded off competing crime groups through advantages derived from their dominant position.

A second factor involves a unique cultural ethos—a set of traditions and organizational principles supportive of organized crime and very adaptable. A key element of this ethos, anchored in kinship and ethnicity, is a bounded solidarity and enforceable trust that group members can rely on for illicit activities. Other elements include distrust of government, clannishness, and proclivity for sanctioned violence.

The third factor is reputation—a set of beliefs or capacities that represent advantages the mafiosi as entrepreneurs enjoys over their competitors. The set includes the credible threat of violence, the ability to neutralize law enforcement, and the wherewithal to 'get things done.'

A fourth factor is the ability to recruit a disciplined workforce and prospective leaders. Mafia groups have been able to draft, almost effortlessly, reliable and able recruits from within kin networks and Italian-Sicilian neighborhoods where Mafia-based values and traditions have been in force, and where an abundance of young 'toughs' covet the fear and respect that mafiosi still engender.

A final element is durability itself. A crime network (e.g., the Mafia) that has been around a long time gains credibility by showing it can withstand either efforts to repress it or the loss of members from time to time.

These five factors also can be treated as analytic devices for broadly evaluating the strength of organized crime groups and their 'peculiar threat' relative to each other and to other forms of crime. The more these conditions can be said to characterize a group, the greater its strength, staying power, and threat relative to other organized crime groups. Furthermore, today's aggressive law enforcement effort to dismantle established crime groups will be successful only if it greatly reduces the competitive advantages described above. Likewise, strategies aimed at preventing the emergence or stabilization of comparably powerful crime groups will be effective only if they prevent the build up of such assets.

Crime: Sociological Aspects

The study of sociological aspects of crime is marked by controversy, beginning with definitional issues. There is general agreement that crimes are 'events and actions that are proscribed by the criminal law of a particular country' (Wilkins 1968, p. 476). The latter proviso, however, and the continually evolving nature of criminal law, render crime difficult to measure, describe, and explain. Laws vary greatly, between and within nation-states. Not all crimes are defined in criminal law. Entire classes of crimes, e.g., white collar and corporate crimes, encompass many behaviors that are defined by administrative and regulatory law. Correspondingly, 'criminals' in such cases are often corporations and other organizations. Nevertheless, the focus on law—law making and breaking, law breakers and their victims, and the control of law breaking and law breakers—is a unifying theme for an otherwise extremely diverse discipline and profession.

Some who study crime argue that crime should be defined as harm, whether or not specified in the criminal law. This ideological position charges that criminologists too often support 'existing structures of power and oppression,' and urges instead active promotion of change in these structures (Henry and Einstadter 1997, p. 418).

The vast majority of sociologists and other scholars who study crime and criminals reject this view, holding—in spirit, if not always in practice—to the cannons and the methods of science. The scholarly study of crime has become more truly interdisciplinary and, despite variations in substantive foci, methodological and theoretical approaches, attempts to integrate theories from a variety of disciplines are now common. Sociologists are at the forefront of such efforts (see, e.g., Tittle 1995).

1. *Sociological Issues in the Study of Crime and Criminals*

Sociological aspects of crime can be divided roughly into the following broad categories: (a) sociology of law; (b) conceptual issues; (c) measurement issues; (d) the social distribution of crime; (e) explanations of crime; and (f) issues related to crime control. Because they are so closely related to each other, conceptual and measurement issues are discussed together, as are the social distribution and explanations of crime.

1.1 *Sociology of Law*

The sociology of law focuses on the foundations of legal orders, patterns of legal change, and the role of law in social life. Definitions of behavior as criminal vary greatly in different times and places. Because laws define what is criminal or otherwise subject to sanction by governmental action, study of the law making process and of the effect of law on behavior is of particular interest to sociologists (Selznick 1968).

Law changes continuously, influencing and influenced by societal contexts. It is both enabling and constraining, conferring both rights and obligations. Legal ferment in many societies is related to changes in such matters as the status of females, the young, racial and ethnic minorities, homosexuals, and the indigent (McIntyre 1994). Understanding how and why such changes occur are major challenges to sociologists of law. Conflict and Marxist theories of crime draw much of their support from evidence that status inequalities bias law making and enforcement against the less powerful. The effects of legal sanctions on offenders and on those who might offend is also of interest to theorists of crime and policymakers alike.

1.2 *Conceptual and Measurement Issues*

Because crime consists of a very large number of heterogeneous criminal acts, no single index can capture its nature. Scholars and crime control agencies therefore find it necessary to reduce crime into more homogeneous categories. How these categories relate to one another is important both for understanding and controlling crime.

Official crime counting systems are designed primarily to serve institutional purposes such as documenting police or court activity, justifying budget requests, and evaluating institutional performance. They reflect the laws and practices of the jurisdictions with which they are associated. Data on crime and criminals are correspondingly affected. A great deal of effort has gone into standardizing definitions and reporting systems in order to enhance their comparability and research usefulness.

Having participated in developing measures of crime and crime reporting systems in many countries, sociologists continue to seek their refinement. Most countries now collect data on crimes known to the police and persons arrested, persons appearing before juvenile and adult courts, and persons convicted and sentenced to various forms of correctional sanctions. Interpretation of such data is guided by two principles.

(a) The further removed from its commission is a measure of crime, the less reliable and valid it is of the phenomenon. (b) Because the police must rely on victims and others to report most crimes, only data on serious crimes, which are most likely to be reported, are regarded as reliable. Therefore, measures based on serious crimes reported to the police or in surveys of victims of crime are favored when the object of study is the *distribution* of crimes. Similarly, for purposes of studying offenders, study of persons *arrested* for serious crimes are regarded as superior to data on persons who are incarcerated for those crimes.

Dissatisfaction with official data sources motivated the search for other measures. *Self-reports* of involvement in criminal and delinquent behaviors were developed in the 1950s and have been refined and solicited from better samples since that time. Reports of criminal *victimization* began to be developed during the latter part of the twentieth century and are now common in many countries.

Because crime is so varied, alternative measures and classification systems seek to reduce such heterogeneity (see Wilkins 1968). Thus, police classify separately more serious offenses against the person (homicide and non-negligent manslaughter) from other such offenses (aggravated assault; assault with intent to kill; and forcible rape). Offenses against property are similarly distinguished according to seriousness.

Typologies of criminal behavior systems yield important descriptive material on criminal techniques, careers, and lifestyles, but none has succeeded in capturing the full range of criminal behavior. Moreover, most crimes are committed not by specialists but by persons who vary the crimes they commit, contingent on their needs, abilities, opportunities, internal and external constraints.

1.3 The Social Distribution and Explanation of Crime

The basic data for sociological explanations of crime rest heavily on how crimes are distributed among such social categories as age, gender, social class, racial and ethnic status, over time, and in differing social and cultural circumstances. Most ordinary crime in all modern societies is committed primarily by young males, and is concentrated among those who are disadvantaged by economic and/or racial and ethnic status. The major exception is 'white-collar' crime, first identified as crimes committed by corporations or persons of high status, but later focusing primarily on violations of fiduciary responsibility or public trust.

Scholars associated with a variety of disciplines and professions study and theorize about crime and its control. The primary data employed by sociologists are *crime rates* and their distribution among groups, organizations, communities, and other political units. This *macrosocial* level of explanation seeks to determine what it is about such entities—their cultures, subcultures, and structural conditions—that explains varying crime rates. Sociologists who study the *individual* level of explanation focus on the influence of social and cultural factors, social interaction and individual learning experiences. Until late in the twentieth century, the lines between disciplines were clearly drawn and controversial. A third level of explanation, the *microsocial*, focuses on criminal behavior as a function of characteristics of situations, and of ongoing interaction among actors in situations (Short 1998). Theories that seek to integrate explanations of crime challenge disciplinary hegemony. Bridging theoretical levels of explanation and theoretical integration nevertheless remain difficult and contentious.

1.4 Issues Related to Crime Control

Crime control brings the sociological study of crime full circle, back to the law. The effects of law, law enforcement, and the imposition of legal sanctions on offenders and on others are major sociological concerns. Extensive research on the effects of legal sanctions on criminals, and on those who might offend, have resulted in few firm conclusions. Public concern with rising crime rates during the second half of the twentieth century resulted in higher rates of incarceration of convicted offenders, which accelerated during the last quarter of the century. A National Research Council report concluded that increments to crime control from incapacitation of offenders were modest (the size of the inmate population in the US doubled over a decade, resulting in an estimated reduction in crime of 10 percent), extremely expensive, and socially destructive (see Blumstein et al. 1986). Evaluations of other 'get tough' measure of crime control reach similar conclusions. As crime has increasingly become an issue of political contention, the relationship between knowledge about crime, criminals, and crime control has become controversial among scholars, criminal justice professionals, and the public. Efforts to bridge these sometimes conflicting interests nevertheless continue, theoretically (Braithewaite 1989) and in the form of experimental programs supported by governmental agencies in many countries.

2. The History of Explanations of Crime

Although eighteenth century philosopher/reformers and physicians/physiologists introduced modern thinking about crime, scientific study came later when European scholars such as Guerry, Quetelet, Durkheim, and Tarde began to search for regularities in the distribution of social phenomena. Durkheim and Tarde, especially, set the tone for a distinctively

sociological approach to the study of crime (Durkheim 1951/1897, Tarde 1886). Durkheim's insistence that social facts such as suicide and homicide rates were *sui generis* drew a boundary between sociology and psychology that profoundly affected the development of both disciplines.

Sociology was one of the earliest disciplines to include crime and criminals among its research and theoretical interests, and sociology continues to be the primary field of the majority of criminologists. Criminologists also study other basic social science disciplines, however, and in criminal justice programs. The professional field most closely associated with the study of crime, aside from criminal justice professionals, is law.

Several early strands of sociological research form the basis for much current theorizing. The first, building on the earlier work of the moral statisticians, sought to establish and interpret the social distribution of crime and delinquency. Following the framework of sociological and ecological theory developed by Thomas (Thomas and Znaniecki 1920) and Park and Burgess (1924), Shaw and his associates (Shaw et al. 1929, Shaw and McKay 1942) related crime and delinquency rates to social conditions in community areas in Chicago and elsewhere. Their chief findings—that rates of delinquency were highest in local communities characterized by poverty and high rates of population heterogeneity and turnover—and the theory advanced to account for them, social disorganization, remain of vital importance (Sampson et al. 1997).

Social disorganization theory hypothesized that socially disorganized areas lacked the means of both formal and informal social control because population turnover and heterogeneity were assumed to weaken social institutions, networks of primary relationships, and channels of communication, all vital to the supervisory capabilities of communities.

Case studies of delinquent boys led to a second theoretical conclusion, viz., that socially disorganized areas lacked sufficient socializing capabilities to protect children from involvement in delinquency and crime. Evidence of this sort led Sutherland (1939) to focus on the process by which individuals become criminal, a process he called 'differential association.' That crime and delinquency are learned behaviors, acquired in the course of interaction with others, remains an important principle. The further insight that definitions and labeling as criminal (in law, in interaction with others, and by authority figures) has behavioral consequences is the basis, as well, for theories stressing the importance of one's self-concept for behavior, and for labeling theory. In order to illustrate the applicability of differential association to crimes that were significantly different from ordinary crime, Sutherland also studied white-collar crime and professional crime, thus encouraging the strategy of studying different patterns of criminal behavior.

A third major sociological perspective on crime causation appeared with the publication of Merton's (1938) seminal theory of 'Social structure and anomie,' focusing on the consequences of disparities between culturally emphasized goals and structural limitations on the means for their achievement. Merton noted that the cultural emphasis on achievement of economic success posed special problems for those who were disadvantaged by virtue of their social class, racial, or ethnic status. Theoretical elaboration of anomie theory, as Merton's formulation has come to be known, have taken a variety of forms. Messner and Rosenfeld (1994) theorize that the domination of institutional life by economic institutions weakens the ability of other institutions to control crime. Cloward and Ohlin's (1960) 'opportunity theory' joins anomie theory with both social disorganization and differential association to explain variations in delinquent subcultures. Others shift the focus of Merton's formulation to individual strain, viewing crime as a means for reducing psychological strain caused by failure to achieve a variety of goals, such as autonomy, status, respect, and reciprocity in relationships with others.

3. *Continuity and Change in Criminological Theory and Research*

Much sociological theory about crime continues to be based on these theoretical traditions. A large-scale community study in Chicago, for example, found that a measure of 'collective efficacy' (willingness to intervene for such common goods as supervision of children and maintaining public order) had a strong effect on suppressing violent crime (Sampson et al. 1997), thus systematically documenting impressions gained from ethnographic research (Anderson 1990).

Rapid social change and new developments in research and theory continually influence sociological criminology. New and improved governmental statistical series inform criminal offending and victimization, and sophisticated self-report and observational studies provide insights into the lives of delinquents, criminals, and their victims, and the institutional and community contexts of crime. New techniques of statistical analysis yield new interpretations of empirical studies. Large-scale funding by governmental agencies and foundations permit more ambitious studies, including longitudinal data sets, experiments, and multiple methodologies and theoretical approaches. Theoretically integrative work combines insights from a variety of theoretical perspectives and levels of explanation.

Social disorganization, control, and opportunity theory continue to evolve as massive social changes alter the conditions of crime. Disciplinary boundaries become less distinct as sociologists find it necessary to take into account the impact of a rapidly changing global economy and new political alignments;

developmental and learning theorists must accommodate findings made possible by technological advancements in brain and neuropsychological research and by studying life-course patterns of individuals who were studied when they were very young.

A major impediment to theoretical advance is the lack of adequate data to measure new concepts and theoretical formulations that have been stimulated by the inquiries they have made possible. Theories such as 'control balance' (Tittle 1995) reach beyond criminal behavior and require measurement of the amount of control exercised by an individual, the amount of control experienced by that individual, ratios between these measures, and a large number of motivational, opportunity, and situational contingencies that are hypothesized to relate to a variety of forms of deviance, including crimes. 'Integrative shaming' (Braithewaite 1989), extending labeling theory and insights from control theory, requires measures of social integration of communities, their ability to shame norm violators, and their willingness to reintegrate them into the community, as well as of these same motivational, opportunity, and situational contingencies. 'Social capital' theory requires measures of the capacity of communities and institutions to provide supportive interpersonal and institutional relationships that bridge the generations while socializing the young.

Knowledge of substantive areas such as organized and professional crime and white-collar crime continue to suffer because systematic data are unavailable or inappropriate for extant theories. Rapid social change, driven by advances in science and technology, create new opportunities for crime even as they enhance crime control efforts. The same technological advances that greatly enhance computational abilities and complex data analyses pose new challenges for institutions of social control even as they improve their reach and their efficiency. Communication and data transfer technologies, for example, have transformed criminal justice agencies and created new opportunities for criminal behavior. Other technologies, such as nuclear and biotechnologies, lend themselves to widespread victimization, blackmail, and terrorist attack. Traditional distinctions between individual and corporate behavior that is defined as crime, and the behavior of nations that, although harmful to citizens of those nations previously was considered beyond the purview of other nations, are changing rapidly. New laws and new rules continually evolve as global markets alter commercial activity.

Crime, Sociology of

The sociology of crime is the study of crime causation in relation to social determinants, as opposed to biological or psychological factors. Causation is understood in a nondeterministic way as the necessary and sufficient antecedents or conditions of criminal conduct. Not being much older than a hundred years, the sociology of crime is a recent undertaking and its findings are best presented as a series of opposites, the first of these bearing on the definition of crime. For detailed treatment of the various elements discussed within these opposing perspectives and for further reference see *Anomie*; *Conflict Sociology*; *Control: Social*; *Crime: Sociological Aspects*; *Crime: Organized*;

Crime: White-collar; *Delinquency, Sociology of*; *Sociology: Overview*; *Criminal Justice, Sociology of*; *Gangs, Sociology of*.

1. *Sociology of Crime vs. Sociology of Criminalization*

Although crime is discussed as early as Plato's *Laws*, its empirical study really began at the turn of the last century with the Italian Positivist School. The most prominent members of this school articulated an objectivist perspective according to which crime was a universal fact that shared identical features across cultures. Hence, Garofalo developed his theory of the 'natural crime' and Lombroso his views on the 'born criminal.' In contrast, the French sociologist Émile Durkheim defined crime as a legal construct resulting from the social obloquy directed at certain forms of behavior (Durkheim 1958). Crucially, Durkheim not only asserted that social reaction varied according to context but that it was a force that asserted itself independently of the character of the behavior defined as deserving penal sanction: in a cloister of saints, the most benign misconduct would still attract harsh punishment. Both positions—crime as a natural fact and crime as a cultural construct—have shaped sociological thought on crime.

Sociologists tend to fall on either side of this divide largely on the basis of the type of crime that they study. The more predatory the crime the more realistic will be the perspective, either in respect to the crime itself or to its harmful consequences for victims (Young 1994). In contrast, the sociology of victimless crime and lifestyle delinquency stresses the constructive aspects of their legal definition. It must be emphasized that the sociology of crime has traditionally devoted a significant part of its inquiries to youth crime and juvenile gangs.

2. *Predetermined Behavior vs. Learned Behavior*

The concept of causation used in the sociological study of crime allows for many interpretations. On the one hand, the determinants of criminal behavior may be viewed as factual antecedents that do not depend on language communication to influence behavior. The various forms of deprivation associated with criminal behavior—such as lower-class status, unemployment, poverty and poor housing conditions, dysfunctional families and child sexual abuse, lack of education—are such relatively immediate determinants. On the other hand, criminal behavior can be seen as the result of a learning process which is progressively effected through language. In 1939, Edwin Sutherland famously objected to the causation through deprivation theory that it only applied to lower-class crime (if it did at all) and utterly failed to explain the crimes of the powerful (Sutherland 1983). In later work, he attempted to demonstrate that his own theory of differential association—according to which criminal behavior is learned in association with those who define such behavior favourably and in isolation from those who define it unfavourably—accounted as much for the crimes of the powerful as for the crimes of the powerless. The theory of differential association, which Sutherland and his collaborator, Donald Cressey, constantly refined, has exercised a powerful influence on the sociology of crime.

2.1 *Multifactorialism vs. Generalizing Theorists*

This opposition is closely related to the previous one. In his 1939 address on white-collar crime, Sutherland ridiculed sociological research that accrued so-called independent variables in order to produce a deterministic account of a selected part of criminal activities. As mentioned, he preferred to build an all-embracing general model that accounted in theory for all forms of crime. He was not the only sociologist of crime to favor theory building over the collection of heterogeneous sets of data. Most explanations of crime were developed by researchers who relied on broad single concept approaches, whether it was social disorganization (the Chicago School), anomie (Durkheim 1952, Merton 1967, and the subculture theorists, Cloward and Ohlin 1960), cultural and class conflict (Sellin 1938, Marxist criminology), the labeling process (Becker 1963), or routine activities (Cohen and Felson 1979). However, despite Sutherland's work, the crimes of the powerful have remained a largely underdeveloped field in the sociology of crime. The adherents of multifactorialism have pursued their unabated data collection in order to establish meaningful correlations between crimes of the powerless, which make up the overwhelming majority of reported crime, and various forms of deprivation.

3. *Consensus vs. Conflict*

There is one interpretation of social causation that stretches the concept of cause to its logical limit. It is the view that crime is the result of a conflict between different norms of conduct. Crime is then considered less as a thing *per se*—a given kind of behavior—than as a relationship between behavior and norms of conduct, where it is the latter that triggers the definition of certain kinds of behavior as being criminal (Sellin 1938). Within this framework, it is entirely conceivable that new rules of conduct may be established, which retrospectively define as being criminal certain kinds of behavior that were not previously seen as rule violating (e.g., private ownership in postrevolutionary Soviet Russia). In this case, it would appear that the causative

element follows in time the crime that it paradoxically generates.

This conflict of norms has been seen by sociology in opposite ways. Durkheim (1964) first proposed that conduct was criminalized because it strongly offended the collective sense of morality. His position implied that nearly all members of a given society shared a common ethos from which the lawbreakers were excluded. This view of the rules governing society as being the outcome of a consensus later came under increasing criticism. Rule definition was no more seen in the light of an opposition between the collective and the individual but in terms of power: those who were dominant within society, either through their numbers or, more importantly, through their status or their wealth, imposed their own definitions of proper behavior upon those whom they dominated. This latter perspective, known as 'conflict sociology,' reached its apex between 1960 and 1990 in Marxist studies, which upheld that criminalization was intended to perpetuate the domination of the ruling class over the working class (Greenberg 1981). Elements of the working class were actually defined as 'dangerous classes' in the sociological inquiries undertaken during the nineteenth century, and reappeared under the designation of the 'underclass' in the twentieth century.

3.1 Labeling Theory

Labeling theory carried the logic of conflict sociology to its logical term by not only asserting that social groups created deviance in making the rules that defined it but also by concluding that deviance was not a quality of the act a person commits but a consequence of the application by others of rules and sanctions to a labeled 'offender' (Becker 1963). Labeling theory was presaged in the work of Lemert (1951 and his concept of secondary deviance. According to Lemert, by being stigmatized as 'criminals,' offenders were excluded from mainstream society and left with no alternative but to sink deeper in crime. Thus the trapping of offenders in the ghetto of labeled criminals was a source of induced reoffending (secondary deviance).

4. Strain Theory vs. Control Theory

No dichotomy has attracted as much attention as the opposition between strain and control theories, which was articulated by Hirschi (1969). Strain theories rest on the concept of anomie, which was borrowed from Durkheim by Merton (1938) in an article that was revised several times in subsequent work (Merton 1967). Although Merton's conception of anomie differs much from Durkheim's, they are both framed in terms of a discrepancy between means and ends. For Durkheim, anomie is the hallmark of a troubled social predicament where people have unlimited cravings and limited means to fulfill them. This strain generates a normative vacuum which is for some conducive to self-destruction. For Merton, anomie results from a breakdown in the relationship between culture goals and the legitimate or institutionalized means to achieve them. This breakdown, particularly when it occurs between goals that are accepted and legitimate means to achieve them that are either unavailable or rejected, is a source of strain that may erupt in criminal behavior.

Anomie and strain theory basically tries to answer why and how people embrace criminal behavior. Therein lies the fundamental disagreement between strain theorists and control theorists such as Hirschi. For the latter, the question worth addressing is not why people break the law but why they actually conform to it. Then, the central concern of a sociology of crime should not be deviance but conformity. The sources of deviance can nevertheless be derived from breakdowns in the machinery that fosters conformity. Control theory originally answered its question about the roots of conformity with reference to civil society. Hirschi explained conformity by social bonding relationships that strengthened the ties between an individual and law-abiding society. These relationships consisted of attachment to family, school, and peers; commitment to conventional lines of action; involvement in conventional activities; and belief in the values that triggered these social bonding mechanisms and kept them functioning. Although that was not the path originally chosen by Hirschi, conformity could also be explained in political and legal terms, that is, by pointing to the fear of sanctions meted by the state upon lawbreakers. In this way control theory is connected with deterrence theory, and more generally with research into how people are coerced to conform by the state apparatus (see *Criminal Justice, Sociology of*; *Police, Sociology of*). In this process, the sociology of crime draws a full circle: it first begins as a sociology of deviance and then, striving to explain conformity, it is transformed into a sociology of social bonding and, ultimately, a sociology of the efficacy of the penal system. Furthermore, the notion of the positive delinquent whose behavior is impelled by multiple determinants is superseded by a perception of delinquents as individuals who exercise rational choice. Deterrence theory is predicated upon such a perception.

4.1 Delinquent Subcultures vs. the Subculture of Delinquency

As reinterpreted by Merton, anomie resulted from a breakdown between culturally valued goals and legitimate avenues of access to them. By combining the

acceptance or the rejection of culture goals with the acceptance or the rejection of institutionalized means, Merton generated a typology of four modes of social adaptation to strain: 'conformity' (goals and means are both accepted); 'innovation' (goals are accepted, but means rejected); 'ritualism' (goals are rejected, but means accepted); and 'retreatism' (goals and means are both rejected). To these, Merton added a fifth mode of adaptation, 'rebellion,' which is triggered when goals and means are not only rejected but also replaced. In combination with differential association theory, Merton's typology developed into the theory of differential opportunity and into the sociology of delinquent subcultures. Merton's mode of innovation would then beget a subculture of crime against property, rebellion could lead to conflict and to a subculture of violence, and retreatism to a subculture of drug taking (Cloward and Ohlin 1960).

It was quickly objected to subculture sociology that there may be a subculture of delinquency but that it was not a delinquent subculture (Matza 1964). The main point of this objection is that the notion of a delinquent subculture obscures the similarities between the conventional culture and the subculture of delinquency. In the subculture of delinquency, the acceptance of norms and, particularly, of legal norms is undermined by techniques of neutralization such as the negation of the offense, the sense of injustice, rudimentary conceptions of the sense of tort, and the primacy of custom. Yet the result of the application of these techniques is generally provisional. Delinquency is characterized by its deep ambivalence, the values promoted by conventional culture, and by the subculture of delinquency being convergent on key points.

4.2 *Microsociology vs. Macrosociology*

The critique of the sociology of delinquent subcultures was also indirectly critical of the general theories that underlaid this sociological trend, that is, the theory of anomie and of differential association. Such criticism caused a further split in the sociology of crime. In Matza's subsequent work, and in phenomenological and ethnomethodological research, the search for explanations was not only replaced by descriptive work but the descriptions eschewed quantitative generalizations for qualitative in-depth investigation of cases selected for their significance. Such investigations were influenced by the methods of ethnography and ethnolinguistics.

Concurrently, however, grand theorizing was being rediscovered with a premium by the Marxist sociology of crime. Sociologists influenced by Marxism attempted to develop a political economy of crime that ranged over the whole field of the social sciences; they also tried to articulate the notion of a structural or systemic mode of causation. Since it is impossible to divorce Marxist science from a Marxist project of class emancipation, this trend in the sociology of crime began to lose strength with the collapse of communist societies.

5. *Recent Trends*

The sociology of crime has evolved from a dichotomous field into a fragmented and an eclectic one. At least, the theories proposed on either side of the divides that we have been acknowledging were often highly integrated. At the beginning of the twenty-first century, the sociology of crime is in the grip of various centrifugal forces.

5.1 *A Wealth of Objects*

A factor that favored the theoretical integration of the sociology of crime during a long period of its development was that research focused on relatively few objects, youth crime providing an enduring reference. Social and political concern about forms of deviance as diverse as organized crime, terrorism, computer crime, and collective violence is now splintering the field into various specialties that defy integration. Some of these objects, such as organized crime and terrorism, strongly resist definition and they are nearly impervious to empirical research.

5.2 *The Shock of the Feminist Critique*

There are too many strands of feminism to present it as an integrated approach. Moreover, the sociology of women's crime is still in its infancy, despite important pioneering work (Carlen 1988). A significant part of feminist research has been directed at women considered either as victims of male predators or as subjects of oppression by criminal justice rather than as crime perpetrators. Nevertheless, the feminist critique has succeeded in casting a doubt on whether extant sociological theories of crime apply as much to women's crime as to men's and whether they account for the obvious gender difference in the perpetration of crimes. The answer to such questions will require a serious effort in research. It is dubious that in the short term this effort will foster the integration of the sociological theory of crime.

5.3 *Beyond the Sociology of Crime?*

One innovative theory that was developed during the late 1970s was the 'routine activities' theory (Cohen and Felson 1979). 'Routine activities' refer to the set patterns of behavior within the spatial environment of three kinds of social actors: (a) motivated offenders; (b) capable guardians of persons or property; and (c) suitable targets of criminal victimization (targets may

be persons or places). The interconnection of these patterns may account for criminal activities. For instance, the growth of the service industry since the end of World War II has multiplied evening work shifts that keeps people away from home as guardians of their property, while increasing their accessibility as targets when they come back home at night. Routine activities theory include 'guardians' as a variable explaining the occurrence of crimes. Guardians, who may be public police or private security agents, are however as much a factor in explaining crime as they are in accounting for crime prevention. This is why routine activities theory may act as a bridge between the sociology of crime and the sociology of crime control and of the production of security. This bridge is problematic as it may serve to integrate both disciplines into a consistent whole or to dissolve any claim to consistency that either of them has made.

Crime: White-collar

The term 'white-collar crime' was coined by Edwin H. Sutherland, in a 1939 presidential address to the American Sociological Society, as 'crime committed by a person of respectability and high social status in the course of his occupation' (Sutherland 1940, 1949, p. 9). In the better part of the century that followed, scholars continued to disagree about this definition of the concept—from its focus, not on illicit acts, but on specific characteristics of individual lawbreakers, to its characterization of their misdeeds as 'crimes.' Though more eschewed than embraced his early definition, Sutherland's compelling label persists. But a vast collection of synonyms giving linguistic expression to conceptual, theoretical, and ideological differences proliferated—upperworld, elite, suite, of-the-powerful, corporate, organizational, occupational, employee, avocational, trust, business, economic, official, governmental, or political crimes, illegalities, offenses, violations, deviance, misconduct, harms, or violence. After decades of fruitless conceptual debate, most scholars have agreed to disagree.

This babel of competing verbiage and the disparate phenomena it embraces would be a mere annoyance were it not for the fact that the term was born, as Robert Merton once observed (Merton 1957, pp. 90–2), of an effort to 'liberate' scholarship from 'cognitive misbehavior' reflected in the well-accepted but spurious correlation between poverty and crime. Concepts tell us where to look, and where we look affects what we find. Sutherland asserted that criminologists, obstructed by conceptual blinders, had been looking in the wrong places:

> …[white-collar crimes] are not included in the criminal statistics nor are individual cases brought to the attention of the scholars who write the theories of criminal behavior. The sample of criminal behavior on which the theories are founded is biased as to socio-economic status, since it excludes these business and professional men. This bias is quite as certain as it would be if the scholars selected only red-haired criminals for study and reached the conclusion that redness of hair was the cause of crime (Sutherland 1949, pp. 8–9).

In other words, if scholars look only at crimes committed by the poor, it is not surprising that they conclude that poverty and its associated pathologies cause crime. For Sutherland, this selection bias is the *raison d'être* of inquiry into white-collar crime. These offenses evoke that nagging sense of all that is ignored by traditional criminology and that cause us to misunderstand the nature, causes, and consequences of crime and its control.

In the ensuing years, white-collar crime has become a subject of inquiry in its own right, of course. But selection bias continues to symbolize the essence of white-collar crime scholarship, simultaneously signaling its promise and foreshadowing its vulnerability, accounting for why the work is provocative and

groundbreaking, and yet so often misguided. This entry explores this dual tension, thereby featuring a handful of the major contributions of this scholarship and the challenges that social scientists face in doing it well.

1. Removing the Blinders

We begin by considering how some of the standard topics in criminology are transformed when one looks in the unconventional places captured by the varied conceptions of white-collar crime.

1.1 The Social Organization of Offending

Although Sutherland's early definition explicitly referred to individuals, his empirical work (Sutherland 1949) on the offenses of the seventy largest manufacturing, mining, and mercantile corporations in the United States took organizations as the unit of analysis, a legacy reflected in the generations of scholars he spawned. Though organizations surely commit misdeeds, they cannot do so without the complicity of individuals, often countless individuals plucked from disparate branches of the corporate tree and from tiers spanning the organizational hierarchy, indeed individuals often situated outside of the organization altogether—lawyers, accountants, investment bankers, brokers, agents, consultants, advertisers, competitors, even regulators. But coordinating the activities of such a diverse collection of collaborators situated across the globe, many of them ignorant of the illicit activities to which they contribute and often engaged in concerted action spanning years or decades, is not easy. Organizations need to maintain secrecy, lest the activities be exposed. They must insure that some conspirators remain unwitting of the consequences of their actions, lest they refuse to participate or blow the whistle to regulators inside or outside the organization. They must maintain loyalty and commitment and cool out those with little taste for offending, lest disgruntled or disaffected conspirators sell out their colleagues. They must buffer those in positions of power from those carrying out their directives to shield the former from accusations of culpability or to build a paper trail that deflects responsibility away from those most complicit. They must deceive and cover up their activities from victims to insure their continued victimization and to postpone discovery. They must destroy or doctor evidence to subvert regulatory discovery and to undermine the prosecution of their misdeeds, if discovered. These are massive organizational tasks perhaps better suited to the theoretical paradigms emanating from organizational sociology than from traditional criminology and that provoke unique challenges for systems of social control (Stone 1975).

1.2 Victimization

White-collar crimes exploit impersonal trust, asymmetric relationships in which principals entrust strangers to provide specialization, intermediation, and collectivization (Shapiro 1990). Victims of white-collar crime, therefore, typically lack expertise and access to the information necessary to evaluate the conduct of trustees. Because many participate in 'futures transactions' such as investment and insurance where payoff is delayed or protracted, victims have no tangible data in the interim to assess the likelihood that commitments will eventually be honored. Victims of white-collar crimes, therefore, tend to be unwitting. Because victims of common crimes are readily aware that they have been robbed, burglarized, assaulted, or victims of larceny, and members of their social networks know when associates have been killed, systems of social control (and researchers as well) tend to be reactive. They wait for victims to tell them that a crime has occurred. Reactive systems of social control yield little, stale, and biased data (about more blatant misdeeds) when most victims are unwitting. The policing (and study) of white-collar crime therefore requires different methods than those characteristic of common crimes.

White-collar offenses also differ from common crimes in the recruitment, pattern, scale, and impact of victimization, and in the relationships between victims and offenders. Because some relationships of trust collectivize the interests of multiple principals—in financial institutions, mutual and pension funds, insurance pools, and the like—victimization from the abuse of trust is often massive. Moreover, because white-collar crimes tend to be delivered by organizations whose activities touch countless consumers, clients, employees, investors, and neighbors (who drink the water and breathe the air poisoned by the corporation), victimization is often extensive and its cost enormous. Research finds that the organizational complexity of an offense is 'the single most powerful predictor of victimization' (Weisburd et al. 1991, p. 93). Hence, the organization itself becomes the 'weapon' in white-collar crime. It is 'for white-collar criminals what the gun or knife is for the common criminal—a tool to obtain money from victims' (Wheeler and Rothman 1982, p. 1406).

1.3 Enforcement

Systems of social control can be differentiated into those which seek 'compliance'—preventing the occurrence of law violations—or 'deterrence'—reacting to violations that have already occurred (Reiss 1984). Because white-collar offenses portend significant victimization with respect to cost, harm, consequences, irreversibility, and numbers of victims, enforcement systems frequently opt for compliance over deterrence. Regulators would rather prevent toxic waste or abort

a securities swindle than punish those responsible, especially when the unwittingness of victims often means that significant harm has been done by the time reactive deterrence systems learn of the illegality. And many find that cooperative enforcement techniques are better able to secure compliance than those structured to deliver punishments (e.g., Grabosky and Braithwaite 1986).

Compliance systems are more common in the enforcement of white-collar than common crimes as well because the former are more predictable. Because would-be organizational offenders are relatively stable and visible, as they seek to market their wares, they can be licensed, given preclearance, inspected, monitored, and subject to regulations and mandated procedures.

The policing of white-collar crime is also more diversified than that of common crime, which is undertaken largely by the state and private police (e.g., security guards). The costs and consequences of white-collar crimes, the penalties imposed, and the loss of reputation and the diminution of institutional trust (which are the lubricants of continued business) are so great, that those likely to bear these costs often undertake their own social control. Insurers, stock and commodity exchanges, professional or trade associations, and organizations themselves undertake or mandate self-regulation or buy the regulatory services of outside auditors, inspectors, bond-rating firms, and the like.

1.4 Prosecution and Punishment

Scholars object, with good reason, to Sutherland's classification of white-collar offenses as 'crimes.' Many—perhaps most—so-called white-collar 'crimes' are, in fact, not prosecuted as crimes at all or subject to criminal penalties. Compliance systems of social control have little use for the criminal justice system (aside from the incentive that potential criminal penalties give for undertaking self-regulation or abstinence). Criminal sanctions come too late, after the damage is done; they require standards of proof that are difficult to meet, especially with extensive obfuscation and cover-up that shield those most complicit; they do little to remedy the harm, lessen its impact, or impede future wrongdoing. Moreover, the choice between imprisonment and relatively small criminal fines offers limited options when the criminals are wealthy organizations. White-collar offenses are often dealt with by civil injunctions or administrative remedies that are better able to abort incipient or ongoing violations, contain the damage quickly, remedy the harm, provide restitution to victims, and fashion remedial solutions that will reduce opportunities for future wrongdoing without exacerbating the harm to innocent parties. Moreover, because wayward organizations or their insurers often have deep pockets, victims and the private plaintiff's bar have strong incentives to undertake civil litigation against white-collar malefactors. Private litigation often plays a significant role in rectifying the misdeeds, securing compensation, meting out punishment, and deterring future misconduct.

1.5 Criminological Theory

As even these few selected features of white-collar crime scholarship make clear, Sutherland's *raison d'être* for drawing attention to these offenses was prescient. By broadening the expanse of crime and its control from those patterns and institutions evoked by the stuff of traditional crime statistics to those insinuated in organizational offending and abuse of trust, the limitations of criminological theory are readily exposed. The challenge of incorporating into criminological theory the phenomena observed once the conceptual blinders were removed has been less successful.

Over the years, there have been sporadic attempts to develop a general theory of crime that accounts for both white-collar and common crimes. Sutherland's theory of differential association—that the techniques and motivations for criminal behavior are learned through contact with others—represents the earliest attempt (Sutherland 1949, p. 234). Some scholars have extended Merton's anomie theory of deviance or variants of strain theory, proposing that, like ordinary deviance, white-collar crimes arise when legitimate means to achieve material success or to attain organizational goals are blocked or unavailable. And other theories of white-collar lawbreaking have drawn on opportunity, neutralization, and conflict theories originally developed to account for traditional crimes. A more recent effort is seen in Gottfredson and Hirschi's (1990) general theory of crime, which asserts that white-collar crime, like all crime and deviance, is impulsive, arising from the self-interested pursuit of pleasure and the tendency to seek short-term, immediate gratification, coupled with low self-control. Ironically, their erroneous conclusion that there are no differences between those who offend in the streets and those in the suites (Hirschi and Gottfredson 1987, pp. 970–1), brings us full circle, as it results from the same selection bias—reliance on conventional Uniform Crime Report arrest statistics—that Sutherland exposed a half-century earlier.

These varied theoretical paradigms have been subject to extensive and justifiable criticism for imprecision, tautological reasoning, inability to account for compliance and law-abiding behavior, confusing correlation and cause, or lack of empirical support. Most white-collar crime scholars eschew such grand theories, developing explanations for specific misdeeds or those that account for variation within particular datasets.

2. Methodological Pitfalls

The empirical challenges to the study of white-collar crime far outweigh the theoretical ones. First, because of victim unwittingness, relationships of impersonal trust, the protection of crime in the suites by institutions of privacy, complex cover-up schemes, the commission of crime with organizational weapons rather than physical ones, and the ability to buffer misdeeds in long-latent futures transactions, the dark figure of undetected white-collar crime probably exceeds that of all other crimes combined. And even where law enforcement officials have discovered white-collar offenses, they are often unable to ascertain or pin the blame on those most responsible. The most common sources of data on traditional crimes—arrest records and crime statistics, victimization surveys, and observation studies—therefore yield little and very biased data on white-collar crime.

With limited access to data, researchers often rely on materials in the public domain—typically, sentencing data, reports of administrative agencies, journalistic accounts, hearings, and official inquiries. But selection bias is the price of easy access. Journalists produce what sells—the egregious, scandalous, shocking, clever, costly, and devastating offenses committed by notorious or colorful characters, where those in high stations fell from grace, where safety nets failed, where victims should have known better, where offenders received excessively lenient treatment—many of the same features of offenses that incite public hearings and legislative inquiry. Hardly the mundane stuff of white-collar crime day in and day out. In selecting research subjects from the news media and political tribunals, scholars replicate Sutherland's red-haired crime fallacy. We come to believe that these crimes are committed (with impunity) by the rich and powerful, when a less biased data source would reveal that they are typically carried out by members of the middle class, and that, contrary to expectation, the severity of punishment of white-collar criminals appears to increase with social standing (Weisburd et al. 1991).

Turning to public records of convicted criminals incurs other selection biases. Convictions represent a very small and unrepresentative tip of the iceberg. Research on the US Securities and Exchange Commission, for example, indicates that not even five of every 100 parties found after investigation to have violated the securities laws are convicted of a crime (Shapiro 1984, pp. 155–61). Criminal courts are less likely to process the misdeeds of organizations (than of individuals), that were uncovered by compliance (rather than deterrence) systems of social control, and that were committed by those atop corporate hierarchies who were able to conceal their responsibility or inculpate others in exchange for immunity from criminal prosecution. When offenses are ongoing, victimization is extensive, and the impact is significant, law enforcers opt for compliance—halting the misdeeds, forestalling, and remedying the harm, minimizing the likelihood of recurrence, and doing so with more immediacy, less litigation, and lower standards of proof—over criminal proceedings. Therefore, although serious significant offenses can certainly be found at the tip of the iceberg, so can some of the most trivial for which no remedy other than criminal prosecution is available. Researchers concentrate on the tip of the iceberg at their peril.

Because of these biases embedded in the social construction of white-collar offenses as 'crimes,' many scholars choose not to concentrate solely on criminal cases. Some study offenses that carry criminal penalties, even if they have been resolved instead by private settlements, warnings, injunctions, civil or administrative proceedings, lawsuits, or other remedies. But a slippery slope looms below the tip of the iceberg. As the labels shift from 'crimes,' to 'violations,' 'offenses,' 'misconduct,' 'harms,' 'wrongs,' 'deviance,' 'violence,' and so on, the literature becomes cluttered with studies of torts, liability, malpractice, accidents, mistakes, or inadvertence committed by corporations or those in high-status occupations. We dilute white-collar crimes with all manner of misfortune. To include these harms among crimes in the suites is like including fender benders in an ice storm among crimes in the streets.

Sadly, the ideological passions that animated Sutherland's work and that of many of his intellectual progeny, which cause us to be suspicious of corporations and individuals of wealth, status, and power, also cause us to get sloppy. They permit us to confuse mistake or accident with intentional noncompliance. They lead us to believe what comports with our assumptions, relying on the thin anecdotal data that are readily available rather than probing deeper, using published reports and secondary data rather than collecting primary materials and triangulating data sources. They blind us from questioning and making problematic what seems intuitively true. As a result, we are destined to learn that some of the classic and repeatedly cited 'landmark narratives' of corporate crime—for example, the Ford Pinto affair and the Challenger disaster—actually got the story wrong, confusing misconduct with mistake, and venality and amoral calculation with banal normalized organizational routines (Lee and Ermann 1999, Vaughan 1996).

We are also learning what it takes to get the story of long-running technologically, financially, and organizationally complex potential white-collar crimes right. In the case of the Challenger disaster, it took 10 years of persistent, painstaking, methodical research which probed the entire decade that preceded the shuttle explosion that cold January morning; systematic analysis of more than 122,000 pages of documents, 2,500 pages of hearing transcripts, and 9,000 pages of depositions; dozens of new interviews

and site visits; the commitment to learn technical science and engineering; and the willingness of a publisher to print an affordable 600-page scholarly book with almost 100 pages of technical charts, diagrams, memos, and thousands of footnotes to transform a seductive but erroneous account of organizational misconduct into a creditable one of the normalization of deviance and the sociology of mistake (Vaughan 1996). Vaughan's chronicle, with the conventional (erroneous) account in boldface type juxtaposed against the fuller complex documentary and ethnographic narrative, starkly demonstrates what is at stake in the social construction of white-collar crime scholarship and what is required of future scholars.

3. *White-collar Crime and the New Social Science*

> …societies have been undergoing an organizational revolution. Just as the forests and fields of the physical environment are being replaced by streets and skyscrapers, the primordial institutions around which societies have developed are being replaced by purposively constructed social organization (Coleman 1990, p. xv).

Perhaps nowhere has James S. Coleman's influential call for a new social science attuned to the transformation of social life occasioned by the displacement of natural persons by 'purposive corporate actors' been better realized than in the study of white-collar crime. White-collar crime scholarship does not hold a monopoly on the study of organizational offending, of course. Even traditional criminology (which concentrates on the natural persons who populate the primordial social organization which Coleman argues is 'withering' away) has produced the occasional study of gangs, organized crime, terrorism, the distribution of illicit goods (e.g., drugs, gambling) and services (e.g., prostitution, fencing), and the like. But white-collar crime scholarship more than any other area of criminological inquiry has made problematic the difficulties of regulating organizational life and insuring norm compliance within organizational contexts, areas of investigation which will become ever more important in the new century. White-collar crime offers a bridge to the new social science and a compelling window onto the changing structure of social life. As we gaze through the window, we realize the myopia our blinders have imposed.

Criminal Defenses

Modern legal systems worldwide accept, at least in principle, the notion that punishment should correspond to the extent of an individual's responsibility for an act. Unless the crime is an absolute or strict liability offense, what must be established during the criminal trial is the mental state of the individual at the time he or she committed the action in question. Whether there were any circumstances which would warrant holding a defendant less responsible, thereby resulting in less punishment, also has to be established. In every case the issue is what constitutes condign punishment.

In order for an individual to be found guilty, the prosecution must establish that the defendant had the requisite *mens rea* or intent and that the defendant committed the *actus reus* or act. The law in the Anglo-American tradition is only concerned with whether or not the accused intended to commit the act, which the law defines as a crime. The reason why a defendant intended to violate the law is not deemed relevant to the question of guilt (except where motive is part of the definition of the crime, i.e., for self-defense where one kills in order to save one's own life and for specific intent crimes such as child sexual abuse where the touching must be for the purpose of sexual gratification). The twentieth century view of *mens rea* as merely legal guilt, represents a shift in thinking from earlier times when a defendant had to be shown to have both legal guilt or intent as well as moral guilt or motive. The trend toward a narrower version of *mens rea* may reflect a practical judgment that it is difficult to prove motives.

The criminal defenses that have developed over the past century are often predicated on the idea that an individual's alleged criminal act was not entirely voluntary. The social science evidence presented in court, ordinarily through the testimony of expert witnesses, is designed to show that the defendant lacked the necessary intent to be held fully responsible for the offense. In some cases there may be doubt as to the legitimacy of a particular defense, and there may also be doubt as to whether the defendant properly invokes the defense. Nevertheless, whether or not it is possible to prove that an individual acted under an imperative, legal systems guarantee the right to invoke these defenses during the trial.

Through colonialism, countries with common law and civil law traditions imposed their legal systems, along with their defenses, on many parts of the world. Consequently, many, though not all, of the defenses discussed have been employed in courts across the globe. Yet, even where one finds the same defenses in different countries, the use of the defenses varies by jurisdictions.

Most of the defenses discussed are invoked in both common law and civil law types of legal systems.

1. *Justification: Self Defense*

Some defenses are classified as justifications, meaning that the person was correct in his or her action and should therefore not be considered culpable at all. The classic example is self-defense, under which it is justifiable for a person to use force to save his or her own life. Though self-preservation may justify the use of force, the law generally holds that a person should only use as much force as is necessary to save his or her life. Not only must there be proportionate use of force, but the situation must present an imminent danger of unlawful bodily harm. For example, some courts have held that a person has a duty to retreat where possible.

2. *Excuses*

When raising this second type of defense, defendants admit their action was wrong but maintain they should be excused because of the circumstances.

2.1 *The Insanity Defense*

One of the most important criminal defenses is the insanity defense, which is based on the proposition that a defendant with a mental defect should not be held criminally responsible (see *Law: Defense of Insanity*). Most formulations of the insanity defense are based on either cognitive or behavioral impairment (for analysis of the German 'biological test,' see Silving 1967). With respect to cognitive impairments, it is considered unjust to punish a person who suffers from a mental defect that prevents him or her from comprehending the nature of his or her action. Where the insanity defense relies on a cognitive dysfunction, the famous M'Naghten test is frequently used: did the defendant know the nature and quality of the act, and if he did, did he know that what he was doing was wrong? One ambiguity with the M'Naghten test has to do with the interpretation of 'wrong.' When a defendant argues that he knew the act violated the law but felt that he was morally right, courts accept this insanity defense only in cases where the defendant claims to have been following a divine commandment.

Where the defendant was aware that the action was wrong but could not make his or her behavior conform to the law, this is known as a volitional dysfunction. A common version of the volitional impairment is the irresistible impulse test, and a kleptomaniac exemplifies the sort of person who would invoke the volitional insanity defense.

The insanity test has remained controversial for several reasons: (a) the fear that malingerers will avoid punishment (i.e., 'beat the rap'); (b) the concern that poorer defendants will be less able to retain expert witnesses who are as persuasive as those provided by the state (see *Expert Witness and the Legal System: Psychological Aspects*); and (c) the erroneous belief that those committed to mental institutions will be released earlier than those who are incarcerated in prisons.

The meaning of the insanity defense has evolved as new conditions are documented. For example, the medical and psychiatric communities have recognized the existence of culture-bound syndromes such as 'running amok.'

2.2 *Diminished Capacity/Partial Responsibility*

The diminished capacity defense may be used where a defendant cannot be considered insane according to

the strict tests in effect in a given jurisdiction, but nevertheless suffers from some sort of mental abnormality. There are two variants of the diminished capacity doctrine: the '*mens rea*' variant and the 'partial responsibility' variant. The essential distinction between them, is that in the *mens rea* variant the defendant negates one of the elements of the crime (and so he is not guilty of the crime charged), while in the partial responsibility variant, the defendant argues that his responsibility is lessened by virtue of his mental abnormality at the time of the commission of the crime (and so he deserves lesser punishment).

The rise of new versions of diminished capacity is worth noting. The defenses are frequently versions of post-traumatic stress disorders including a *post partem* defense, an intoxication defense, a Vietnam Veteran's defense, and the Battered Woman defense. The automatism defense is sometimes regarded as a type of insanity defense but is different in character. Automatism refers to the behavior of an individual who acts either unconsciously or by reflex or spasm, including conditions such as somnambulism. The standard view of the automatism defense is that it does not relate to *mens rea* but rather to the *actus reus*. The notion is that a person who acts while unconscious should not be held responsible for illicit conduct because the act was not a voluntary one, not because of a failure to form the necessary intent.

2.3 Mistake of Law and Mistake of Fact

The traditional maxim 'ignorance of the law is no excuse' is followed for the most part. If a person was unaware that his or her conduct was proscribed by law, that is not an excuse. This strikes some as unfair as it is unrealistic to expect individuals to know all the laws in their justice systems, even assuming that was possible in earlier times.

By contrast, a mistake of fact can excuse otherwise criminal conduct, as long as the mistake is objectively reasonable. To determine whether mistake of fact excuses depends on the following: if the facts were as the defendant believed them to be, the act would not have been a crime; the mistake of fact excuses the behavior. Contrariwise, had the facts been as the defendant imagined still been a crime, then the mistake furnishes no excuse. In rape cases, men have invoked this defense to claim that they were mistaken as to the consent of the women.

2.4 Necessity and Duress

Some defenses are meant to show that individuals had no real choice when they committed the crimes. The defense of necessity was used, for example, in the famous nineteenth-century 'Case of the Mignonette,' when sailors in a dinghy without provisions devoured a cabin boy. When they were later prosecuted for murder, the argument was that either one had to die or they all would have died. Thus, the choice was one of lesser evils. Although the court rejected the defense of necessity in this case, necessity has been interpreted as both a justification and an excuse. Modern legal systems treat it as an excuse.

In contrast to necessity, which is a consequence of natural forces, duress requires that the pressure of an unlawful threat come from another human being. Defendants argue duress when they are ordered by someone else to kill and must comply in order not to be killed themselves.

2.5 Partial Excuse—Provocation

Provocation, also known as the heat of passion rule, is one of the most ancient defenses in the criminal law. Found both in common law and in most homicide statutes, the 'provocation/passion formula,' which can reduce a murder charge to one of manslaughter, is based on the idea that a person who is provoked to kill does so without the malice aforethought required for the crime of murder, and is therefore less culpable. Often raised by jealous husbands who kill their wives, the provocation defense is the classic example of a partial excuse. Because the infidelity of a wife is considered likely to elicit a violent reaction on the part of husbands, the provocation defense is said to be 'cross-culturally ubiquitous, perhaps universal' (Daly and Wilson 1997). This defense is found around the world (Isedonmwen 1988, Vasdev 1968, Feltoe 1983–1984, Stanley 1992).

If the jury is persuaded both that the defendant was provoked and that the so-called 'objective reasonable person' would have been provoked by the action in question, then a charge of murder is reduced to manslaughter. The defendant is not exonerated, but rather is convicted of a lesser charge. But it is sometimes difficult to prove that one's response is that of a reasonable person, as in the case of culturally specific insults that are offensive only to members of a particular ethnic community.

2.6 The Witchcraft Defense

Another controversial defense, which has been widely used in colonial and formerly colonial settings, is the so-called witchcraft defense. Much of the literature about the defense concerns its use in African contexts (see, e.g., Aremu 1980, Chukkol 1983, Mutungi 1977), but it has also been invoked in other parts of the world (see, e.g., Clark 1980, Hobgin 1935). When invoking the defense, a defendant claims to have killed a person because that person used supernatural powers against him or his family. The defense has frequently been formulated as a version of self-defense or of insanity.

Its use has often been problematic either because courts conclude that the 'reasonable person' would not believe in witchcraft or that a belief in witchcraft does not demonstrate insanity on the part of the defendant since sane members of the community strongly believe in witchcraft. Although the defense was largely unsuccessful in colonial settings, in the past it was considered acceptable for the state to kill witches in Europe and the US (Currie 1968).

3. *Controversial Defenses*

Attorneys sometimes suggest new defenses such as the brainwashing defense. When defendants invoke the brainwashing defense, they argue that they should not be held responsible because their criminal actions were a consequence of mind control. The 'rotten social background' defense, championed by Judge Bazelon and Professor Richard Delgado in the US, depends on the idea that individuals who grew up in the ghetto may be predisposed to use force as part of a survival strategy. As a consequence, defendants argue that they should not be held fully responsible for their illicit conduct. There is also the 'Black rage defense' which lawyers sometimes use when they wish to attribute their clients' illegal activities to racism.

The cultural defense, which has received little support, is employed primarily by immigrants and refugees (see *Cultural Rights and Culture Defense: Cultural Concerns*). The defense takes as its premise the idea that individuals were socialized to behave in particular ways, some of which may clash with the law of the new homeland. If an individual is predisposed to act in ways that violate the law, or is required by customary law to avenge a death, then the cultural defense would require that the legal system should at least take the cultural imperatives into account in determining the correct degree of culpability.

Religious defenses, which have been invoked when members of religious minorities are prosecuted for using drugs in religious ceremonies, for hunting endangered species like eagles and panthers, or for marrying more than one woman, fare no better because governments' interests in enforcing the law apparently override the right to religious liberty.

The apparent proliferation of new criminal defenses has led some critics to condemn the 'abuse excuse.' Critics find this trend deplorable as they believe criminals should accept responsibility for their actions and not seek to blame others for their misconduct. The counter-argument has been that legal systems have long sought to achieve individualized justice by tailoring punishment to the particular attributes of defendants (e.g., adults are distinguished from juveniles; the sane treated differently from the insane). The acceptance of the battered woman defense also shows an acknowledgment of gender differences in the perception of, and reaction to, violence.

Whether the defenses are formally incorporated in legal systems is important to criminal defendants. If officially recognized, this means in practical terms that defendants will be entitled to present specific kinds of evidence in court. Without a formal defense, judges are more likely to exclude the evidence as irrelevant.

4. *Expert Witnesses*

The success of defenses often hinges on the presentation of evidence by expert witnesses (see *Expert Witness and the Legal System: Psychological Aspects*). Social scientists play a crucial role in the presentation of information relevant to particular defenses, which serves to provide the context for the defendant's action. If the defense is a novel one, there may be some question as to whether the expert satisfies the requirements for serving as an 'expert.' This determination usually turns on the degree to which the evidence constitutes a body of knowledge widely accepted within the relevant professional or scholarly discipline.

5. *Role of Criminal Defenses*

Criminal defenses are important to guarantee that the accused only receives as much punishment as is deserved. Should the defense fail, however a judge can still mitigate the punishment during the sentencing phase of the trial. Thus, even if a defendant is convicted of a crime that is really too serious, given the nature of his or her act, the defendant may ultimately receive less punishment than one might expect. Indeed, judges sometimes hold criminals responsible, finding them technically guilty, even though they impose suspended sentences or probation. By so doing, they maintain the rule of law, the idea that justice is applied in an even-handed way to all defendants, even though in reality they mete out varying sentences.

6. *Future Uses of Criminal Defenses*

The question of what defenses are acceptable emerged anew in the 1990s during the drafting of the Statute for the International Criminal Court. As efforts were underway to harmonize competing legal conceptions from the common law and the civil law, a decision had to be made as to which defenses should be part of the operating procedure of the international tribunal. Human rights advocates found disturbing the acceptance of the defense of superior orders, even under limited circumstances, a defense according to which soldiers should not be held responsible for war crimes and crimes against humanity if they were simply following the orders of their superior officers.

The question of which criminal defenses are legitimate remains an open one in most legal systems. With

the advent of new medical, technological, and psychological breakthroughs, it is likely that new defenses will continue to emerge on the horizon.

Criminal Justice, Ethics of: Aspects of Human Dignity

Important ethical issues can be identified at many levels of the theory and practice of crime control in the modern state. One important contrast is between

substance and procedure, with different procedural systems generating professional roles with distinctive ethical problems. The adversarial system of criminal procedure in Anglo-American regimes is associated with such problems for lawyers and government officials who must honor duties to adversarial interests as well as to the achievement of just overall outcomes. The accusatorial systems of Continental Europe generate different types of role conflict by confining in a single professional role responsibility for both the repression of crime and the assurance of fair criminal procedure. Across all varieties of criminal procedure, the enormous discretions vested in all modern punishment systems present ethical problems of great importance and indeterminate resolution. The only way to reduce discretion is with mandatory punishment rules that may be more problematic than the practical outcomes of discretionary systems.

This article will not survey the wide variety of ethical issues found in modern criminal justice. Instead we wish to emphasize one central concern: the strategic importance of imposing limits on the punishment of criminals to ensure the respect of government for citizenship and individual dignity. Serious criminal offenders present the least attractive case for claims to limit government power, but they are, for that reason, the most important frontier for defending the limits of that power. If the claim of human rights is only as strong as its weakest link, that will almost always make the rules and limits of criminal punishment of central importance to respect for individual dignity as a limiting principle throughout government.

This article will first sketch out the argument for considering criminal punishment as a critical arena for human rights and then discuss those areas within criminal justice where the claims for limiting government are most important. A second section addresses the politics of governmental limits on punishment. A third section focuses on conditions of imprisonment. A fourth section contrasts two styles of characterizing the role of government in punishing criminals.

1. *Appeals for Government Power*

To the extent that power held by government comes at the expense of restrictions on the liberties of individual citizens, there is a natural tendency for citizens to resent increases in governmental power and to desire limits on government. Where citizens have continuing power over governmental policy, new powers must be approved on the basis of the need for government to produce common benefits that citizens value more highly than the liberties they surrender. The need to justify governmental power in terms of collective gains that are more important than lost liberty is spread over the full range of governmental powers from taxation and spending to military force. Crime and punishment have a special strategic importance in this dynamic to establish the limits of governmental power, because criminals are the most frightening and most unpopular citizens in a democratic state. Fear of crime means that citizens will cede authority to government for crime control that they might not be willing to surrender for other reasons. The public hostility toward criminals will support harsh punishments administered by government because criminals are to receive them. Citizens will approve conduct in the punishment and control of crime that they would hesitate to support or tolerate in other domains.

Because criminal punishments are the most extreme deprivations that government will inflict on any citizen, most enforceable limits in governmental power will be limits on criminal punishments. Further, because of hostility to criminal offenders, public opinion and democratic institutions will support punishments of high magnitude. Expanding power to punish in democracy will be easier than in other arenas of government, and limiting power through democratic institutions will be more difficult.

That the punishment enterprise is the boundary territory for the maximum exercise of negative government power explains the historic importance of criminal justice in the basic architecture of limited government. The Bill of Rights to the US constitution has eight amendments dealing with the relationship of government and individual citizens. Five of these eight amendments (4, 5, 6, 7, and 8) are chiefly concerned with criminal justice.

2. *An External Constraint*

Concern about excessive governmental power is external to the usual topics of effectiveness and individual desert in the determination of appropriate punishment. To worry about whether it is proper for modern governments to extinguish life as a criminal sanction is not to address either topics like deterrence or incapacitation that concern the effects of punishment on crime rates or to address what particular punishment might be morally justified by the commission of a particular act. Restraints on government power of this sort are prior conditions to setting a scale of punishments based on individual desert or deterrence. Citizens are potential victims in this setting both of criminals and of government; and they need not imagine themselves as criminal offenders to feel threatened by a government that is without restraints in pursuing its policies.

The external concerns that motivate restraints on punishment can produce debates in which the contestants are talking past each other, and in which differences of opinion exist even about the topic being debated. In many disputes about capital punishment,

retentionists typically assume that the topic is crime control and therefore the issues are individual desert and deterrence, while abolitionists see the topic as the appropriate limits of power in the modern state, a concern that has little use for criminological data or expertise. Often the debate is decided by which side succeeds in establishing its view of the topic under discussion.

What we are calling a 'human rights' perspective tends to be most prominent in circumstances where citizens have special concerns about the organization and limits of government. Change of regime is one obvious circumstance where citizens have pressing concerns about limiting governmental power. The widespread abolition of capital punishment in Central and Eastern Europe after the end of Soviet domination is one recent example of this. A second is that the abolition of the death penalty in Europe after World War II was first evident in the nations that were defeated and changed regimes, that is in Germany, Italy, and Austria (Zimring and Hawkins 1986). Only later did abolition spread to the major powers that were victorious, to the UK and France.

3. *The Politics of Governmental Limit*

All the major democracies in the world have substantial constitutional limits on the government's power to punish criminals that include prohibitions of torture, and all the major democracies except the USA and Japan prohibit the death penalty. All the developed democracies impose substantial minimal procedural conditions that must be met before punishing. The current pattern is that those nations with substantial democratic influence on government power also have more limits on punishment than nations with less citizen control on government, but this is no paradox. Authoritarian regimes do not choose to limit themselves and their citizens lack the power to force limits.

More interesting are the motives and mechanisms which limit punishment power in democracies. If a government responds to popular will, why not give it total discretion in the choice of punishment for criminal offenders? One problem with that position is that changing political circumstances is a risk that cannot be discounted. Governments may cease to be accountable, so that whatever safety came from popular control might disappear. But there is also a possibility of majority will supporting excessive use of force. In almost all nations, discrete minority populations support restrictions on government power in part because of a fear of popular control. And while self-interested enthusiasm for limits on government power is easiest to imagine for those with conspicuous minority identities, there are few of us immune from being outvoted in a matter of important personal preference. All citizens are potential minorities on contested issues.

So the reason democratic regimes have more restrictions on government power than autocratic regimes is that democracies allow such limits to exist. We know this because the strongest support for limits on government will come from those who have recently experienced autocratic governmental excesses. Limits on government power are quickly imposed once iron curtains fall.

How might a government constrained by limits on power tempt its citizens to remove such limits? Fear of crime and of criminals is one obvious technique, and this creates a strong motive for governments that desire additional power to exaggerate the danger of crime and criminals. The political task is to convince citizens that criminality is a greater threat to them than government excess.

Not all areas of criminal justice are of equal concern from a human rights perspective. The maximum dangers cluster at the extreme edges of the system—the most serious offenders, the most fear-inspiring crime problems, and the most extreme punishments. The most serious and hated criminal offenders are the justification for new incursions of state power. The serial killer, the murderer of children, the predatory sex offender, and the drug lord are the principal arguments put forward for extensions of the severity of punishments available and the length of incapacitation. Terrible crimes are always urged as the justification for terrible punishments. But more than the heinousness of individual offenders, the justification for new intensities of punishment depends on the public's sense of insecurity in combating the particular problem that is urged as the necessity for the extension of state punitive power. It is citizens' sense of vulnerability more than their distaste for particular criminal offenders that justifies the extension of state power. A sense of public emergency thus becomes the leading enemy of moderation and the limitation of government power.

The importance of public feelings of vulnerability about crime to support for the expansion of punitive power explains not only the incentive of ambitious governments to scare their citizens but also the cyclicality of the public sense of emergency about particular crime problems. From the war on drugs, to gang violence, to the Mafia, each campaign to make citizens feel acutely threatened has a relatively short effective life after the threatened Armageddon does not happen. So governments intent on consistent expansion of punishment powers will need to rotate the particular problems that are pushed to justify penal inflation. When drug wars are followed by panics about juvenile violence, the shift in topic may be the only way supporters of expansion in governmental power can generate consistent levels of public anxiety.

While extreme forms of criminality are the focus of support for extensions of governmental power, extreme forms of punishment attract the attention of the enemies of unlimited governmental power, particularly when a punishment is distinct from more standard penal measures in kind as well as degrees. Torture, beatings, and execution have been the targets of choice for human rights reformers, practices which inspire citizen empathy with the subject of the punishment, and types of deprivation that are easy to distinguish from more common penal measures such as imprisonment and fines.

Penal practices which differ from those in common use in extremeness but not in kind are more difficult targets for the human rights reformer to identify and to attack. An illustration of this phenomenon of current importance concerns what has come to be called 'the maxi-maxi prison' that has proliferated throughout the USA since the 1980s. Designed to impose unprecedented levels of individual isolation and psychological deprivation, the maxi-maxi prison is nonetheless a more difficult target for the human rights reformer than canings or torture because the institution can be defended by government as merely another form of prison.

The general acceptability of imprisonment as a penal sanction becomes that major premise in a syllogism; the minor premise is that these maxi-maxi institutions are prisons; and the conclusion is that therefore they must be acceptable penal measures. To date, these extraordinary institutions have not received the attention they deserve from either reformers or the wider community.

4. *Impulse and Obligation in Conditions of Imprisonment*

Imprisonment is the most serious penal sanction that is frequently imposed in the modern state and a stunning example of the conflict and complexity involved in the protection of individual dignity during punishment. The imprisoning state administers an institution where the totality of the offender's life is under its control and restraint. For this reason, sociologists describe such facilities as 'total institutions.' For the modern prison, the same government that condemns and wishes to punish offenders controls every aspect of their daily life: eating and drinking, social contact, excreting, communication with the world outside the prison, exercise, light and darkness are all state-administered conditions in the modern prison.

The totality of state power over individual life means that the punitive impulse that inspires imprisonment could in theory influence every aspect of the conditions of confinement. Why should those who have murdered and raped get decent meals or the opportunity to communicate with family and friends? What is the argument for allowing those who are being punished by imprisonment to enjoy movies on cable television or build their muscles in exercise rooms that have been equipped at public expense? One version of objections to positive conditions in prison acquired the label 'less eligibility': an argument that conditions in confinement should not be better than those available to the poorest members of the law-abiding community. But the broader argument is why not make the conditions of confinement in penal institutions punitive in all their details?

Two points of importance in considering the limits of punitive agendas on conditions of imprisonment echo general concerns which we adverted to earlier in this article. The first is that the source of any limits on the punitive content of imprisonment will be external to the purposes of punishment. One cannot derive compelling arguments for cable television in prison through analysis of concepts like deterrence and retribution. The second point is that the popular will in democratic government will be an unlikely source for conferring amenities on prisoners. The general hostility to the subjects of imprisonment is not self-limiting.

The limiting principal necessary to minimum standards of confinement is the governmental obligation to respect the human dignity of the prisoner. The content of this obligation is not easy to determine and will vary with economic resources and other social conditions. Deprivations that are not necessary to maintaining the restriction on liberty that make prisons punitive are gratuitous, and the claims of the prisoner as human being against the state make most gratuitous punitive conditions of confinement seem problematic. But the most that one can conclude from a discussion of the purposes of punishment is the lack of necessity to push further, a sense of what might not be necessary in order to condemn the punished offender or to deter others.

Yet more than a general notion of parsimony informs prohibitions on torture and execution. And the use of torture is prohibited even when it might prove quite useful to interrogations. As with torture, we believe that gross conditions of isolation and sensory deprivation that are intentionally imposed in hypermaximum security prisons in the USA also violate free-standing conceptions of human dignity that are no less important because they are imprecise.

But enforcing restrictions on punitive conditions of confinement through the political process is difficult not only in autocratic political regimes, but also in democracies. The authoritarian government is unwilling to constrain the tactics it uses in conflict with domestic enemies. In democratic regimes, citizens will be unwilling to spend resources to confer benefits on hated criminal offenders, particularly when politicians portray spending money on prison conditions as a status competition in which the citizen must choose

between the interests of prisoners and the interests of crime victims (Zimring et al. 2001 Chap. 11). Under such circumstances books for prison libraries and educational programs in penal institutions might be regarded as a direct affront to the victims of crime.

Enforceable limits on the punitive content of imprisonment can be maintained in two ways even when they are unpopular. The first is by a commitment of government to constitutional principles that render some conditions of confinement beyond the reach of governmental discretion. This is a 'bill of rights' approach to the limitation of gratuitous punishment. It requires enforcement somewhere in government, but not necessarily by the executive branch that administers prisons.

A second strategy for protecting imprisonment from gratuitous punitive content is to make the detailed conditions of imprisonment the responsibility of expert governmental actors whose discretion is insulated from populist politics (Zimring et al. 2001 Chap. 10). This has the advantage over a 'bill of rights' approach of allowing detailed consideration of conditions of confinement by governmental officials who have ongoing responsibility for administering imprisonment. The disadvantage of delegating to the warden and the prison guard is the threat of conflict of interest, that prison administrators will themselves prefer unjustifiably punitive conditions for their least favorite prisoners for reasons of animus or administrative convenience. The recent history of maxi-maxi prisons in the USA suggests that administrative controls within the executive branches of government have been manifestly insufficient protection of the human dignity of prisoners.

5. *State and Society in the Punishment Enterprise*

When governments push for increased power to punish criminals, they assert an identity of interest between the state and society in the punishment process. Executions are necessary to protect the community from murderers and rapists, and preventive detention is required because individual citizens demand safety rather than for any distinctive self- interest of the government. The plea for power is premised on an identity of state interests, community interests and individual interests.

Those who oppose the expansion of state punishment power will typically emphasize the differences between the interests of government and of social groups. In this view, state power can suppress rather than facilitate the interests of social groups and individuals. State power is presented not as an extension of social power but as power over society exercised by outsiders. This contrast in the rhetoric of punishment limits suggests a relationship between state and society that should predict the appeal of restraints on punishment power. In settings where there is an ideology of either identity or strong overlap between state and community, limits on government power to punish will be a hard sell, even if the populace has some control over government policy. States which govern simple and homogenous societies in accord with traditional principles will be difficult places to argue for a bill of rights, just as the identity of state and society assumed by theocratic and totalitarian regimes makes it difficult to imagine the appeal of limits on government to those who govern.

By contrast, limitations on government power have a natural constituency for citizens and social groups when the interests of government are regarded as separate from those of significant social groups. The simple example here would be the popularity of limited government to a population that has been recently been occupied by an alien political regime. For the same reasons, states which govern complex and plural societies will have a much more difficult time convincing citizens that the government will instinctively serve the interests of constituent social groups. The larger the number of groups and the more diverse the values and interests of groups within the boundaries of a political state, the more likely will be a consensus that limits on governmental power to punish serve the common good.

This simple hypothesis can help to explain the relative popularity of limits on government power to punish both cross-sectionally and over time. Those nations that encourage complexity and diversity also embrace limits on the exercise of governmental power generally, and punishment power specifically. The theocratic regimes of Islam are notoriously inhospitable to constitutional limits on government because the apparatus of state power is regarded as the faithful servant of a single dominant social group. In totalitarian states, on the other hand, limitations on governmental power are unthinkable because social groups are regarded as the faithful servants of the state.

Trends over time in state and society provide some reason for hope, but not without cautionary countertrends. Those areas of the world where pluralism and complexity are encouraged have become the breeding ground for domestic and international limits on government. The European community and the British Commonwealth nations are examples of political development in the direction of constitutionally limited regimes. Globalization and multinational economic organizations favor the development of limited government. But the march of history has not been inevitably in that direction. Totalitarian regimes were a twentieth-century development that often succeeded simpler social frameworks, and there are also strong theocratic trends in some areas of the world that run counter to theories of inevitable liberalization.

6. Penal Restraint and the Human Rights Agenda

In one key respect, the punishment of criminals is not a frontier issue for consideration of the obligation of the state to its citizens. Criminal justice is not the area where governments can be expected to innovate in the extension of opportunities and entitlements to citizens. Such innovations will usually first be extended to dependent populations with much higher social reputations than criminals—the elderly, children, and to those handicapped through no fault of their own. The strategic role of the criminal offender is in defining the absolute minimum obligation of state to citizen, so that adequate provisions for prisoners is a defensive necessity. Assuring the human dignity of the murderer and the rapist is not a strategy for expanding the entitlements of schoolchildren and senior citizens; instead it is a strategy to prevent the erosion of citizen claims against government, to prevent regressions applied to the least popular of dependent populations which might thereafter be applied more broadly.

The defensive significance of offenders' interests in the human rights dynamic has two implications. The first is that the entirety of a human rights agenda can never be exclusively based on offenders' interests. The defence of prisoners' rights is always a necessary but never a sufficient condition for a human rights agenda.

A second corollary of the defensive strategic position of offenders' interests is that efforts to protect this particular flank will be much more important in bad times than in good times. In periods characterized by good will and the growth of government concern for citizens, the advocacy for offenders' rights will be somewhat easier in its own right and less necessary for the protection of other vulnerable populations.

When a social climate turns threatening, the defense of offenders' interests becomes at once tactically more difficult and strategically more important. It is during eras of bad feeling that the interests of vulnerable populations are most at risk. The path of least resistance to the erosion of individual rights will always be to target those domestic enemies assembled in the criminal justice process.

Criminal Justice, Sociology of

1. The Origins of the Concept

The term 'criminal justice system' (hence designated as CJS) is a recent acquisition of the scientific and professional vocabulary. Since the publication of the United States. President's Commission on Law Enforcement and Administration of Justice report 'The Challenge of Crime in a Free Society' (1967), the term has been used with a somewhat precise meaning.

However, in the process, the Commission's investigation led to the claim that the goal of the 'war on crime'—the fight against insecurity and the foundation of public safety of the persons, goods, and moral integrity of the citizenry—necessitated a comprehensive concept inclusive of all the institutions concerned in this objective. The breadth and complexities of this conceptualization led to the identification of incongruities between some of its parts, allowing critics to call it a 'nonsystem,' referring to the apparent incoherences and contradictions in the functioning of the overall system.

It became evident for the Commission that there existed a real and a virtual inter relationship, reflecting an interdependency between legislations, institutions, organizations, and scattered offices throughout the machinery of criminal justice, whose goal is the maintenance of public order, the safeguard of liberty, physical integrity, and concern for the victims of the failings of the protective shield, extended by the law and protected by the Constitution. Recognizing these historically and nonlogically ordered institutions, laws, services, and so forth, the Commission wanted to give a degree of coherence to all of them in order to secure a better, more efficient coordination, built around a common goal: assuring, under the supremacy of the law and the Constitution, equal justice and protection to everybody. Despite the criticism, the concept of the CJS was born. Thanks to this organizational principle (a 'system' necessitates some logic), overlapping jurisdiction, duplication of services, and irrelevant goals or functions were identified. The Commission's logo—with its input and output/entrance and exit design—illustrated graphically how, from arrest to release, from sentence to punishment, the whole process of criminal justice constituted an administrative and logical 'whole.' This holistic approach provided the reformer with a blueprint and a compelling agenda for reform.

However, these recent origins of the CJS should not hide the basic fact that the inspiring and commanding center of their systematizing approach can be understood as a development of the *code d'instruction criminelle of 1808*. This code was characterized by (a) rigorous penal procedural rules; (b) the availability of material and technical conditions to implement those rules; (c) a reasonable degree of coherence among the constitutive elements of the system, principally the offices of the prosecutors, magistrates, and other officers of the judiciary. Similar transformations took place in other Western countries that incorporated a systematic approach. The principle of the separation of powers, the presumption of innocence, and the independence of the judiciary were nowhere threatened by the emergence of the CJS, with the notable exception of course in the totalitarian countries.

2. *Practical Impact of the Concept of the Criminal Justice System*

A radical transformation in public administration began as early as the middle of the nineteenth century, accelerating after World War I and continuing beyond World War II. One result was the emergence of an activist and interventionist social policy. A similar transformation in criminal justice administration did not occur until later. In the process of its consolidation, it confronted the cultural revolutions of the 1960s and the 1970s, and even some basic principles of the penal procedural law underwent some changes.

Among the consequences of the development of legal structures and philosophies were a loosening up of the system, allowing an increased role for a defense attorney (human rights legislation had a major impact on the proactive role of the defense councils), and resulting in an increase in the burden carried by law enforcement agencies to accommodate the increasing demands of defense attorneys as well as rules edicted by commissions of human rights (the need for 'foolproof' proofs required by tribunal became more cumbersome and proceedings slowed down notably). The increase of the workload in the prosecutor's offices, as well as at the courts, was not in step with the necessary budgetary requirements allowing a decent discharge of the increased workload devoluted to the CJS in charge of the 'post-arrest' phases.

Additionally, there was a growing incoherence between segments inside the diverse components of the CJS. Undue competition has arisen between services, which should have been submitted to rules prescribed by their common goals. Moreover, a growing politicization has taken place. The power of unions is increasing everywhere: the judges, the prosecutors, and police are organized in their own unions. Some unions of magistrates, particularly in France and in Italy, are playing an active and sometimes radical role inside of the CJS. Thus the coherence of the CJS has suffered from the centrifugal forces in its own ranks. This worldwide phenomenon is affecting open societies, and while the European continental nations, in line with their centralizing traditions, are seeking new measures in tune with their traditions, all of them are also facing similar problems.

3. *Components and Goals of the Criminal Justice System*

The 1967 Presidential Commission, which is *de facto* the originator of modern research on crime, delinquency, victimology, and criminal justice agencies, introduced and somehow accredited a rather artificial distinction between research carried out on the CJS and criminology. This discipline was related, if not assimilated, to etiological research on crime causation. Its continental origins were stressed. Criminal justice research, born of the common law tradition, postulated the existence and interdependence of all components of the CJS, including law enforcement, criminology, criminal justice administration, prosecutor's offices management, sentencing guidelines for judges, and so forth. Of course, 'corrections,' a new designation for penology, was a major aspect of research on the CJS. These distinctions also reflect a growing attention to the evolution of ideologies, to new tendencies of penal philosophies, justifying research on alternatives to the actual CJS, which answers to the needs of victims and new sentencing philosophies. The analysis of the performance of the CJS, evaluation of alternatives for this system, and all kinds of innovations, were also an integral part of research on the CJS. Also, the treatment of offenders, their resocialization, programs of crime prevention, and experiences with 'restorative justice' became the spearheads of research in criminal justice.

Many of the major changes which the CJS underwent are related to the sudden surge of the world economy and commerce in the direction of globalization. Accordingly, the problems facing the CJS became global, embracing the whole world. One has to face the fact that crime and justice have to be addressed in an open world, at the level of the global economic and financial system working with the tools of the newest information and technology. The sociopolitical system and the political power structures are closely related to the new financial, commercial, and economic trends and powers. The magnitude of the challenge facing all the components of the CJS is tremendous. Consider, after 1980, that the volume of the sales of foreign stocks and bonds increased drastically on the market (Adler et al. 1994).

However, many countries are largely decentralized and have residues of common law traditions. There, the integration and internal coherence of the CJS is limited; rather the tendency is toward internal incoherence and diversity. Thus it is not surprising that

these countries, illustrated by the USA, are much slower to ratify or contribute to international criminal and penal jurisdiction. An example is the US government's refusal to adhere to the Naples' convention sponsored by the UN to create an international penal tribunal.

4. Criminal Justice System and the Courts

In this context of global integration, the thrust toward internationalization increasingly impacts local crime scenes (arms dealing, etc.) so that, directly or indirectly, they become integrated into international activities through the operation of off-shore banking, among other devices, intermingling, sometimes, with secret service operations (e.g., the Panama-Noriega scandal); and with illegal merchandising traffic, tax frauds, illegal financial contributions to political campaigns or parties, and so forth. Money laundering is the lifeline of all these criminal and illegal activities. Out of necessity a new international CJS is emerging with the support of the UN and the European Union (EU). Other tribunals in Africa and Asia are in process of being established.

One can see that open democratic societies are building new lines of defenses using legislations and sharpening legal tools available to the police and prosecuting attorneys. A new Europe-wide legal system is being created and is slowly and systematically building structures and defenses, which are both reactive and proactive. The building of such a coherent system was, in part, a response by the CJS to challenges initiated in continental countries under the auspices of the EU.

5. The Debate on the Definition of Deviance and Criminality

In the 1970s sociology questioned what distinguishes a 'criminal' act from a 'deviant' one, thereby adding a substantial burden to the functioning of the CJS. Such questioning created difficult dilemmas for the CJS, whose task is to enforce the existing laws. Problems arose as to where to draw the limits of the interventions of the jurisdictions of the CJS agencies in controlling or repressing the 'criminal' and unlawful activities of large, and certainly vocal, minorities. The frontiers between crime and deviant behavior became blurred. The law enforcement agencies, occupying the first line of defense in securing public safety, became hesitant in the application of the law. This environment of questioning and doubt encouraged the increasing activism of human rights defense groups, critical of the law. And when the police tried to enforce questionable laws, they were frequently confronted by activist groups, sometimes with violence. Many court actions followed violent confrontations in the streets. Also, accusations against the police for being prejudicial created a major impediment to efficient policing.

The manifold increase in the charges burdening the prosecutor's offices, mainly in major cities, reflected itself in the overflow of cases brought in front of the judges. Plea bargaining before the trial (essentially a kind of out of court settlement between the prosecutor and the defense council) became an accepted way of proceeding. For several decades it has been the only way to avoid the complete paralysis of the whole judicial process. These negotiations are questionable, morally as well as legally, and sometimes they are clearly illegal, although they are still currently practiced in the US courts system. In contrast, these practices are strongly rejected by the European continental legal system, but the future of its integrity is, unfortunately, an open question. The caseload of the courts is increasing constantly and political power negatively confronts the judiciary in several important Western European countries. The main issues are political corruption, bribery, and abuse of power. We have yet to see the outcome of this type of conflict inside of the continental system where political power negatively confronts the CJS.

6. Changes in the Philosophy of Punishment

Imprisonment was a notable advance over the all-too-common previous method of punishment: the death penalty. Virtually from its beginnings imprisonment developed in response to religious concerns (largely from nonconformist denominations—Methodist, Congregationalist, Presbyterians, Quakers, Baptists, etc.), and was informed by ideas of the continental Enlightment, as well as English social contract and utilitarian theories, and the views of Scottish moral philosophers.

In the north-east sector of the USA these religious and intellectual forces combined to encourage a massive social experiment in punishment, which was grounded in the emerging belief that humans are social beings possessing 'natural' or inalienable rights, capable of reason, and inherently good or virtuous: the infant cannot be evil. From this perspective the logic of imprisonment would not only punish the wrongdoer, but seek also to rehabilitate that wrongdoer, as well as to deter others. Elmira, Auburn, and Cherry Hill were famous attempts to express this evolving penal philosophy, and de Tocqueville's tour of these institutions was an example of European continental interest.

This complex and integrated humanistic view, issuing from the Enlightment, was challenged by developments in sciences such as medicine and psychiatry. These disciplines understood criminal acts to arise from personality disorders rooted essentially in social, biological, or psychological conditions. In a sense, the 'medical model' retained but transformed

elements of the 'humanistic model.' The goal of rehabilitation was retained, but its justification was to be found and legitimized in scientific methodology. One consequence of this scientific approach, as it gained influence, was to impact the CJS through legislative reforms and judicial practices, for example, the rapid spread of indeterminate sentences, and the transferal of the principle of rehabilitation from being a concern of the larger society (religious activists, legislators, educators, etc.) to become the concern of medical sciences.

7. *Emergence and Hegemony of the Medical Model: Conflicts of Goals with the Legal Tradition*

The nature of the scientific method is the permanent questioning of existing proofs and practices. For example, in medicine, it results in a continuing revision of therapeutic practices and rehabilitative techniques. Naturally, a continuing tension and conflict develops between the ever-changing medical-therapeutic approach and the desire of the CJS to retain humanistic principles of equity, rights, and equal treatment before the law. This situation threatens its coherence and creates an increasing vulnerability for the CJS, especially to its claims of legitimacy.

The challenge to legitimacy was not limited to the confines of the CJS, but permeated the entire open, pluralistic, humanistic society. Everywhere, a profound crisis of values occurred: in the family, and in institutions of authority, including the medical and academic communities. The identification of who or what was responsible for this turmoil emerged from a variety of diverse sources, making it impossible for a generally agreed upon understanding to be reached, and so disarray prevailed.

The impact on the CJS, which became closely associated with the medical model, was disastrous in that it allowed for both an immunization of the 'underclass' against claims of criminal behavior, and the emergence of new prophets with new social and cultural constructs. An attempt to correct this situation, and to devise a means of bridging the chasm separating the reality of crime and the CJS, was Von Hirsch's (1976) doctrine of 'just deserts.' This doctrine promised law and order while accommodating the new forms of behavior. The end result was a temporary compromise in which the CJS maintained and protected the core values concerning material and personal security, while adapting itself to the demands of the 'post-Woodstock' society.

8. *Some Future Perspectives*

The real and symbolic ruins that were the reality of the CJS under the conditions of this temporary compromise were, fortunately, addressed by H.L. Packer (1968). Packer identifies two models. The first is the 'due process model,' characterized by the jurisprudence of the Warren Court, in which most of the odds were placed against the defender of public safety and order. This model amplified the 'rights' of the individual, and encouraged a critical, reactive attitude on the part of the judiciary. This model has a rule-oriented rather than a substantive-oriented approach.

The second is the 'crime control model,' which emphasizes the existence and exercise of official power. Its validating authority is ultimately legislative (although approximately administrative). It can be viewed as consistent with, and a continuation of, humanistic-Enlightment principles. In light of the lessons of the eighteenth century, and because Packer's theories are deeply rooted in humanistic-Enlightment principles, one can surmise that his crime control model will prevail in the near future.

9. *Conclusion*

In conclusion, the contributions of the social sciences to the CJS are varied. In continental Europe, the social sciences, as an academic discipline, had limited influence, notwithstanding contributions of outstanding scholars. In North America the social sciences have established a strong academic position and exercised a direct influence on the CJS. This influence also included a contribution to the intellectual and moral crises which characterized the 1960s and the 1970s. This was largely due to an epistemological crisis, which shook the very foundations of social and behavioral sciences. Whether or not they will recover their empirical scientific tradition is still an open question. Hopefully, the positive renewal of the CJS, influenced in part by Packer's writings, may have a spillover affect into the social and behavioral sciences.

Criminal Law and Crime Policy

1. Introduction

While the forms and functions of criminal justice institutions vary significantly around the world, trends can be observed that reveal a shrinking planet where countries are heavily interdependent, capitalism is triumphant, and pressure is keen for universal norms of political, economic, and social life. Although data from developing nations are often either inadequate or nonexistent, and much crime policy seems to be in flux, the available information suggests similar patterns in both Western and non-Western nations (with exceptions for some Islamic states). Whether the society is democratic or authoritarian, industrialized or developing, its police and courts are expected to deal strictly (often harshly) with law-breakers—particularly those who have committed violent offenses and violations of drug laws—and to respond to demands for protection from the public, ordinary citizens as well as elites. Rapid developments in transportation, communications, and trade have provided new opportunities for transnational crime and local crime increasingly to reflect and shape global events. In response, the nations of the world are trying to coordinate strategies to address crimes like drug trafficking, arms smuggling, and fraud that cross national borders. Crime policy is affected by political change, too. The spread of constitutional democracies on several continents and the breakdown of traditional mechanisms of informal social control in the Third World are creating a new awareness of rights in nations where they have previously been unknown, a development with significant implications for peoples' expectations that criminal justice will operate efficiently and fairly.

As with the policy measures of the early twentieth century, get-tough morality—this time in the form of a worldwide war on drugs, fought with treaties and international cooperation as well as with conventional law enforcement—coexists with efforts to find alternatives. Today, however, the innovations are often taking place outside state-centered justice systems, in the spread of private policing and the use of community dispute resolution in both traditional societies and industrialized urban areas. New paradigms for dealing with incidents that disrupt community harmony—principally the restorative justice ideals behind programs like 'family conferencing' in New Zealand, Australia, and elsewhere—seem likely to have a communitarian influence on criminal justice. The full effect of globalization on official social control remains to be discovered.

2. The Punitive Trend

No clear relationship exists internationally between levels of crime and the prevalence of official punishment. A 1997 analysis of 34 countries conducted as part of the Fifth UN Crime and Justice Survey found no significant associations between sentencing rates (per 100,000 population) and crime rates (Newman 1999, p. 91). Similarly, harshness in penal law may accompany either increasing or decreasing crime rates. Crime control policies in South Africa and the United States, for instance, show quite similar directions, even though trends in the incidence of crime are very different. In the 1990s, violent crimes like robbery, assault, and car-jacking were on the rise in South Africa but falling in the United States. Both countries, however, adopted longer and mandatory sentences, asset forfeiture laws, and limits on bail eligibility. Penalties for property crimes continued to be relatively light throughout Western Europe during that period, despite significant increases in rates of offending in several countries, while in North America lower rates for such crimes did not reduce sentences.

These illustrations of statistical patterns suggest two important realities of crime policy around the world at the millennium. One is that it is generally quite punitive, at least if one defines 'punitive' to mean the criminalization of many behaviors deemed undesirable and heavy reliance on the deprivation of

liberty. The other is that the United States—in many respects the most punitive of the developed countries (and growing more so all the time)—has tremendous direct and indirect international influence.

In the 1960s Packer articulated two conceptions of the criminal justice process—the crime control model, which gives priority to the efficient capture and containment of potential and actual law-breakers, and the due process model, which looks beyond immediate community protection and seeks to guarantee fundamental fairness to all those who come within the reach of the criminal justice system (Packer 1968). While scholars and policymakers are still wrestling with the tension between these two concepts of the function of the criminal sanction, it seems clear that the crime control perspective dominates the operations of police and courts around the world.

According to data from the United Nations Surveys of Crime Trends and Operations of Criminal Justice Systems (UNCJS)—admittedly limited to those countries that respond and compromised by inevitable differences in reporting standards, methods, and capabilities—prison is a more popular sanction in most countries than noncustodial penalties like fines (a common alternative) or community supervision. (International numerical comparisons in this section come from the Fifth UN Crime and Justice Survey (Newman 1999, pp. 89–119) unless otherwise noted.) Whether it is Vietnam—where smuggling as little as 100 grams of illicit drugs can warrant the death penalty—or the United States—where federal guidelines instruct judges to sentence youth more harshly than adults for commission of the same crimes—harsh punishments have great appeal.

One standard measure of harshness is the rate of incarceration per 100,000 population. On this score Russia and the United States are the clear leaders, Russia with a rate of 411 in 1994 and the US with a rate of 468 in 1999 (as of June 30), the last years for which data are available (Bureau of Justice Statistics 2000). Many countries' incarceration rates rose substantially during the first half of the 1990s, particularly in Eastern Europe; in Italy the rate increased 100 percent between 1990 and 1994, perhaps due to a new and harsher drug law passed in 1990 (repealed 3 years later).

Despite opposition from the Catholic church, international political bodies, and human rights organizations, the death penalty continues to be used widely in developing countries and in the United States, where 3,652 people were on death row at the start of year 2000 (NAACP Legal Defense and Education Fund 2000, p. 1). Amnesty International reports that 1,813 people were known to have been executed in 31 countries in 1999, with China, Congo, Iran, Saudi Arabia, and the United States accounting for 85 percent of that number (Amnesty International 2000). Many countries show considerable ambivalence towards capital punishment. Russia abolished and reinstated it three times in the twentieth century, and the Philippines recently began executing people after a 20-year moratorium. More countries are likely to abolish the death penalty since it is a requirement for membership in the European Union.

Criminal justice policy can also be assessed by noting procedural protections provided to accused persons. Although the common law countries tend to emphasize constitutionally-mandated defendants' rights (like the presumption of innocence and rigorous standards of proof at trial), it is by no means clear that in practice they are more protective than civil law countries, which often incorporate similar protections into the inquisitorial process in less formal ways. It is in English-speaking countries, in fact—Britain, South Africa, India—that the right of the accused to remain silent has recently come under attack; in the United States, the imperatives of the war on drugs have caused significant erosions of the prohibitions against unreasonable search and seizure and self-incrimination. In 1999, the British Home Secretary called for an end to the ancient and automatic right to trial by jury. He also criticized the prohibition against trying a defendant more than once for the same crime (double jeopardy), a constitutional provision in the United States that has been weakened by a number of court-approved exceptions.

The most obvious influences of United States' criminal law and crime policy on other countries' punitive trends can be seen in innovations related to the war on drugs, among them the forfeiture of suspects' assets, money-laundering laws, and elaborate sting operations. The long arm of US policy has reached into other areas as well. Laws that require community notification when a sex offender is released from prison have gone into effect in the United Kingdom and Canada. Another American export is habitual offender legislation (the 'three-strikes-and-you're-out' policy that helped to swell California prisons at the end of the twentieth century), which is now common in Europe and has been adopted recently in Australia and New Zealand. American dominance meets with occasional resistance, but the trend is likely to continue as long as federal law enforcement personnel staff American embassies and provide training in crime control both at home and abroad.

The punitive trend is not universal. UNCS data from 1994 indicate that fines comprise more than 70 percent of sentences in a number of countries on three continents; the survey found that in Japan fines were imposed in 95 percent of cases. One study of increases in violent juvenile crime and policy responses in Europe and the US found that, although in Britain, the Netherlands, and the US sentences have been lengthened and procedural protections narrowed since the late 1980s, most of the countries studied have retained programs that provide options besides secure detention and are working to develop social and vocational services intended to prevent juvenile crime

(Pfeiffer 1998). Ideas about alternatives to incarceration that have become standard for minor offenses in Japan are taking hold in developing countries, though they have yet to materialize as policy. In India in 1996, the Law Commission recommended legislation providing for noncustodial punishments. In Kenya in 1999, a conference of criminal justice professionals, UN representatives, lawyers, and judges pledged to work toward the decongestion of prisons by expanding alternatives to incarceration for minor and first-time offenders. (It should be noted, however, that these sentences are not always less punitive than short prison stays and that they rarely reduce incarceration rates.)

3. *Policing and the Public*

A prominent comparative scholar of policing recently has warned that most of the world's police forces are 'regime police,' answerable to government and its needs and 'organized to be responsive upward' (Bayley 1999, p. 3). The undemocratic essence of such policing is its inability to respond to public demands and the resulting unwillingness of members of the public to turn to police in anything less than emergency situations. Two worldwide developments—community policing and government investigations of police behavior—may soon alter Bayley's conclusion. Through these innovations, policymakers, concerned citizens, and international organizations are seeking greater police efficiency, accountability, and transparency with unprecedented vigor, though it is difficult at this point to say to what effect.

'Community policing' is an international buzzword that may mean anything from citizen patrols in Kuala Lumpur and Singapore to the highly professional commitment of police working with residents and city agencies in Chicago neighborhoods (Skogan and Hartnett 1997). The vagueness of the term and the potential for abuse—empowering vigilante groups, dividing neighborhoods by building networks of citizen informers—gives warning of its antidemocratic possibilities, and flaws in concept and implementation are notable everywhere. But in theory, community policing promises visible patrols, decentralized command, and the chance for the public to communicate with police about community problems (Skogan and Hartnett 1997, p. 6). Its appeal is an indicator of the public's desire for participation in and oversight of the institution that is at least theoretically charged with the politically neutral protection of a community's security. In volatile and crime-ridden Bogota, Colombia, the police chief sees community policing as a remedy for public distrust; in Lusaka, Zambia, businessmen assist the officers assigned to patrol the commercial district; in March 2000, the Israeli Minister of Internal Security announced his intent to reallocate some resources from defense to community policing. Western countries that have already embraced a paradigm shift from the old aims of professionalism and paramilitary discipline in policing to the new community-oriented perspective are coming to the aid of less developed countries that want to get on board. The US has helped El Salvador initiate foot patrols and community relations efforts, the UK has held training sessions for Chinese police chiefs, and officials from the Czech Republic have been consulting with the Canadian Mounted Police.

Greater public accountability is also furthered by governmental concern over the police brutality, bias, and corruption that are endemic in many countries. In the US, the Crime Act of 1994 has given the federal government unprecedented authority to investigate abuses in local police departments; investigations of police practices in Los Angeles, New York, and Buffalo, among other cities, have resulted. In Britain, the race relations law has been expanded to include liability for police bias, following the charge of institutional racism made against the London Metropolitan Police after a botched investigation of the murder of a black teenager killed by whites. Anticorruption campaigns in Latin America and Africa include a focus on police, and local corruption in Japan led the National Police Agency to institute random inspections of prefecture management and conduct. While it is unlikely that major changes in police culture will occur soon as the result of these measures, they are reinforced by international pressures, some of which carry powerful incentives for change. Turkey's effort to comply with requirements for admission to the European Union includes new legislation that would encourage the prosecution of police who torture.

4. *Future Crime Policy Issues*

Even as the public police around the world are subjected to increasing scrutiny, reliance on them may be diminishing. Policing is no longer solely a state function but has been 'pluralized' (Bayley and Shearing 1996). In South Africa, Australia, the US, and many other industrialized countries, private guards outnumber public police several times over, providing security for companies, government buildings, and affluent neighborhoods. The policing function—combined with adjudication of minor crimes in some developing countries—is also carried out by volunteer groups, who are sometimes informal community associations, sometimes adjuncts of the criminal justice system. To some degree, these institutions are reflections of a community's view that the formal justice system is unresponsive or unfair, but they may also manifest a need for indigenous solutions to conflict that is fundamental to a particular culture (Ebbe 1996, Brogden 1996). Developing regulatory

schemes for these domains of policing seems likely to be a policy challenge of the future.

The globalization of trade, communications, and transportation has brought more than international consulting opportunities to criminal justice policymakers and practitioners. Controlling transnational crime has become a major issue. Celebrated incidents like the 1993 terrorist bombing of the World Trade Center and more routine (but often violent) crimes like drug trafficking across national borders have brought about calls for internationally coordinated crime control strategies (Muller et al. 1997, p. 137), but law enforcement in this context—the intersection of criminal law and international law—presents problems of sovereignty, proportionality, and privacy. Without adequate regulation, pre-existing agreements between countries may be unnecessarily abrogated and amorphous behaviors (like conspiracy) over-criminalized. Constraints on police authority and conduct, which are difficult to impose in a single country, will be even more difficult to enforce at the international level. International law enforcement efforts may be rejected or ineffective because of an insufficient understanding of the particular political and cultural traditions of individual countries.

Recognizing these potential pitfalls but acknowledging the need for curbing illegal traffic in drugs, arms, and immigrants, as well as bribery of public officials, the International Penal Law Association in 1999 adopted a resolution on transnational organized crime. It recommended a parsimonious definition of international crimes; the regulation of extraterritorial jurisdiction and police cooperation; the adoption of standards for judicial assistance and cooperation; and the protection of defendants' rights in international criminal proceedings (International Enforcement Law Reporter 1999). The issues raised by this resolution are likely to be debated for the foreseeable future.

Cooperation in fighting transnational crime must obviously also include information exchange, often electronic. The US Attorney General has proposed a Global Criminal Justice Information Network that would link criminal and intelligence databases from all over the world and would be run by the US Department of Justice. But the prospect of globally-shared investigative data and international data surveillance raises difficult issues of privacy, accuracy, and dissemination. It is unclear at this time what criteria would be used for the protection of data or how they would be enforced.

Two other issues highlight the increasing internationalism of efforts at crime control. Countries in transition from authoritarian to democratic regimes often experience rising crime. Borders that were formerly closed become permeable, encouraging the growth of multination organized crime syndicates. More generally, freedom brings license; Nelson Mandela, commenting on the increase in violent crime in South Africa's affluent white suburbs, has noted that liberation frees criminals, too. Corruption in democratizing countries is also common, though what appear to be an increase in incidence resulting from regime change may in reality be the effect of placing a new light on an old problem, as seems likely in some of the Eastern European countries. The determination of whose standards to apply in addressing these problems and how to arrive at international consensus is a challenge for international policymakers.

A related issue is the handling of war crimes, genocide, and crimes against humanity. The recent prosecutions of the former dictators of Chile (Augusto Pinochet) and Chad (Hissein Habre) by the courts of other countries may signal an end to the traditional deference countries show to one another's sovereignty where serious violations of human rights have occurred. The international law principle of universal jurisdiction—the idea that a former head of state can be tried anywhere for atrocities committed while in office—is becoming operational. Empowered by the United Nations Convention against Torture and national laws that confer jurisdiction over human rights crimes, a number of European courts have charged foreign officials with crimes committed in Rwanda and the former Yugoslavia. Furthermore, the establishment of a permanent International Criminal Court (in 2002) to try these crimes will further institutionalize a far-reaching concept of international criminal liability. Proponents of the court also believe that it will have a deterrent effect on heads of state, though its authority is likely to be weakened by the refusal of several countries, including the US and China, to support it.

5. *Conclusion*

At the dawn of the twenty-first century, crime policy in a number of countries reflects a departure from some of the assumptions of modern, liberal criminal justice systems. The aim of both civil and common law traditions is to elicit the truth of what happened in a particular situation that gave rise to a criminal charge and to determine the legal consequences of that truth for the individual offender (and perhaps for the victim, whose concerns are now getting increased attention). But legislators, judges, and scholars are beginning to depart from the exclusive goal of individualized justice and articulate a larger concern for what happens to community life as a result of the incident under consideration and others like it. This focus can take a number of directions, two of which are showing up as policy innovations with potentially far-reaching consequences.

Sometimes called 'actuarial justice,' the more common of these directions has entered the mainstream in American criminal law and criminal justice practice (Feeley and Simon 1994). Sentencing, probation, and parole have become risk assessment functions. Deter-

mining penalties and how offenders are supervised as they pay those penalties depends on the degree to which the defendants pose a risk of reoffending, given not only who they are but what their salient demographic characteristics are (age, employment status). The 'New Penology,' as two prominent critics have called it, no longer seeks to change or to punish lawbreakers, but 'to regulate groups as part of a strategy of managing danger' (Feeley and Simon 1994, p. 173). The other approach—a burgeoning movement in a number of countries for the resolution of minor disputes and deviance—is restorative justice, in which the victim and the offender join in a ceremony that acknowledges the wrong that has been done but seeks social reintegration of the offender and assistance to the victim, restoring harmony through a mutually beneficial process (Braithwaite 1989). One researcher reported in 1999 that at least 300 victim–offender reconciliation programs are operating in North America and over 500 in Europe (Umbreit 1999).

The managerial aspects of the actuarial model are obvious; the crucial decision is made by legally empowered figures in a centralized hierarchy of state institutions. They place primary emphasis on the outcome as the force that will assure community security and pay only cursory attention to individual autonomy. Restorative justice, on the other hand, relies on decisions made locally and jointly by the parties and others involved in the incident, and the community is expected to benefit from the process of arriving at the decision as well as from the resolution of the problem. If surveillance dominates actuarial justice, empathy and what Braithwaite calls 'reintegrative shaming' characterize restorative justice.

It is unclear which of these models of criminal justice will prevail in the next decades, or whether they will continue to co-exist. Taken together, their departure from the individualistic models of twentieth-century jurisprudence and criminology is stunning, overshadowing even the changing nature of policing, the privatization of prisons, globalizing influences on criminal justice, and get-tough sentencing policy. Their emergence, and the ways in which they will interact with the other developments mentioned, points to our century-spanning generation as a decisive moment in the history of criminal justice.

Criminology: Psychopathological Aspects

1. Introduction

A study on the relationship between criminology and psychopathology would have to start from questioning its existence, its terms, and whether it is one of causality or of association. A causal relationship could be based on nosographic parallelism because psychopathology and criminology share mutual grounds

so that symptoms are equal to crimes and vice versa, or on epidemiological decisions that some mental states cause criminality. However, a relationship of association would have to specify the factors through which the association holds. Aristotle (1941) already expressed an interest in the relationship between psychopathology and criminology, but the large number of mental patients in prisons and the publicity generated by major crimes in which a mental patient has been involved have increased the interest in later years. In addition, depictions of criminals with twisted minds in movies and television spread the opinion that crime and mental illness are related. Unfortunately, very infrequently does the media provide realistic portrayals of the abuse, homelessness, social disenfranchisement, or social neglect that are common reasons why some mental patients are arrested. In this article, therefore, the author has two purposes: first to disentangle the existence and parameters of a relationship between psychopathology and criminology and second, to review risk factors that could determine the relationship.

2. General Statement on Psychopathology

2.1 Definitions

Criminology is the scientific study of crime and criminals and their motivations for criminal behavior. Psychopathology is the study of personality factors that are somewhat out of regular conscious awareness and that lead to behavior outside the norm in a particular social group. It studies abnormal emotional or personality phenomena that underline symptoms or behavior. Psychopathology provides criminology with methods to analyze elements of a criminal act within the personality structure and aims to find out the motivations for the crime. The interest is centered on the individual, or criminal, as somebody who is different from the rest because of personal or social deficiencies that have led him or her to commit a criminal act. Act and actor are the focus of study and intervention. In this type of criminology of difference the crime is a fact, and the criminal is singled out as an object of study.

From a wider perspective, any criminological study would ideally include the context in which the criminal behavior has taken place. This interpretation involves the criminal as wrongdoer, sometimes even as victim, the identified victim, the determinant elements of the social circumstances in which the crime has been committed, and the deciding role of the law. In this criminology of process, the crime is the result of a conflict and the criminal is the subject, or actor, caught in a web of social circumstances and legal definitions that are required to identify the act as criminal. No act could be defined as a crime without the social and legal identification that places the actor within a conflict with the group that, eventually, qualifies the act as infraction deserving of sanctions (Debuyst 1997).

2.2 Psychopathological Methods

It would be tempting to study every crime and its actor from the point of view of a criminology of process, but this approach has countless ramifications about the meaning of the act; and teleological implications about criminal responsibility. Although this perspective has high heuristic value, it would contribute little if the aim of the study is to gain a deep knowledge of the criminal. From a practical standpoint, singling out a person for study and dissecting the motivations underlying the act makes a statement that the criminal is different and in need of being separated from the rest of the group. Separateness is an objectifier that demands knowledge of psychopathological methodologies to do the separating and the dissecting.

There are crimes where the motivations could be placed entirely outside the range of personal psychopathology, but these are rare. For example, highly politically organized crimes take the victim as the representative of an order considered oppressive by a majority. In these crimes the immediate actor may not have personal motivations, but acts as an instrument of the group. Although such pure, politically motivated crime on behalf of the group could be studied from a historical, political, and social perspective, it would still have to be examined against a possible backdrop of social pathology, and the motive of the immediate actor would have to be examined to determine personal pathology. Regicides and magnicides committed by a lone criminal without social backing usually relate to personal psychopathology. Other forms of political crime, such as a leader's need to eliminate his or her opponents, although couched on political terms, would have to be examined as to whether the leader's thrust for power at all costs, including the need to preserve power that allows for satisfaction of plain personal greed, is rooted on psychopathological demands. In Mafia executions, for example, when somebody is 'rubbed out?' strictly 'for business,' the leader's need to preserve personal power may collude with the executioner's own psychopathology and callous disregard for life. Similarly, a leader's psychopathology could be linked to social pathology as in cases of genocide, when atavistic fears or deep resentments and anger against a group are brought to the surface in a cauldron of hatred fed by the leader's own hatred and psychopathological features. Ordinarily the leader uses charismatic power to manipulate the masses which allows for the emergence of primitive impulses of revenge, violence, and destruction. In turn, this frenzy proves the leader right and consolidates power. Political gain and revenge are the usual motivations of terrorism that depend on the

ability of the terrorist to objectify the victim, in itself a psychopathological construct.

Any other type of crime involves usual motivations such as greed, envy, lust, power, anger, overpossessiveness, and sometimes, even love. In any crime, however, the criminal, the victim, and society are inextricably tied in a web of emotional and social interactions mediated by the criminal act. Social sciences such as history, criminology, sociology, law, anthropology, psychology, and psychiatry converge on an act to label it criminal, and on the criminal to study the motivations.

The sciences diverge from that point on. For history, sociology, anthropology, and criminology look for answers in wider systems of social, political, and legal domains whereas psychiatry, law, psychology, and applied criminology are pragmatic sciences that explicitly objectify the criminal in order to justify interventions to change criminal behavior. In the elaboration of a psychopathological historiography, psychopathology seeks to understand the criminal act as a chain of personal events that have preceded the act and that will repeat in the future, if no intervention is undertaken. Sometimes a chain of similar acts has already been committed. In this 'package concept' of the criminal and crime, the instant event is only one expression, or symptom, of subjacent maladaptive processes that permeate all aspects of the personality. Maladaptive processes such as impulsivity, or callousness, are 'transnosographic' constructions (Widlöcher 1997) that span the spectrum of the personality. Constructs of this nature are rooted in character structure and may gain expression through criminal behavior or through symptoms of more obvious pathology such as depression or schizophrenia.

There are two types of psychopathological populations. First, the patients whose psychopathology is easily diagnosable as a mental condition such as anxiety, affective disorders, schizophrenia, or dementia. Patients are usually cared for in psychiatric units or in mental hospitals by general psychiatry. Second, criminals whose psychopathology may not be so obvious. They constitute the subject matter of penitentiary psychiatry in charge of studying the behavior, no matter how aberrant. Criminals are usually affected by deep personality disturbances that lead them repeatedly to crime such as thieving, assaultiveness, extreme forms of violence, substance dependencies, or deviated sexual practices. These two psychopathological populations are not usually so neatly separated because many persons suffer from co-morbid or dual conditions, or because there is an overlap whereby mental patients, like anybody else, could commit crimes and criminals, like anybody else, could become mentally ill.

Psychopathological explanations of crime have to be placed together with the sociological explanations that give meaning to the circumstances, historical and social, that surround the actor, or to the immediate triggers of the criminal act. Not to take these factors into account would do no justice to the criminal and it would deny an essential foundation to diagnostic interpretations and to treatment recommendations that might follow. A crime does not exist without a context and no criminal can be excised from the environment in which the crime took place.

2.3 Applications

A psychopathological evaluation of the criminal and the meaning of crime is an essential component, if not the *raison d'être* of forensic psychiatry. Forensic psychiatrists evaluate the mental condition of an accused for purposes of determining competence as required for legal purposes. To the contrary, treatment is not a regular concern of forensic psychiatrists. In correctional and penitentiary psychiatry evaluations do not dwell extensively on diagnostic issues, but rather, on the motivations for the crime to determine best treatment alternatives. Correctional treatment has two prongs: clinical treatment for symptoms of obvious psychopathology such as anxiety or depression, and correctional treatment to prevent or decrease recidivism usually through psychological or criminological methods. Unfortunately, sometimes clinicians in prisons are driven by a belief on rehabilitation and provide treatment without properly evaluating outcomes post-release over time.

3. Parameters of the Relationship

Psychopathological expressions could be subtle and difficult to elucidate, or other persons could be enrolled to demonstrate the pathology as in *follie à deux*, or in families where one member becomes the identified patient expressing the pathology of the other members. Psychopathology among criminals range from serious personality disorders to outright symptoms of mental illness. In between, there is a gamut of symptoms and crimes where the boundaries between criminology and psychiatry become blurred. Five levels of interactions could be described.

3.1 Crime as Symptom

These are cases in which a one-to-one relationship exists in the sense that the expression of the symptom constitutes the crime. For example, diagnosing some sexual pathologies such as pedophilia or exhibitionism is to acknowledge that a crime has been committed. A frotteur, for example, will not get sexual satisfaction by masturbating or by rubbing himself against an inanimate object; the compulsion is to do it against another person, yet anonymously, hence the crime happens in crowded places such as public transports.

The symptom is a crime against public morals and an assault for undue touching. A person who presents with fantasies about children, or about compulsively exhibiting in public, has not yet expressed the symptom and has committed no crime. To enter a diagnosis of pedophilia or exhibitionism at this stage would not be correct and could cause the person innumerable social and legal complications if the diagnosis is found out. In many crimes of this group the motivation is expressed as a desire, even compulsion, to indulge on the symptom and clearly precedes and determines the crime; thus, when psychopathology is present, the symptom is the crime.

3.2 Crime as Possible Symptom

One-to-one interactions could be observed in some other crimes. For example, firesetting is indicative of psychopathology, usually of an obsessive nature, and is found with some frequency associated with mental retardation, sexual pathology, or psychotic conditions. A diagnosis of firesetting could not be entered without immediately thinking that a crime, arson, has been committed. However, arson could also be a political or economical crime. Some shoplifters suffer from depression and anxiety, but shoplifting could simply be the result of a survival need, or even a business.

3.3 Crime as Correlate to Symptom

The third level of interaction presupposes a more distant relationship and takes place when a crime could be committed in order to indulge the symptom. An addict, for example, cannot do without the drug, but for as long as the drug is obtained legally because funds are readily available or because goods such as sexual favors could be bartered, the addict is free of crime. An addict commits a crime, either against property or sometimes against the person, when the drug cannot be purchased due to lack of funds or if there is nothing to barter. Sometimes, a child is sold or bartered as sexual pawn, or the addict agrees to a major violent crime in order to secure the drug. In these situations, the relationship between psychopathology and criminality is established not by the symptom itself, craving the drug, but by the drug-obtaining behavior at any cost. A similar situation could be envisaged among persons with developmental disabilities who display impulsive violent or destructive behavior. Usually the intervening factor is low frustration tolerance to irritating or annoying situations, or a poor grasp of heterosocial interactions leading to a sexual crime when willing partners, usually with similar disabilities, cannot be found.

3.4 Crime as Result of Symptom

This level involves a relationship where the crime is not the symptom nor is the crime related to the symptom through a criminal need in order to indulge the symptom, but it is the end result of several paths found in the course of some mental conditions. These include the following.

3.4.1 Crimes that follow the dictates of a symptom. Symptoms that could lead to crimes are only part of a multitude of other symptoms that accompany a particular mental condition such as paranoid states, schizophrenia, or major affective disorders. The majority of these patients may never be involved in any offences so crimes are not part of the definition of the condition. Furthermore, if the symptom is present, the patient could learn to control it by recognizing it as part of the illness, or through other forms of treatment such as medications. However, patients in this group could commit a crime when they follow the dictates of a symptom as happens in cases in which psychotic symptoms lead a person to believe in a certain state of affairs and, eventually, dictate that the person take action so as to modify a perceived negative course of the events.

3.4.2 Unexpected, unmotivated crimes. Sometimes a crime results from impulsive acts that are committed unpredictably and without time to foresee the consequences. This could be observed in persons suffering from intermittent explosive disorders, in the unreasonable, and unpredictable crimes of some patients suffering from schizophrenia, or in homicides, sometimes followed by suicide, of seriously depressed persons.

3.4.3 Crimes of interaction with social conditions. Finally, crimes could be part of the general social expression of a mental illness when social factors such as homelessness, deprivation, or poverty lead chronic mental patients to commit minor violations, usually motivated by survival needs punishable by a few days in a prison, or when a patient reacts violently to abuse or victimization. In this latter case, the crime may be caused not by the mental condition, but by a completely normal motivation of personal protection, or the mental condition may have affected the modulation of affect and aggravated the extent of the response.

3.4.4 Crime as an expression of being. Although characterizing crime as fate may seem pessimistic, criminal tendencies are so intimately linked to personality structures in some individuals that nothing

else could be expected, but a life career of crime. Being-in-the-world for these persons constitutes an extravagant display of predatory behavior in order to satisfy needs and sometimes perversions that are egosyntonic and whose satisfaction, which in the extremes could involve the humiliation, mutilation, and death of another, produces no guilt or remorse, but an urge to further predations. Many of these individuals present a range of behaviors, from the mildly antisocial to the extremely psychopathic and sadistic. Serial and sadistic murderers are usually found in this category.

4. *Epidemiological Evidence*

While a relationship between mental illness and criminality could be ascertained through the use of epidemiological methodologies, a relationship between psychopathology and crime can only be ascertained through the painstaking study of the individual criminal. Epidemiological studies cannot answer questions about fine personality traits or about motivation, which are usually buried in the very abyss of the human soul.

Epidemiological studies, however, can give a picture of the limit of psychopathology, as measured by the prevalence of criminality among psychiatric patients, or of mental illness among criminals, whether in or out of institutions (Arboleda-Flórez 1998). Analytical epidemiological methods have been used to determine causal factors between mental illness and violence, but much more refinements have to be introduced in the methodology of these studies before a statement of causality could be made (Arboleda-Flórez et al. 1998).

5. *Biological Determinants of Criminality*

Criminal behavior can be explained on sociological or anthropological terms or as responding to biological determinants. Criminal behaviors with a psychopathological substratum require a biological layer of explanation through biological mechanisms that involve personality aspects, genetic and hereditary factors, physiological alterations, cerebral damage caused by perinatal insults or head trauma, or acute intoxication.

5.1 *Personality*

Some physiological correlates of personality are also related to criminality, especially by individuals with antisocial and psychopathic personalities. Higher thresholds for excitability and higher impulsivity accompanied by lower levels of skin conductance, pulse, and electroencephalographic markers for excitability than found among normal individuals are found among psychopaths which could explain their thrill-seeking behaviors (Hare 1982). Similarly, low pulse has been found to be related to regulatory patterns of inhibitory conduct among adolescents, juvenile delinquents, and those diagnosed with conduct disorders.

5.2 *Cerebral Damage*

Neuropsychological tests could demonstrate cerebral damage, but this is best done with imaging. MRI, PET scans, and SPECT examinations have demonstrated frontal lobe damage among extremely violent individuals, serial murderers, and non-psychotic personality disordered persons (Goyer and Semple 1996). Cerebral pathology is related to intermittent explosive disorders, and frontal lobe insults have been associated with levels of impulsivity (Barratt 1987) which in turn have been related to levels of serotonin (Brown et al. 1989).

5.3 *Genetics and Heredity*

A familiar component has been described relating antisocial behavior, criminality, and violence, which in turn are related to paternal violence, poverty, single parent families, and rough neighborhoods. These interfamily variation factors, as known in genetic epidemiology, change from family to family but remain constant as a load in one single family. It is not possible, yet, to differentiate within members of a family the quantities that could be attributed to the genetic load (genotype) from that attributed to the environment and that result on a particular form of behavior (phenotype). Link and association studies demonstrate that some genetic disorders such as alcoholism, Gilles de la Tourette syndrome, and the fragile-X syndrome could be related to antisocial behavior and violence (Carey 1994). Furthermore, adoption studies of twins indicate that there exists a genetic relation between antisocial personality and alcoholism (Cadoret et al. 1986).

5.4 *Intoxicating Substances*

Toxic substances are common correlates of criminal behavior either ingested voluntarily or through exposure in the environment. The impact of alcohol on infants *in utero* resulting in fetal alcohol syndrome or intellectual damage suffered by normally born babies exposed to high levels of lead in the environment are well documented. Developmental delays and injuries to the developing brain are risk factors for criminality. Alcohol has a well-known impact on the frontal lobes (Baron and Richardson 1994) which are in charge of inhibitory functions, and on the limbic structures in charge of vegetative and instinctive functions. The effects of alcohol and drugs are well known in forensic psychiatry because of violent crimes including sexual attacks committed while intoxicated and the emerg-

ence of dissociative and automatic states of mind (Arboleda-Flórez 1999). Figures bear this relationship, 42 percent of arrested individuals are inebriated and 29 percent are under the effects of drugs at the time of arrest. Furthermore, 57 percent had used drugs within one month prior to their arrest, and 83 percent of inmates in state prisons and 73 percent of those in federal prisons had utilized drugs at some time in their lifetimes (Mumola 1998).

5.5 Biological Reductionism

Some authors have expressed a concern that biological explanations could lead to a fruitless search for easy solutions to the complexities of crime. They point out that such way of thinking could distort the truth because of the weight paid to biological facts, could raise false hopes for easy solutions, and could engender fears, prejudice, and apprehensions in the population worse than the actual dangers represented by crime (Brain 1984). Myths surrounding biological investigations of crime have retarded the development of this profitable area of research (Stoff and Cairns 1996).

6. Social Determinants of Criminality

Social explanatory models of criminality demonstrate that there is a relationship between social situations and crime. Anthropological and social definitions of crime at a larger scale indicate that some forms of behavior are acceptable in some cultures or localities, but not in others. For example, corporal punishment of children and spousal abuse may be considered appropriate in some subcultures or countries, but frowned upon and punishable as serious crimes in others. Cultures of crime exist in rough neighborhoods and social definitions of acceptable behavior follow local definitions of morality. These broad determinants are independent of other generally acceptable correlates of criminality such as labeling, poverty, deprivation, exposure to violence at home or in society in general, breakdown of social lines, or the social fabric at times of political, economical, or wartime unrest, and availability of guns. Unfortunately, none of these models have wholesome parsimonious value although most can explain crime under some circumstances.

7. Conclusions

Criminality responds to multideterminant and multidimensional processes that demand a broad understanding and knowledgeable approach to its study, away from reductionistic beliefs, be they biological or social, and away from solipsistic solutions that would deny possibilities for study and conflict resolution. Learning about the psychopathological, biological, and social correlates of crime opens the door to instituting remediation strategies aimed at rehabilitation and successful reintegration of the criminal into society.

Critical Legal Studies

'Critical legal studies' (CLS) is an umbrella term for a variety of movements of legal intellectuals, most of them in law faculties in the USA, Britain, and France. The movements originated in the late 1970s and achieved their peak of influence in the 1980s and 1990s. Their adherents are generally on the political left, critical of existing distributions of wealth, power and status rewards and of patterns of domination and subordination by class, race, gender, and other 'illegitimate hierarchies.' Unlike classical Marxists, they do not treat law as a merely 'superstructural' reflection of a material ' base' of determining economic relations, or as simply an instrument of ruling-class power (see *Marxism and Law*), ; they take the content and forms of law and legal reasoning seriously, as relatively autonomous active force fields in the construction and interpretation of the social world. Critics (or 'crits') target their critiques to the dominant modes of legal reasoning, scholarship, and teaching in their legal cultures, which usually pretend to be neutral and apolitical, but which the critics see as expressions of conflicting political ideologies. The ideologies hidden in law often serve to produce, reproduce, and justify inequalities and illegitimate hierarchies, but they also express utopian aspirations and point to plausible alternative social arrangements. The critics' general aims have been to bring into view the hidden ideological biases and effects of the existing legal order, to capture and re-orient enclaves of legal scholarship, teaching, and practice, and to use them to reimagine and to implement alternative legal ideas and policies.

Within these broad commonalities of outlook and concern, the CLS movements have tended to fragment into many different schools, informed by diverse intellectual antecedents and committed to divergent views of the role of law in social life and of the political ambitions of intellectual critique and reform.

The US movements receive most attention here, since they attracted the most members, produced the largest literature, and penetrated the furthest into centers of legal education; also, their types of scholarship and internal quarrels parallel those of CLS movements elsewhere. CLS-USA came into being in 1977 at a conference of law teachers rebelling against their own legal education and its seeming irrelevance to the contemporary ferment of social movements (anti-Vietnam War, civil rights, feminist, environmental, etc.). By the 1980s critical teachers made up a significant fraction (four or more faculty) at Buffalo, Harvard, Miami, Northeastern, Stanford, UCLA, and Wisconsin law schools and a token presence at many more, eventually producing students who went into law teaching themselves, a substantial bibliography (Kennedy and Klare 1984, Bauman 1996), and a series of national conferences.

1. *Antecedents of CLS*

To critique the orthodoxies of their legal culture, American critics in the first phase of their movement found resources in various European theories, especially Western neo-Marxist theories of law as 'ideology' and an instrument of 'hegemony' (Gramsci 1971), humanist social histories of subordinated groups (Hay 1975, Thompson 1975), structuralism, and phenomenology. But their main resource turned out to be their domestic forerunners, the American legal realists of the 1920s and 1930s who critiqued the classical–formalist legal orthodoxy of their own day (see *Legal Realism*; *Legal Formalism*). That orthodoxy had claimed that the operating rules of the legal system could be derived from a few basic principles induced from a scientific arrangement of precedents, such as the protection of property, the basing of liability to others on 'fault,' and the enforcement of the 'free will' of parties to contracts. This system added up to a natural and neutral mode of ordering private life, and legislative interferences with this system of rules would be struck down as unconstitutional unless they met strict tests of validity.

The realists' critique, in brief, was that (a) the principles were too vague, and the precedents too flexible, to determine outcomes, and in actual operation produced results varying over time and with contexts; (b) the actual determinants of results were latent and unarticulated policies, ideologies, and social vision; and (c) the 'private' law rules of property-tort-contract that undergirded the natural-seeming private sphere of free choice in free markets, protected against interference by constitutional law, were no less artificial, no less exercises of state policy, and no less coercive, than the 'public' rules of legislation and administration. A property right, for example, delegated to its owner the ultimate power to use state force (self-help, private guards, the police or the army) to exclude others (such as union members or black people) he did not want to hire or deal with, and to condition access to his property (tools, land, wages, the assets of a marriage) on those others' submitting to his orders. The coercive state was always involved in the market and business firms and family life; the issues for legal policy were thus not *whether* the state should be involved, but *how*, and *to what ends*—issues that courts, as well as legislatures and administrative agencies, could not avoid and had to resolve.

By the1950s and 1960s, however, the leading currents of American legal thought had settled into a new orthodoxy, one that absorbed elements of the realist critique but blunted its more radical implications (see *Legal Scholarship*). Some postwar schools held that law (including law made by judges), although not autonomous from clashing social interests, had neutral craft techniques for balancing those interests; others that law properly interpreted served social purposes on which there was presumed to be a general con-

sensus; and others that courts differed from legislatures in that judge-made law promoted general 'principles' rather than specific 'policies.' In the late 1960s, emerging schools of law-and-economics sought to rationalize legal doctrine, especially the private law of property, tort, and contract, as serving the aims of efficiency or wealth maximization. (For an overview see Duxbury 1995; see *Law and Economics*.)

2. *Early CLS*

CLS began as a set of critiques of these postwar modes of legal reasoning. Unlike other movements that carried on the legal–realist critiques, such as the law-and-society movement (which investigated empirically the social influences that helped to form, and the actual social effects of, legal rules), the critics deployed an internal critique: attacking the prevalent modes of doctrinal and policy argument practiced by law teachers, judges, and other officials on their own terms, aiming to develop counterarguments to teach to law students and practicing lawyers.

Following neo-Marxist writers and the critical social theorists of the Frankfurt School, the critics pictured legal doctrines and arguments ('legal discourses') as ideology, a partial vision of the world that presents itself as a universal vision. These discourses function so as to portray existing constellations of rights, powers, privileges, and immunities recognized by the legal system as if they were natural and inevitable ('false necessity'), and as close to being good as they could be ('false legitimation'). By such means the law 'reifies' and thus helps to freeze in place scripted social roles such as manager and worker, landlord and tenant, husband and wife, consumer debtor and bank creditor, property owner and picketing laborer, that blind the ordinary people who play those roles to alternative possibilities for action and organization (see e.g., Gabel 1980).

Like the legal realists, the critics' method was to unearth and make transparent the latent subtexts of legal doctrines and policies, the hidden framing conceptions, empirical assumptions, and social visions on which conventional legal reasoning, and the scripted social roles it gave people to play, relied. But the aim was not simply to unmask; it was to develop alternative doctrinal and policy arguments in particular fields of law, and by so doing to open a path for a revisionary politics based on different views of social reality and human potential.

In its first decade, CLS developed a distinctive model of such critiques, which, taught to and adapted by adherents and disciples, was replicated in about 100 articles covering a wide variety of legal fields. The model critique identified some deep-level tensions, polarities, or contradictions underlying a field of legal policy or argument. In a pioneering article, Kennedy argued that contract law doctrines tended to cluster around opposing conceptions of human nature, social obligation, and the functions of law: one favoring formal rules and 'individualist' views of economic transactions and social duty, the other favoring informal standards and 'altruist' ethics of sharing and cooperation (Kennedy 1976). The law in force at any given time oscillates between the opposing poles as it moves from one subject to another, but tends to privilege one pole and suppress the other, reserving it for exceptional or marginal situations.

Doctrines from the suppressed pole, however, are always available as a 'dangerous supplement' which at any moment may, and sometimes do take over the privileged position (Kelman 1987). One pioneer (Unger 1975) generalized the critique across legal fields to 'liberalism' as a whole; but most practiced it as a form of local critique, whose content varied with the field of law that was being criticized. The model also spawned its own genre of structuralist legal history, showing how legal fields come to be structured around contradictory organizing principles and social visions. For example, doctrines reflect people's need for other people and fear of them; the desire for a state powerful enough to protect rights that will not also trample them, and for contract and property law that will carry out parties' intentions and underwrite their freedom of action but also protect their (and others') security. The legal system tries to 'mediate' the contradictory doctrines by confining each to a limited field of operation, yet such systems become unstable as the mediating devices become incoherent and exceptions spill over limits to swamp the rules (see e.g., Alexander 1987, Kennedy 1979, Mensch 1982).

This strand of CLS was often misunderstood. Critics argued that the structuring of legal fields around such 'contradictions' meant that law was 'indeterminate' because it could (and historically often did) enable judges, advocates, or reformers to make valid arguments (according to internal criteria of the legal system) for opposed positions. Doctrinal or policy arguments could always be 'flipped' by appealing to principles at the opposite pole. This did not mean that law was a facade, sham, or arbitrary meaningless jumble, or that doctrine was just a mask for raw political choice; rather, its indeterminacy was patterned and systemic, an effect of law's (or liberalism's) contradictory structures. Nor did it mean that law was unpredictable, because arguments drawn from one pole or another tended to be stable in the medium term. Nor, finally, was it an indictment of a legal system to say that it was 'indeterminate.' It was merely a fact, one papered over by mediating devices leading to the appearance of natural, necessary, and almost-as-good-as-it-could-be law.

3. *Later CLS*

CLS also extended the method beyond private law doctrine to the powerful emerging new forms of policy

analysis, legal economics, attacking certain core premises of the new science including the Coase theorem, cost-benefit analysis of legal entitlements, public choice theory, and submission to the will of others as rational consent (see e.g., Kennedy and Michelman 1980). Others extended it to institutions: Simon identified opposed models of welfare administration, mechanical rule-application by low-skilled workers and the professional informal discretion of caseworkers. He showed how the welfare system had evolved from discretion to rules with damaging results for clients and argued for restoration of discretion (Simon 1983).

Critics also revived and extended the legal realists' critique of the distinction between 'public' (coercive regulatory) and 'private' (freely–willed contractual consensual market) relations. Following the realist R. L. Hale (see Fried 1998 for an intellectual biography), they argued that all 'free choice' is made by actors with property and power endowments and under baseline conditions structured by the legal system, even choice in the most intimate spheres of life such as marriage relations. Their aim was to supplement Foucault's (1977) account of the pervasive regulation of social interactions through 'disciplines' with an account of the pervasive structuration of transactions and interactions in business and personal life through law.

Much critical effort went into history (see Gordon 1984). Some critical historians worked in the tradition of the social history of subordinated groups, using historical examples to show how ruling groups had used neutral- and equal-sounding legal doctrines to extend and justify their rule. Horwitz (1977) showed how early-nineteenth-century law had reworked private law rules of property, tort, and contract to favor entrepreneurs in the early nineteenth century, then later froze the new rules against redistributive revision by imposing constitutional restraints on legislation. Klare (1978) showed how conservative judges had drained the National Labor Relations (Wagner) Act of the New Deal of its potential as a charter of workers' rights to participate in management. Critical historians often read the past as a repository of lost social experiments, long since crushed or forgotten, which might serve as models for reconstructing aspects of social life—as did Frug with the nineteenth-century model of powerful autonomous city governments (Frug 1980), and Simon did with 'social–republican' property models of landholding and producers' cooperatives (Simon 1991). Other histories explored the legal structuration of social relations, especially those of master and slave, employer and employee, husband and wife (see e.g., Steinfeld 1991, Olsen 1983).

By the mid-1980s CLS had entered a new phase. One group of critics, perhaps responding to accusations that CLS was 'nihilist' in its attachment to destructive criticism ('trashing'), turned to concrete programmatic work. Unger's (1998) was once again the most ambitious, proposing large-scale programs for the democratization of the economies of both developed and developing societies; most others were small-scale proposals for reforming specific legal policy fields, such as worker participation in ownership and management (Stone and van Wezel 1988), treatment of workers in plant closings (Singer 1988), regulation of injurious speech (Abel 1994), intellectual property (Boyle 1996), disability law (Kelman and Lester 1997), and property rights in ex-Communist societies (Alexander and Skapska 1994).

Another group focused on developing critical theories of law to a new level of sophistication, integrating them with postmodernist and poststructuralist theories, especially those of Foucault and Derrida (see e.g., Balkin 1987, Heller 1984, Peller 1985).

4. *Challenges and Erosion*

Around the same time, CLS experienced intensifying challenges from neighboring left legal–intellectual movements, especially feminism and critical race theory. The new movements asserted differences from CLS in focus and method—differences that provoked vigorous arguments throughout the 1990s. CLS had criticized liberal legalism for its claims to have solved the problem of domination by constructing 'rights.' Some critics said rights increased the alienation of individuals by constituting them as monads isolated from one another (Gabel 1984). Others argued that rights mystified the realities of power relations, while still others argued that social movements' crusades for rights (such as the black civil rights movement) often ended up giving them only symbolic victories and unenforceable claims still others contended that rights, like other legal doctrines and policies, were always in conflict—the right to equal treatment in accommodations, housing, and employment, for example, with the right to associate—and that the conflicts could not be resolved by appeals to rights (Tushnet 1984). Race theorists (e.g., Crenshaw 1988) counterargued that whatever might be the weaknesses of rights-rhetoric, claims using the language of rights had been essential to the gains of subordinated groups. CLS scholars had also stressed the indeterminacy, manipulability, and contingency of social arrangements and legal discourses, the fluidity of meanings and identities. Some feminist and critical-race theorists, by contrast, wished to insist at least provisionally on the grounded objectivity of experiences of subordination, the common shared elements that made up sexual or racial identity and the authenticity of personal narratives of the lives of the subordinated (see *Critical Race Theory*; *Feminist Legal Theory*).

CLS had helped to open up and to institutionalize space—in the form of places for faculty positions, room for articles in law reviews, slots on the programs of conferences—for a legal–academic left, a novel

phenomenon in the USA (and wholly missing in other professional faculties such as business schools). By the end of the 1990s, however, most of that space, like most of the energy going into novel work, was occupied by gender and race studies. CLS ideas continued diffusely to pervade both mainstream and critical fields of scholarship and policy analysis—notably its critiques of the public–private distinction and of the legal foundations of neo-liberal political economy. But as a distinct school CLS had faded away.

5. *European CLS*

European critical schools of law followed similar paths, with important differences due to national variations in the strength and programs of left-wing political parties and intelligentsia, and the objects of critique—traditional modes of legal training and reasoning—on the other. (A European Conference on Critical Legal Studies was organized in 1981.) In Britain, critical legal studies were first concentrated in social science faculties and grew out of the radical sociology of law, oriented in its early years to the critique of the 'State' and its legal controls of poor and working people through labor, policing, criminal law, and professionalized social services, later evolving into broader critiques of law as ideology (see e.g., Cain and Hunt 1979). In the 1980s CLS was taken up by law teachers, especially in the polytechnics. They organized the Critical Legal Conference in 1984, proclaiming 'a shared rejection of the dominant tradition of Anglo-American legal scholarship, the expository orthodoxy or … "black-letter law" tradition' (Fitzpatrick and Hunt 1987, p. 1). Believing that their American counterparts focused too narrowly on the internal critique of legal doctrine and reasoning, British critics maintained their connections to socio-legal studies and to radical law practices; they also developed new alliances with feminist, deconstructionist, psychoanalytic, and literary approaches. Critical legal studies in the UK, as in the USA, are a very fragmented enterprise, but unlike its American counterpart, it is flourishing (for exemplary collections and overviews see Fitzpatrick and Hunt 1987, Douzinas et al. 1994).

In France the combined influence of (a) Marxist traditions treating law as 'merely superstructural' and (b) separation of faculties of legal philosophy and theory from faculties of law, held back the development of left-wing legal studies until the late 1960s, when radical social movements and the surge of interest in the social theories of Althusser, Gramsci, and Foucault led to critiques of law as forms of ideology that structure and legitimate the functioning of capitalist order. After the 1980s the movement shifted emphasis from general theory to concrete case studies of the norms, reasoning modes, and institutions that went into the construction of everyday legal relations. French CLS has not deeply penetrated the centers of university training of the legal elite, but has gained a foothold in some faculties and in research centers at St. Etienne, Lyon, and Montpellier (see Arnaud 1993 for a concise summary).

Critical Psychology

The term 'critical psychology' has been applied to various approaches to psychology which, in the last decades of the twentieth century, typically share hardly anything more than a resistance to so-called mainstream or traditional psychology, an affinity to the moral ingredient of the Marxist critique of capitalism, and an aspiration to fight for the oppressed and the excluded.

Critical psychologies of whatever nuance are not connected to I. Kant's critical philosophy or to neo-Kantian approaches to psychology despite the fact that one of the authorities of critical psychology, S. L. Rubinshtein, started out as a student of neo-Kantianism in Marburg.

One division in the heterogenous stream of critical psychologies is named *Critical Psychology*. This is a school of psychology that chose to spell its name with capital letters; it originated in the 1970s in West Berlin, and is centered around the work of K. Holzkamp. It describes itself as being Marxist–Leninist, scientific (in a Marxist sense), and critical of what it calls bourgeois psychology. Critical Psychology will be the primary object of this article as it is so far the branch of critical psychology with the most noticeable degree of social coherence and of theoretical consistency.

1. Origins and Early History of Critical Psychology

The second half of the 1960s witnessed a rapid increase in the university student population in the Western world. The resulting tension and uneasiness combined with the televised atrocities of the Vietnam war to produce an international agitation for global revolutionary changes in a world engaged in Cold War.

An important factor in the student revolt, especially in Germany, and also in the formation of critical psychology and Critical Psychology, was the Critical Theory of the Frankfurt School, a strain of Marxism embodied by T. W. Adorno, M. Horkheimer, H. Marcuse, and J. Habermas. Especially pertinent at universities was their critique of positivism in sociology and in other social sciences, and generally of positivism in the sciences as prominently advocated by K. Popper. The positivist emphasis on the priority of observable events and empirical data over hypothetical constructs and theoretical terms was criticized as a deceptive disguise for sinister theory, especially for reactionary ideology in the service of capitalism. Therefore the key reproach against positivism was its presumed lack of scientific relevance and of relevance for social change.

The Frankfurt School was not interested in the academic discipline of psychology. But psychology students watched the positivism controversy and applied it to their own field. A student Action Committee Critical Psychology disturbed the customary serenity of the congress of the German Society for Psychology at Tübingen in 1968, and, in order to coordinate various local initiatives, students met for a singular and tumultuous Congress of Critical and Oppositional Psychology in Hanover in 1969.

The term 'critical psychology' appeared for the first time as a book title *kritische psychologie* in 1969. This is an anthology compiled by Bochum university psychology students comprising pirated texts by T. W. Adorno, W. Reich, K. Holzkamp and others, and various resolutions exchanged at the Hanover Congress and at earlier occasions. Sold in many psychological institutes, it established the term as a trademark for revolt, and stepped up rebellious behavior which few university teachers could stomach. The concept of

critical psychology covered a multitude of different convictions, from an engagement for the weak and the betterment of society, to the use of psychology in a Marxist class struggle, to the conviction that psychology is unredeemably reactionary and should be dumped on the dungheap of history. Views of the future of psychology varied accordingly.

Among the few university professors who engaged in extended dialog with critical psychology students was Klaus Holzkamp (1927–95), holder of a chair of psychology at West Berlin's Free University. He had, in 1964 and in 1968, published a critique of psychological experimentation wherein he denounced the lack of criteria for the evaluation of the relevance of psychological experiments for psychological theory. He tried to improve the diagnosed situation by following the constructivist philosophy of science of H. Dingler, the most prominent European proponent of operationalism.

In an invited speech at the Berlin section of the German association of professional psychologists in 1968, Holzkamp applied the concepts of technical and emancipatory relevance, which he had taken from J. Habermas, to psychology and declared emancipatory relevance superior to all other forms of relevance. Through his discussions with critical students Holzkamp was introduced to an analysis of society and its dominance relations according to Marxist lines. In his collection of essays, *Critical Psychology* (Holzkamp 1972), he called his change in outlook the *Critical-Emancipatory Turn of Psychology*. Activity at the West Berlin psychological institute was characterized by studies in the history of psychology which strove to uncover its quality as a tool of oppression in the ongoing class struggle (Geuter and Mattes 1984), and by practical engagement for the underprivileged. This approach to the practice of psychologists remained what Holzkamp later called 'voluntaristic,' that is, appealing to the good will of psychologists and a willful decision for partisanship for the weak and needy.

As the antiauthoritarian and nonconformist student movement slowly became organized by political parties and splinter groups in the early 1970s, so were the critical psychologists. At the psychological institute in West Berlin, one faction drifted into the sphere of influence of the Marxist–Leninist party (SED) ruling East Germany (DDR) and its West Berlin vassal party (SEW); another faction gathered around Beijing-oriented Maoist lines; others become Trotskyites, while a good many remained nonaligned. The psychologists around Holzkamp enlisted in the Marxist–Leninist camp. They withdrew from dialog with other factions, fashioned their own publication outlets and, to emphasize their distinctness, from the middle of the 1970s spelled their field as Critical Psychology. This group has also been known as the Holzkamp school, or the Berlin critical psychologists, despite other critical psychologists protesting that it was merely one offshoot of a much broader critical psychology unjustifiably trying to usurp the appellation and to eclipse the other approaches. The Marxist–Leninist turn has led Critical Psychology indubitably away from Adorno, Critical Theory, and the New Left.

2. *Creation of Critical Psychology*

Critical Psychology defines itself as a Marxist–Leninist psychology (Holzkamp 1983, p. 27). It looks toward the writings of K. Marx, F. Engels, and V. I. Lenin for orientation, and adopts as its scientific and epistemological foundation or superstructure dialectical materialism and historical materialism. It embraces as pioneering works in this kind of psychology the publications of the historicocultural approach devised during Stalin's reign by L. S. Vygotsky and his disciples, in particular S. L. Rubinshtein and A. N. Leont'ev. These authors were *de rigueur* for prefaces to be considered ideologically impeccable in the psychology of the DDR and the USSR, even though few serious scientists paid more than lip service to the ideological superstructure.

Holzkamp's turn away from critical-emancipatory psychology towards Critical Psychology became visible with his book on *Sensory Cognition* (1973) where K. Marx is the most often cited author, and *Das Kapital* provides the model of human consciousness as dependent on and determined by the material and historical foundation of economic and social practice. Traditional psychology, now named bourgeois psychology, however, is perceived as erroneously proclaiming the independence of consciousness from this material basis.

Critical Psychology had not only an ideological superstructure, but a rarely considered material basis as well, namely the chair of psychology at the Free University in West Berlin held by Holzkamp and the power and privileges that went with it. A German university professor is a civil servant, but at the same time enjoys a very high degree of academic freedom in research and in teaching, as guaranteed by the constitution. This freedom, however, may have one limitation: A professor of psychology is obliged to train and examine future psychologists according to the canon of the Examination Regulations.

Critical psychology's critique of traditional or bourgeois psychology had purportedly unveiled the latter's theoretical hollowness and its practical use as a weapon of the ruling classes against the proletariat. This brought Holzkamp into a 'dilemma' (1973, p. 13). He could either go on teaching and training in bourgeois psychology and thereby lose his credibility as a critical psychologist, or he could stop training psychologists altogether, limit himself to criticizing psychology and face the loss of his professorship and its benefits. He resolved this 'fatal alternative' (1973, p. 15) in a way that he thought allowed him to preserve

critical credibility and to keep the material basis as well. He devised Critical Psychology, a new brand of psychology professedly consistent with the results of the critique of traditional psychology and also suitable as a foundation for the training of future practical psychologists.

Holzkamp and his co-workers had to prove that Critical Psychology could deliver. They formed a secluded group and started out to present to the public the various areas of psychology mentioned in the Examination Regulations according to Critical Psychology.

3. *Organization of the School of Critical Psychology*

Critical Psychology organized itself as a school of psychology with defined teacher–pupil relations and clear boundaries between insiders and outsiders. Its center was the chair of psychology occupied by Holzkamp, who was surrounded by assistants, doctoral students, and students. The notable names are gathered in the reader *Critical Psychology* (Tolman and Maiers 1991). The West Berlin case remained unique. Critical Psychology could never gain a similar foothold in another university institute.

A series of textbooks, *Texte zur Kritischen Psychologie*, started to appear in 1973. It was supplanted in 1977 by another series, *Studien zur Kritischen Psychologie*, which appeared in the publishing house of Marxist–Leninist orthodoxy. The journal *Forum Kritische Psychologie* began to appear irregularly in 1975, and was turned into a biannual journal in 1977. A congress of Critical Psychology was held in the West German university town of Marburg in 1977; further congresses, now named 'International,' were held there in 1979 and 1984, and a fourth congress, not 'International,' in Berlin in 1997.

The 1980s and 1990s seem to have been a time of stagnation for Critical Psychology. But steps were undertaken to introduce an international public to Critical Psychology (Tolman and Maiers 1991, Tolman 1994). The latest developments may be followed at *www.critical-psychology.de*.

4. *Themes and Topics of Critical Psychology*

Work done in Critical Psychology is to an uncommon degree conceptual work. Basic categories of psychology are put under scrutiny in the so-called functional-historical *analysis of categories* with the aim of reconstructing them under more satisfactory conditions. Psychological categories (or rather what they contain), like perception, motivation, learning, emotion, cognition, are considered in their phylogenic, historical, and ontogenic evolution. At the end of this process, newly defined or rehabilitated categories are offered for the construction of an encompassing system of psychology.

Functional-historical analysis blends two things. One is C. Darwin's theory of evolution. It is utilized mainly for armchair paleozoology and paleoanthropology, and amplified and revised by the other constituent, Hegelian dialectics in its specific modification formulated by K. Marx, F. Engels, and later luminaries of Dialectical Materialism like G. V. Plekhanov. Functional-historical analysis therefore includes controversial Marxist tools of thought like negation in nonconceptual matters (antithesis), contradiction as causal agent (thesis–antithesis clash), or qualitative leaps or transitions (resulting in syntheses as unities of opposites, and forming the new theses for more dialectics). Such qualitative leaps are, among others, the transition from prepsychical to psychical organisms, the differentiation of special psychical functions, the evolution of learning, and the emergence of the societal nature of human beings.

These tools of thought are usually disregarded in science. It is therefore difficult for the reader not trained in their applications to follow the train of cogitations in which they are used. It is also not feasible to paraphrase them adequately in nondialectical prose, and therefore it may be fitting to let Critical Psychology speak for itself. This is a summary of the five steps of the functional-historical method according to Holzkamp (1983, p. 78):

> 1. Identify the real historical dimensions within the preceding developmental stage of the organisms at which the quantitative transformation in question took place; that is, determine the 'position' that is dialectically 'negated' by the qualitative transformation and thereby bring the specificity of the new developmental stage into relief.
> 2. Identify in the external conditions the objective alterations that constitute the 'environmental pole' of the inner developmental contradiction that causes the new quality to emerge. Such alternations involve a 'moderate discrepancy' that, on the one hand, demands 'compensations' from the organismic system, yet is supportable within its capacity. If it is not, the overall organism–environment system collapses, the inner contradiction is turned into an external opposition, and its antipodes will no longer be mediated as 'poles' in further development.
> 3. Identify the change in function of the relevant dimension demonstrated in step 1 as the 'organism pole' of the developmental contradiction and with it the origin of the first qualitative leap, that is, the development of the specificity of the new function under the altered conditions. This dialectical negation of a previously prevalent function does not determine the overall process but, in a sense, still serves to maintain the system at the earlier stage.
> 4. Identify the change of dominance between the earlier function characteristic of the system's maintenance and the new function, which then determines the specifics of the system. (This change presents itself as a discontinuous reversal of the relationship between two continuously changing dimensions.)
> 5. Identify the ways in which the overall development of the system is restructured and assumes new direction (that is,

> analyze the 'specific-secondary alterations,' and so on) after the qualitatively more specific function has become determining for the system's maintenance. With this identification of the qualitatively new dimensional structure, in which further qualitative transformations will occur, follows a return to the first step of the analysis but at a higher level. (Tolman and Maiers 1991, p. 39f.).

Categorial analysis leads to three characteristics of the human societal mode of existence: action possibility, action potency, and subjective situation. The latter is a personal assessment of one's own action possibilities and of where one stands in a particular objective situation. This derivation leads to a novel understanding of subjectivity and of the famous quote from Marx: 'The essence of man is conscious activity.'

In personality psychology and psychotherapy, Critical Psychology tries to utilize Freudian psychoanalysis. After a deft functional-historical analysis of its categories and of the fumbling efforts of Freudo-Marxists, it presents itself as the Marxist alternative to psychoanalysis.

The enthusiasm of early critical psychology to investigate the history and function of psychology is not followed by Critical Psychology. There is no critical historical analysis of the fate of psychology and psychologists in the USSR, especially during the times of Stalinism and anticosmopolitanism when Vygotsky initiated the historicocultural approach, and Rubinshtein and Leont'ev became its proponents. Nor is the practical application of psychology in the USSR or DDR, particularly in their armed forces and secret services, examined.

5. *Critique of Critical Psychology*

There have been numerous controversies around Critical Psychology, among them the following.

Holzkamp and the not yet capitalized critical psychology came under attack by H. Albert and others (Albert and Keuth 1973) who championed a Popperian position for psychology and the social sciences. The ensuing debate in psychology reiterated the main positions of the positivism controversy between Popper and the Frankfurt school.

Holzkamp's turn to Critical Psychology and the associated Marxist-Leninist position provoked the criticism of other tendencies in the spectrum of critical psychology. This resulted in a number of more or less ephemeral publications, the most accessible of which is edited by Busch et al. (1979). Points of criticism were the usurpation of the name 'critical psychology,' the political orientation on Marxist-Leninist lines, and a perceived retrocession to bourgeois conceptions of psychology.

Disapproval of Critical Psychology by psychologists working in the DDR could not be uttered before the collapse of Real Socialism and the Soviet empire. But then they could report that party officials reprimanded their local psychologists for staying aloof from party doctrine and advised them unpleasantly to follow the ideologically blameless example of Critical Psychologists.

6. *Other Critical Psychologies*

It is not appropriate to call Critical Psychology German critical psychology, as Teo (1998) does. There are and always have been other critical psychologists in Germany who have no affiliations with Critical Psychology. They gathered around the journal *Psychologie und Gesellschaft*, which was established in 1977 and renamed *Psychologie und Gesellschaftskritik* in 1978. Rexilius (1988) assembled some of the non-aligned voices.

An early voice in critical psychology was that of Peter Brückner (1922–82). From 1967, he occupied the chair of psychology at the Technical University in Hanover. There was no professional training of psychologists. Brückner did not publish systematic treatises on his view of psychology or on standard examination topics, but he authored a *Social Psychology of Capitalism* (1972), and papers on political psychology and on psychoanalysis (1983). Although he had some disciples, they did not organize a school.

A comparative portrayal of three early critical psychologies, Vygotsky's, Holzkamp's, and K. F. Riegel's dialectical psychology, was published by Ijzendoorn et al. (1984).

There is a recent tendency in English-speaking countries for various New Left tendencies to rally under the name of 'critical psychology.' Information on present trends may be found in Fox and Prilleltensky (1997), Sloan (2000), the newly launched *Annual Review of Critical Psychology* (from 1999), the *International Journal of Critical Psychology* (from 2000), or the Critical Psychology website at *www.sar.bolton.ac.uk/Psych/Main/WebRing.htm*.

It seems to be too early to extract consensus and divergence among the positions found here, although the Marxist moral critique of capitalism appears to be a pervasive constituent, not infrequently connected with the moral part of Lenin's critique of imperialism. The theoretical pillars of Marxism, however, like the labor theory of value, the theory of class struggle as the motor of social change, the theory of the approaching collapse of capitalism, and dialectical and historical materialism seem to be losing plausibility lately.

7. *Concluding Remark*

The various critical psychologies present worthwhile case study material for research in the predicament of the discipline of psychology or the dialectics between psychology as a science and as a profession. When in the twentieth century psychology was hastily metamorphosed into a practical profession, the university institutes had to be converted from pure research

institutions into training establishments—and they had to somehow cope with the egregious gap between the high-minded expectations of application-minded students and the comparatively limited amount of effective tools psychology had to offer. This left many students dissatisfied and a prey of neophilism.

Critical Race Theory

In contemporary US social life, it is popularly accepted that racism is a form of injustice and that state law has the moral obligation, not only to refrain from perpetrating racist acts against citizens, but to provide remedies in certain circumstances to the victims of non-state racism as a matter of public policy. Most debates over antidiscrimination law and policy focus on whether the state's obligation to reject racism requires eschewing all race-conscious state and non-state public action, or whether race-conscious action should be permitted or even required in certain circumstances in order to remedy past and continuing racial discrimination. Both positions implicitly assume that racism is not integral to contemporary law or society and can be eliminated with determined efforts.

Writers who associate themselves with critical race theory take the position that racism is ordinary and normal in American society (Delgado 1994), indeed perhaps integral to it. Accordingly, critical race theorists attempt to show how contemporary law—including contemporary antidiscrimination law—accommodates and even facilitates racism. The critical race theory project inevitably calls into question fundamental assumptions about legal institutions and legal reasoning, about the trajectory of American history, and about the nature of injustice.

One tendency within critical race theory, deriving from the tradition of civil rights activism and jurisprudence, is strongly reformist in bent and seeks to galvanize moral outrage and direct it toward constructive legal change. A second influence on critical race theory is the poststructuralist tradition, within which the very possibility of overcoming racism through discursive structures such as law is considered a false hope. Critical race theory thus reflects a distinctive mix of reformist zeal and critical pessimism (Harris 1994). For example, Derrick Bell has urged civil rights activists to accept that, although there is a moral duty to challenge racism, racism is a permanent feature of American society (Bell 1992).

1. Origins of Critical Race Theory

Critical race theory emerged in the USA in the 1980s as a product of political, intellectual, and sociological developments in American legal academia. Politically, the 1980s were a time when many American civil rights activists and left-wing legal scholars felt themselves caught up in a conservative backlash against the gains of the 1960s. The scholars who would later call themselves critical race theorists sought explanations for why formal legal equality had produced only modest success in improving the lived experience of most African–Americans and other people of color,

and why hopes for social 'integration' with whites seemed largely to have faded (Crenshaw 1988).

Intellectually, the early 1980s saw the heyday of Critical Legal Studies (CLS) in the American legal academy. CLS introduced into legal scholarship post-structuralist ideas that had already permeated other disciplines focused on the interpretation of texts, including philosophy, literary criticism, and anthropology. Within legal studies, CLS scholars challenged the divide between 'law' and 'politics,' arguing that legal rules were radically indeterminate. CLS called for the deconstruction or 'trashing' of legal doctrine in order to expose the reification of legal concepts and the hegemonic function of traditional legal reasoning (Kelman 1987). CLS also provided an intellectual opening for broad-based critiques of law based on hidden norms of race and gender exclusion. For example, the first collection of essays in critical race theory appeared under the title 'Minority Critiques of the Critical Legal Studies Movement'; its authors were CLS sympathizers who nonetheless were disappointed with CLS's failure to extensively engage with racism (Delgado 1987, Williams 1987).

Sociologically, the 1980s saw the gradual entry into legal academia of African–Americans and other people of color, albeit in small numbers. Many of these new scholars were drawn to study race and the law, were frustrated by the disappointing outcomes of traditional avenues of legal reform in an era of backlash, and perceived traditional civil rights scholarship as a literature that ignored the voices of people of color (Delgado 1984). Several key figures in what would become critical race theory were radicalized as students by the departure of Derrick Bell—one of the pioneering African–American scholars critical of existing civil rights jurisprudence—from Harvard Law School, and by the administration's failure to hire an adequate replacement. These Harvard students created their own course on race, racism and the law, and staffed it with visiting scholars from around the country. The movement known as 'critical race theory,' and the term itself, emerged from this working group of students and teachers (Crenshaw et al. 1995).

2. *Themes of Critical Race Theory*

One of the earliest themes to appear within critical race theory was epistemological in nature, and was reflected in a distinctive method. Why were people of color much more likely to see American society as racist and to be pessimistic about the possibility of eliminating racism than whites? Did they know something whites did not? Was there a distinctive 'voice of color' that was missing in public policy, indeed in legal scholarship? Many critical race theorists argued that existing antidiscrimination law omitted the perspectives of the racially subordinated, and that subordinated groups in any social system have knowledge that the privileged lack. Thus, in a famous essay Mari Matsuda argued that civil rights scholarship and practice should 'look to the bottom' of society for leadership and insight (Matsuda 1987).

Critical race theorists also frequently abandoned the third-person objective voice in their legal writing in order to openly 'tell stories.' For example, Derrick Bell's 'Civil Rights Chronicles' featured an imaginary character who could travel through time, and who used her magical powers to criticize American civil rights doctrine from the founding of the Constitution to the present (Bell 1985, 1992). The telling of personal anecdotes or fables was intended not only to convey ideas that could not be expressed in traditional scholarly language, but also to criticize the assumption that the existing norms of legal scholarship, legal reasoning, and legal institutions operated objectively and produced neutral assessments of public policy. Critical race theorists hoped to show that the legal scholar's 'perspectivelessness' (Crenshaw 1989b) was in fact a perspective aligned with white privilege. Thus, for example, Patricia Williams, trained in post-structuralist theory and CLS, used personal stories, a dense web of allusions, and literary techniques to critique the social and legal construction of racial realities (Williams 1991).

The assertion of a distinctive voice of color proved controversial; critical race theory, like CLS before it, was bitterly attacked as racial 'special pleading' and as degrading the rigorous standards of argument and research established by traditional legal scholarship (see, for example, Kennedy 1989). Legal 'storytelling' was similarly attacked as sloppy scholarship and as an attempt to destroy the legacy of the Enlightenment. In this attack critical race theory was taken to be a postmodernist assault on truth itself (see, for example, Farber and Sherry 1997).

Most of the writing within critical race theory, however, has not taken on philosophical questions but rather has consisted of a sustained attack on the US Supreme Court's recent jurisprudence, particularly its constitutional jurisprudence. For example, throughout the 1980s and 1990s, the Court asserted its fidelity to four constitutional 'traditions' (Hayman Jr. 1995). First, the Court has increasingly favored a position of 'colorblindness,' under which all government racial classifications are presumptively unconstitutional, except perhaps when necessary to compensate a group of plaintiffs who can demonstrate the existence of conscious, deliberate racial bigotry that caused material disadvantage. Second, the Court has frequently deferred to legislatures, to state and local governments, and to the discretion historically exercised by public actors such as criminal prosecutors and juries when these actors are charged with racial discrimination. Third, the Court has deferred to private choices and free markets to produce the optimal allocation of resources. Fourth, the Court has

supported traditional indicators of 'merit' when these are challenged as racially biased.

Critical race theorists have painstakingly attempted to show how these jurisprudential developments block the possibility of political, economic, and social redistributions that would disrupt systemic racism. Some critiques have focused on unpacking the rhetorical structure of judicial opinions concerning race, or the deep structure of the Court's contemporary race jurisprudence (Ross 1989, Siegel 1997). Other scholars have mounted sustained attacks on recent doctrinal developments. For example, in an influential article Charles Lawrence III attacked the requirement that plaintiffs invoking the 14th amendment equal protection clause must prove that the defendants harbored the conscious desire to discriminate on the basis of race (Lawrence 1987). Lawrence, Mari Matsuda, Richard Delgado, and Kimberle Crenshaw have criticized the Court's apparent elevation of first amendment speech rights over 14th amendment norms of equality; the authors suggest that racist hate speech may constitutionally be sanctioned (Lawrence and Matsuda 1993).

In keeping with CLS's denial of any meaningful distinction between 'law' and 'politics,' critical race theorists have also sought to place jurisprudential developments in a larger political and historical context. For example, the Supreme Court trends just described coincided with political attacks on affirmative action by conservatives, a 'war on drugs' that locked up more and more African–American and Latino men in American prisons and jails, social panic about Asian and Mexican immigrants to the USA (reflected in nativist measures such as English-only laws and cutbacks of social welfare benefits for noncitizens), and the noisy public debate over whether curricula in American history and literature should be 'multicultural.' Critical race theorists sought to connect the Supreme Court's jurisprudence with larger political developments in a narrative of resurgent racism—a racism that constantly changes in form and expression (Calmore 1997, Siegel 1997).

A third theme within critical race theory has been an effort to understand how racism interlocks with other forms of oppression, including those focusing on gender, class, and sexuality. From the beginning, many critical race theorists regarded themselves as feminists, and several addressed the failure of mainstream feminism to respond to the interests and perspectives of women of color (Crenshaw 1989a, Harris 1990). Later writers in this tradition sometimes refer to themselves as 'critical race feminists' (Wing 1997), and have produced a body of work that criticizes legal institutions and legal doctrine from the perspective of women of color, particularly African–American women (Roberts 1997). Most of the work in this tradition has come to treat 'race' as only one axis of a multidimensional system of status oppression (Hutchinson 1997). A notable exception is Regina Austin, who treats racial identity as the primary focus of her work and examines state and nonstate constraints on 'the black public sphere' (Austin 1994).

Most recently, an offshoot of critical race theory—Latina Critical Theory or 'LatCrit' as it has been familiarly dubbed—has devoted itself explicitly to exploring the interplays of race, ethnicity, religion, national origin, class, and sexuality (Valdes 1998). The appearance of LatCrit also marks a move beyond the traditional 'black/white paradigm.' Much traditional US civil rights jurisprudence, and much early critical race theory, focused on caste racism against African–Americans. Scholars associated with LatCrit have explored the racialization of Latinos, Asian–Americans, and American Indians, and have treated immigration law as a branch of race law (Williams 1991, Perea 1997). These scholars identify nativist racism as a phenomenon distinct from, although related to, caste racism (Chang and Aoki 1998). Critical race theorists have also sought to recover and examine aspects of American race history, such as Asian exclusion and the colonization of Puerto Rico, that have been neglected because they do not fit the traditional emphasis on African–American civil rights (Chin 1998, Roman 1997).

Finally, a fourth theme within critical race theory has been the effort to work out the implications for legal theory of understanding 'race' as a social construction, rather than a natural fact. Some scholars have imported the work of sociologists Michael Omi and Howard Winant on 'racial formation' into the legal academy, studying the influence of state law on the racialization of 'whites' and 'Mexicans' (Haney Lopez 1996, 1998). Others have traced the differing meanings of 'race' within judicial discourse and within social and political discourse, to show how conflicts often involve an unacknowledged manipulation of the term (Gotanda 1991, Hernandez 1998).

3. *Future Directions for Critical Race Theory*

One recently emerging interest for critical race theorists is reestablishing the 'praxis' link between the now-burgeoning theoretical literature and the world of practicing civil rights attorneys, for whom much critical race theory is foreign and intimidatingly 'academic.' Scholar–activists such as Eric Yamamoto have called for a reconstruction of civil rights practice in light of critical race theory's skepticism about legal reasoning and legal institutions, its emphasis on coalition-building among groups suffering from discrimination, and its suggestion that law is only a weak and uncertain tool in the greater political struggle for empowerment (Yamamoto 1997).

Critical race theorists have also recently begun to incorporate in their analyses the facts that not all groups racialized as nonwhite experience racism in the same way, and that racial minorities are frequently in relations of competition and subordination rather

than solidarity (Yamamoto 1999). As the white population of the USA shrinks and the Asian–American and Latino populations increase, the binary relationship of white versus nonwhite will be increasingly inadequate to understand racialized relations of power. Similarly, critical race theorists have begun to address the issue of class, ethnic, and color distinctions within particular 'races.'

A third recent development within critical race theory has been a growing interest in 'white privilege.' One aspect of this development is an interest in exploring white identity, facilitated by the growing literature on 'critical white studies' outside the academy (Flagg 1998, Delgado and Stefancic 1997). Additionally, there is growing interest in taking racial 'privilege' rather than 'discrimination' as the object of study and critique (Wildman 1996). The traditional focus on racial victimization leaves unexamined the everyday ways in which persons who are not direct perpetrators of racism nevertheless benefit from racial hierarchies. In keeping with the structuralist ambitions of critical race theory, the turn toward privilege moves beyond the focus on immediate perpetrators and victims.

Moreover, critical race theory seems to be moving toward placing the US experience in the context of a world system of economic and status inequality. Scholars of international human rights and international relations have begun to incorporate critical race theory into their work (Hernandez-Truyol 1996, Gordon 1997). LatCrit scholars have followed their interest in immigrant communities within the USA to the transnational relationships of labor and capital that govern immigrant flow. Critical Race Theory has begun to converge with postcolonial studies in developing a historical perspective on the USA that treats it as a country still in recovery from its colonial history. Critical race theory has also begun to see the USA as part of an international system that divides the 'North' from the 'South' and that concentrates economic and political power in the North. In contrast with its beginnings as a movement largely rooted in and focused on the USA, critical race theory in the twenty-first century seems to be ready to 'go global.'

Critical Realism in Geography

Critical realism is a philosophy of and for the social sciences that has had an impact on methodology in geography since the 1980s, although there have always been realist elements in geographical thought. With the rise of critical realism, these and further elements were developed and promoted self-consciously, while non- or anti-realist elements were attacked.

1. *A Definition*

Critical realism argues that the natural and social worlds we study exist largely independently of the researcher, and that there is necessity in the world which enables and constrains what can happen. Causation is to be understood in terms of the powers that objects possess rather than in terms of empirical regularities among events; if and when these 'causal powers' are activated, the results depend on contexts, and are unlikely to be regular. Since social phenomena such as actions and ideas are intrinsically meaningful, unlike the subject matter of the physical sciences, their meaning also has to be interpreted. The world can only be understood in terms of available discourses. While there are no privileged routes for discovering the truth about the world, and empirical tests are themselves fallible, it is often possible to distinguish better from worse accounts in terms of their adequacy for informing material practice.

2. *Intellectual Context*

Critical realist philosophy was developed by Roy Bhaskar out of his earlier work on the philosophy of natural science ('transcendental realism') (Bhaskar 1978, 1989). The latter sought an alternative to both those positions which treat knowledge as straightforwardly based on observation and experience (empiricism) and for which truth is a simple matter of correspondence between statements and the objects to which they refer, and various relativist positions which treat the truth of theories as purely relative to discourses. Critical realism also steers a course between positions which regard social science as the same as natural science and those which treat it as entirely different.

3. *Realism and Fallibilism*

The most fundamental realist assumption is that much of the world can exist independently of our knowledge of it. The plausibility of this assumption rests upon the

fallibility of knowledge; the fact that knowledge claims sometimes prove to be mistaken and generate false expectations implies that the world is not a product of our thought but is whatever it is regardless of what we think about it. Realists reject the empiricist view that reality is whatever we can experience since this implies an improbable coincidence between the world and the limits of our sensory powers, and implies that either knowledge is already complete, or that new knowledge creates new objects. Critical realists accept that our observations and knowledge are always formed through available discourses or are 'theory laden', so that we can never escape from our conceptual frameworks to see how they compare with the world they seek to represent. However, that observation is theory laden does not necessarily mean that it is entirely determined by theories and so it can still be possible to compare the adequacy of different theories from within discourses and find observations which contradict expectations. This offers a way of avoiding the relativist view that truth is merely relative to theoretical systems. It also implies that science can make progress in explaining the world even though absolute truth is not an intelligible goal.

Critical realism therefore does not involve claims to have a privileged access to the truth about the world, a uniquely 'realistic' view, for the very independence of the world from our knowledge of it renders such claims problematic. It must necessarily view all knowledge as in principle fallible, although this does not mean, of course, that it is all false or all equally true or untrue.

4. *Key Arguments and Their Influence on Geography*

Critical realism became influential in geography partly for the above reasons, for geographers, like other scientists, were seeking a way of understanding science that avoided the unappealing alternatives of empiricism and relativism. However, a further important factor was probably its view of causation and systems. Some of the first discussions of critical realism in geography emphasized this issue and its implications for the nature of theorizing in geography (Sayer 1982, 1985).

The scientific revolution in geography, exemplified by *location theory* and *spatial analysis*, had largely assumed that causation was a matter of empirical regularities or 'constant conjunctions' among causes and effects. It was expected that understanding of the regularities in spatial organization of phenomena would grow to the point where it would be possible to formulate laws about them. This regularity-based view of causation had dominated the philosophy of science despite the fact that, particularly in social sciences like human geography, there appear to be few enduring precise empirical regularities, so that the search for laws of social and spatial behavior has been singularly unsuccessful. For realists this is unsurprising. For them, causation is a matter of what produces change, not a matter of empirical regularities in sequences of events. Objects have causal powers, that is, the power to act in certain ways. A seed has the power to germinate, a person the power to work. These objects have these powers in virtue of their structures, such as the biochemical constitution of the seed, or the anatomical and mental structures of a person. Whether these powers are ever activated depends on conditions whose presence is contingent, that is, neither necessary nor impossible, such as moisture and solar energy in the case of the seed or a need for food in the case of the person. Furthermore, the particular effects which follow when these causal powers are activated depends on conditions which again are contingent. The germination of the seed may be encouraged by fertilizer or halted by herbicides, the attempt of the person to work may be hampered by lack of tools or encouraged by their availability.

This alternative conception of causation has far-reaching implications. First, since it dissociates causation from empirical regularities, it enables understanding of how unique events, as much as repeated ones, can be caused. Second, it focuses on necessity rather than regularity or the search for empirical order. Third, in view of this, explanation does not require repeated observations: what makes something happen has nothing to do with the number of times it has or has not been observed to happen. It follows from this that the old debate in geography between idiographic and nomothetic approaches—the former a supposedly nonscientific study of the unique, the latter a supposedly scientific search for laws—was falsely based. Regardless of whether phenomena were unique or widely replicated, they could be explained in the same way.

The uniqueness of many geographical phenomena no longer posed a threat to geography's scientific status. Fourth, it became possible to see that the search for generalizations is distinct from explaining how causes work; generalizations, as the term suggests, attempt to tell us how common or extensive certain phenomena are, and this is different from explaining how they are produced. The greater part of standard literature on the philosophy and methodology of science had confused these two things, and many geographers had done so too. Fifth, the realist account offers a way of understanding how it is possible for the same cause to produce different effects and for different causes to produce the same effects, since the relationship between causal powers and empirical outcomes is not one of automatic regularity but is dependent on the conditions within which they are located.

An example of this can be given from a kind of economic geography which was popular at the same

time critical realism became influential. The geography of industrial restructuring looked at changes in economic geography in terms of how competitive pressures upon firms to restructure produced responses (e.g., Massey and Meegan 1982). In realist terms, competitive pressures on profit margins were considered as the main causal power of interest here, with their effects being mediated by a wide range of contextual circumstances, such as the particular cost structures of the firms under pressure, the scope for technological change, and the availability of various kinds of labor. Thus, in an industry such as clothing, which had little scope for further automation or speeding up work, and in which wages were a major element of costs, a common response was to seek out cheaper sources of labor, sometimes by relocating.

By contrast, in industries which were more technology intensive and had scope for further automation, a more common response was technological innovation. By such means, it was possible to explain how the same or similar causes could produce radically different results according to context, whereas approaches which rested upon the discovery of empirical regularities foundered. Similar research also illustrated how a single kind of outcome—job losses—could have completely different causes, e.g., a drop in demand for the firm's products, or the introduction of automation during steady or rising demand, or reorganization of work routines to eliminate idle time and intensify work (see also Henry 1992). For further discussion of these topics see *Economic Restructuring: Geographic Aspects*.

One of the most important and lasting influences of critical realism on geography has been on its empirical research designs (Sayer 1992). Hitherto, the dominance of conceptions of explanation as tied to generalizations about empirical regularities had been used to privilege 'extensive' research designs which sought to uncover such regularities or patterns of covariation. Although these are, as the term indicates, useful for establishing how extensive certain phenomena are, they do not necessarily identify causes, as opposed to spurious correlations. The latter are likely to be thrown up by extensive research because it preselects groups of objects taxonomically, that is, on the basis of similarities (e.g., industries of a certain kind), rather than functional connection. By contrast, intensive research designs, including ethnographic case studies, focus on causal rather than taxonomic groups and follow up causal connections wherever they lead—often between heterogeneous objects, such as firms of different kinds. Intensive research is typically more exploratory, since the purpose is to discover the relevant causal groups. It is often time consuming to do this for large numbers of cases, and therefore it is not always a good basis for generalization. However, as we have seen, this lack of generalizability does not undermine the status of causal explanations of the particular cases which are studied intensively. Consequently, having formerly been regarded as unscientific, intensive studies have now become more accepted in geographical research.

Critical realism acknowledges that the methodology of social science must diverge from that of the natural sciences because human, social phenomena are intrinsically meaningful. While the objects that, say, geologists study, are what they are regardless of any meaning people may give to them, objects such as socially segregated urban areas depend on the meanings actors give to them. To understand what these are, one has to know what their meaning is in society, whereas the nature of a rock does not depend on how its constituents understand one another, as they do not. Consequently, an important part of the methodology of human geography, no less than other social sciences, is interpretive understanding. For example, to understand the geography of the Middle East, we would have to understand what significance its land had for Jews and Arabs in terms of their identities.

Although this interpretive understanding has also been the focus of *humanistic geography*, critical realists make certain qualifications which the latter might not. The three most important are as follows. First, critical realists argue that although we have to interpret the understandings that actors have of their situations in order to make sense of how they act, their understanding is not necessarily a good one, indeed it may be systematically flawed. Moreover, these misunderstandings may have important effects which actors cannot explain. Thus a mysogynist may believe that the proper spatial location for women is in the home, on the false grounds that they are incapable of coping with life in the public sphere; the falsity of this understanding makes a difference to what happens and therefore has to be acknowledged in scientific accounts. Further, different actors may give contradictory accounts of the same situation: where this is the case the researcher cannot sit on the fence and say both are correct. Actors' accounts of situations therefore face social scientists' accounts both as objects of study and rivals. It is therefore likely that researchers' accounts will be at least implicitly critical of actors' accounts—a conclusion which humanistic geographers are generally unwilling to accept. It is primarily for this reason that Bhaskar's philosophy of social science is called *critical* realism.

Second, among the intrinsically meaningful aspects of social phenomena are actors' reasons. Critical realists argue that reasons can be causes, since they can be responsible for producing change, by prompting actions. This, of course, implies that realists do not limit causation to physical processes. To deny that reasons are causes is to imply that the giving of reasons by actors is ineffectual and redundant, which of course makes it unclear why they are given. Third, an insistence on the necessity of interpretive understanding should not allow us to forget that social life is also material, embodied, and spatially situated, and that

things happen *to* people, so that, for example, they can be dominated, sometimes regardless of their understanding of the situation.

The realist facility for explaining irregular processes was particularly attractive to a discipline such as geography, concerned as it is with spatial differentiation and uneven development, and hence unable to ignore—as, say, economics tries to do—the problems of applying equilibrium models or making generalizations which are supposed to hold across time and space. The systems which geography and other social sciences study are *open*, that is, their elements can themselves be undergoing internal qualitative change—actors aging and learning, for example—and the relations among the elements are not constant, with the result that any empirically regular behaviors are unlikely to be durable or widespread. Evolutionary change and disequilibrium rather than equilibrium are the norm.

Where previous attempts at scientific explanation in geography had tried to evade the prevalence of differentiation and irregularity, on the mistaken grounds that explanation required the discovery of regularity, human geography began to re-embrace differentiation, nowhere more strikingly than in Doreen Massey's influential *Spatial Divisions of Labour* (Massey 1984). This was closely followed by a burgeoning literature on locality studies, which typically focussed on how economic restructuring worked out in different localities, and how those differences impacted back on the restructuring process (e.g., Cooke 1986).

5. Critical Reception

Some geographers feared that such concerns heralded an abandonment of theory and generalization and a slide towards the empiricist documentation of facts (e.g., Harvey and Scott 1989), indicating a resistance to the critical realist de-emphasis of generalization. These fears were not merely methodological but partly about a weakening attachment in economic geography to a particular kind of theory—Marxism—and also a tendency to treat critical realism as a source of substantive theory rather than as a philosophy, when it had no such pretensions. At the same time, some of the attempts to use critical realism in localities studies invited justified criticism by arbitrarily translating it into the study of general, supralocal causal processes interacting with local contingent conditions. However, critical realism did not license such an extraordinary alignment of scale and necessity: the supralocal is no more or less the realm of necessity than the local, nor is the local any more the realm of contingency than the supralocal.

Towards the end of the 1980s a newer generation of geographers became influenced by postmodernism (see *Postmodernism in Geography*). In some ways this continued the emphasis on differentiation—only phrased as 'difference' which had connotations of social differences of identity. Societies were seen as inherently messy, and skepticism towards grand universalizing accounts of the world grew. One of the positive features of this literature was that it gave greater concern to the textual nature of accounts of the world (Sayer 1989, Stones 1996). At the same time, some postmodernist writers rekindled relativist, anti-realist tendencies (e.g., Barnes 1996, Graham 1990), although sometimes by mischaracterizing realism as claiming privileged access to the truth rather than as having a fallibilist view of knowledge. The debate continues (e.g., Peet 1998).

Critical Theory: Contemporary

Critical theory was originally associated with the Frankfurt Institute in the 1930s, the key figures of which included Max Horkheimer,Theodor Adorno, Walter Benjamin, and Herbert Marcuse. Critical theory embodied the Hegelian and psychoanalytic reorientation of Western Marxism during the 1930s in which theory was transformative, rather than contemplative, engaging with historical processes to enhance human emancipation (Horkheimer 1972). Unlike more orthodox Marxism, it accorded central significance to culture, including mass media, authoritarianism, science and technology, and gender. Central to their thinking was the apparent eclipse of the revolutionary proletariat in the wake of Stalinism, Nazism, and mass consumption capitalism. Many of these themes, expressed for example in Horkheimer and Adorno (1973), were to become central to social theory some 25 years later. As this happened, the distinctive character of critical theory became less clear, although it remains an important focus of critical theoretical debate.

1. *Contemporary Critical Theory*

Much contemporary critical theory though has been shaped by Jürgen Habermas (b. 1929) who, despite often being described as the 'heir' to earlier critical theory, has criticized many of its claims. He regards the apocalyptic despair of Horkheimer and Adorno's work as having ignored the 'unfulfilled potential' of Western modernity to expand rationality and democracy (Habermas 1987, p. 113). They too readily accepted a Weberian nightmare of an iron cage of total domination, in which philosophy could only keep alive the possibility of a better society while lamenting the lost opportunity for emancipation (Benhabib 1981). For Habermas though, the very possibility of critique must presuppose the existence of a rational criteria of a better society against which the present is being judged (Habermas 1987, p. 113). Habermas aims to recover and explicate this potential, to which end he has undertaken an elaborate reconstruction of the grounds of everyday communication.

1.1 *Communicative Turn*

Habermas' early work focused on the constriction of the public sphere through technocratic politics and commercial mass media. Though less central to later work, this theme is manifest in Habermas' distinction between two social orders, of lifeworld and system. The former is the sphere of communication and culture, mediated by norms and language. The latter refers to forms of social 'steering' by money and power, which are not available to normative discourse. While Habermas insists that the market and state are essential in modern societies, there is a continual tension along the boundaries of lifeworld and system along which new social movements arise. An example would be environmental protests over nuclear reprocessing that open debates about the rationality and morality of projects previously driven by technological and financial criteria.

In recent work though Habermas has identified emancipatory practice not by appeal to agents of change (such as the proletariat) but through 'universal pragmatics'—the reconstruction of rationality implicit in speech acts. Habermas argues that the potential for rational agreement is present whether we acknowledge it or not, in sociolinguistic rules of communication. He uses Chomsky's linguistics and Austin and Searle's theory of speech acts to reconstruct communicative rules, arguing that the elementary units of communication (speech acts) involve validity claims that are 'naively accepted' in conversations. For conversations to occur we assume agreement about grammar and illocution (we recognize something *as* a promise, an assertion, an order, etc.). Similarly, judgments about the comprehensibility of actions involve evaluations as to whether good reasons have been provided. Although moral choices are often regarded as matters of personal conviction, Habermas agues that the requirement to provide good reasons, subject to public scrutiny, renders these choices 'capable of truth.' The evaluation of moral choices is comparable to the evaluation of empirical claims, in that in both our proffered reasons are subject to critical testing (Habermas 1992, p. 76). Thus Habermas seeks a practical and cognitive basis for critical theorizing.

These are not timeless linguistic structures, but unfold historically through the formation of post-traditional (modern) worldviews. Unlike Marxist theories, which view social development as the succession of modes of production, Habermas' theory refers to stages of cognitive and moral learning, which parallel childhood development. Premodern forms of moral authority involve conventional attachments to externally given value systems, underwritten by sacred beliefs. Echoing Kant, 'maturity' involves post-conventional distance from rules and the capacity to evaluate and argue whether adherence to a moral injunction is appropriate. Successful post-traditional sociality institutionalizes new levels of cognitive and moral learning, thus normative structures are the 'pacemaker of social evolution' (Habermas 1979, p. 120). Modern worldviews dissolve sacred authority into rational justifications of morality.

This process of the 'linguistification of the sacred' is potentially liberating because it releases the 'argumentative force of language' grounded in the capacity of assent or dissent from any proposition, whether empirical, moral, or aesthetic. In each of these spheres any attempt to reach an understanding of the truth of

a proposition, the sincerity of the speaker, or the appropriateness of the utterance can be disputed. Habermas claims that entering into dialog about the validity of utterances involves a specific type of discussion (*Diskurs*) oriented towards examining these conditions (Habermas 1984, p. 28). But here is the nub of the argument. Such practices will be successful only if we assume equality of access to speech acts and freedom to move from level to level in *Diskurs*, since it is only under such conditions that consensus could be motivated by the force of better argument. This enables Habermas to introduce the 'general symmetry requirement' (also called the 'ideal speech situation') which states that if a consensus is to be reached guided only by the force of better argument, then whether we recognize it or not we routinely assume certain conditions. That is:

everyone has an equal chance to deploy, initiate, and perpetuate speech acts;
utterances are comprehensible;
their propositional content is true;
what is said is legitimate and appropriate;
it is sincerely spoken.

Habermas realized, of course, that these conditions of communicative competence are counterfactual and rarely present in actual speech, but it is precisely this that justifies two further claims. The first is that the goal of normal communication is disturbed by power relations, which intrude to prevent questions being raised or validity claims being tested. Second, these constraints on communication are self-defeating since they contradict the underlying assumptions that make dialog possible at all. From this it follows that rationality can be measured by the degree of openness or closure in communication. The goals of truth, freedom, and justice are not mere utopian dreams, but are anticipated in ordinary communication; and therefore the goal of emancipation is presupposed in the constitution of the species as linguistic beings (Habermas 1991, p. 244). If the unspoken authority of all communications can potentially be challenged, then perhaps democratic social relations are already implicit in everyday communications. For this insight to have practical significance though, it would need to be linked to the formation of emancipatory social movements: feminism, ecology, civil rights, and democratization movements (Ray 1993, pp. 57–78).

1.2 How Critical is Critical Theory?

Contemporary critical theory has developed a wide range of debates and projects in the course of which Habermas' has been extensively criticized. For some (Hullot-Kentor 1989) he has abandoned the earlier critical thrust of Horkheimer and Adorno. For others, he privileges communicative functions of language over others, such as irony or aesthetic expression (Thompson 1982) and has misunderstood or misused speech act theory (Rasmussen 1990, p. 37). One of the most frequent criticisms is that if Habermas envisages domination-free dialog as an attainable state, this is an implausible utopian dream (Jay 1988, p. 31). If it is not an attainable state then the force of his critique is lost. Similarly, Habermas' emphasis on communication and language is idealist and perhaps ignores the importance of material structures (Dux 1991). Brian Fay suggests that emancipation through rational reflection encounters limitations imposed by 'embodiment,' since authority is inscribed into conditioned patterns of activity, which cannot readily be subject to rational refection (Fay 1987, p. 148). Two areas of controversy in particular serve to highlight the relevance of critical theory to contemporary debates.

2. Critical Theory and Feminism

Some of the most interesting critiques of Habermas have come from feminist critical theorists, who share his commitment to the explication of power, knowledge, and morality, but differ with him on other issues. A central issue is that Habermasian theory stands in the Enlightenment tradition which many feminists have rejected (Meehan 1995). Universal pragmatics deals with highly abstract and depersonalized speech rules. By contrast, feminist critics have identified discursive forms that represent experience of embodied female subjects. For example, Nancy Fraser (1985) argues that Habermas fails to examine the gendering of his core concepts such as citizenship, universalism, public sphere, and civil society. The role of citizen is premised on male occupation of the public sphere in which a civil contract amongst brothers is contrasted with the feminization of the private sphere.

Seyla Benhabib criticizes what she sees as the disembodied transcendental rational ego that is the subject of ideal speech. Drawing on communitarian critics of the 'unencumbered self' (Taylor, MacIntyre), she sees in Habermas's attempt to reconstruct universal morality an autonomous male ego, which universalism privileges as a point of reference. Since subjects are finite and social, contexts of gender and community are central and people are not only generalized others (moral persons with reason) but also concrete others. The negotiation between the 'generalized other' and collective concrete others takes place in a male public sphere from which women disappear (Benhabib 1992, p. 13). Nonetheless, Benhabib applauds Habermas' shift to communication, which departs from reason as a psychological attribute of consciousness to an intersubjective view of ethics and dialog.

A similar point is made by Kate Soper, who notes the 'all male monastical atmospherics of the Frankfurt School,' but sees nonadversarial dialog as similar to consciousness-raising, and his distinction between normatively secured and communicatively achieved

dialog as a means of opening up unquestioned conventions (e.g., family) to explicit discussion. Indeed, there is some anxiety among these critics that the theory risks losing sight of universalism in favor of Romantic particularism. Benhabib asks, 'would a moral theory restricted to the standpoint of the concrete other be sexist, racist, culturally relative, and discriminatory?' 'No,' she replies, 'rights must be an essential component of any such theory.' The problem here (cf. Soper 1992) is that 'rights' must involve abstraction from particularity otherwise the grounding for the demand for equal treatment is removed.

3. *The Debate over Modernity*

Critical theory seeks to salvage Enlightenment rationality. Habermasappears to be the only contemporary theorist willing to defend the tradition of modernity, and is frequently called to do so in debates with theorists like Lyotard, Gadamer, and Foucault. Yet critical theory shares with postmodernism an attention to knowledge and communication media, the fragmentation of culture and identity, and the end of historical narratives. Nonetheless, for critical theory, postmodernism denies the grounds of its own critique and permits celebration of spontaneous power of imagination. That, on the contrary, modernity is not exhausted but unfulfilled, was demonstrated by the anticommunist 'rectifying revolutions' (*die Nachholende Revolution*) of 1989. They posed anew the core issues of modernity—rights, civil society, market governance, cultural autonomy, and democratic association (Habermas 1990, 1994, p. 62).

The robust defense of modernity and enlightenment is, paradoxically, as much a challenge to earlier critical theory as to postmodernism. An evaluation of contemporary critical theory should assess its success in identifying emancipatory impulses neglected by earlier theorists. Habermas gestures towards social movements as representing new communicative structures, although he says very little about these in detail. The key issue is whether the theory of communicative action is a plausible reconstruction of the emancipatory potentials inherent in everyday speech. Even if we find these arguments persuasive, the question remains whether these are cultural conventions or deeper structures constitutive of discourse.

Critical Theory: Frankfurt School

Critical theory has a narrow and a broad meaning in the history of the social sciences. 'Critical theory' in the narrow sense designates several generations of theorists in the Western European Marxist tradition known as the Frankfurt School. According to these theorists, a 'critical' theory may be distinguished from a 'traditional' theory according to a specific practical

purpose: a theory is critical to the extent that it seeks 'to liberate human beings from the circumstances that enslave them' (Horkheimer 1982, p. 244). Because such theories aim to explain and transform *all* the circumstances that enslave humans, many 'critical theories' in the broader sense have been developed. They emerge typically in connection with social movements that identify varied dimensions of the domination and oppression of humans in modern societies. In both the broad and narrow senses, however, a critical theory is a form of social inquiry with a particular practical and normative intent.

This critical and practical orientation gives rise to three questions about critical social inquiry. First, is critical theory a distinctive form of social inquiry? Second, what sort of knowledge does such inquiry provide in order to provide insight into social circumstances and justify social criticism? Finally, what sort of verification does critical inquiry require? The debates about theoretical uniqueness, the epistemic superiority of the critics, and the practical verification of criticism have produced different forms of critical inquiry with different political goals.

1. *What is a Critical Theory?*

Although myriad in its forms, 'critical theory' (or more generally critical social inquiry) has a distinctive purpose and overall structure. Critical social theorists generally aim at constructing social theories that link explanation and criticism and thus have both normative and explanatory features. Furthermore, such theories must also be 'practical.' 'Practical' here does not simply mean useful or that critical theories are connected to practice generally, but rather to a particular purpose of human emancipation (Horkheimer 1982, Habermas 1971). The philosophical problem of critical social inquiry is to identify precisely those features of its distinctive explanations that give them their distinctive normative character in underwriting social criticism. A closer examination of paradigmatic works across the whole tradition from Marx's *Capital* (1871) to the Frankfurt School's *Studies in Authority and the Family* (1939) and Habermas's *Theory of Communicative Action* (1984, 1987) reveals neither some distinctive form of explanation or a special methodology that provides the necessary and sufficient conditions for such inquiry. Rather, the best such works employ a variety of methods and styles of explanation and are often interdisciplinary in their mode of research (Horkheimer 1993). What then makes them works of critical social science?

There are two competing answers to this question. The first is that they employ a distinctive comprehensive theory that unifies such diverse approaches and explanations and underwrites the epistemic authority of the critic. The second is practical. According to this view, such theories are distinguished by the form of politics in which they are embedded and which also provides the method for practical verification. Even if critical social science is best unified practically and politically rather than theoretically or epistemically, it is not thereby reducible to democratic politics. It is rather the moment of social inquiry from within the normative perspective of a participant within such practices.

As evidenced by the turn to historical materialism in Marx and its constant reconstruction thereafter by critical theorists, the practical solution has not been the favored one in the history of critical social science. The theoretical solution provides the critic with an epistemically superior status over and above the limits of the participants' perspective; it underwrites the claims that such criticisms are 'scientifically justified.' It also provides the basis for going beyond a 'mere' pluralism and for adjudicating among the contradictory claims of theories and explanations in the social sciences; those explanations that cannot be organized into the unity of the comprehensive social theory are rejected by theorists such as Marx as inadequate to justify criticism. This theoretical conception is not devoid of politics. Rather, corresponding to this single comprehensive theoretical framework is the comprehensive political goal of human emancipation. If we reject such theoretical and political convergence, where does critical social science begin amidst such theoretical and political pluralism? Such pluralism requires that we abandon what Marx saw as the criterion justifying the superiority of historical materialism: a unique fit between critical explanation and the goals of a particular political practice.

The alternative practical account links critical inquiry to cooperative and reflexive practices. Indeed, any cooperative practice demands ongoing inquiry into the social conditions and normative basis of its activities. As practices of inquiry embedded in other practices, all the social sciences establish specific relationships between inquirers and other social actors. Habermas and Marcuse consider such social inquiry that only develops strategic and instrumental solutions to be 'technocratic' (Habermas 1970, Marcuse 1964). It models the social scientist on the engineer, who masterfully chooses the optimal solution to a problem of design according to criteria of success as set by independent standards of rationality. Only the practical stance of the reflective participant is fully dialogical, giving inquirer and agent equal standing as agents in a shared practice (whatever the goals of that practice may be). It is this political relationship of equal agency that critical inquirers seek to establish, as they address their criticism to actors who will engage in public reflection on the nature and goals of the practices in which inquirer and actor both participate. As in Kuhn's distinction between normal and revolutionary science, second-order critical reflection considers whether or not the framework for coop-

eration itself needs to be changed. Such criticism is directed at the framework of current institutions as well as towards formulating new terms of political cooperation under which problems are solved.

2. *The Status of the Critic: Theoretical and Methodological Pluralism*

An examination of the history of critical theory shows that the shift away from the distinctiveness of some comprehensive theory to a more practical orientation leads to a pluralistic account of social inquiry. This shift has three phases. The first phase is the Frankfurt School's 1930s program of an 'interdisciplinary historical materialism.' This phase is characterized by a pluralism of social scientific methods within a unified theory of historical materialism (Horkheimer 1993) and this synthesis proved unstable; the Frankfurt School gradually abandoned historical materialism (Horkheimer and Adorno 1972, Wiggershaus 1994). As the leading theorist of the second generation, Habermas constructed a theory of communicative action for explanatory and normative purposes (Habermas 1984, 1987). While comprehensive, this theory actually unifies many different theories: a theory of rationality, of modernization as social and cultural rationalization, and so on. The final phase is the recognition by Habermas of the full implication of both methodological and theoretical pluralism. This thoroughgoing critical pluralism shifts normative weight to the role of the critic in the pluralist practice of democracy, and the public sphere as a social location in which social criticism can take place and have emancipatory effects (Habermas 1989).

The justification of this two-sided (pluralistic, yet comprehensive) approach is worked out in more detail in Habermas's writings on the philosophy of social science and is the common thread that connects *On the Logic of the Social Sciences* (1988) to *The Theory of Communicative Action* (1984, 1987). The problem of pluralism is not new in the philosophy of social science. As Habermas sees it, Max Weber was among the first to recognize that the social sciences combine various cognitive operations: explanation as well as interpretation, historical comparison as well as transhistorical theoretical terms. This mixed status leads social scientists to combine seemingly contradictory and heterogeneous methods, aims, and theories into more or less coherent wholes. Just as in the analysis of forms of inquiry tied to distinct knowledge-constitutive interests (Habermas 1971), Habermas accepts that various theories and methods each have 'a relative legitimacy.' The most fruitful approach to social scientific knowledge is to bring all the various methods and theories into relation to each other: 'Whereas the natural and the cultural or hermeneutic sciences are capable of living in mutually indifferent, albeit more hostile than peaceful coexistence, the social sciences must bear the tension of divergent approaches under one roof …' (Habermas 1988, p. 3). In *The Theory of Communicative Action*, Habermas casts critical social theory in a similar pluralistic, yet unifying way. In discussing various accounts of societal modernization, critical theory takes on the task of critically unifying the various theories and their heterogeneous methods. 'Critical theory does not relate to established lines of research as a competitor; starting from its concept of the rise of modern societies, it attempts to explain the specific limitations and relative rights of those approaches' (Habermas 1987, p. 375).

Such a pluralist approach need not deny the possibility of fruitful large-scale theories, so long as their success is established by a wide range of empirical evidence and by the diversity of sub theories that they fruitfully integrate (Bohman 1991). Indeed, the mixed status of the social sciences as combining explanation and interpretation indicates that elaborating such combinations and connections is the proper goal of social theory. It suggests a theoretically modest, but practically robust pragmatism about critical inquiry. First of all, comprehensiveness does not ensure explanatory power. The second problem is that a close examination of standard critical explanations, such as the theory of ideology, shows that they typically appeal to many different social theories and methods at many different levels (Bohman 1991). Inquiry located in democratic practice suggests a different model: that criticism motivated by whatever theory or method must be verified by those participating in the practice and that this demand for practical verification is part of the process of inquiry itself.

Such a form of inquiry does not need to deny that there is an important role for general theories as 'general interpretive frameworks' in light of which it is possible to construct 'critical histories of the present' (McCarthy and Hoy 1994, pp. 229–30). Such interpretations are validated by the extent to which they open up new possibilities of action that are themselves to be verified in public debate and democratic inquiry. General theories are then best seen as practical proposals whose critical purchase is not moral and epistemic independence but practical and public testing according to criteria of interpretive adequacy.

3. *The Practical Verification of Social Criticism*

Merely to identify a number of different methods and a number of different theories connected with a variety of different purposes and interests leaves the pluralist critical theorist in a rather hopeless epistemological dilemma. Either the choice among theories, methods, and interests seems utterly arbitrary, or the critical theorist has some special epistemic claim to survey the

domain and make the proper choice for the right reason. The former, more skeptical horn of the dilemma is one endorsed by 'new pragmatists' like Rorty (1991) who sees all knowledge as purpose-relative, and by Weber in more decisionistic moments in his methodological writings (1949). The latter demands objectivist claims for social science generally, and for the epistemic superiority of the critical theorist in particular, that Habermas and other critical theorists have been at pains to reject (Habermas 1973, p. 38).

The problems of a critical pluralism cannot be avoided simply by shifting the debate to practical criteria. Not only are there many distinct practical interests or purposes, the social sciences may also be practical in many different senses. To the extent that we can identify the epistemological basis of the social sciences in forms of practical knowledge, the dilemma of pluralism becomes more tractable as a problem: identifying the type of knowledge required by the specific social context of inquiry. The analysis of interests takes us some of the way toward a solution (Habermas 1971). Technical knowledge does not only represent a particular interest, say the interest in controlling outcomes; in the case of the social sciences, it also presupposes a particular practical relation between the social scientists and the subjects of their inquiry. In order to gain democratic control over certain social processes, a particular context of inquiry must be created: emancipation as the regulative control of institutions over certain kinds of practices or processes. As second-order reflection, critical social inquiry addresses the subjects of inquiry as equal reflective participants, as knowledgeable social agents. In this way, the asymmetries of the context of technical control are suspended; this means that critical social inquiry must be judged by a different set of practical consequences, appealing to increasing the 'reflective knowledge' that agents already possess to a greater or lesser degree. As themselves agents in the social world, social scientists participate in the creation of the sort of contexts in which their theories are publicly verified or rejected as critical proposals.

The goal of critical inquiry is not to control social processes or even to influence the sorts of decisions that agents might make in any determinate sort of way. Instead, its goal is to initiate public processes of self-reflection (Habermas 1973). Thus, critical social science can measure its success against the standard of attaining such a practical goal. In most cases, the goal may be attained only through a functioning public sphere; hence, the success of critical social inquiry may be measured by its practical consequences for the quality of discussion and debate in the public sphere. Such a standard is the same measure of success for the contributions of any reflective participant in the public sphere. But it may not always be the case that a well-functioning public sphere exists; and even if one exists it may be difficult to initiate reflection on various social themes or self-reflection on aspects of the public sphere. Such cases are the subject matter of most standard critical theories, such as the theory of ideology, leaving the critic once again in a position of epistemic superiority. This problem, too, is less intractable from a pragmatic point of view: no such strong claims are required, since the critic's theory does not provide the practical warrant independent of a public process of verification and reflection.

On the practical view of critical theory, social scientific knowledge helps agents to see their circumstances differently, especially at that point when mounting problems indicate that some change is practically necessary. Habermas argues that participant-critics cannot employ reflexive theories in an 'objectivating fashion.' The fact that agents do not now accept some proffered interpretation of their practices does not refute such a criticism; the practical conception of verification allows that agents could be mistaken about the character of their practices. Just as technical knowledge depends on creating the social conditions of a community based on free and open critical examination in order to validate its predictions, so too critical inquiry aims at creating the appropriate social conditions under which agents themselves may verify or falsify the criticism offered. Agents in this new social context can retrospectively judge their past knowledge as reflectively inadequate; but apart from undertaking this process of practical verification that involves taking into account many different perspectives on problematic situations, there is no way of knowing the truth or falsity of a criticism as a 'fact of the matter.' Rather, a criticism is verified if it is acceptable to those to whom it is addressed under the appropriate reflective conditions in a public process of judgment and validation.

A further advantage of the practical account is that it makes it easier to see why there are many different critical theories in different historical contexts. When criticisms are justified solely on the basis of the superiority of theoretical knowledge, the critic has no foothold in the social world and no way to choose among the many competing approaches and methods. On a practical account, critical inquiry aims at creating the reflective conditions necessary for its own practical verification. In practical verification, agents may not in the end find these insights acceptable and thus may not change their second-order self-understandings. The publicity of such a process of practical verification entails its own particular standards of critical success or failure. This sort of critical success also helps explain the political pluralism of the many social movements, all of which employ critical social theories and methods as the moment of inquiry of their democratic politics. As new forms of critical theory emerge related to racism, sexism, and colonialism, reflective social agents have transformed these same democratic ideals and practices in the interest of emancipation.

Critical Thinking, Cognitive Psychology of

Critical thinking is often used as a synonym for good or clear thinking. When viewed from the perspective of cognitive psychology, critical thinking is the use of those skills and strategies that increase the probability of a desirable outcome, where the definition of what is desirable depends on individual goals and values. Thus, it is generally acknowledged that the quality of one's thinking is evaluated within a value system. The content of critical thinking courses in cognitive psychology is embedded in the theory and empirical research of the discipline. It includes instruction in scientific thinking, formal and informal logic, thinking probabilistically, evaluating the quality of information, generating and selecting alternatives and goals, and analyzing arguments for the soundness of conclusions. The use of the word 'critical' represents the notion of a critique or evaluation of the processes used in thinking and the outcomes of the thinking process. It is not meant to be negative (as in a 'critical person'), but is used in the sense of a reflective review or informational feedback. The cognitive psychology of critical thinking has a long history. In 1909, John Dewey used the term 'reflective thinking' in a discussion of good thinking that was surprisingly similar to the definitions of critical thinking being used by cognitive psychologists almost a century later.

1. The Critical Need for Critical Thinking

Changes in necessary workplace skills and the increasing complexity of a technology-mediated society have created an increase in the demand for citizens with the abilities to think effectively. It is in this context that critical thinking has emerged as a standard course in many college curricula, often offered as a 'general education' requirement for every college student. Despite the popularity of critical thinking courses, the faculty and administrators who teach the courses and organize knowledge into academic disciplinary categories often disagree over the content and objectives of these courses and the transferability of critical thinking skills and knowledge within and across domains of knowledge.

1.1 The Politics of Critical Thinking

Unlike many other topics in cognitive psychology, critical thinking has gained widespread popularity as, arguably, the most important subject matter and cognitive skill needed for effective citizenship and economic growth in the third millennium. The development of critical thinking skills was identified as one of the primary goals of Education 2000, a national agenda for education in the United States, with support from both Republicans (e.g., President George Bush) and Democrats (President Bill Clinton) (National Education Goals Panel 1991). Unfortunately, and despite bipartisan political support, the goal to improve the critical thinking skills of educated adults was never funded. The failure to fund critical thinking as a national priority touched off a (somewhat cynical) debate over the question of whether politicians really wanted an electorate that was capable of

critical thinking. There are political implications to the development of an academic discipline that purports to improve adult-level thinking skills. Future interaction between academics concerned with the cognitive psychology of critical thinking and politicians concerned with the politics of critical thinking could have profound effects on the development of this academic discipline.

2. *Interdisciplinary Perspectives*

No single discipline can claim sole ownership of or be the sole authority on 'thinking.' For cognitive psychologists, the study of thinking originated in the German laboratory of Wilhelm Wundt, the generally acknowledged 'father of psychology.' Modern cognitive approaches to the study of thinking have generally followed two different approaches—descriptive and prescriptive. The descriptive approach has catalogued common fallacies, such as the reliance on small samples and confusion of correlation and cause, and biases, such as the preference for evidence that confirms a favored hypothesis. The descriptive approach to critical thinking has focused on the ways in which 'thinking goes wrong,' and instruction using this framework usually involves admonishments to prevent fallacious thinking. By contrast, the prescriptive approach focuses on principles for good thinking, such as the appropriate use of base rate information and scientific principles of evidence. When the prescriptive approach is used, there is less emphasis on the pragmatics of thinking, such as the way familiarity and abstractness influence how people think.

The philosophical study of reasoning predates the ancient Greeks, so not surprisingly, critical thinking courses are sometimes offered in departments of philosophy. Content in these courses tends be heavily weighted with the principles of formal and informal reasoning and their application. Education, English, and communication departments also offer courses under the critical thinking rubric, emphasizing skills of persuasion in writing and oral formats. Despite these differences in emphases and historical origins, the central concern in all courses on critical thinking is the enhancement of thinking skills, with the general goal that students will be better thinkers because of the course content.

3. *Evidence that Thinking Can Be Improved With Instruction*

When critical thinking is taught within the framework of cognitive psychology, the principles of scientific reasoning are a primary component of the course. These principles require an empirical basis for sound conclusions. Accordingly, critical thinking instruction needs to be evaluated by its own criteria. Despite considerable skepticism, there are numerous studies that have shown that thinking can be improved when students learn to recognize and apply appropriately the skills and strategies of critical thinking. A general list of skills that are useful across contexts would include understanding how cause is determined, recognizing and criticizing assumptions, analyzing means–goals relationships, and recognizing problems. The evidence for the beneficial effects of critical thinking instruction shows that specific instruction designed for transfer to novel contexts can lead to better thinking in a variety of settings. There are numerous empirical results that support this conclusion: evaluations of students' thinking and writing about novel topics conducted by evaluators who did not know which of the students had received instruction in critical thinking (i.e., 'blind' evaluators); changes in the organization of knowledge so that it comes to resemble the structure of expert knowledge; and gains in adult cognitive development (see Halpern 1996, 1998 for a review of the literature).

4. *A Network Model of Thought and Knowledge*

The cognitive approach to critical thinking uses basic concepts in cognitive psychology as a way of organizing content and designing instruction to improve thinking. It is built upon a model of thought and knowledge in which meaning is represented in memory as a network of interconnected semantic concepts called 'knowledge structures.' The internal representation of meaning in memory determines the way information is used and the circumstances in which some memories are retrieved and others are not, depending on context cues. Meaning is embedded in the interconnections among knowledge structures, which get their meaning(s) from the other knowledge structures to which they are connected. The network model of knowledge representation is an analogy for the patterns of neurochemical activity or biological bases of thought. It is an 'as if' statement for the biological underpinnings of cognition. The network model is a useful way of thinking about critical thinking: a faulty thinking pattern, such as confusing correlation with causation, is represented by connections between the knowledge representation for 'co-occurrence' of two events and the knowledge representation for 'causation.' In correcting this faulty thinking path, the connection needs to be weakened or pruned and replaced with connections between concepts like 'random assignment to conditions' and 'causation.' The faulty connection is particularly strong or salient when the co-occurrence and causation link is consistent with an individual's other beliefs about the cause of a particular outcome (e.g., marijuana use causes the use of 'harder' drugs).

As critical thinking skills are developed, new connections are added to the network and additional knowledge structures are formed and new retrieval

cues effectively access stored memories. The network model of thought and knowledge is dynamic in that individuals are continually modifying their knowledge structures and remaking connections among knowledge structures. It also posits the learner/thinker as an active seeker of information who applies thinking skills or strategies when 'thinking through' the maze of available information stored in memory. Individual differences in one's willingness to engage in the effortful cognitive 'work' of critical thinking and in the individual nature of stored knowledge are also an important part of these models.

5. *Four Components of Critical Thinking*

A four-part model of critical thinking based on the network model of thought and knowledge has been proposed. It includes: (a) the dispositions for the effortful thinking and learning needed for critical thought; (b) knowledge of critical thinking skills; (c) structure training to facilitate cross-contextual transfer; and (d) metacognitive monitoring.

5.1 *Dispositional or Attitudinal Component*

Critical thinking requires an attitude or disposition to engage in effortful, active, and prolonged mental effort because many of the skills of critical thinking require extended thought, which includes a concern for accuracy and attention to details. The dispositional or attitudinal component blurs the distinction between cognitive psychology and topics in emotion and motivation, for example, antidogmatism, the willingness to evaluate information fairly, and the insight to distinguish between rationalization and reasoning. These noncognitive aspects of a critical thinking disposition include the ability and willingness to see a problem from multiple perspectives and a tolerance for ambiguity and uncertainty. These components of critical thinking overlap with emotional and affective topics in psychology; cognitive and emotional processes operate in concert, exerting mutual influences on each other. Instruction in dispositional aspects of critical thinking includes an emphasis on planning, suppression of impulsivity, and the use of situational and social context variables in directing thought and action.

5.2 *Skills Component*

Critical thinking skills are sometimes referred to as 'higher order skills' to differentiate them from 'simpler' (i.e., lower order) skills, such as rote memorization or routinization. Critical thinking skills require judgment, reflection, analysis, synthesis, and attention to context. The complexity in thinking critically often comes from the multidimensional nature of the problem or the need to make a decision or solve a problem when the information that is available is incomplete, probabilistic, or not completely credible. A short taxonomy of critical thinking skills includes the verbal reasoning skills needed to defend against common persuasive techniques, argument analysis skills that include determining the strength of conclusions based on reasons and evidence, skills used in scientific thinking, the use of likelihood and uncertainty to make probabilistic decisions, and the ability to generate multiple alternatives and goals in problem solving and decision making situations. The focus is on component skills that can be specified, identified, practiced, and used spontaneously across domains of knowledge. Although there are several different lists of necessary skills for critical thinking, there are commonalities among them. Fisher and Scriven (1997), for example, list reasoning, problem solving, decision making, communication, evaluation, explanation, analysis and synthesis, metacognition, and formal and informal reasoning as examples of such skills. Most texts target similar skills, with differences among them occurring mostly in their emphases and in the perspectives that they take on these topics.

5.3 *Structure Training to Promote Transcontextual Transfer*

The skills of critical thinking and the dispositions to use them are not sufficient for successful critical thinking, unless these skills are used appropriately in novel contexts. The general question of transfer of skills within and across domains of knowledge has been a knotty problem for cognitive psychology and education. There is ample evidence that the transfer of critical thinking skills is not a necessary or automatic outcome of thinking skills instruction within a single domain of knowledge or traditional content-based courses (Nisbett 1993 provides ample evidence for this conclusion).

Critical thinking skills need to be deliberately taught in ways that enhance transfer. The probability of transfer can be increased with the use of examples from multiple contexts and by making the underlying structure of problems more salient so that problem structure can act as a retrieval cue that triggers memories for the appropriate skills. The structure sensitivity of thinking, especially as a problem solving strategy, was made clear by Hummel and Holyoak (1997) who believe that, 'First thinking is structure sensitive. Reasoning, problem solving, and learning … depend on a capacity to code and manipulate relational knowledge' (p. 427). Relational structures among meaningful concepts are primary in cognitive models of comprehension and thinking. Structure

training is based on models of human cognition in which meaning is conceptualized as being embedded in the relationships among concepts stored in memory. In order to trigger the 'reminder' that a particular skill is needed, the structure of the problem, not its topical information, needs to serve as a retrieval cue. The goal of structure training is to learn to recognize when particular skills may be useful (e.g., regression to the mean or the need to consider multiple alternatives) regardless of the content of the problem.

5.4 Metacognitive Monitoring

The executive or control function of critical thinking is 'metacognition,' which refers to knowledge about one's own cognitive abilities and the use of this knowledge as a guide for thinking and learning. It includes decisions about the allocation of time and resources to a particular problem and the type and extent of effort expended for the cognitive task. Good metacognitive knowledge will include an assessment of what is known and what needs to be known and a determination of goals and a plan for achieving them. Critical thinkers also know when they do not have enough information to reach a meaningful conclusion as well as the difference between a probable outcome, an unlikely outcome, and a certain outcome. Metacognitive monitoring is a conscious consideration of one's cognitive abilities and an accurate assessment of cognitive resources, hence it serves as the boss or 'executive function.'

Metacognition directs three activities that are critical to the execution of critical thinking: monitoring, controlling, and knowing. Monitoring is important during the acquisition of knowledge—it assesses how well new material is being learned and how completely a difficult concept is being understood. The controlling function is important because it provides direction for cognitive effort—if the learning or understanding is not going well, then additional attention and effort needs to be directed to these processes. The knowing function is used to make judgments about one's confidence in his or her confidence in whether a solution is satisfactory. Thus, metacognition underlies multiple, successive processes that are essential to critical thinking.

6. Creative and Critical Thought

Creative thinking is the production of unusual and good responses to problems. This definition of creative thinking is compatible with the definition of critical thinking being used in this article, differing only in that creative thinking requires the use of unusual strategies or skills. By comparison, the thinking skills used in critical thinking could be either common or unusual. Thus, critical thinking is a superordinate of creative thinking. Critical thinking requires creativity (unusual and good solutions) in many aspects—generating alternatives to problems, redefining goals, and recognizing which critical thinking skills are needed in novel situations. There is no clear demarcation between critical and creative thinking because it is impossible to determine where one type of thinking ends and the other begins; commonly used thinking skills and unusual ones lie along a single continuum.

In an analysis of creative thinking, which includes several case studies, Weisberg (1993) traced the origins of creative thought to experiences that generalized across domains of knowledge. He acknowledged that far or remote transfer of thinking skills is unusual, which is the defining attribute of creative thinking—an unusual solution or insight. It is for this reason that structure training designed to improve transferability of thinking skills across contexts is a critical component to instruction designed to improve critical thinking. When these skills are applied in a novel domain of knowledge, their use in that domain may be unusual, or, in other words, creative. Thus, heuristics that encourage novel ways of making associations and the use of examples from many different contexts are an important part of critical and creative thinking courses.

7. The Role of Context and Judgment

Critical thinking instruction recognizes the need for different sorts of skills, depending on the context, and the ability to recognize that a thinking skill that was used in one context (e.g., determining the effectiveness of a drug) is useful in a very different context (e.g., deciding if trade embargoes will improve political relations with a foreign country). In this way, instruction in critical thinking differs from instruction in formal logic, with its heavy use of syllogisms and linear orderings, which are fully rule dependent and do not vary with context. Critical thinking is more complex than rule-driven deductive logic. To be ecologically valid, critical thinking would require judgment, usually under conditions of uncertainty and ambiguity, two conditions that are common in most real-life situations. Critical thinking is sometimes referred at as 'authentic thinking' because it incorporates some of the 'messiness' of real-life problems. Practice examples often come from a variety of real-life scenarios, such as the arguments presented in newspaper editorials, decisions taken from real life such as which medical procedure to select from a set of imperfect alternatives, and solving problems like making one's money last until the next pay check. Some of the antagonism between critical thinking as cognitive psychology and critical thinking as philosophy is over the extent to which each discipline prefers rule-based vs. heuristic-based (probabilistic) approaches to the subject matter.

8. Critical Thinking as a Formal Discipline

The principles of cognitive psychology have provided researchers and educators with a useful model for the enhancement of critical thinking. There is a considerable body of evidence showing that better thinking can be an outcome of education when critical thinking is explicitly taught for transfer across contexts, when the disposition to think critically is enhanced, and when metacognitive monitoring is used as a guide to the thinking process. Critical thinking is cognitive psychology's finest offspring. It offers the best hope for the future because the ability to think well is the best preparation for a future that is rapidly changing and becoming increasingly complex. Perhaps the disasters that doomsday experts are predicting for the third millennium can be prevented with large-scale efforts to help more people become better thinkers. Critical thinking is emerging as a formal discipline with its own content area and adherents. Its current status as a subtopic under cognitive psychology is likely to change over the coming decades, when it will emerge as a major theoretical perspective on how people acquire and use information more effectively, so that they can become better thinkers and learners.

Cross-cultural Psychology

Cross-cultural psychology is the systematic study of behavior and experience as it occurs in different cultures, is influenced by culture, or results in changes in existing cultures. This subdiscipline of psychology is used by those interested in studying the relationship of culture with psychological processes.

1. Relationship with Cultural and Indigenous Psychology

Cross-cultural psychology (CCP) is different from cultural psychology (CP) (see *Cultural Psychology*) and indigenous psychology (IP) in a number of ways. CCP is closer to psychology and uses a universalistic theoretical framework that assumes the psychic unity of humankind. CP and IP are closer to anthropology and use relativist frameworks and examine how culture and psychology 'make each other up.' Some versions of CP and IP do not assume the psychic unity of humankind. CCP is widely used by social and organizational psychologists, CP is favored by developmental psychologists.

CCP searches for universal (etic) as well as culture specific (emic) findings. It tries to study them using both emic and etic measurements. It emphasizes equivalence of measurement of the constructs in each culture. In addition it aims at culture-sensitive measurement in each culture by making use of both emic and etic items (questions, stimuli) in each culture that correspond to etic constructs. Only etic items can be used to compare cultures. However, both emic and etic items can be used to describe cultures.

CCP uses methods that include little context (e.g., questionnaires, projective tests, experiments), while CP and IP use methods that emphasize context (e.g., participant observations in real life situations, content analyses).

CCP conceives of culture as outside the person, i.e., as a context for perception and action that influences universal psychological processes. For example, the probability of an act is a function of the frequency of the reinforcement of the act. But in some collectivist cultures (see *Collectivism: Cultural Concerns*) the reinforcement may be given to a valued member of the ingroup rather than to the individual whose action is being studied. In individualistic cultures (Triandis 1995), the reinforcement must be given to the person under study, otherwise it has little impact. Thus, in the universal process the frequency of reinforcement is linked to the probability of an act; in the culture-specific process that operates in some collectivist cultures, one need not reinforce the person who is acting, but can obtain the same results by reinforcing a significant other of that person.

Cultures have many elements. Some elements change slowly, perhaps after a few generations, and others change very quickly, such as particular ways of using words. CCP focuses on the more stable elements; CP and IP focus mainly on the changeable elements, especially on the meanings of key concepts. CCP is favored by social and industrial psychologists who study people who have been members of their cultures for a long time. CCP considers differences in meaning, in different cultural communities, as barriers to research. These barriers must be overcome by using specially developed methods of data collection, e.g.,

local (culture specific) standardization of items. Some people have argued that CCP is a method and does not have specific content.

CCP is interested in individual differences. CP and IP do not focus on individual differences, and assume that members of a culture are more or less alike. The cultural distance between the researcher and the culture under investigation is very different in the case of these three perspectives. Cultural distance refers to differences in language (e.g., are the two languages members of the same language family or belong to very different families), differences in social structure (e.g., monogamy vs. polygyny), differences in religion, politics, economic conditions, level of literacy, and the like. Psychologists who study IP are usually members of the culture they study. By contrast, psychologists who use the CP perspective study cultures that are very distant from their own culture. Psychologists who take the CCP perspective hold an intermediate position, studying cultures that are somewhat distant but not too different (e.g., managers in Japan and France). Since cross-cultural psychologists use psychological methods, they are limited to studying people with whom such methods can be used. Such methods can be used only with the people who are more or less familiar with them. Standardized tests, experiments, and the like are meaningful only in the cultures in which they were developed or in similar cultures. On the other hand, participant observations or interviews are less problematic in distant cultures. Thus, psychologists who use the IP or CP perspective use these proceedures more frequently, while CCP researchers use them less frequently.

2. *History*

Since antiquity people have been interested in the manners and morals of people different from their own, as well as in their own psychology. Herodotus in the fifth century BC had the insight that all humans are ethnocentric (use their own culture as the standard for the evaluation of other cultures, and evaluate those cultures that are like their own more positively than the cultures that are very different from their own). In the nineteenth century Darwin's theory of evolution stimulated great interest in mental measurements in different parts of the world. Expeditions by Rivers (1901, 1905) supplied the first data. Jahoda (1993) provided an excellent history of the field.

Wilhelm Wundt published a *Voelkerpsychologie* in 10 volumes (1900–14), which summarized findings of anthropologists, linguists, and historians that had relevance for psychology. After the First World War a movement developed that rejected ethnocentrism and stressed the understanding of cultures in their own terms. Notable events in the history of CCP are the publication of Klineberg's (1954) social psychology text, which did include a great deal of cultural information; the publication of the *Cross-Cultural Psychology Newsletter* (Triandis 1967), which became the *Cross-Cultural Psychology Bulletin*; the publication of the first *Directory* of individuals interested in cross-cultural research (Berry 1968); the publication of the *Journal of Cross-Cultural Psychology*(Lonner 1970); the establishment of the International Association for Cross Cultural Psychology (Dawson 1972); and the publication of a code of ethics for cross-cultural research (Tapp et al. 1974). The *Annual Review of Psychology* started chapters reviewing cross-cultural work in 1973, the establishment of the *Association pour la Recherche Interculturelle* (ARIC) occurred in 1984, the publication of the first *Handbook of Cross-Cultural Psychology* (Triandis 1980–1981) in six volumes, and the second edition (Berry et al. 1997) in three volumes, consolidated the field. The avoidance of ethnocentrism by searching for different perspectives on a phenomenon and developing appreciation of emic points of view; the local standardization of psychological instruments; the development of methods that use both emic and etic items; the use of converging multimethod measurements; the testing of rival hypotheses; and the acceptance of testing of hypotheses using data from the Human Relations Area Files as well as data obtained from research participants became important distinguishing features of cross-cultural psychology.

3. *Examples of Significant Work in CCP*

3.1 *Theory and Method*

The desirability of the CCP, IP, and CP perspectives discussed above is one of the topics being debated. In addition, issues such the extent to which anthropological, genetic, evolutionary, and other approaches must be integrated with CCP are subjects of debate. The methodology of the field was presented in Triandis and Berry (1980). Van de Vijver and Leung (1997) summarized newer methodological developments. Berry et al. (1997) reviewed the most recent issues about theory and method in CCP. Amir and Sharon replicated several social psychological studies published in the *Journal of Personality and Social Psychology* in Israel, and found that only about half the findings replicated. Adamopoulos and Lonner identified numerous cultural universals.

Irvine did much work on psychological testing across cultures, showing that elaborate pretests, parametric studies, and careful analyses are needed if data from different cultures are to be compared meaningfully. On the subject of methodology readers may wish to study the work of the following individuals in particular: John Berry, Michael Bond, Don Campbell, Kwok Leung, Roy Malpass, Raoul Naroll, Fred Strodtbeck, Ype Poortinga, Harry Triandis, and Fons

Van de Vijver. Each method has its own meaning in each culture, so that multimethod measurements and convergence of findings across methods are essential. Local standardization of the measurements (Triandis 1992) is most important. Checking if the cultural differences that have been identified are due to culture rather than to some other factors that happen to be associated with culture, requires the testing of many rival hypotheses.

Berry (1976) developed an ecological framework that linked aspects of the ecology, such as whether people make a living by hunting or by agriculture, to attributes of cultures and attributes of culture to psychological adaptation. People in stable, agricultural cultures conform more than people in hunting cultures.

3.2 Basic Processes

Berry et al. (1997) reviewed the basic and developmental processes using both the CP and the CCP perspective. Specifically, Segall, Campbell and Herskovits (1966) showed that the perception of visual illusions is influenced by culture. For instance, people in carpentered environments (with many right angles), such as those found in industrial cultures, are quite susceptible to the Mueller–Lyer illusion while people in environments where most buildings are round, as in Africa, are not so susceptible. Exposure to many right angles during socialization has the effect of incorrectly seeing the ends of the lines in that illusion as representing right angles.

The relationship of language and thought was investigated by Hunt and Agnoli, M. Cole, Gay, Glick, Scribner, Sharp, and others investigated the effects of literacy on cognition. Literacy was shown to be a major factor in shaping cognition because the unschooled have difficulty making abstract judgments. Extensive studies of different educational systems, such as those of East Asia, the Qur'anic schools, and comparisons with Western education have shed light on the advantages and disadvantages of each educational system. Studies by Stevenson and his associates have shown that the mathematical performance of East Asian students is far superior to the performance of American students, yet American parents are quite satisfied with their schools, while parents in East Asia are dissatisfied with their schools.

Ekman, Frijda, Kitayama and Markus, and Matsumoto, among others, linked culture and emotion. It appears that some aspects of emotions are universal and other aspects are culture specific. In most cultures individuals are emotionally sensitive to certain contingencies (e.g., danger of rejection by the group) and respond in similar ways (e.g., crying, or hostile behavior). But there are culture-specific norms specifying what emotions may be displayed. In other words, there is evidence that the antecedents of emotion have similarities across diverse cultures, but there is also evidence that no emotion term has an exact correspondence to any other emotion term, even when the languages are very similar, such as German and Swiss-German. Although basic emotional processes appear to have universal components, emotional expression is definitely controlled by culture-specific norms.

Osgood, May, and Miron investigated universals of affective meaning. The meaning of any concept can be conceived as the projection of the concept on the dimensions of evaluation, potency, and activity, emically operationalized in each culture. The study was carried out in 27 diverse cultures. An *Atlas* of affective meaning was developed that consists of 600 concepts judged on evaluation, potency, and activity in the 27 cultures. The information is archival, and has been used by many researchers for different purposes. It can be obtained from the Osgood Center of the Department of Psychology, University of Indiana/Purdue, in Indianapolis, Indiana, USA.

3.3 Developmental Psychology

Most developmental psychologists prefer the CP perspective (see *Cultural Psychology*), so here only a few examples that use the CCP perspective will be mentioned. John Whiting, Beatrice Whiting, Irving Child, William W. Lambert, and Leigh Minturn examined the settings within which child development takes place. For example, the presence or absence of grandparents constitutes a difference in setting. Observations and interviews converged in showing that nuclear vs. extended household type was associated with the contrast between authoritarian aggressive and social-intimate child behavior. Ron Rohner used three kinds of data: questionnaire responses within culture, ethnographies of different cultures, and the Human Relations Area Files (summaries of available ethnographies classified by topic). All three data sets indicated that parents who are warm, supportive, and cuddling have children who are optimistic and well adjusted; in contrast, parents who are cold and unavailable or rejecting have children who are pessimistic, emotionally unresponsive, hostile, aggressive, and poorly adjusted. Jerome Bruner, Patricia Greenfield, Joan Miller, Barbara Rogoff, and Charles Super showed that cultural differences increase throughout the life span of development.

Eckensberger, Miller, and Shweder have reported studies of moral development in different cultures. For example, Miller showed that in India helping another person is obligatory in more situations than it is in the USA. Kohlberg's stage theory of moral development was tested in many cultures, but the materials were translations with minor adjustments of the dilemmas

used to test it in the West. Critics have emphasized that it is both a Western and an androcentric theory. Eckensberger has developed a method of testing that is more culture sensitive. It uses the core of a dilemma and an interview which allows the participant to reveal his or her thinking about the dilemma. The answers are then scored according to a stage model. The data suggest that there are stages of moral development, but they do take culture-specific forms, especially at the higher levels of moral development.

3.4 Social Processes

Berry et al. (1997) reviewed this topic (see also *Collectivism: Cultural Concerns*). Emiko and Yoshi Kashima found relationships between culture and the use of language (e.g., in collectivist cultures, 'I' is not required in sentence construction), as did Semin and Zwier (e.g., collectivists frequently use action verbs and individualists use state verbs). Giles and Gudykunst investigated cultural differences in communication behaviors. Poyatos (1988) has edited a volume on nonverbal behaviors such as gestures in different cultures.

Bilingualism was investigated by W. E. Lambert (e.g., middle-class English speakers that went to a French-speaking school became fluent in both languages; the same person speaking in French or English is perceived quite differently). Triandis (1972) found differences in the meaning of roles and social behaviors in Greece and the USA; he also investigated the meaning of value terms in Japan, India, Greece, and the USA and found that words that could refer to either a collective or an individual attribute (e.g., 'progress') were perceived as attributes of a collective in collectivist cultures and as individual attributes in individualist cultures.

Doob as well as Levine examined the meaning of time in different cultures. For example, empirical work has shown that there are fast- (Switzerland, Ireland, Germany, Japan), moderate- (Hong Kong, Costa Rica, Taiwan, Singapore, USA), and slow-moving cultures (China, Syria, Indonesia, Brazil, Mexico). Within the USA, Boston, Buffalo, and New York are fast, Nashville, San Diego, and East Lansing moderate, and San Jose, Sacramento, and Los Angeles slow. In large cities, rich, individualist cultures, and cold climates, people tend to be faster than in rural settings, poor, collectivist cultures, and warm climates.

Berry provided a typology for the study of acculturation that has implications for social policy. Social policies might favor the melting pot concept of assimilation, i.e., those who come from culture (A) and come in contact with a dominant culture (B) are expected to drop culture A and only use culture B. A sounder policy for mental health, according to Berry's findings, is integration or biculturalism, i.e., A + B. Other undesirable policies are segregation, i.e., keeping A and rejecting B, and anomie or marginalization, i.e., rejecting both A and B.

Williams and Best showed that gender stereotypes are quite similar in different cultures. Men are stereotyped as strong, aggressive, cruel, coarse, and adventurous; women are stereotyped as weak, appreciative, softhearted, gentle, and meek. They argue that the pancultural similarities greatly outweigh cultural differences. The biological differences between men and women can be amplified or diminished by cultural influences.

Inkeles studied modernity and found that in all cultures there are segments of the population that are modern. The more educated segments of the society, factory workers, and those who read the newspapers respond to attitude questions in a more modern way than those who have not had these experiences.

Brewer and Campbell explored ethnocentrism, social perception, and the similarity–attraction link in a large number of African cultures. All humans are ethnocentric to some degree. In the case of extreme ethnocentrism, people consider the norms of their culture as the only ones that are 'natural' and 'correct'; they see their customs as universally valid, and believe that it is natural to cooperate with ingroup members and feel proud of their ingroup, whereas they are distrustful and even hostile of outgroups. Ethnocentrism can be reduced by exposure to different cultures, especially 'successful' cultures from the point of view of the people under study.

The more similar two African cultures are to each other, the higher is their evaluation of each other. The autostereotypes (how members of a target culture see their own culture) of the groups were correlated with the heterostereotypes (how members of other cultures see the target culture) received by these groups from the other groups. This correlation was higher for cultures that were in frequent contact than for groups that were not in much contact. This suggests that stereotypes become more accurate as contact increases.

Buss linked the desirable attributes of marital partners to culture and showed that the theory of evolution can explain the observed differences. Specifically, women in all cultures are looking for a mate who is reliable and well established; men in all cultures look for a mate who is physically attractive. Since women invest much time in rearing children they look for mates who will provide for them; men use physical attraction as a cue to good health and probable fertility.

Earley, A. Fiske, Hofstede, Kagitcibasi, Markus and Kitayama, U. Kim, and Triandis carried out extensive work on collectivism (see *Collectivism: Cultural Concerns*). It will not be reviewed here. Leung has shown that dispute resolution is different in different cultures. People in collectivist cultures tend to avoid confrontations and seek to resolve disputes by using mediation by respected third persons. Foa, Leung,

and Hui have studied cultural differences in the use of equity (to each according to contribution), equality, or need in the distribution of resources. For example, equity is used when individualists distribute resources or when collectivists distribute resources to outgroup members; equality is used when collectivists distribute resources to ingroup members.

Miller, Morris, and Peng showed that culture influences the way people make attributions. For example, people in individualist cultures are more likely to use internal factors (e.g., ability, attitudes, or personality), whereas people in collectivist cultures are more likely to use external factors (e.g., what other people did, the task, the norms of the group) in explaining social behavior.

Segall, Ember, and Ember examined aggression and reported that aggression is ubiquitous, all societies attempt to control it, but punishment is not effective in controlling it. Attending to fictional violence contributes to aggression. High frequency of warfare is predicted from resource unpredictability and from territorial and ethnic conflict. In societies where there is severe punishment for wrongdoing and family violence, there is more warfare.

4. *Applications*

Draguns and Marsella investigated culture and psychopathology relationships. Culturally invariant and variable components of psychopathology, especially depression and schizophrenia, have been identified. Some symptoms appear only in one or a few cultures. Psychopathology is manifested in different cultures somewhat differently and the dimension of collectivism-individualism seems promising in organizing and integrating the findings. Pedersen and Leong explored the relationship between culture and counseling.

Bhawuk, Brislin, Landis, as well as Triandis, published extensively about cross-cultural training. For example, culture assimilators have been developed to aid in such training. They consist of scenarios that describe the interaction of members of two cultures, the culture of the trainee, and the target culture. The trainee reads the scenarios and picks one of four or five attributions that may explain why members of the target culture acted the way they did in the scenario. After selecting an attribution, the trainee receives feedback that explains why the attribution is correct or incorrect from the perspective of the target culture. This way the trainee learns to make attributions that resemble the attributions that members of the target culture make when they think of the scenarios. Thus, trainees learn to give the same meaning to behaviors that occur in the target culture as members of the target culture do, and that increases the effectiveness of the trainee's work abroad, as well as reducing the culture shock experienced by the trainee. Culture-general assimilators describe events in many cultures. Culture-specific assimilators are limited to a particular culture, and sometimes to specific demographic categories, e.g., a European-American supervisor working with African-American first-time employees.

Adler, Earley, Erez, and Wilpert investigated the effects of culture on organizational behavior. The main topics included differences in motivation, the meaning of work in different cultures, organizational commitment, communication, the effectiveness of ethnically heterogeneous groups, leadership in different cultures, participative management and industrial democracy in different cultures, reward schemes and their effectiveness in different cultures, organizational development, and intercultural negotiations.

5. *Conclusions and Future Direction of Theory and Research*

A conclusion is that almost every aspect of psychological functioning has both universal and culture-specific components. This perspective suggests that CCP provides an important way to study the relationship of culture and psychological processes.

An important issue is the extent CCP, IP, and CP will develop as separate subdisciplines or become integrated into a coherent approach that uses all three types of investigation. Perhaps the future will bring the integration of these approaches.

The theory of convergence holds that cultures are becoming more similar over time. However, most cross-cultural psychologists believe that convergence is occurring in only a few elements of culture, and that divergence remains in the other elements.

H. C. Triandis

Cross-cultural Research Methods

Cross-cultural studies involve persons from different countries and/or ethnic groups; a defining characteristic is their comparative nature. Most studies employ quantitative methods of data collection and analysis. Studies of cultural topics that are noncomparative and apply a qualitative methodology can be found in sociology ('cultural studies,' e.g., Alasuutari 1995), cultural psychology (Greenfield 1997), and cultural anthropology (Naroll and Cohen 1970) see *Phenomenology in Human Science*; *Ethnomethodology: General*).

The range of instruments used in comparative studies is very broad, ranging from highly standardized psychological tests, to observation schedules, and free interviews. In many studies existing Western instruments (mental tests, survey questionnaires, personality inventories) are administered in a new cultural context, either or not adapted to enhance their cultural appropriateness.

If two persons from different cultural groups show different scores on a reliable and valid measure of subjective well-being, these score differences may refer to individual differences in subjective well-being. However, the score differences may also arise from differential social desirability or some other response style, inappropriate translation, or inadequacy of the item to measure well-being in both groups. The example illustrates a central problem in cross-cultural research: observed score differences are often susceptible to multiple explanations (Campbell and Stanley 1966, Cook and Campbell 1979, Poortinga and Malpass 1986). When the same instrument has been administered to persons from different ethnic groups, it cannot be taken for granted that the same scores obtained in different cultural groups have the same psychological meaning.

The ambiguity of interpretation is a consequence of the methodological nature of culture as an independent variable. In laboratory studies researchers randomly assign subjects to experimental treatments (see *Laboratory Experiment: Methodology*). The random assignment leads to a firm control of ambient variables; ideally an experimental and control group are matched on all outcome-relevant characteristics (e.g., personality characteristics and socioeconomic status), except for the treatment variable studied (see *Internal Validity*). However, like gender and other intrinsic subject characteristics, culture is not an experimental treatment that can be manipulated. Groups with a different cultural background tend to differ on a variety of outcome-relevant characteristics. These differences may constitute rival explanations of observed cross-cultural differences. Without precautions to rule out these rival explanations, observed cross-cultural differences are open to multiple interpretations. Findings in cross-cultural research are more convincing when rival explanations have been more adequately dealt with.

Bias is the generic name of an important family of rival explanations (see *Test Bias*). It refers to the common problem in the assessment of nonequivalent groups that scores obtained in different cultural groups are not an adequate reflection of the groups' standing on the construct underlying the instrument. If scores are biased, their psychological meaning is group dependent and group differences in assessment outcome are to be accounted for, at least to some extent, by auxiliary psychological constructs or measurement artifacts. A closely related concept is equivalence which refers to the absence of bias and hence, to similarity of meaning across groups. The two concepts have somewhat different historical roots and areas of application. Whereas bias usually refers to nuisance factors, equivalence has become the generic term for metrical implications of bias.

Bias and equivalence are not inherent properties of an instrument but arise in a group comparison with a particular instrument. Score comparisons of groups that differ in more test-relevant aspects will show a higher susceptibility to bias.

1. Sources of Bias

There are three bias sources in cross-cultural research. The first is called construct bias; it occurs when the construct measured is not identical across groups. Ho's (1996) work on filial piety (psychological characteristics associated with being a good son or daughter) provides a good example. The Western conceptualization is narrower than the Chinese, according to which children are supposed to assume the role of caretaker of their parents when these grow old and become needy. Construct bias precludes the cross-cultural measurement of a construct with the same measure. An inventory of filial piety based on the Chinese conceptualization will cover aspects unrelated to the concept among Western subjects, while a Western-based inventory will leave an important Chinese aspect uncovered.

An important source of bias, called method bias, can result from sample incomparability, instrument characteristics), tester and interviewer effects, and the method (mode) of administration (see *Test Administration: Methodology*). Examples are differential stimulus familiarity in mental testing and differential social desirability in personality and survey research. Some sources of method bias can be dealt with by careful preparation of the assessment instrument and its instruction manual (e.g., proper test instruction with a clear specification of what is asked from participants, standardization of administration, and adequate training of testers and interviewers). Yet, it may be impossible to eliminate all outcome-relevant sample characteristics, in particular when the cultural distance of the countries involved is large. There are indications that a country's Gross National Product (per capita) is positively related to its mean score on mental tests and negatively to its mean score on social desirability. Particularly in comparisons of culturally highly dissimilar groups it may be hard or even impossible to eliminate the impact of sources of method bias such as sources familiarity and social desirability.

Finally, bias can be due to anomalies at item level (e.g., poor translations); this is called item bias or differential item functioning. According to a definition that is used widely in psychology, an item is biased if persons with the same standing on the underlying construct (e.g., they are equally intelligent) but coming from different cultural groups, do not have the same

Table 1
Strategies for identifying and dealing with bias in cross-cultural research

Type of bias	Strategies
Construct bias	Decentering (i.e., simultaneously developing the same instrument in several cultures) Convergence approach (i.e., independent within-culture development of instruments and subsequent cross-cultural administration of all instruments)
Construct and/or method bias	Use of informants with expertise in local culture and language Use samples of bilingual subjects Use of local surveys (e.g., content analyses of free-response questions) Nonstandard instrument administration (e.g., 'thinking aloud') Cross-cultural comparison of nomological networks (e.g., convergent/discriminant validity studies, monotrait-multimethod studies, connotation of key phrases)
Method bias	Extensive training of adminstrators (e.g., increasing cultural sensitivity) Detailed manual/protocol for administration, scoring, and interpretation Detailed instructions (e.g., with sufficient number of examples and/or exercises) Use of subject and context variables (e.g., educational background) Use of collateral information (e.g., test-taking behavior or test attitudes) Assessment of response styles (e.g., social desirability, acquiesecence) Use of test–retest, training and/or intervention studies
Item bias	Judgmental methods of item bias detection (e.g., linguistic and psychological analysis) Psychometric methods of item bias detection (e.g., Differential Item Functioning analysis) Error or distracter analysis

Source: Van de Vijver and Tanzer 1997 *European Review of Psychological Assessment* (reproduced with the permission of Swets and Zeitlinger)

average score on the item. The score on the construct usually is derived from the total test score. If a geography test administered to pupils in Poland and Japan, contains the item 'What is the capital of Poland?' Polish pupils can be expected to show higher scores on the item than Japanese students, even when pupils with the same total test score would be compared. The item is biased as it favors one cultural group across all test score levels. Of all bias types, item bias has been the most extensively studied; various psychometric techniques are available to identify item bias (e.g., Camilli and Shepard 1994; Holland and Wainer 1993).

An overview of common ways of addressing bias is given in Table 1.

2. *Types of Equivalence*

Elaborating on categorizations in the literature, four different types of equivalence are proposed here (cf. Van de Vijver and Leung 1997). The first type is labeled construct inequivalence. It amounts to comparing apples and oranges (e.g., the comparison of Chinese and Western filial piety, discussed above). Comparisons lack an attribute for comparison, also called tertium comparationis (the third term in the comparison). The second is called structural (or functional) equivalence. An instrument administered in different cultural groups shows structural equivalence if it measures the same construct in both groups (e.g., Raven's Standard Progressive Matrices test has been found to measure intelligence in various cultural groups). Exploratory factor analyses followed by target rotations or confirmatory factor analysis of correlation matrices (structural equation modeling) may be applied to examine structural equivalence. Structural equivalence does not presuppose identity of measures across groups. The measures may use different stimuli across groups. If different operationalizations have been chosen, structural equivalence can be examined by comparing nomological networks across groups.

The third type of equivalence is called measurement unit equivalence. Instruments show this type of equivalence if their measurement scales have the same units of measurement and a different origin (such as the Celsius and Kelvin scales in temperature measurement). This type of equivalence assumes interval- or ratio-level scores (with the same measurement units in each culture). It applies when a bias factor with a fairly uniform influence on the items of an instrument affects test scores of different cultural groups in a differential way. Social desirability and stimulus familiarity may exert this influence. Observed group differences in scores are then a mixture of valid cross-cultural differences and measurement artifacts. When the relative contribution of both sources cannot be estimated, the interpretation of group comparisons of mean scores remains ambiguous. Multigroup comparisons of confirmatory factor analytic models have been utilized to examine measurement unit equivalence. This technique, based on comparisons of covariance matrices, can identify bias sources that affect the covariance of items or tests but it cannot differentiate between valid differences in mean scores and bias sources with a uniform influence on all parts of an instrument.

Only in the case of scalar (or full-score) equivalence can direct comparisons be made; it is the only type of equivalence that allows for the conclusion that average scores obtained in two cultures are different. This type of equivalence assumes the same interval or ratio scales across groups. Conclusions about which of the latter two types of equivalence applies are often difficult to draw and controversial. For example, racial differences in intelligence test scores have been interpreted as due to valid differences (scalar equivalence) and as reflecting measurement artifacts (measurement unit equivalence). Scalar equivalence assumes that the role of bias can be safely neglected. The demonstration of scalar equivalence draws on inductive argumentation. Therefore, it is easier to disprove than to prove scalar equivalence. This can be made plausible by measuring presumably relevant sources of bias (such as stimulus familiarity or social desirability) and showing that they cannot statistically explain observed cross-cultural differences in a multiple regression or covariance analysis.

The distinction between the latter two types of equivalence is immaterial when comparing experimental conditions or changes across cultures (e.g., developmental trajectories or training effects). Scales that show measurement unit equivalence, measure changes at the level of full score equivalence.

Structural, measurement unit, and scalar equivalence are hierarchically ordered. The third presupposes the second, which presupposes the first. Moreover, higher levels of equivalence are more difficult to establish. It is easier to demonstrate that an instrument measures the same construct in different cultural groups (structural equivalence) than to demonstrate numerical comparability across cultures (scalar equivalence). On the other hand, higher levels of equivalence allow for more detailed comparisons of scores across cultures. Whereas in the case of structural equivalence, only factor structures and nomological networks can be compared, scalar equivalence allows for more fine grained analyses of cross-cultural similarities and differences, such as comparisons of mean scores across cultures in t tests and analyses of (co)variance.

2.1 *Linguistic Equivalence*

The concept of linguistic equivalence is developed in multilingual studies. Versions of an instrument in

different languages show linguistic equivalence if these have the same characteristics that are relevant for the measurement outcome such as meaning, connotations of words and sentences, comprehensibility, and readability. Linguistic equivalence can be jeopardized by various sources, such as incorrect translations, words that are hard or impossible to translate (e.g., the English 'distress' does not have an equivalent in many languages), idiomatic expressions and metaphors (e.g., 'feeling blue'), and imprecise quantifiers ('rather often').

Because linguistic equivalence is not always guaranteed by a literal translation, it has become increasingly popular to utilize adaptations. In an adaptation, parts are changed (instead of literally translated) with the aim to improve an instrument's suitability for a target group.

Many studies employ a translation–back-translation procedure (Brislin 1986, Werner and Campbell 1970). This amounts to a translation, followed by an independent back-translation and a comparison of the original and back-translated version, possibly followed by some alterations of the translation. Such a procedure provides a powerful tool to enhance the correspondence of original and translated versions that is independent of the researcher's knowledge of the target language. Yet, it also has some disadvantages. It puts a premium on literal reproduction; this may give rise to a stilted language use in the target version that lacks the readability and natural flow of the original. The problem may be compounded by translators' awareness of their involvement in a translation–back-translation procedure.

A second problem involves translatability. The use of idiom (e.g., the English 'feeling blue') or references to cultural specifics (e.g., references to country-specific public holidays) or other features that cannot be represented adequately in the target language challenges translation–back-translations designs (and indeed all procedures in which existing instruments are translated). During the 1990s there was a growing awareness that translations and adaptations require the combined expertise of social and behavioral scientists (with a competence in the construct studied) and experts in the target language(s) and culture(s). In this so-called committee approach in which the expertise of all relevant disciplines is combined, there is usually no formal accuracy check of the translation. Usage of the committee approach is popular in large international bodies in which texts are translated in many languages like the United Nations and the European Union.

When versions in all languages are developed simultaneously, a procedure called 'decentering' (Werner and Campbell 1970) can be used. No single instrument or cultural group is then taken as starting point; individuals from different cultures jointly develop an instrument, thereby reducing the risk of introducing unwanted references to a specific culture.

The judgmental evidence of the designs to enhance linguistic equivalence can be easily combined with statistical approaches to establish equivalence. Reports of multilingual studies often provide a combination of judgmental–linguistic and empirical–statistical evidence to demonstrate the adequacy of an instrument and its translation. There is a tradeoff between the type of translation and the level of equivalence that can be obtained. When most or all questions of an instrument are adapted, structural equivalence is the highest level possible. When most or all items are literally translated, measurement unit and structural equivalence can be obtained. Recent statistical advancements in item response theory and structural equation modeling have made it possible to retain scalar equivalence, even when not all stimuli are literally translated (provided that all items measure the same underlying construct in each group).

3. *Sampling Cultures and Subjects*

Cross-cultural studies can apply three types of schemes to sample cultures. Three types of sampling can be envisaged. The first is probability (or random) sampling. Because of the large cost of a probability sample from all existing cultures, it often amounts to stratified (random) sampling of specific cultures (e.g., Western cultures). The second and most frequently observed type of culture sampling is convenience sampling. The choice of cultures is governed here by availability and cost efficiency: researchers decide to form a research network and all participants collect data in their own country. In the third type, called systematic sampling, the choice of cultures is more based on substantive considerations. A culture is deliberately chosen because of some characteristic, such as in Segall et al.'s (1966) study in which cultures were chosen on the basis of features of the ecological environment such as openness of the vista.

In survey research there is a well-developed theory of subject sampling (Kish 1965). In the area of cross-cultural research three types of sampling procedures of individuals are relevant as they represent different ways of dealing with confounding characteristics. The first is probability sampling. It consists of a random drawing from a list of eligible units such as persons or households. Confounding variables are not controlled for. The second type is stratified sampling. A population is stratified (e.g., in levels of schooling or socioeconomic status) and within each stratum a random sample is drawn. The purpose of stratification is the control of confounding variables (e.g., matching on number of years of schooling). The procedure cannot be taken to adequately correct for confounding variables when there is little or no overlap of the cultures (e.g., comparisons of literates and illiterates). The third procedure combines random or stratified

sampling with the measurement of control variables. The procedure enables a statistical control of ambient variables (e.g., using an analysis of covariance).

4. Individual- and Country-level Studies

The 1990s saw a growing interest in studies combining individual- and country-level data. Two kinds of studies have been reported. In multilevel hierarchical models (Bryk and Raudenbush 1992), a regression model is used to explain individual variation (e.g., explaining pupils' achievement scores on the basis of their intelligence) and class, district, or country variation (e.g., the explanation of the relationship between intelligence and achievement by means of school quality indicators). The second line of research involves the study of the same phenomena at different levels of aggregation (multilevel covariance structure analysis or multilevel factor analysis, Muthén 1994). From a conceptual point of view this line is more complicated, because it is well documented that (des)aggregatation can lead to methodological artefacts such as the ecological fallacy (see *Ecological Fallacy, Statistics of*), the incorrect application of culture-level characteristics to individuals. In each country a proportion of women is pregnant, but obviously, this proportion does not apply to any individual woman. In addition, equivalence issues have to be dealt with (Leung 1989). Hofstede's famous study of values is based on country characteristics; the four dimensions he reported (individualism, power distance, uncertainty reduction, and masculinity–femininity) are characteristics of countries and their applicability to individual behavior cannot be taken for granted and has to be established. Multilevel covariance structure and factor analysis are powerful tools to examine the equivalence of phenomena at different levels of aggregation, answering questions like the structural (in)equivalence of concepts like individualism–collectivism at individual and country level. For these and various other concepts the structural equivalence at different levels of aggregation is still unresolved.

Cross-cultural Study of Education

Results of educational research from Western cultures may not be universally valid. Extending research to other cultures may reveal relevant phenomena and processes and allow the specification of universals and culture specificities as influenced by genetic and environmental factors relevant to development and learning.

Education is understood here as cultural transmission resulting from enculturation and socialization in informal or formal learning contexts. It includes intentional and unintentional influences on a person's thinking and behavior. Culture is not conceived of as a set of independent variables 'outside' of education influencing people in a unidirectional and unavoidable way. Culture is understood here as a certain commonality of meaning, customs and rules (not a homogeneous entity) shared by a certain group of people and setting a complex framework for learning and development.

1. Formal and Informal Education

Formal and informal educational contexts are of special interest for studies on education. Both contexts provide opportunities for and constraints on individual learning and development. These may function in different ways, depending on the cultural context.

1.1 Differentiation of Formal and Informal Education

Formal education, following the 'Western model,' consists of systematic instruction in 'universal' knowledge and skills, provided at prearranged times and places by specialists. Formal education also exists as indigenous education including initiation ceremonies, instruction provided in age-grade societies, and various forms of religious schooling, such as Quranic schools. There are cultural differences in the institutionalization of formal education, e.g., in the organization of the educational system, the relation between public and private schools, the length of compulsory schooling, the number of years of elementary and secondary schooling, the school curriculum, teaching, and instruction.

Informal education includes life-long socialization influences from interacting, e.g., with family members or peers in settings related to culture-specific values and norms useful for everyday experience. In all cultures, education takes place informally in everyday situations, in response to momentary needs, and sometimes simply involves observation and imitation (for a summary, see Segall et al. 1999, pp. 78–88). *Informal traditional* education including moral and spiritual aspects as well as manual labor, is in essence adapted to the local cultural system which it tends to perpetuate. According to Désalmand (1983), characteristics of traditional (African) education as compared with schooling are as follows: it is provided everywhere, all the time, and by everyone; it is closely tied to the environment, integrated with productive work, and addresses the needs of the society. It emphasizes cooperation rather than individual competition; everyone can be successful. Parents and elders play an important role, relations among participants are personalized, and occurs in the local language.

As Bruner (1996, p. ix) remarks: 'Schooling is only one small part of how a culture inducts the young into its canonical ways. Indeed, schooling may even be at odds with a culture's other ways of inducting the young into the requirements of communal living.'

1.2 Transmission of Know-how in Informal Education

1.2.1 Apprenticeship. An essential process in informal education is apprenticeship. Informal education can transmit specific, economically useful knowledge and often follows a very structured, albeit implicit, pedagogy. This was demonstrated in Greenfield and Lave's (1982) study of weaving apprenticeships among Zinacanteco girls in Mexico and tailoring in Liberia. Masters employ scaffolding to effect a progression within each step, allowing trial and error only if there is no material risk. Informal education thus involves more than just observation and imitation. Verbal instruction is an integral part of the apprenticeship process, but the pupils seldom speak and do not ask questions.

Based on her studies with Nahua Indians of Mexico, Chamoux (1986) provides a typology of know-how (or skill) and its transmission that distinguishes between 'incorporated know-how' and 'the mastery of algorithms.' The former results from personal, concrete experience; one may have a certain skill but not be able to describe it. It is therefore not easily transmitted by formal teaching and is best acquired through apprenticeship, i.e., by participating in the activity.

Incorporated know-how may be general or particular, i.e., transmitted to everyone or only to certain individuals who become specialists. Transmission occurs either with a master or through gradual immersion; the latter is possible in the case of cultural activities that can frequently be observed.

1.2.2 Ethnotheories. 'Indigenous theories of education' structure the pedagogical modalities in a coherent fashion (Chamoux 1986, Super and Harkness 1997). In some types of traditional informal education (e.g., for Nahuas), observation is preferred to instruction as a learning method, and may be combined with low pressure to learn and high preference for the will of the apprentice.

1.2.3 Guided participation in cultural activity. The way caretakers structure the activities of children is

another characteristic, studied by Rogoff et al. (1993), who observed caregivers and their toddlers in four settings: Mayan Indians in a small town in Guatemala, a tribal village in India, and two middle-class urban neighborhoods in Turkey and the USA. In the first two communities, children were nonverbally encouraged to observe adult activities; they were basically responsible for their own learning. In the two middle-class settings, mothers tended to structure explicitly their children's learning, used verbal interactions, and provided 'lessons' removed from the context of ongoing activities. They also tended to organize their schedule to separate adult activities from time devoted to interacting with children. In the two rural communities, adults shared their attention among a variety of activities, managing several tasks at the same time, including socializing with other adults and facilitating the children's involvement and learning. The behavior of the middle-class mothers can be seen as a preparation for schooling. Rogoff et al. (1993) suggest that many school reforms move in the direction of group work in which the children become more responsible for their own learning.

1.2.4 Schooling and apprenticeship. The transferability between practical and school-based knowledge is of special importance in education research. Delbos and Jorion (1984) observed how empirical knowledge is conveyed in traditional professions in France in contrast to scientific, school-based knowledge. In activities where competence is acquired through experience within the family, knowledge is transmitted not explicitly but through participation in daily life and as if it were an unquestionable truth. While this knowledge is specific, school knowledge is rather general and abstract but transferability does not always live up to the facts.

2. *Educational Effects*

One aim of education research is to specify conditions for development and learning. However, it is difficult to derive general conclusions on the basis of only Western-world theorizing and methodology.

2.1 *Effects of Different Educational Systems*

What are the effects when an educational system is implanted into another culture? The export of Western-type schooling into 'traditional' societies is often criticized because of its lack of cultural relevance and practical use. Julius Nyerere (1967) (a former President of Tanzania and also a teacher) was one of the first critics. Serpell and Hatano (1997) provide excellent coverage of the inportation of Western-type schooling during colonial times (in what they call 'hegemonic imposition') and summarize the present situation for Africa: 'The entire design of public schooling in Africa tends to bear very little relevance to the demands of economically productive adult life in rural settings, where the vast majority of school-leavers will spend their lives' (p. 363).

In contrast, Kagitçibasi (1996) points out the many positive effects of schooling, notably in terms of health promotion and women's rights, and is concerned that critiques of schooling may impede the implementation of policies to attain the UNESCO goal of 'education for all.'

Effects of formal and informal education are difficult to disentangle since both interact. Sometimes cumulative effects on learning can be observed when the educational goals of family and school fit together. This may be one reason for the higher achievement of Asian as compared with North American students (Stevenson 1988). For example, in Japan and Korea, teachers and mothers share the same educational values and coordinate informal and formal education.

Transfer of education between different contexts is easier when the same goals are functional. For example, the traditional Quranic education attempts to train memorizing by teaching fixed formulas, thus providing elements of social and cognitive skills required by modern schooling (Wagner 1988).

Negative effects on learning occur in the case of conflicting or nonmatching educational goals, e.g., in the case of involuntary acculturation when children from a minority group attend a majority-group school. The attainment of certain educational goals (e.g., acculturation, achievement) profits from the coordination of informal and formal education by cumulating their functional properties.

The effects of formal or informal education or their combination differ according to developmental age and depend on the person, the environmental conditions, and the adaptive function of the specific skill. According to studies by Wagner and Spratt (1987) language background and preschool experience have different effects on the reading acquisition of rural and urban Moroccan children in the first year of primary school. 'Modern' and 'traditional' preschooling need not differ with respect to higher level reading measures. The traditional Quranic preschool can be beneficial for literacy acquisition in Arabic. However, differences in literacy between urban and rural (or Arabic-speaking and Berber-speaking) children in Morocco caused by maternal language and preschooling could not be eliminated by mainstreaming modern primary schools. The effects of an urban environment were longer lasting than those of language background and preschool experience. These studies are relevant for analyzing effects of multicultural education.

Formal schooling can influence general and domain-specific skills (e.g., literacy, logical thinking). Studies on Quranic-schooled adults in Liberia which isolate the effects of schooling and literacy show that literacy increases specific memory skills but can be acquired without Western schooling (Scribner and Cole 1981). Formal schooling can profit from informal education in contexts which have practical significance for arithmetic skills. However, informally acquired arithmetic skills in comparison to school-based algorithms have their limits (for a review, see Segall et al. 1999).

2.2 International Comparison of School Achievement

Formal schooling usually follows the 'Western model,' giving preference to such cognitive skills that facilitate success in highly technological and scientifically structured environments.

The Program for International Student Assessment (PISA) aims to provide nationally representative data from OECD countries on 15-year-old students' knowledge and skills in mathematics, science, reading, and cross-curricular competencies. Three large-scale comparative studies (First, Second and Third Mathematics and Science Study; FIMS, SIMS, TIMSS) by the policy oriented International Association for the Evaluation of Educational Achievement (IEA) demonstrate significant differences in school achievement (for a review, see Baumert 1998). Even among societies with a common language (Switzerland, Germany, Austria), significant differences occurred. Comparisons of mathematical achievement demonstrate significantly higher achievement of Japanese and Taiwanese as compared with North American children (Stevenson and Stigler 1992). High-achieving students from Asia as compared with Germany and North America show better mathematical performance. The test scores of Chinese and Japanese students in mathematics and science are higher than those of their American peers at all age groups (Stevenson et al. 1993).

These differences are presumably related to several factors, including differences in educational systems, teaching and learning styles, time use, cultural values, and relations between informal and formal education (e.g., Stevenson 1988). East Asians place a higher value on education, focus on the role of effort in academic achievement, hold higher aspirations, devote more time in academic effort, and report more parental involvement in their children's academic work (Stevenson et al. 1993). Differences in cognitive skills can be mediated by motivational and socioemotional factors (Kornadt et al. 1980, Kornadt and Trommsdorff 1996). Whether these are also affected by education has to be studied in future research.

3. Outlook

An increasing number of studies include culture in educational research. However, systematic comparisons are rare. Also, results on effects of culture and education are not consistent. This is related to several problems.

One problem lies in the fact that the focus of research was on either informal or formal education as *separate settings* ignoring their specific and possibly cumulative effects. School quality, family, and peer groups interact in various ways depending on the cultural context, thus affecting development and learning (Chamoux 1986).

Another problem lies in the fact that possible effects of genetic dispositions have rarely been studied and the role of education often has been overestimated. Research in the tradition of the nature–nurture controversy focusing on either biological or environmental conditions ignore the role of the active, self-reflective person (the learner as the producer of his/her development). Future research should take into account the impact of genetic dispositions on the development of abilities and the readiness for learning certain skills, and on interactions between environment (education) and person (Weinert and Perner 1996).

A further theoretical and methodological problem is the validity of the data. This is partly due to experimental artifacts and the context dependence of the behavior studied. Also, much cross-cultural research is based on Western theories and methods without explicit reference to culture. Often the role of certain skills in a specific culture is neglected. The functional equivalence of variables and measurements needs to be ascertained for valid comparisons. Here problems of etic (comparative) and emic (culture-specific, indigenous) methods are to be solved. Both approaches are necessary to arrive at universal and culture-specific theorizing (Trommsdorff 1986, Segall et al. 1999).

Education research needs a solid theoretical frame. An eco-cultural approach seems promising since it relates cultural conditions to educational and psychological processes. One basic assumption is that in the case that educational goals and practices are relevant in a culture, one can expect qualified development of related skills. For example, in hunting as compared with agricultural societies, spatial skills are needed for survival; they are more valued and more efficiently learned. In some cultures, holistic rather than analytic problem solving and group discussion rather than individual reflection are valued; educational goals are defined accordingly (for a review, see Serpell and Hatano 1997). Comparative research on intelligence is another example of how the culture-specific meaning was clarified (for a review, see Berry 1984). Conceiving intelligence as the adaptation of mental activities to the environment requires culture-specific measures of

'intelligent' action and appropriate educational conditions for its development.

An eco-cultural approach starts from the insider's understanding and specifies what has to be accomplished (in various domains of behavior) in order to live in a certain cultural context. This allows one to link cultural context and cognitive skills and to study indigenous actions as part of the respective culture and as an indicator of 'practical intelligence.' A 'practice theory of culture and cognition' attempts to analyze educational processes affecting cognitive skills (Wagner and Spratt 1987). Related research on 'everyday cognition' follows the sociohistorical approach rooted in Vygotsky's writings (for a review, see Segall et al. 1999).

These approaches are linked to the theoretical framework of the developmental niche proposed by Super and Harkness (1997) who assume that three subsystems surround the child: the physical and social contexts in which the child lives, the cultural educational practices, and the psychological characteristics of the caretaker, including their ethnotheories.

The developmental niche adapts to social change and thus allows for adaptation on the individual level, including acculturation. This theorizing is related to Bronfenbrenner's work and the eco-cultural framework suggested by Segall et al. (1999).

These theoretical approaches assume that education is linked to the given context which provides constraints and resources for learning and development. This needs further empirical testing. Once a solid theory has been developed, problems of measurement and the application of education research will be more easily solved.

Cross-modal (Multi-sensory) Integration

1. Multiple Sensory Representations in the Brain

Large brains generally are found in large animals. This is primarily because the body evolves in concert with the neural architecture necessary to handle the information it provides and to control its movement. Although there are certainly exceptions to the rule, and the human brain is disproportionately large, the actual acumen of the host is not as relevant to overall evolution of brain size as one might think, and even big dim-witted animals can have big brains.

Because animals have multiple senses, and each requires a good deal of neural circuitry to make them work, much of even the largest brain ends up being devoted to representing the sensory complex. Thus, the cerebral cortex, generally considered the highest stage of information processing and the seat of perception, appears to have a large portion of its area organized into a succession of higher order sensory (and motor) processing stations. Thus far, a minimum of 32 visual, 15 auditory, and 8 somatosensory areas have been identified in the primate cortex. Somehow, though no one really knows how, the co-ordinated operation of multiple cortical areas, each responsible for dealing with a limited set of stimulus qualities, produces a unified perceptual experience.

That so much of the brain is devoted to sensory processing and its associated motor commands is due to the fact that survival depends on the speed and accuracy with which an organism can evaluate external events and properly react to them. Consequently, having many senses is generally better than having few and, despite the increased metabolic cost of building and maintaining the necessary underlying brain circuits, there are significant overall gains. For one thing, sensory modalities can substitute for one another in different circumstances (e.g., sight and touch substitute for vision in the dark). For another, multiple senses allow the organism to simultaneously sample very different forms of environmental energy, changes in any one of which may provide important information about an event. Multiple inputs from different senses also increase the likelihood of correctly identifying a given event, for it may be difficult to distinguish on the basis of a single sensory dimension (two events may sound alike, but look different).

2. Multi-sensory Integration and Perception

Yet, the brain is able to make more of its multiple senses than might at first be apparent, and by synthesizing information from two or more modality-specific inputs it creates something entirely new. At the level of sensation/perception, the new product of this 'multi-sensory integration' is a unique experience. For example, what we think of as 'taste' is not due solely to the signals the brain receives about the food-induced chemical changes on the tongue. Rather, taste represents a synthesis of signals derived from these chemical changes (gustatory) and those from the aroma (olfactory) and texture (somatosensory) of the food. Thus, multi-sensory integration provides a mechanism for producing much richer and more diverse sensory experiences than would otherwise be possible. At the neural level, multi-sensory integration appears to create a new, amplified signal that is greater than that produced in response to either of its constituent modality-specific cues. In fact, this signal is often greater than the sum of the constituent responses; an excellent biological example of the whole being greater than the sum of its parts. Such an enhanced sensory signal is strongly correlated with an increased probability of a behavioral response. Furthermore, as will be shown below, the multi-sensory amplification process is selective; it increases the brain's ability to detect and identify events by amplifying only those cross-modal sensory signals whose spatial and temporal properties indicate that they are likely to have a common origin. Indeed, those cross-modal signals that appear to be derived from different events can be minimized via these same synthetic mechanisms. When the stimulus conditions do favor an enhanced multi-sensory signal, not only is the detection of the event and the probability of an appropriate response enhanced, but the speed of the response is increased as well. These multi-sensory consequences have been demonstrated in both animals (Frens et al. 1998, Stein et al. 1989) and humans (Frens et al. 1995, Goldring et al. 1996, Hughes et al. 1994). Furthermore, multisensory integration has been associated with enhancing object recognition (Giard and Peronnet 1999, O'Hare 1991), increasing the apparent intensity of a signal (Stein et al. 1996) and aiding in speech perception (see Massaro and Stork 1998).

It has been known for some time that multiple sensory inputs must be bound together to produce what we experience as a 'unitary' perceptual experience, and that this 'binding' process can have potent perceptual consequences. Yet, we are largely unaware of its actual operation. Perhaps we don't notice the process because it is the normal mode of brain operation. For example, seeing a speaker's face enhances our ability to perceive what is being said (see Sumby and Pollack 1954). Yet, we are rarely conscious of this except, perhaps, in a noisy room where the benefit of combined visual-auditory inputs is particularly important and, as a result, we try very hard to focus on the speaker's face. The consequence is an enhancement of the brain activity that underlies speech perception (e.g., see Calvert et al. 1999, Sams et al. 1991) induced by the congruent visual (lip movement) and auditory (spoken words) stimuli we receive and integrate. Indeed, visual-auditory integration in speech perception is so seamless that we are quite

surprised when we experience the so-called 'McGurk effect.' Here, the coupling of the sound of one word with the lip movements of another produces a cross-modal product that differs from either. One example of this is hearing the word 'bows' while seeing lip movements that form the word 'goes' and perceiving 'doze' or 'those.' This cross-modal illusion underscores the potent multi-sensory interactions that normally occur between vision and audition.

Whereas the perceived meaning of the signal is altered in the McGurk effect, the perceived location of the signal is affected in another compelling visual-auditory illusion, the 'ventriloquism effect' (Howard and Templeton 1966). In this illusion a visual cue (e.g., movement of the lips) provides a signal that alters the apparent location of the source of the sound. We commonly experience this illusion when watching a movie. Voices always seem to be coming from the appropriate characters, regardless of their location or movement on the screen and despite the fact that all the sounds actually originate from the same location—the speakers at the sides of the screen. There are many other compelling illusions involving different senses, such as the 'parchment skin' illusion, in which the apparent texture of the skin is changed as a consequence of coupling the sensation of rubbing of the fingers with a grating sound that is played through earphones the subject is wearing (Jousmaki and Hari 1998), or the oculogravic illusion (Graybiel 1952), in which vestibular cues alter visual perceptions. Although the neural basis of these individual illusions is poorly understood at present, we have begun to understand some of the general principles by which individual neurons in the brain combine simple stimuli from different sensory inputs to produce a multisensory signal. It is believed that understanding these principles will help us better understand the behavioral and perceptual consequences of multi-sensory integration.

3. *Multi-sensory Neurons and the Superior Colliculus (SC)*

In order to effect multi-sensory integration at the level of the single neuron, there must be sites in the brain where neurons receive converging inputs from different senses. Such regions have been found at nearly every level in the central nervous system (see Stein and Meredith 1993), thereby paralleling areas that are devoted to processing information for each individual sensory modality. As a consequence of these seemingly parallel systems, higher animals have developed a curious duality: some areas of the brain are specialized for processing information on a sense-by-sense basis, and probably give rise to the peculiar subjective impressions that are so closely bound to one modality or another (e.g., the perceptions of color, pitch, tickle, or itch). Conversely, other areas are specialized for information processing regardless of the specific sense or senses from which that information is derived. These latter areas depend on a convergence of inputs from different senses onto a common set of (multisensory) neurons.

One of the best known structures in which multisensory convergence occurs is found in the midbrain: the superior colliculus (SC). In fact, researchers have leaned heavily on the responses of multi-sensory SC neurons to develop a model that is helpful in understanding the general neural properties of multisensory integration, and this has proved to be an excellent strategy for a host of reasons. First, the SC is richly endowed with converging visual, auditory, and somatosensory inputs, and thus has many multisensory neurons that can be studied electrophysiologically. Second, the SC is also known to play an important role in producing motor actions that are guided by sensory stimuli. Specifically, it is involved in generating orienting behaviors to stimuli in contralateral space and, thus, for example, mediates rapid shifts of gaze (i.e., eye and head movements) to objects of interest. These factors make it possible to use the same structure to explore the principles governing multi-sensory integration at the neuronal and behavioral levels.

A multi-sensory SC neuron has multiple receptive fields, one for each sensory modality to which it is responsive. A receptive field defines the area of sensory space (e.g., visual space, auditory space, somatosensory space) where a given stimulus will be effective in activating the neuron. For multi-sensory neurons, their different receptive fields are in spatial register with one another. For example, a visual-auditory neuron with a visual receptive field in central space will be responsive to auditory cues in an overlapping region of auditory space as shown in Fig. 1. The spatial register among the modality-specific receptive fields of a multi-sensory neuron plays a critical role in its synthesis of cross-modal cues. Such register is characteristic of multisensory neurons regardless of where they are found in the nervous system, and is maintained even if, for example, one set of peripheral sensory organs moves. Thus, for example, any eye movement will shift visual space relative to auditory (head-axis) or somatosensory (body-axis) space because the retina and its receptor cells have moved. Rather than disrupt receptive field alignment, movement-induced misalignment of sensory reference frames sets into motion compensatory neural mechanisms that attempt to maintain receptive field register. Thus, a shift in eye position to the right produces a rightward shift in the auditory receptive field of an SC neuron (Harrington and Peck 1998, Hartline et al. 1995, Jay and Sparks 1984). Similarly, there is even evidence that the somatosensory receptive fields of visual-somatosensory neurons show compensatory changes as a consequence of eye movements (Groh and Sparks 1996). Although the mechanisms

Figure 1
The individual receptive fields of a visual-auditory neuron are in good spatial register. The circles shown here are schematic diagrams of visual (left) and auditory (right) space. The intersection of the horizontal and vertical meridians depicts a point directly in front of the subject, and each concentric circle represents 10°. The frontal half of auditory space is shown by the central sphere, and the caudal half is represented by the two hemispheres that have been split and folded forward. The respective receptive fields of a typical multisensory neuron are shown by the shading. Note that superimposing the diagrams of visual and auditory space will show that most of the two receptive fields overlap each other. S = superior, I = inferior, N = nasal, T = temporal

underlying these dynamic shifts in receptive fields are not well understood, using the retina as a referent for shifting nonvisual receptive fields in the SC reflects its principal role in generating gaze shifts to targets of any modality, including those that are multi-sensory. This is not the case everywhere multi-sensory neurons are found. In regions of premotor cortex, where visual-somatosensory neurons are found and whose activity generates limb rather than eye movements, movements of the limb produce compensatory changes in the location of visual receptive fields (Gentilucci et al. 1983, Graziano et al. 1994). Once again, cross-modal receptive field register is a key element in the maintenance of a modality-independent coordinate frame to properly code movement.

4. *Principles of Multi-sensory Integration in Single SC Neurons*

4.1 *Spatial*

The enhanced multi-sensory response of a neuron depends on stimuli having access to its two (or more) receptive fields simultaneously or within a short window of time. Given the spatially overlapping nature of receptive fields in multi-sensory neurons, the activating stimuli should derive from the same location in space, such as when they originate from the same event. The consequent multi-sensory response typically is a train of discharges that contains more impulses than one evoked by either of the modality-specific stimuli. Indeed, if the modality-specific responses are themselves weak, the response to the combined stimulus often exceeds the arithmetic sum of the modality-specific responses (Fig. 2).

If, however, the stimuli are derived from different locations (e.g., originate from different events), so that one stimulus falls outside its receptive field and is spatially discordant with the other stimulus, no such response enhancement is produced. In fact, under such circumstances there is a good probability that the opposite effect, response depression, will occur. In such cases, even vigorous visual responses can be abolished (Fig. 2). These changes at the single neuron level are reflected at the behavioral level as enhanced attentive and orientation responses to spatially coincident cross-modal stimuli, and depressed attentive and orientation responses to spatially disparate cross-modal stimuli (Stein et. al. 1989).

These opposing effects of the same stimuli are believed to be due to a neuron receiving synergistic excitatory inputs when its two input channels are stimulated by spatially aligned stimuli (both stimuli fall within the excitatory receptive fields of that neuron), but, because some receptive fields have inhibitory regions at their borders, response depression can be explained by the antagonism between the inhibitory input from the stimulus outside the receptive field and the excitatory input produced by the stimulus within its receptive field (Kadunce et al. 1997).

4.2 *Temporal*

Integrated multi-sensory responses also depend on the relative timing of the stimuli. When the interval between the occurrence of the stimuli is too large, they are recognizable in the neuronal response as discrete events. In other words, no integration takes place. Nevertheless, for any given neuron this temporal 'window' may be several hundred milliseconds and generally is predictable from the duration of its response to the stimulus that causes the earliest excitation. So, for example, if a somatosensory stimulus elicits a response that lasts 200 milliseconds, a multi-sensory interaction will occur if the activation produced by a stimulus of a second modality occurs during that period (Meredith et al. 1987, Wallace and Stein 1997).

This is important because even though different senses may be activated by the same event, the speed with which the modality-specific components activate a multi-sensory neuron can differ substantially (auditory and somatosensory information reaches SC neurons in 10–25 ms, while visual information requires

Figure 2
The presentation of two visual-auditory stimulus pairs, that differed only in their spatial coincidence, resulted in very different neural responses. Top left: within the visual (dark shading) and auditory (lighter shading) receptive fields of this multi-sensory neuron are icons depicting the close spatial coincidence of a moving bar of light (arrow) and a stationary auditory stimulus (speaker). At the bottom are shown the neuron's average responses to each stimulus alone (V = visual, Ai = auditory within the receptive field) as well as to their combination (VAi). The dark bar shows that the multi-sensory response exceeded the arithmetic sum of the individual visual and auditory responses (multi-sensory enhancement). Right: when the auditory stimulus was presented far from its visual counterpart and outside its receptive field (Ao = auditory outside the receptive field) it abolished the visual response (multi-sensory depression)

40–120 ms). If precise coincidence were required, very few multi-sensory interactions would take place. Nevertheless, the temporal interaction window is finite and different neurons respond best to different stimulus asynchronies. Generally speaking, the magnitude of the interaction reflects the degree to which the modality-specific activation patterns overlap in time. Thus, the magnitude of the interaction diminishes rapidly as this period of temporal overlap declines (Fig. 3). In some cases, temporal intervals that are transitional between those that produce enhanced responses and those that produce two independent responses give rise to response depression. In the case of visual-auditory neurons, the ability to respond differentially to stimuli with different input latencies suggests a tuning to events occurring at different distances from the animal. Whether there is some systematic organization of these neurons that may be helpful in localizing stimuli in 3-dimensional space remains to be determined.

4.3 Inverse Effectiveness

The degree to which the response to a multi-sensory stimulus exceeds that to either of the unimodal component stimuli is most often inversely related to the effectiveness of the modality-specific stimuli. This makes intuitive sense if we consider the possible functional consequences of multi-sensory enhancement. By definition, very effective stimuli evoke strong neural responses and are very likely to elicit a behavioral response. Thus, if the objective of multisensory enhancement is to increase the probability of detecting and/or responding to a stimulus, there would be little gained from augmenting an already vigorous modality-specific response. On the other hand, substantial benefit might be had by combining the influences of weak modality-specific stimuli. But what is to be gained from this? One could argue that increasing the sensitivity to relatively weak stimuli would make the system susceptible to environmental and/or neural 'noise.' However, one could counter this argument by noting that the probability that spatially and temporally coincident activation occurring on independent modality-specific channels by chance is low and that, more often than not, this circumstance would correspond to a real event in the external world. It is this sort of reasoning that has provided the impetus for many organizations (most prominently, industry and the military) to develop

Figure 3
The temporal window for a multi-sensory interaction in one visual-auditory neuron. The magnitude of a multi-sensory interaction is plotted here as a function of the interval between the onset of the two stimuli. Positive values represent response enhancements, negative values represent response depressions. Note that in this neuron simultaneous onset of the visual and auditory stimuli (V = A) produced the greatest multi-sensory enhancement. The enhancement was lost in this particular neuron when the visual stimulus preceded the auditory stimulus by more than 100 milliseconds or when the auditory stimulus preceded the visual stimulus by more than 50 milliseconds. Asterisks depict significant interactions, and the shaded region represents the temporal window within which significant multi-sensory interactions were obtained. Different neurons showed their maximum multi-sensory response at different cross-modal intervals (generally within 50–100 milliseconds of simultaneity) and had different temporal windows (generally 100–500 milliseconds)

Figure 4
Inputs from association cortex are critical for multi-sensory integration in the SC. Shown here is a representative example of an SC neuron whose sensory responses were examined before, during, and after temporarily deactivating association cortex by cryogenic blockade (cooling). Under control conditions (precool), this neuron exhibited a substantial multi-sensory response enhancement to the visual-auditory stimulus combination. When a region of association cortex (the anterior ectosylvian sulcus, AES) was deactivated (cool AES), this enhancement was abolished, even though the neuron retained its normal responses to the visual and auditory stimuli when presented individually. Following rewarming of AES (postcool), the enhanced multi-sensory response was reinstated.

sensor-fusion devices for navigation or to aid in searching for objects embedded in 'noisy' environments such as a forest or sea floor.

5. *The Essential Circuit For Multi-sensory Integration in SC Neurons*

One might reasonably assume that any neuron receiving inputs from two different sensory modalities would have the ability to integrate these inputs. However, this is not the case. Multi-sensory neurons in the SC receive converging modality-specific inputs from many sources (see Stein et al. 1993). However, recent experiments in cats have shown that modality-specific inputs derived from a region of cerebral cortex play a critical role in mediating multi-sensory integration in SC neurons (see Jiang et al. 1999, Wallace and Stein 1994). As shown in Fig. 4, when the SC is deprived of inputs from this region of the cortex (by reversible cryogenic blockade of cortical activity), SC neurons retain the ability to respond to inputs from different sensory modalities, but lose their ability to integrate them and thereby enhance their responses. Rather, they respond to combinations of cross-modal stimuli in much the same way as they would respond to the most effective of these modality-specific stimuli in isolation.

Presumably, these cortical deactivation-induced physiological changes in SC neurons would disrupt SC-mediated multi-sensory behaviors. A test of this was made by training animals to respond to visual cues in the presence or absence of auditory stimuli, and then testing them with or without this region of cortex deactivated (Fig. 5). When the cortex was temporarily deactivated (with either a local anesthetic injection or cryogenic blockade) there was no change in the animal's responses to the visual cue, but the ability of the auditory cue to enhance (spatially coincident stimuli) or degrade (spatially disparate stimuli) re-

Figure 5
Multi-sensory orientation behaviors are affected by cortical deactivation as predicted from physiological studies. Three cats were trained in a perimetry device (bottom) to orient to and approach an illuminated light-emitting diode (LED) for a food reward. During testing, the intensity of each LED was manipulated until each animal responded correctly to that LED on approximately 50 percent of the trials (black bars, visual alone). The pairing of the auditory (speaker) with the visual stimulus at the same spatial location dramatically enhanced the probability of a correct response (visual + auditory). However, during deactivation of the left AES (shading on animal's head), these multi-sensory behavioral response enhancements were compromised in the contralateral hemifield (V + A/AES deactivated). Data is shown for 5 stimulus locations from left to right: 45° left (−45°), 30° left (−30°), directly ahead (0°), 30° right (+30°) and 45° right (+45°). Asterisks denote where statistically significant effects of cortical deactivation were obtained. In agreement with the results of physiological studies (see Fig. 4), responses to a modality-specific (visual) stimulus alone were unaffected by cortical deactivation (not shown) (modified from Wilkinson et al. 1996)

sponses was severely disrupted (Wilkinson et al. 1996). These behavioral observations, coupled with the electrophysiological results described above, demonstrate that the neural circuit in the SC essential for multisensory integration must include inputs from the cerebral cortex.

6. *Commonalities in Multi-sensory Integration Across Species*

Although many of the specifics that were presented above were drawn from experiments in cats, most of the sensory features that characterize the SC of this animal are also found in every other laboratory species that has been examined thus far. Particularly important in the current context is the spatial register among the different receptive fields of multi-sensory neurons. This has been found in rodents, carnivores, and primates. The widespread nature of this scheme for coupling inputs from different sensory modalities, and its presence in neurons of the nonmammalian homologue of the SC, the optic tectum (see Stein and Meredith 1993), suggest that it was preserved during

the transition from nonmammalian to mammalian forms and is adaptable to a wide variety of ecological circumstances. Furthermore, its utility is not restricted to neurons involved in SC-mediated behaviors, as it is also characteristic of multi-sensory neurons in many neocortical areas (e.g., Bruce et al. 1981, Duhamel et al. 1991, Fogassi et al. 1996, Graziano et al. 1997, Ramachandran et al. 1993, Rizzolatti et al. 1981a, 1981b, Stein et al. 1993, Wallace et al. 1992), where such neurons are likely to be involved in functional roles very different from those involving the SC. The few experiments that have examined multi-sensory processes in cortical neurons have yielded similar results. Indeed, despite the observation that spatially disparate stimuli produce a weaker inhibitory interaction in cortex than SC, many of the same principles of multi-sensory integration appear to be operative in both areas. This lends credence to the notion that the fundamental principles of multi-sensory integration are likely to supersede structure, function, and species.

This does not mean that there are not substantial species differences in the stimuli that are effective in activating multi-sensory neurons or in differences in the roles played by multi-sensory neurons in different regions of the brain. Nevertheless, it does appear likely that despite the various specialized characteristics of multi-sensory neurons in different animals and/or structures, there exists a common set of principles by which they pool information from their different sensory channels. The presence of a common set of integrative principles that operate at different levels of the neuraxis is likely to provide a comparatively simple means of simultaneously enhancing or degrading (i.e., coordinating) the activity of different brain areas that cooperate in the production of an integrated behavior. It now remains to be seen whether that postulate is confirmed.

Cross-pressures: Political

1. The Fundamental Conceptual–Theoretical Structure

1.1 Basic Propositions

Cross-pressure theory has been employed primarily in the analysis of decision-making, asking how the decision-making process is affected by the presence of divergent and conflictual antecedent factors. The theory entered the study of politics in the 1940s and 1950s via the then new quantitative analysis of voting behavior.

As originally formulated, cross-pressure theory predicted three effects on voting behavior: (a) vacillation; (b) delay; and (c) withdrawal. In other words, the cross pressured voter (a) will shift back and forth in his/her voting choice; (b) will delay making a decision; and (c) will completely avoid making a decision and withdraw from participating in the election altogether.

The predictions of cross-pressure theory derive from three basic propositions:

(a) Cross-pressures (motivational inconsistencies), as all conflicts, give rise to psychic tension.

(b) High tension levels and tension increases are experienced as painful and low tension levels and decreases in tension are experienced as pleasurable.

(c) All living organisms (including humans) prefer pleasure to pain. They will act so as to keep tension low, by trying to prevent conflicts from arising. They will also act so as to reduce high levels of tension, by trying to resolve, remove, or disclaim conflicts (including cross-pressures).

These three prepositions, in one form or another, are part of practically all anticonflict theories, including cross-pressure theory. (For a discussion of the anticonflict nature of cross-pressure theory, see Sperlich 1971, pp. 179–221.) Unfortunately, propositions (b) and (c) are factually incorrect.

Proposition (b) embraces as axiomatic that high tension levels and tension increases will necessarily be painful. It ignores first, that adequate proof in support of this proposition has not been developed, and second, that there is considerable evidence to the contrary, to be found in various forms of deliberate stimulus and adventure seeking, voluntary risk-taking and exploratory behavior, as well as in the frequently unpleasant nature of low tension states (stimulus deprivation). For an extended review, see Sperlich 1971, pp. 52–9.

Proposition (c) takes unconstrained hedonism as axiomatic. It lacks any recognition that—however important pleasure may be—it is not the only goal that human beings can, or do pursue. It altogether ignores the vast compendium of philosophical and empirical inquiries into the complexity and multiplicity of human motivations. As examples can serve the various studies of gratification delay, of demonstrations of (costly) loyalty, of the keeping of (burdensome) promises, and of altruistic behavior—all of which involve choosing lower pleasure and/or greater pain (Sperlich 1971, pp. 85–9).

1.2 Externally and Internally Generated Cross-pressures

Several different types and constellations of factors are said to produce cross-pressures in persons, in-

cluding demographic, social, and cognitive (psychic) variables. The first two of these are experienced as external pressures brought to bear on the deciding person; the third factor is internal. Examples of demographic factors are occupation, education, religion, age, and ethnicity. Examples of social factors are memberships in family and friendship groups. (The crucial distinction here is comprehensive personal interaction, lacking for members of social groups.) The internal factors include preferences, attitudes, beliefs, and informational elements.

In respect to the external factors, traditional cross-pressure theory simply assumes what can neither be proven nor automatically granted: that the norms and preferences of the demographic and social aggregates to which the person belongs will generally be subjectively real. But to produce cross-pressures, these orientations first must be perceived, and second must become active elements in the person's decision-making processes. If a given voter belongs to religion A (the norm of which is to vote for party X) and also belongs to ethnic group B (the norm of which is to vote for party Y), he/she must first of all perceive the existence of the groups' majority preferences, and second must incorporate these positions into his/her own decision-making activities. Lack of information about group norms, as well as indifference to these norms, may invalidate the three cross-pressure predictions noted earlier. Traditional cross-pressure theory has neglected to take these matters into account, as it has failed to take into account the issue of causal ambiguity prominent in cross-pressure analyses (compare Lipset 1954, pp. 584–98, vs. Campbell et al. 1960, p. 83)—which is one of the explanations of its predictive failures.

Internal cross-pressures constitute a clearer causal case. It is not a vast conceptual leap to infer the presence of cross-pressures, if the voter states that he/she prefers the economic policies of candidate A, but the foreign policies of candidate B. Yet, other matters should be taken into account. For example, fluctuation, avoidance, and withdrawal are not likely to occur if, in the present example, the voter only cares about economic policies and is wholly uninterested in foreign policy matters. Again, traditional cross-pressure theory ignores the question of the relative strength of the elements in conflict—one more explanation of its predictive failures.

1.3 Cross-pressure Valences

Cross-pressures can have different valences, that is, different evaluative directions. The economic vs. foreign policy dissonance is an example of approach/approach (+/+) conflicts. Of course, it is also possible that the voter dislikes candidate A for one reason and candidate B for another—an example of avoidance/avoidance (−/−) conflicts. However, few voters will perceive only positive or only negative qualities in candidates or parties. The most realistic explication of cross-pressures is the double approach/avoidance (+ −/+ −) scenario, where the voter likes certain aspects and dislikes other aspects of each candidate or party. Or to state the matter in motivational language:

(a) Approach–approach conflict: the conflicting motivations simultaneously push the individual toward (make the individual desire) two incompatible choices, e.g., favoring two candidates, but being able to only vote for one of them.

(b) Avoidance–avoidance conflict: the conflicting motivations simultaneously push the individual away from (make the individual disdain) all available choices, one of which, however, must be chosen, e.g., disliking both candidates, but being obligated to cast one's vote for one of them.

(c) Double approach–avoidance conflict: the conflicting motivations simultaneous push toward, and push away from both candidates, e.g., when the voter is aware of negative as well as positive aspects of each candidate.

It is quite obvious that each of these three types of conflict is likely to be experienced differently and to have different consequences. The avoidance/avoidance conflict, for example, is likely to be more unpleasant—and more likely to produce withdrawal—than the approach/approach conflict. Traditional cross-pressure theory ignores the question of the qualitative nature of the conflict—yet another explanation for its predictive failures.

The potential costs of the errors of cross-pressure theory are not limited to the effects on political science and other academic disciplines. Cross-pressure theory is concerned only with reducing tensions, maintaining low tension states, 'and thereby maximizing pleasure—to be accomplished by eliminating conflicts, disagreements, and inconsistencies. The theory fails to acknowledge higher-level human functions and concerns. It is a partial and rather primitive conception of human nature. Necessarily, the theory is unable to understand and predict actual human behavior. In effect, the theory supports and encourages policies of cultural conformity. It tends to view differences between the individual and the community as problems of individual mental health, to be managed by personal adjustment, and even forcefully corrected by behavioral therapies or similar frights.

Politics and conflict are closely related. Politics is the conflicts and tensions between the various groups and their interests, as well as the efforts to find workable compromises. The concept of freedom makes little sense unless one has the ability and right to differ. Cross-pressure theory, however, regards diversity and its conflicts as societal dysfunctions. The implicit preference is for a conflict-free and harmonious system. What the theory fails to understand is that complete harmony and uniformity can only be achieved (if at all) by force and oppression.

2 *History of Cross-pressure Analysis*

Cross-pressure theory entered political science via the analysis of voting behavior at Columbia University (Lazarsfeld et al. 1948, Berelson et al. 1954) and the University of Michigan (Campbell et al. 1954, Campbell et al. 1960). The basic notion of cross-pressures, however, is considerably older. The idea that persons and other living entities, who are pushed (or pulled) in two (or more) directions at once, and hence are burdened by special cognitive and behavioral difficulties, is ancient. It can be found, for example, in Aesop's fable of the donkey starving to death between two equidistant piles of hay. In the more recent academic literature, the concept of cross-pressures can be traced to the writings of Georg Simmel. Simmel (e.g., 1921), however, did not employ the German equivalent of 'cross-pressures.' He used '*Kreuzung sozialer Kreise*,' which strictly translated means 'the crossing of social circles.' It was Bendix (in Simmel 1955), who translated Simmel's phrase into 'cross-pressures.'

The general idea of conflicting pressures received systematic attention almost simultaneously in political science and sociology, as well as in psychology and social psychology. In sociology the theory was stated mostly in terms of 'status equilibrium' and 'status crystallization' (Lenski 1961, 1964). The psychological fields generated the concept and theory of *cognitive dissonance* (e.g., Festinger et al. 1956, Festinger 1957. Cognitive dissonance theory has had a more illustrious career than its political-science and sociological equivalents. Indeed, the concept of cognitive dissonance has entered popular speech, even political campaigns. There has been serious and significant work in respect to cognitive dissonance, including sustained attention to systematic testing, improved measurement, and theoretical refinement of the propositions of cognitive dissonance (Davis 1993, Rabin 1991, Shultz and Lepper 1996). Such efforts are largely lacking in respect to cross-pressures. Only a single monograph exists exploring the nature, accuracy, and utility of cross-pressure theory (Sperlich 1971).

After an initial flurry of interest in studies of voting behavior—where it generally failed to produce confirmed predictions and useful explanations (see Sperlich 1971, pp. 9–26)—cross-pressure theory has fallen into almost universal disuse, even in voting behavior studies. Benney (1956), for example, provided a detailed analysis of social class voting, of multiple influences on voting choice, and of those who changed their voting intention during the campaign. He also used the term 'group pressure'—not, however, any real cross-pressure analysis. Similarly, Butler and Stokes (1974) spoke occasionally about 'cleavages [that] cut across the electorate,' but did not engage in actual cross-pressure analysis in their study of British voting behavior. Books dealing explicitly with conflict show a similar neglect (for example, Lipset 1985, Porter and Taplin 1987, Reilley and Sigall 1976), as do works in most other sub-fields. Kourvetaris (1997), for example, presents a conflict model of political sociology, but makes no use of cross-pressures concepts; psychologically oriented examples include; Freedman and Freedman 1975, Renshon 1974, Stone 1974, Moran 1985), rejects what he calls a 'civility model' and develops a 'conflict model' instead, dealing extensively with social cleavages, such as those associated with class, religion, race, and nationality.

Moran's book seemed well suited for the use of the idea of cross-pressures—but it did not make any such use. Similarly, Mayer (1977) included discussions of class conflict, cognitive dissonance, and cross-cutting vs. segmental cleavages, but not of cross-pressures (for other examples see: Almond and Verba 1963, Duverger 1972, and Meny and Knapp 1998). Rokkan (1970) developed a 'cleavage model' of politics without the use of cross-pressures. Numerous general discussions of politics, political systems, and political behavior entirely, or largely, omit discussions of cross-pressures (e.g., Alker 1973, Bellamy 1993, Delury 1987, Eulau 1996, Needler 1996, and Polsby et al. 1963).

3. *Disuse and Problems*

Upon closer inspection, the extensive non-use of cross-pressure theory is not surprising. It is theoretically inadequate. Two of its three basic propositions are in error. It ignores the problems of causal directionality and subjective reality when dealing with external cross-pressure factors. It has developed no measurement of the relative strength of a cross-pressure conditions, only recognizing a dichotomized presence or absence of cross-pressures. Further, it has paid no attention to the valence of the conflicts.

Proposition (b) is in error when it assumes that high tension and tension increases are invariably unpleasant. (Though, of course, some high-tension situations in respect to voting may indeed be experienced as unpleasant, particularly if the person is already subject to high tension levels in other aspects of his/her existence, and if the conflict is of the $-/-$ variety.) Proposition 2 needs to be revised as follows:

(a) A given tension level may be experienced as comfort or discomfort, depending on the tension requirement of the organism at the time; appropriate tension magnitudes will be experienced as comfortable, inappropriate ones (not enough, as well as too much tension) as discomfort.

(b) A change (increase or decrease) in the tension level may be experienced as pleasure or pain, depending on the direction of the change in respect to the tension requirements of the organism at the time; changes in the direction of the appropriate tension magnitude will be experienced as pleasurable, changes away from that magnitude as painful.

Proposition (c) is in error when it assumes that hedonism (maximizing pleasure and minimizing pain) is the only existing human motivation. It needs to be revised as follows:

(a) Human beings aim at a large variety of goal states and their actions are guided by a multiplicity of motives. Maximization of pleasure and minimization of pain are important, but are not the sole aims of human striving. There are acts to which the pleasure/pain calculus is irrelevant.

(b) The more dominant in any given situation the aims and motives associated with ego and conscience, the less will behavior be guided by organismic (id) demands for pleasure and gratification, such as expressed in attempts to resolve all conflict.

Research has shown that as long as the theory fails to take into account causal directionality, subjective reality, the strength of the cross-pressure conditions, and the valence of the conflicts, it cannot generate correct predictions of human behavior (Sperlich 1971, pp. 9–26) The introduction of better measures and the adoption of the necessary theoretical revisions, however, have been shown to yield highly successful predictions (Sperlich 1971, pp. 90–168).

Crowding and Other Environmental Stressors

We typically describe environmental problems as endangerments to physical health amenable to technological solutions. Yet human behavior occupies center stage for virtually every major environmental

problem confronting humankind. On the one hand, both personal and societal decisions and actions are the root cause of most ecological problems, and on the other, environmental quality can affect psychological health and functioning. The focus of this entry is on the impacts of environmental quality, specifically crowding, noise, and pollution upon psychological functioning.

The construct of psychological stress (see *Stress: Psychological Perspectives* for further details) has proven useful for understanding how the physical environment can affect human well-being. Psychological stress refers to behavioral and physiological reactions to environmental demands that exceed or tax the adaptive capacities of the organism. These demands are termed stressors. Adaptive capacities of the organism encompass genetic predispositions, cognitive and behavioral coping strategies, and social characteristics (e.g., social support) that can alter the balance between environmental demands and individual capacity.

1. Psychological Consequences of Crowding, Noise, and Air Pollution

The primary index of crowding is residential density (people/room). Other measures of crowding, particularly those at a larger scale, such as people per acre, have proven inconsequential for health and behavioral outcomes. This is one reason why demographic and epidemiological approaches to crowding and health have largely proven futile—for example, density statistics based upon census tract data are typically uncorrelated with a host of health outcomes, including disease, mental illness, and crime (Evans in press). Use of aggregate level density indices also leads to misleading cross-national comparisons of crowding and pathology. As an illustration, comparisons of crime rates across countries reveal lower crime rates in Hong Kong in comparison to the USA even though the number of people per acre in the USA is markedly lower than people per acre in Hong Kong. On the other hand, people per acre in Manhattan is not lower. Most likely it is the immediate experience of unwanted or uncontrollable social interaction that lies at the root of the crowding experience. This can be illustrated by the following dilemma: Would you rather share a very large room with one other person or have a small, even cramped room for yourself? Exposure to traffic congestion may be a related form of crowding stress largely caused by interference with progress towards one's destination. In this case exposure to peak traffic levels rather than average levels of congestion is decisive.

Noise, which is defined as unwanted sound, is usually measured in terms of sound intensity metrics such as decibels (dBA). Both average levels of sound intensity (Leq or Ldn) as well as peak levels of sound intensity exposure appear to be consequential. Leq is an arithmetic average, and Ldn is a weighted average incorporating a night time noise exposure penalty. Ldn is the most typical index of noise exposure used around airports in the USA. It is important to note that decibels is a logarithmic scale. An increase of 10 dBA is perceived as approximately twice as loud. In terms of hearing loss, the duration of exposure is as important if not more so than the actual level of sound intensity, unless extreme. Unfortunately, the implications of exposure duration for stress effects of noise have received insufficient attention.

Air pollution exposure is measured by atmospheric concentrations of known pollutants (e.g., sulfur dioxide) or toxins that are a major constituent of pollution (e.g., ozone as a component of photochemical smog). Both average levels of exposure as well as peak exposure levels are of importance for human well-being.

Precise estimation of individual exposure to environmental stressors like crowding, noise, and air pollution has proven difficult because of spatial and temporal mobility of human samples. Ambient air pollution illustrates well the challenge of accurate exposure estimation. Not only do people move around during the day, they spend time commuting as well as transferring back and forth between interior and outdoor settings. Each of these factors alters personal exposure to ambient pollutants.

For all three environmental stressors, human psychological functioning has been assessed across a range of experimental studies in the laboratory, cross-sectional field studies and, in a few instances, longitudinal studies with assessments of changes in exposure associated with outcomes of interest. Therefore caution is warranted in interpreting the conclusions described here since many of them are based primarily on acute, short term laboratory studies, or on cross-sectional field comparisons. On the other hand, convergence between laboratory and field studies is generally high (Evans 2001).

1.1 Psychophysiological Stress

Both laboratory and field research indicate that high density elevates blood pressure and neuroendocrine indices (e.g., epinephrine) of stress. Trends suggest that these effects are heightened for males and can occur in children as young as six years of age (Baum and Paulus 1987, Evans 2001). Parallel psychophysiological data have been found in field studies of traffic congestion.

Acute noise elevates cardiovascular and neuroendocrine parameters, but these effects rapidly habituate unless experimental participants are placed under moderately intense physical or cognitive

demands. There is also some evidence that noise-sensitive individuals do not readily habituate to acute noise exposure. Cardiovascular data from occupational noise exposure are inconsistent and lie on a foundation of poorly designed studies rendering definitive conclusions impossible. Better designed community studies show modest elevations in blood pressure associated with airport noise exposure. Interestingly, these psychophysiological effects do not habituate with longer exposure duration. Most of the community noise studies have examined children attending elementary schools in airport noise-impact zones. Few community studies have examined adults or neuroendocrine parameters (Evans 2001).

Research on air pollution as a stressor has not examined psychophysiological markers of stress. Understandably most health research on pollutants has focused on respiratory functioning or, in the case of toxins, neurological parameters.

1.2 Cognitive Performance and Learning

Short-term exposure to crowding in the laboratory impairs performance under a limited set of conditions. Performance is degraded only when substantial cognitive load is placed upon the individual, for example by having to monitor multiple signals or to respond to rapid or ambiguous signals (Baum and Paulus 1987). Parallel results have been found for noise (Smith and Jones 1992). Experimental work on pollutants and task performance has primarily been restricted to neurotoxicological testing.

Residential crowding is associated with achievement deficits among school children (Evans et al. 1998, Saegert 1982), and numerous studies have shown associations between chronic noise exposure and reading deficits (Evans and Lepore 1993). The noise studies include some longitudinal evidence, dose-response data, and some work on underlying cognitive processes to account for the findings. Speech perception and language acquisition appear to be negatively impacted by chronic noise exposure. Most of the noise and reading studies ruled out hearing impairment as an alternative explanation.

1.3 Interpersonal Relationships

Crowding induces negative affect, heightens irritability and hostility, and may provoke aggression (Baum and Paulus 1987). Residential crowding is associated with more conflicted family relationships including more corporal punishment (Evans et al. 1998, Saegert 1982). Noise is an irritant that, when coupled with provocation or modeling, can lead to elevated aggression (Cohen and Spacapan 1984). Noise itself does not produce aggression but can amplify hostile reactions already present. Attempts to associate crowding or noise exposure with crime have generally proven unsuccessful. There is also evidence that crowding (Baum and Paulus 1987) and noise exposure (Cohen and Spacapan 1984) can suppress altruism.

Perceptible air pollution can increase negative affect and, if not at high levels, elevate aggression (Evans 1994). The nonlinear relation between air pollution levels and aggression may reflect underlying negative affect (Rotton 1983).

1.4 Psychological Health

Given both experimental and field evidence linking environmental stressors to negative affect and conflicted interpersonal relationships, many investigators have endeavored to demonstrate associations between chronic exposure to environmental stressors and mental health. For all three environmental stressors, the data are mixed, although careful scrutiny reveals some consistent patterns. Studies of residential crowding and mental health that have relied upon individual-level data reveal modest relations. Studies of more serious outcome measures of psychiatric impairment as well as those relying on aggregate-level indices of crowding (e.g., people/acre) typically find no assoication with mental health (Evans 2001).

The data on noise and mental health are more equivocal, with no discernable trends, although many studies have used poor estimates of noise exposure and relied upon catastrophic mental health outcome measures (e.g., psychiatric hospitalization). There is some evidence that those who are noise-sensitive, which is related to neuroticism, may be especially vulnerable to elevated psychological distress in relation to noise exposure (Stansfeld 1993). Air pollution exposure may also be related to psychological distress, although not much data have been collected (Evans 1994, Rotton 1983).

1.5 Summary

Acute and chronic exposure to crowding or noise can elevate cardiovascular and neuroendocrine indicators of stress. Insufficient research has examined similar reactions to pollution. Short-term exposure to crowding or noise can impair performance when cognitive load is high. Chronic crowding has been linked to achievement deficits among children in a few studies, and numerous studies have revealed noise-related reading deficits. Crowding, noise, and air pollution, both in the laboratory and under naturalistic conditions, increase annoyance, irritability, and hostility. Aggression may be more likely to occur when prior provocation or modeling of conflict has occurred. In the case of pollution, evidence suggests that the

relation is nonlinear and may be mediated by negative affect. Residential crowding and exposure to pollutants appear to be associated with elevated psychological distress. The evidence for mental health sequels of noise exposure is equivocal.

2. Underlying Mechanisms

The initial phase of behavioral research on environmental stressors was focused on documenting potential adverse effects on human functioning along with examining possible individual differences in responses. Several reliable gender differences have been uncovered for crowding, suggesting that men react more strongly physiologically, whereas women may suffer stronger negative affective responses. Noise-sensitive individuals tend to react more negatively to noise in a variety or ways in comparison to their less sensitive counterparts. Attempts to identify systematic personality or dispositional differences in reactions to environmental stressors have generally been unsuccessful. The strongest data to date suggest that persons seeking higher levels of arousal or sensation are less adversely affected by crowding and noise (Mahrabian and Russell 1974).

Current research has shifted emphasis, focusing primarily on underlying, explanatory psychosocial processes to help account for the apparently stressful, adverse effects of environmental stressors on human well-being. The two underlying psychosocial processes that have garnered the most attention to date are control and social support.

2.1 Control

Research on all three environmental stressors implicates lack of control as an important component of stress reactions. Two general approaches have led to this conclusion. In the first approach, studies of noise (Cohen et al. 1986), crowding (Baum and Paulus 1987), and air pollution (Rotton 1983) have shown that the negative impacts of each of these stressors are substantially attenuated by providing individuals with a sense of control over the stressor. For example, in a classic set of experiments, Glass and Singer (1972) demonstrated that the negative effects of noise were essentially eliminated if subjects believed they could shut off the noise with a switch. Just the perception of control was sufficient to ameliorate the harmful impacts of noise, regardless of whether subjects actually exercised the control option.

The second approach to examining control as an underlying explanatory process for the stress effects of environmental stressors has been to study motivational deficits associated with learned helplessness among those chronically exposed to environmental stressors. As explained in more detail in the entry *Learned Helplessness*, repeated exposure to uncontrollable stimuli can lead to decrements in motivation caused by the belief that the outcomes of one's actions are independent of those actions. Children chronically exposed to noise or to crowding are less likely to persist in their attempts to solve challenging puzzles (Evans 2001). Adults living under more crowded conditions adapt a withdrawal strategy in group game-playing scenarios. Their degree of withdrawal is closely matched by self-reports of feelings of loss of control over the immediate social environment in their residences (Baum et al. 1981). Physiological stress reactions to traffic congestion have also been shown to be partially attributable to diminished perceptions of control (Evans 2001).

2.2 Social Support

Several studies indicate that residential crowding is associated with diminished social support (Evans 2001). This is believed to occur as a consequence of a common coping strategy for dealing with crowding, namely social withdrawal. Long-term crowding appears to precipitate social withdrawal which, in turn, leads to a breakdown of socially supportive relationships in the home. There is also evidence that deteriorated social support mediates the linkage between residential crowding and psychological distress.

Analogous research has not been completed with noise or air pollution, but there are reasons to suspect that similar processes may be operating. Both of these stressors are clearly irritating and can affect one's propensity for negative social interaction. Furthermore, noise interferes with communication, a fundamental building block of socially supportive relationships.

3. Future Directions

From both a methodological and a policy perspective, there is critical need for prospective longitudinal field studies of environmental stressors and human psychological functioning. Ideally these studies will also generate dose-response functions in order to understand critical values of environmental stressors for human behavior. At the present we know environmental stressors are inimical to optimum psychological functioning, but we cannot say currently precisely how much exposure to a particular stressor is sufficient to produce harm.

Research is likely to continue on underlying processes to explain how and why environmental stressors can interfere with human behavior. Hopefully this kind of research can also incorporate better estimation of human exposure to environmental stressors. Ambulatory monitoring and use of time budget methodologies may prove helpful in this regard.

The contexts in which exposure to environmental stressors occur warrant greater attention. Exposure to environmental stressors is not random. Most of these

stressors are experienced jointly (e.g., noise and crowding) and frequently accompany poverty. More psychological analysis of multiple environmental and social stressors exposure is called for.

The social and behavioral sciences will continue to provide insights that expand our understanding of environment and health. Psychological stress provides one theoretical framework that has proven useful for doing so. Our attitudes towards the natural environment, along with models of ecologically responsible behavior, are two additional topics where the social and behavioral sciences are likely to continue making important contributions to the environmental sciences. Human behavior plays a pivotal role both in the etiology of environmental problems and as an index of their impacts.

Crowds in History

Crowds do play an important role in history. Particularly during times of crisis and revolution, they can function as prime movers in historical–political conflicts. As a constituent feature of everyday public life, the omnipresent crowd is a highly complex phenomenon, especially in modern urbanized societies. In view of the innumerable forms that crowds take, in the most varied of contexts, for pragmatic reasons it is sensible to distinguish between: (a) more trivial everyday crowds as well as crowds of a recurring, institutionalized, and routine nature; and (b) exceptional, unforeseeable crowd events.

For research purposes, crowds can be defined as relatively short-term gatherings of large groups of people (on streets or squares or in the countryside—in any event, in the open air), whose actions are goal-oriented and, as a rule, conflictual. Crowds are assemblages that interrupt the regular course of everyday life and disturb the public order, or at least threaten to disturb it. Under certain circumstances, of course, an everyday or routine crowd can also transform itself into one that will be conflictual.

Crowd history was (and will likely remain) primarily indebted to the social history paradigm: theory-oriented, but seldom fixated on theory—in fact, with a fair bit of skepticism regarding theory; and utilizing a variety of empirical methods, singularly or in combination, from 'thick description' to extensive statistics on protest. Central concerns are the precise reconstruction of crowd events, the involved groups and their identities, and a micro-historical embedding in local contexts. Dominating questions concern exact times, size, duration, frequency, and topography or geography of crowds. Research topics are their physical composition (social status, ethnic identity, religion, age, sex) and the—considerably heterogeneous—behavior of individuals or smaller groupings in these events.

Other focuses are the forms and motives of action (violent tendencies, emotionality, resentment, mentalities, visions), in addition to occasions and possible structural reasons for common action. Furthermore, crowd history investigates the targets of crowd action, as well as the presence and function of peacekeepers in such confrontations. And last but not least, crowd

history discusses the results and long-term consequences of crowd events in consideration of high politics and society.

1. Phases and Schools: Changing Images of Crowds

Academic crowd research was first begun toward the end of the nineteenth century, and its beginnings are conspicuously multidisciplinary: philosophy, psychology, criminology, sociology, and anthropology occupied themselves with the phenomenon; only gradually did historical studies turn their attention to the subject. Against the background of opposing political–ideological positions, several academic schools disputed the 'true essence' or the 'actual character' of crowds. Depending on one's position, interpretations ranged from an extreme damning of crowds as purely negative and regressive destroyers of civilization, to their enjoying an idealized historical–philosophical role as genuine creative agents, as essential driving forces of historical progress. From the historian's perspective, there are at least four important phases.

The starting point was the so-called 'Latin School' of mass psychology around 1900, represented by such authors as the Italian criminologist Scipio Sighele (*La Folla Delinquente*, 1891), the French popular scientist Gustave LeBon (*La Psychologie des Foules*, 1895), and the French criminologist and sociologist Gabriel Tarde (*L'Opinion et la Foule*, 1901). Relying for their historical evidence primarily on one-sided studies of the French Revolution by the conservative historian and philosopher Hippolyte Taine, their speculative theories concerning crowds were a projection of bourgeois-conservative fears of social subversion at the *fin de siècle*: 'Their crowds loomed as violent, bestial, insane, capricious beings whose comportment resembled that of mentally ill, women, alcoholics, or savages' (Barrows 1981 p. 5).

The emerging social–historical school of French Revolution research opposed the conservative LeBon mass psychology by de-demonizing the crowd debate through empirical case studies addressing the character and role of crowds during the French Revolution. One of this school's path-breaking authors was Georges Lefebvre. In *La Grande Peur* (1932) and especially in *Foules Révolutionnaires* (1934), he showed how rebellious groupings were stimulated through various types of oral communication (e.g., spreading of rumors, suspicions, and mental images), and how the *foules pures* of everyday life transmogrified into the *foules révolutionnaires* when seized by a 'collective mentality.'

After the World War II, a modern classic school of crowd research was constituted that traced its ancestry partly to the social–historical school of French Revolution research. The classic school's first important propagator was an occasional student of Lefebvre's, George Rudé, whose 1950 doctoral dissertation treated the Paris workers and their uprisings of 1789–91. In his studies on crowds in the French Revolution and on crowds generally in France and England from 1730–1848 (Rudé 1964), he identified for the first time the 'faces in the crowd.' Together with Eric J. Hobsbawm's early studies of the pre- and early-industrial workers groups whose rebellious behavior was plausibly labeled 'collective bargaining by riot' (Hobsbawm 1952), as well as the related work of Edward P. Thompson, especially his paradigmatic study of *The Moral Economy of the English Crowd in the Eighteenth Century* (Thompson 1971), the classical canon of a new history from below emerged. These historians understood themselves to be an open and undogmatic variant of a Marxist historiography of the West. At first an oppositional subdiscipline, from the 1960s to the 1990s it quickly gained a wide reputation in academic circles, inspiring numerous other studies.

There was a parallel development in the American social sciences, using modernization theory and quantitative measurements in historical–sociological research on crowds. Crucial was a more systematic investigation of possible causal connections between large processes such as industrialization, urbanization, or social crises, and the frequency and geography of crowd occurrences. In a critical test of theory, then-current concepts of collective behavior and of social movement research (relative deprivation, among others) were checked against historical evidence. This led to more refined methods of crowd event analysis, accumulating more precise protest statistics over longer periods and/or testing its geographic diffusion for strategically chosen regions. Exemplary is the work of Tilly et al., in particular the comparative study of France, Italy, and Germany in *The Rebellious Century* (1975), or the strictly quantitative and simultaneously Thompsonian case study of English riots 1790–1810 (Bohstedt 1983).

2. The Unwritten Program: 'Subsistence' and 'Liberties'

For the longest time, European societies of the early-modern period, including the nineteenth century, figured as the classic time frame for the bulk of crowd research. The essential scope of crowd activities was above all defined by the secular processes of state centralization and national state-building, the expansion of market economies, social polarization, and proletarianization. Viewed from the lower-class angle, one is able to speak of a European age of persistent material shortages. Under conditions of subjection and/or political immaturity, the lower classes found themselves in permanent conflict with authorities and social elites for subsistence guarantees, communal rights and freedoms, and cultural autonomy.

Rudé's and Hobsbawm's 'new picture of the crowd' was and remains largely a counter-image to the previously dominant LeBon tradition. Crowds, it was now shown, were not—as a rule—criminal rabble but people of established residence, average working men and women, poor but orderly folk. Their motivations were a frequent mixture of Jacobin egalitarianism and conservative monarchism. Their collective behavior was one of direct action, and they pursued their thoroughly rational goals with fitting means, this sometimes translating into violence. However, it is said that their violence was predominantly symbolic and a question of efficacy. Moreover, their successes were of limited nature, particularly as their actions were so short-lived and lacking of far-reaching visions. Thus, conflict crowds were to be considered forerunners of later social and political movements with lasting organizational structures and long-term social–political programs.

These and related studies established a solid canon of conflicting crowds, a European repertoire of riots. These included: peasant uprisings against noble estates, anti-tax protests against mounting state prerogatives, religious riots between competing confessions, subsistence-based actions of the rural and urban lower classes, moral rebukes in the tradition of *charivari* (rough music), strikes and boycotts of artisans and workers, machine-wrecking, but also aggressive acts of popular monarchic loyalty against alleged enemies of king and church, and xenophobic outbursts against 'strangers.' As the latest research for the UK, France, and Germany has shown, in no other early-modern conflict of any duration were crowds so involved as in food riots.

More than 3,000 food riots have been documented for France between 1560–1860. At their center were the blockades of inter-regional grain trade to prevent scarce resources from leaving their place of origin. Participating in these blockades were mainly the rural and urban lower classes from the highly commercialized farming regions of the far-reaching agrarian hinterlands of Paris. For four decades, ever since 1760, the power struggle over access to limited food resources became permanent in France. The attempt of Controller General Turgot in the fall of 1774 to deregulate the national grain trade according to physiocratic liberal doctrines, ended in the fiasco of the Guerre des Farines (Flour War) of 1775, when over 300 food rebellions forced the government to back down its policy (Bouton 1993).

There have been about 1,000 food riots documented for England in the period 1530–1820, the majority of them taking place in the last 80 years of that time span. With regard to the years around 1800, Bohstedt speaks of a communally anchored 'protocol of riot,' of 'orderly disorders,' with widely accepted public rules for all of the participants. With crowd action as an essential element of community politics, poorer consumer groups, especially in small and medium-sized market towns, participated successfully in the creation of reasonably tolerable living conditions (Bohstedt 1983).

For German regions (1700–1870) over 400 food conflicts have been substantiated. They culminated in the 1840s (shortly before and during the Revolution of 1848), a decade that has been characterized as the 'angry forties.' Particularly in Prussia's East-Elbian provinces, the eighteenth-century myth of a paternalistic 'social monarchy' quickly faded. Market-driven resource scarcities, not least the result of agricultural exports to Western Europe, forced a sharp internal 'dissent about markets.' Even more so than the urban lower classes, the rural poor frequently saw themselves robbed of whole food entitlements (Gailus 1990).

All in all, these recurring pre- and early-industrial mass conflicts attested to not only a simple struggle for calories among the abject poor and hungry, but symbolized a central conflict of values and goals. On the one side were liberal principles and Utopias envisioning abundant markets and property for all, while opposed to it were nontransferable subsistence rights and the blows to the human dignity of rapidly expanding market-dependent classes in an increasingly urbanizing market society.

Probably no other model has so persuasively explained the social and cultural meaning of pre- and early-industrial crowd activities as Edward P. Thompson's classic notion of moral economy, which he developed through an analysis of the rebellious behavior of the working poor in eighteenth-century England. According to his study, the customs and rituals practiced by the crowds in their numerous food riots, their angry outbursts and anxious visions, their claims and demands, were embedded in 'a popular consensus as to what were legitimate and what were illegitimate practices in marketing, milling, baking, etc. This [consensus] in its turn was grounded upon a consistent traditional view of social norms and obligations, of the proper economic functions of several parties within the community' (Thompson 1971 p. 79). For Thompson the word 'riot' is too narrow a concept to adequately describe all the issues at stake in these confrontations. In order to assure their 'way of survival,' crowds (or people) were in permanent collective negotiations with aristocracy and gentry, with officials and the middle classes. The crowds would typically remind the authorities of their traditional paternalistic duties vis-à-vis the weaker members of the community. In the ritualized forms of conflict with ruling elites, in expressive and symbolic confrontations of political 'theatre' and 'counter-theatre,' they actively participated in the social organization of their own living conditions and thus functioned as an influential collective subject. Crowds were exercising direct influence on the epoch's balance of power, which was shaped by the political hegemony of the gentry (Thompson 1991). One can with good reason speak of 'participation by riot' or of popular

'participation before participation.' Despite some critical objections, the moral economy model has asserted itself as the most successful interpretive concept for historical studies of conflict crowds—and not solely for food riots and for European conflict patterns. More recent work attest to its yet fertile analytic potential (Randall and Charlesworth 1996).

Focusing the implications of these old European crowds on a few essential aspects would above all include 'subsistence' (entitlements to food, rights of social share) and 'liberties' (in the sense of additional rights and popular customs). This collective establishing of values was both asserted and defended against outside 'disturbances' and all actual and imagined threats to existence through dynamic penetration of the two great powers, the national state and the expanding modern market. This culture of resistance of conflicting crowds has contributed in manifold ways to the formation of basic political and social rights of modern constitutional states.

3. *Conceptual Constrictions—Widening of Perspectives*

The advance of the modern social–historical school (1960–90) had a lasting effect on the historical image of crowds: the 'bad crowds' of the older conservative orthodoxy turned into the 'good crowds,' possessing a predominantly positive, emancipating function. However, completely or partially obscured were other aspects of crowd history: aggressive, conservative, and nationalistic or chauvinistic mass events, as well as excessively violent and ethnically motivated outbursts. Also criticized has been crowd history's exclusive concentration on rebellious crowds. Too little attention has been given to other forms of nonconflicting crowds. In addition, the 'great watershed' of 1850, allegedly occasioning a transformation of crowds, has hardly been proven. Despite a sneaking institutionalization of crowds over the following decades, they have remained critically important in the industrial societies of the late nineteenth and twentieth centuries (Holton 1978, Harrison 1988).

Crowd history has to pay more attention to violent actions against minorities and outsiders. Excessive crowd violence was mostly reserved for pogrom-like persecutions of the Jewish minorities. These assumed an almost nation-wide character at least twice in nineteenth-century Germany: in the form of 'Hep-hep riots' (1819) against the political emancipation of the Jews, and the forcible expulsion of south German village Jews within the wider context of the rural mass movements of the 1848 revolutions (Rohrbacher 1993). As of the second half of the nineteenth century, pogroms established themselves in eastern Europe with much greater militancy—in Russia, especially the Ukraine, and in parts of Poland—its chief phases encompassing the periods 1881–84, 1903–06, and 1919–21. Until the end of the nineteenth century these actions were perpetrated by crowds of similar compositions to those in other riots (Klier and Lambroza 1992).

There has been an increasing shift of focus to nonconflicting crowds, a development promising to greatly expand the field of research. Dynastic governmental ceremonies, middle-class-inspired national festivals, traditional celebrations, religious feast days, and new-style leisure activities could easily assume the form of mass events, though in different guises and in radically transformed public functions: staged by the ruling class and social elites and hierarchically structured; composed of a mixture of social groups, neither exclusively nor primarily from the lower classes; symbolically strengthening the existing rule and its established social order, as opposed to rebellious behavior protesting destitution and political impotence; in their effects, socially integrative rather than polarizing. The lower classes, usually self-determining actors at the very nucleus of crowd activities, figured here primarily as public, as mere backdrop.

A study of Bristol 1790–1835 shows that next to peaceful 'election crowds,' 'royal and military crowds,' and 'recreational crowds,' unruly 'crowd riots' were among those events occurring with the highest frequency in the city. However, at the same time, 'crowd riots' formed only a minority (22 percent) of a sample that covered all types of crowd occurrences taking place within the city. The local elites of Bristol had ample skill and experience in successfully mobilizing large crowds onto the main streets and squares for purposes of their own (Harrison 1988).

The general European 'nationalization of the masses' in the nineteenth century included a wealth of identity-forming national celebrations and mass manifestations.

A comparative study of middle-class movements for national memorials in France and Germany has demonstrated the precarious and paradoxical strategy of including the lower classes in the mythical 'nation,' while simultaneously drawing sharp social distinctions over and against these very same lower classes. It was above all through the militarization of the bourgeois festival culture that the elites were able to overcome their deep-rooted fear of the masses (Tacke 1995).

Expanded political participation, as well as transformations within the public sphere in industrial and post-industrial societies of the twentieth century in no way contributed—as often asserted—to the disappearance of protesting crowds. Rather, one can speak of modifications, and of coexistence of direct action with newly learned and more organized and representative political forms. After 1850, aside from periodic recurrences of crowd activity in line with the older model (for example, food riots in France, and especially in Italy and Spain), one finds numerous

newly-invented forms of crowd action, above all strikes, boycotts, mass manifestations and the like. However, soon after 1900 the power potential of crowds began to appear less threatening to the established order (in the sense of general overthrow). Crowds were governable, crowds could be manipulated—this was the new slogan of ruling elites.

An empirical study of Berlin 1900–14 shows the high presence of crowd events in early twentieth-century streets. The events fell into three major categories—405 street disorders, 74 violent strikes, and 61 political mass manifestations. The ongoing struggle for the city streets is interpreted as conflict between a 'street politics from below' and a restrictive 'street politics from above' carried out by the state power and its police. It was on the political terrain of the street that exaggerated fear of subversion, strict anti-revolutionary measures, and socially discriminatory police practice clashed with collective demands for greater social justice and expanded political participation (freedom of assembly, the right to demonstrate, universal suffrage). In a much wider sense, these were demands for respect and self-determination fought out by the proletarian majority in the public forum of the street, the traditional political arena of the common people (Lindenberger 1995).

For the extremely crisis-ridden interwar period, one can even speak of a culmination of 'street politics,' increasingly transformed (militarized) through the advent of radical political–ideological movements from both the left and the right. In this civil war atmosphere of rabid party-political action, with the air filled with bellicose slogans such as 'self-help' and 'self-defense,' authentic collective crowd action threatened to be instrumentalized and finally suffocated in the battle of totalitarian movements bent on the conquest of state power (for a comparative study of Berlin and Paris 1919–33/39, see Wirsching 1999).

For some time now the broadening of perspectives has meant the inclusion of non-European regions of Asia, Africa, and Latin America, which have a history of crowds of their own. Important basic forms resemble the European riot patterns: in the center stood collective claims of peasant producers who rebelled against landlords or large land-holding farmers, urban money-lenders or state organs for reasons of land scarcity, imposed duties, debts, or tax pressure. In the East Asian context, in a series of studies, James C. Scott has shown how peasant behavior was culturally embedded in an all-encompassing subsistence ethic with precise norms regarding access to land, acreage, and a fair apportionment of their own produce. The threats posed to these cultural norms in the context of firmly established clientele relationships might have led to open collective resistance, even if—in consideration of the manifold covert and individual 'weapons of the weak'—this remained more the exception than the rule (Scott 1976).

In some regions (particularly of China since the eighteenth-century, and to some degree of Japan and of India in the nineteenth and early twentieth-centuries) the food riot tradition was of considerable historical importance, thus offering comparisons with early-modern Europe (Wong 1983). At the same time, subsistence conflicts of many Third World regions continue to this day, as confirmed by many contemporary eruptions since the 1970s in North and Central Africa (Egypt, Morocco, Sudan, and Tunisia) and Latin America (Dominican Republic, Venezuela, Brazil, and Argentina). In several cases it was food-riot crowds—whose agitation came in the wake of reduced state food subventions and resulting higher prices—that shook and even toppled ruling governments.

4. *Outlook*

The long and hard-fought interpretive battle concerning crowds has been marked by a double disappointment: neither have crowds been shown to be the great negative power, an absolute culture-destroying evil; nor have they been—teleologically speaking—a collective subject to fulfill any historical missions. Crowds have always shown themselves to be multi-layered, ambiguous, and variously interpretable phenomena. And naturally, a certain ambivalence remains. For although emancipatory aspects in the sense of subsistence gains, political participation, and self-determination may dominate the phenomenon of crowds, dangerous exclusionary efforts at expulsion or even destruction of religious, ethnic, and other minorities can also be part of the crowd repertoire. The demythification of the crowd, the gradual opening of political structures to greater popular participation, the modification of collective behavior through historical experience (learning processes that include a growing self-control and adoption of the principle of nonviolence), and other factors may have contributed to crowds having increasingly forfeited their attractiveness as a catch-all for fearful visions or as an instrument for political and ideological agendas imposed from without.

As historical actors in their own right, crowds lay claim to a considerable degree of legitimacy. At the center of this legitimacy stood the collective demands for 'subsistence' (later on: social sharing) and 'liberties' (communal rights, cultural autonomy and, later, political participation) in the context of given governmental and living conditions. Insofar, conflicting crowds were always—more unconsciously than intentionally—indirect collective reformers. Obviously, this seemingly paradoxical role is part of the peculiarities of rebellion and revolution. The political culture of the West—with its human rights norms embodied in the welfare state and democratic institutions since the end of the nineteenth century—would have never attained to the stature it occupies

today had it not been for persistent collective intervention from below. Crowds have helped to draw up the agenda for social and political human rights, and they continue to do so.

Where comprehensive systems of social sharing and political participation have been historically established and long in place, crowds tend toward a shift in their forms and motives. From a purely quantitative standpoint, protesting crowds in recent times have been anything but on the decline. To the contrary, they have been on the upswing, becoming a conventional part of political culture. Although violence has receded, it has not fully disappeared. Rating high are questions other than elementary ones of subsistence and freedom. Demands for social and political egalitarianism have for some time taken a backseat to new values and fresh demands based on 'new social movements.' Those groups affiliated with crowd events are no longer predominantly or exclusively from the lower classes, but are a great mix of people with considerable representation from the public sector, education, science, and culture. Fitting in well with these trends is also the upsurge of class non-specific leisure crowds in the context of new event cultures.

As an elementary form of the public sphere (*Versammlungsöffentlichkeit*), crowds will endure. Certainly modern mass media have continued to occupy strongly the public arena, becoming themselves more and more an embodiment of the entire public. But talkshows have hardly rendered crowds superfluous. Albeit today's media presence largely determines the public perception of crowd events, thereby heavily influencing their effectiveness. In their endless variety, crowds represent the unmediated, face-to-face public. Such gatherings of people for purposes of social and communicative self-awareness is apparently a deep-seated human need that—despite the relative dwindling of traditional conflicting crowds—will not soon disappear.

Cuban Revolution, The

The Cuban Revolution, as Fidel Castro proclaimed in January 1959, was a true revolution. A new society was forged with the triumph of Castro's organization,

the Twenty-sixth of July Movement, over other competing political organizations, and with the institutionalization of a Marxist-Leninist government. Cuba was involved in some of the most serious international confrontations of the last half of the twentieth century. The massive exodus that started in 1960 created a diaspora of more than two million Cubans. This article explores the historical background of the revolution and the policies that made it both a success and a failure.

1. Key Events

1.1 From Independence to Revolution

From 1895 to 1897, the War of Independence between Cuba and Spain was a protracted conflict. The war ended when the USA intervened and occupied the island in 1898. This intervention occurred as the war was starting to turn in favor of the Cubans. Although the Cubans collaborated with the US troops and constituted the fundamental land force that permitted the swift US victory, they were ignored during the peace negotiations at the Treaty of Paris of 1898. The USA aided in the reconstruction of the war-torn country, improving health conditions and education. US investments and the return of Spanish capital contributed to economic recovery. When US occupation (1898–1902) ended, there was only one objectionable point: the Platt Amendment. Imposed by the USA as a requisite for turning over the country to the Cubans, the delegates to the 1901 Constitutional Assembly attached it to the Cuban Constitution. Annexationist interest and the notion held by US officials that Cubans were incapable of self-rule, led to the imposition of the amendment. The amendment, drafted by US Senator Orville Platt, gave the USA the power to intervene militarily in the island and restricted the Cuban government in its international relations.

Traditional and pseudo-Marxist historiography reduces US–Cuban relations to the events that occurred in and after 1898. In this view, 1898 marks the date in which Cuba stopped being a Spanish colony to become a US one. The truth is far more complex. Cuba's economic dependence on US trade was a fact by the mid-nineteenth century. Cuba was the world's foremost producer of sugar and the USA imported 90 percent of Cuba's production. The USA had also been a refuge for Cubans who aspired to independence. The first Cuban political party was created by exiles in the USA under the leadership of José Martí. Martí, although not anti-USA, feared and staunchly opposed North American intervention. At the end of the war, the economic ties between the countries continued to play a direct role in US–Cuban relations.

Liberalism, political participation, the absence of strong partisanship, electoral fraud, administrative graft, and civil unrest characterized the early republic. The postindependence concentration of US and Spanish capital in the sugar industry, together with the Spaniards' domination of banking and commerce, rendered participation in the government the main vehicle for economic success for many Cubans. The creole elite had been nearly destroyed. Spain did not compensate Cubans for the loss of property during the war. Armed struggle was often a means to ensure circulation of elites in public office. The USA intervened militarily to establish order on two occasions and occupied the island for a second time from 1906 to 1909.

Cuba's economy continued to depend on sugar exports. By 1902, the almost miraculous recovery of the sugar industry had turned Cuba into the world's second largest producer. The preferential tariff treatment accorded by the USA in the Reciprocity Treaty of 1903 reinforced the preeminence of sugar, hindered economic diversification, and heightened Cuba's dependence on the USA.

Sugar production and prices rose during and after World War I. The prosperity created a Cuban-born entrepreneurial class with a nationalist agenda. In the 1920s, the collapse of sugar prices and the Cuban banking crash plunged the nation into economic chaos. By 1923, students and workers had joined industrialists and intellectuals demanding abrogation of the Platt Amendment, curtailment of government concessions to foreigners, and the end to the country's dependence on sugar.

General Gerardo Machado's dictatorship (1925–33), coupled with the US government's interference and plummeting sugar exports were the catalysts for the revolution of 1933. A provisional revolutionary government was installed and president, Dr. Ramón Grau abrogated the Platt Amendment unilaterally. His administration, which enacted social, political, and economic reforms, encountered the unswerving opposition of the USA. Benjamin Sumner Welles, the US ambassador, and other opponents denounced the measures as too radical. Although Welles requested US military intervention, Washington opted to withhold diplomatic recognition of Grau's administration. It was axiomatic that no Cuban government could survive without US support. Strikes continued, and in the eastern provinces workers seized some sugar mills and established soviets. On January 1934, Fulgencio Batista, promoted to army chief of staff, deposed Dr. Grau. Although short-lived, the 1933 revolution challenged US hegemony, introduced changes in Cuba's socioeconomic and political structure, and rekindled nationalism. In 1934, the USA abrogated the Platt Amendment, signaling a curtailment of Washington's interference in Cuban affairs.

Batista ruled by proxy until 1940, when he was elected president. The Partido Revolucionario Cubano (Auténtico) came to power with the presidential election of Dr. Ramón Grau (1944–48). Cubans

expected a continuation of the reformist policies enacted during Grau's short administration in the 1930s. Those reforms, incorporated into the 1940 constitution, reflected the revolutionary spirit of the 1930s. Unfortunately, many of the significant political and socioeconomic advances of the Auténticos were combined with governmental graft, corruption, and political gangsterism, which was also the case with the auténtics administration of Carlos Prío Socarrás (1948–52).

In 1947, Eduardo Chibás, a disaffected Auténtico, founded the Partido del Pueblo Cubano (Ortodoxo). The Ortodoxos represented the hopes of a generation for whom the promises of the 1933 revolution remained unfulfilled. Political legitimacy and honesty in public office were at the core of his movement. Chibás's suicide in 1951 created a leadership vacuum and renewed the frustration that plagued Cuban society. A coup, on March 10, 1952, led by General Fulgencio Batista, ended the constitutional experience two months before the 1952 elections. On July 26, 1953, Fidel Castro, a young Ortodoxo, who had run for office in the 1952 elections pre-empted by General Batista's coup, organized the unsuccessful attack on the Moncada barracks in Santiago de Cuba. The daring act provided publicity for Castro and for his nascent anti-Batista organization, the Twenty-sixth of July Movement. When Batista refused the demands for free elections made by a coalition seeking a nonviolent solution to the crisis, the Federación Estudiantil Universitaria (FEU) called for a student strike, and violence escalated. In 1956, Castro and José A. Echeverría, FEU president and head of the Directorio Revolucionario Estudiantil (DRE), joined forces. By December, Castro and his followers had established guerrilla operations in the mountains of the Sierra Maestra, in Cuba's westernmost province of Oriente. On March of 1957, the Auténticos and the DRE stormed the presidential palace and Echeverría was killed in a separate incident during the failed assault. A growing number of the professionals and entrepreneurs joined the fight as the government's repression mounted. Other guerrilla fronts were then established and the underground initiated a terrorist campaign. Several conspiracies in the armed forces were discovered between 1956 and 1957. In 1958, the USA imposed an arms embargo on the Cuban government; a military offensive against the rebels failed and they in turn mounted a counteroffensive. Batista was deposed by a coup in December. On January 1, 1959, the army surrendered to the Rebel Army and the unanticipated communist revolution began its course. The Cuban communist party, Partido Socialista Popular (PSP), had been critical of Castro's Moncada attack and barely participated in the struggle against Batista until 1958. Raul Castro, Fidel's brother, however, was a communist and may have established contacts with the international communists at the Sierra Maestra.

On the eve of the revolution, Cuba was a developing nation ranking among the top five countries in Latin America. The movement to depose President Batista was not anti-Yankee, nor anticapitalist, antibourgeois, or nationalist. By the 1950s, radical nationalism was mostly confined to the intellectual elite. Although the anti-Batista movement had ultimately a heterogeneous class base, members of the middle classes seemed to have comprised the core of the active participants, particularly in the urban underground. Among the insurrectionists, there was also an obvious presence of individuals of middle and upper class backgrounds, such as the Castro brothers and some of their closest collaborators. The Twenty-sixth of July Movement and the other anti-Batista groups focused on political freedom, constitutionality, and fiscal integrity, which were the issues concerning the Cuban middle classes. Castro's social and economic planks were based on the implementation of the provisions of the constitution of 1940, which included agrarian reform.

1.2 Revolution (1959–1970)

Between 1959 and 1961 Cuban society was transformed. Foreign and domestic properties were gradually expropriated. Political parties, elections, freedom of the press, and labor's right to strike were eliminated. Universities, labor unions, and professional associations were purged. The 1940 constitution was proclaimed to be outdated, and the USA was identified as Cuba's enemy. A new currency destroyed the power of the upper and middle classes. All criticism was declared as counterrevolutionary, and political opponents were imprisoned or executed. The first massive flight into exile of Cuba's entrepreneurial and professional sectors was initiated.

Cuba's foreign relations changed just as rapidly. Soviet military advisers and weapons began arriving by September of 1960. In October, the USA imposed a trade embargo and diplomatic relations between the two countries were severed in January 1961. That same year, an invasion was launched by Cuban exiles that had received covert military training and support from the US government. The failure of the Bay of Pigs invasion of April of 1961 consolidated the revolution. The underground was crushed, as an estimated 100,000 persons were detained. On the eve of the invasion, Castro proclaimed the socialist nature of the revolution. One month later, diplomatic relations were reestablished with the USSR, and on December 2, Castro declared himself, for the first time, a Marxist-Leninist.

In 1962, after a US Air Force reconnaissance aircraft discovered the construction of missile-launching sites and offensive Soviet intermediate ballistic missiles in Cuba, an international crisis between the two superpowers ensued. The outcome of the missile

crisis had a dual impact on Cuba's foreign policy. When the USA promised the USSR not to invade Cuba in exchange for the Soviet removal of missiles, any viable external threat was eliminated; however, the Cubans felt betrayed, as the compromise was reached without consulting them. Cuba then sought new allies by promoting and supporting revolutionary movements throughout Latin America. In 1967, these policies and the arrests of several members of the Cuban communist party that followed the Soviet line strained Cuban–Soviet relations. The USSR retaliated by decreasing the amount of petroleum deliveries to the island.

Cuba attempted to chart an independent course during the 1960s. It was, however, facing trading problems similar to those experienced during colonial times. It had changed a trading partner 140 km from its shores for one more than 4,500 km away. By 1963, an ill-conceived industrialization program and the neglect of Cuba's main cash crop caused the progressive indebtedness of the country. The leadership turned again to sugar and a ten million-ton sugar harvest was programmed for 1970. The sugar industry, however, was in shambles by 1964. Professional administrators had gone into exile or were substituted with politically trustworthy personnel, while expert cane-cutters had been transferred to other activities or incorporated into the militia. Already facing the failure of its international policies and domestic economic strategies, coupled with the US embargo, the impact of the Soviet sanctions on the regime was catastrophic. In 1968, Castro supported the USSR invasion of Czechoslovakia, signaling Cuba's capitulation to Soviet hegemony and Castro's determination to remain in power at any cost.

By the mid-1960s the revolution was giving unequivocal signs of fatigue. Juvenile delinquency and crime were on the rise. Disaffected Cubans, together with priests, seminarians and homosexuals, drafted into Military Units to Aid Production (UMAP), were interned in concentration camps from 1965 to 1967. The 1968 'Revolutionary Offensive' nationalized the remaining small businesses. Low worker morale and absenteeism led to low productivity and poor product quality. The strategy of moral incentives failed to mobilize the majority of workers, who were no longer imbued by the revolutionary zeal. The revolutionary process had spent itself by 1970.

1.3 Institutionalization and Foreign Military Adventurism

After 1970 Soviet political and economic models were adopted. Some material incentives were implemented, and peasant markets opened. Institutionalization, however, continued under the charismatic guidance and legitimization of Castro's leadership. In 1974, Leonid Brezhnev's visit consolidated Cuban–Soviet relations. A year later Cuba's African campaigns began with Soviet support, and in 1979 Castro was elected president of the Nonaligned Movement. Cuba's support of the Soviet invasion of Afghanistan, however, diminished its prestige and its claims to nonaligned status.

Although increases in Soviet aid led to improvements in living standards, over 120,000 Cubans abandoned the island during the 1980 Mariel Boatlift. By 1986, the failure of the Soviet models was indisputable. The crisis was compounded by the US embargo being turned again into a powerful economic weapon by the collapse of the Soviet bloc and the breakup of the USSR. By the 1980s Soviet subsidies had reached $3 billion a year. The Soviet Union supplied: 90 percent of the island's oil needs and an inordinate proportion of basic foodstuffs. To confront the crisis, Castro launched the 'Rectification of Errors Campaign' at the Third Party Congress. Material incentives and market reforms were eliminated, and mass mobilization and volunteer work were reintroduced.

In 1989, the arrest, trial, and execution of Division General Arnaldo Ochoa and of the interior ministry's Colonel Antonio de la Guardia signaled an institutional crisis. They were accused of drug dealing and breaching national security. A massive purge followed and several government agencies were dismantled. Many Cubans suspected that General Ochoa had supported political liberalization and economic reforms.

1.4 Back to the Future: Authoritarianism and Capitalism

The 'rectification' measures proved insufficient to preclude an economic collapse. In 1990 a 'special period in peacetime' was declared and policies to develop an autarkical state were adopted. To alleviate food shortages and decrease energy consumption, thousands of urbanites were forced to move to the countryside and to work in food production. Austerity and mass mobilization were expected to extricate the country from the crisis, until foreign investments, tourism, and an incipient biotechnological industry could generate the necessary hard currency.

At the 1991 Party Congress, Castro revealed that he was a 'slave' of power, entrusted with preserving socialism. There would be no political or economic reforms. By 1993, economic reforms were inevitable. Although private initiatives continued to be restricted, free markets for agricultural and consumer products, duty-free zones and 'dollarization' were introduced. Access to dollars, mainly through remittances from exile relatives, tourism, and illicit activities such as black-market participation and prostitution, provided an economic respite to a growing segment of the population. As Castro had suspected, economic liberalization started eroding the state's coercive power. Religious participation increased, critics became more vocal, human rights groups proliferated,

and short-lived rebellions erupted. In 1994, another mass exodus occurred when more than 30,000 people abandoned the island in unique makeshift innertube rafts.

In the 1990s the regime encountered growing criticism from international leaders and organizations. The International Labor Organization, Amnesty International, and the United Nations repeatedly condemned the Cuban Government for its human rights violations. Pope John Paul II urged Cuba to open to the world and condemned the US embargo. In 1996, the embargo had been reinforced by the passage of the Helms-Burton bill, introduced after Cuban Migs had shot down two US light planes in international waters, killing three US citizens. The planes belonged to 'Brothers to the Rescue,' an exile organization that flies over the Strait of Florida in search of rafts carrying Cubans fleeing the island.

2. *Rebellions and Revolutions*

'Rebellions' and 'revolutions' are terms often used to identify a series of political struggles in Cuba's history. As with China, Cuba's official, Marxist historiography proclaims one single revolutionary movement starting with the Ten Years' War (1868–98). Thus, that first war, which was restricted to the western provinces and was a classical war for independence, organized by members of the white middle and upper middle classes, primarily made up of professionals and landowners, is interpreted as a revolutionary crusade. The War of Independence (1895–8) is depicted as a continuation of that struggle, despite its broad popular base comprising workers, the middle class, peasants, and the black and mulatto populations. This second anticolonial, nationalist war, which sought to establish an independent, democratic republic, is then portrayed as a socialist revolution, interrupted by colonial, imperialist, and bourgeois interests until Castro's victory in 1959.

Another taxonomy could divide Cuba's revolutionary history, beginning in 1868, into two anticolonial, nationalist, strictly political revolutions (Ten Years' War and War of Independence); a protorevolution (1933 revolution), which was revolutionary in intent but did not achieve radical social, economic,or political changes; and a true revolution after Castro's triumph in 1959.

3. *Origins of the Cuban Revolution*

The complexity of Cuban society and of revolutions in general becomes evident as one surveys the literature on the causes of the Cuban revolution. Leo Huberman and Paul Sweezy (1961) see it as the outcome of peasant mobilization. Theodore Draper (1962) claims that it was a middle-class phenomenon. Andrés Suárez (1967), among others, argues that it was the product of Castro's charismatic leadership and political maneuvering. To Luis Aguilar (1972), it was the frustrated 1933 revolution and the absence of reforms. Jorge I. Domínguez (1978) emphasizes that it was the fragmentation and individual strength of the labor unions, professional organizations, and other interest groups in prerevolutionary Cuban politics that allowed the revolutionary process to crystallize after 1959. Marifeli Pérez-Stable (1999) sides with contemporary Cuban historiography, and claims the existence of a linear relationship between the republican failure to achieve the aspirations of the wars of independence and the revolution. In essence, there is no agreement among scholars regarding the causes of the Cuban Revolution.

4. *Revolutionary Dynamics*

The Cuban revolutionary leaders implemented strategies commonly used by totalitarian regimes. Castro's policies are reminiscent of Nazi, fascist, and Falangist tactics. The revolution marked a new beginning and required a radical transformation in the collective consciousness. Ernesto Ché Guevara (1971) expounded on the need to create both a new economic base and a 'new man' to build communism. Destruction of the historical memory was fundamental to the creation of a new society. The process of deculturation strove to uproot prerevolutionary organizational and interpersonal social patterns. The institutions of work and education, radically transformed, became the focus of Cuban life. Institutionalized religion was crippled, while attempts were made to destroy the traditional structure and values of the Cuban family. Places and events embody symbolic meanings that provide continuity and solidarity. The names of streets, sugar mills, and other landmarks were changed. The government monopolized all means of communication. Slogans, in which the names of key figures were always present, were incessantly repeated through printed media, billboards, radio, and television. Patriotic and religious holidays were replaced by revolutionary events. In 1968, the October 10, which marks the beginning of the Ten Years' War, was reinstated and the leaders appropriated this patriotic date to proclaim themselves the true liberators of Cuba 'after 100 years of fighting.' Through symbolic manipulations Cuba became synonymous with revolution and the revolution synonymous with Fidel Castro. Thus, through this syllogism, Cuba, Castro and revolution, (Fidel–patria–revolution according to Pérez-Stable 1999) became one in the public imagery.

Mass organizations, which incorporated, voluntarily or coercively, all members of society into the process, were responsible for transmitting the new ideology, introducing new patterns of behavior, conducting constant vigilance, and mobilizing the population. The euphoria that the revolutionary triumph

inspired promoted an environment of fanatical solidarity in which there was no room for dissension. The 'terror' stage, common to revolutionary upheavals, was unleashed by the trials, long jail sentences, executions, and the feeling of being under constant surveillance. A process of self-repression was set in motion among the dissenting population. After the Bay of Pigs fiasco, the exodus intensified, with the massive flight of the urban middle class, including those who had fought against previous oppressive regimes. Their density of networks and their experience in underground activities made them a target of the regime. The government, reluctantly, allowed them to leave, although their flight represented a devastating loss of human capital. The impact of these policies, although not as desired by the government, has been, nonetheless, sufficiently powerful to preclude organized domestic challenges for several decades.

5. *Conclusion*

In the 1990s a Cuban joke that defined socialism as 'the longest road between capitalism and capitalism' summarized the tragedy of a revolution that had gone full circle. Cuba's economy is returning to capitalism and continues to depend on sugar and tourism. Cuban women and men, now from all walks of life, often prostitute themselves to make a living, or in the hope that contacts with foreigners may provide them with the means to leave the country. The revolution's greatest failure has been its historical incapacity to retain the nation's greatest asset: its human capital. Making political survival its main priority, however, has won the leadership its greatest success; it has stayed in power for four decades.

Cultural Assimilation

The term is best understood in contrast with close sociological concepts, some more general (cultural diffusion) and others more specific (acculturation). Cultural diffusion denotes the passage of ideas, norms and practices from one group to another in general. Acculturation is the processes whereby one cultural system conquers the minds of an individual or group. 'Cultural assimilation' is used generally to denote the situation in which a group gradually acquires some traits of a larger society's repertoire of concepts and norms. Two main features are specific to assimilation situations. First, there is a clear asymmetry, often between a majority and a minority but, more importantly, between what are felt to be center and periphery, a dominant culture and a less central one. This is often visible in the way the central group's identity remains unnamed, or else carries the name of the overall society. In this way the leading group in the Austro-Hungarian Empire had no explicit ethnic label, unlike the Czechs, Jews, or Hungarians they ruled.

Similarly, although white Americans of European descent are clearly the majority background against which minorities are defined in the USA, there is no commonly-used ethnic category for them ('Caucasian' is not really used by anyone outside the census bureaucracy). Second, assimilation is the project whereby a group tries to gain a seat at the common table, as it were, but not to dissolve itself. But there may be considerable anxiety that achieving this political and social goal will inevitably dissolve the cultural traits that underpin a sense of common identity and destiny.

The most acute of these debates were conducted among the Jewish minorities of central Europe at the turn of the twentieth century. From this situation in which a general, often violent oppression of Jews as a group combined (in some European polities) with

unprecedented opportunities for Jews as individuals, emerged two different views of assimilation. One recommended a more intense participation in the social and political processes of the wider polities, trusting that common legal arrangements would shield the minority from the worst effects of personal prejudice. The end-goal was to make Jewishness, if not invisible, at least irrelevant to most contexts of social interaction, and therefore accepted in practice. The other, largely Zionist, view assumed that such a project would either fail altogether (inasmuch as the ever-more visible presence of Jews in the larger society would fan the fire of resentment and prejudice) or, on the contrary, succeed all too well, at the price of dissolving Jewish identity and annihilating Jewish culture.

This tension between participation in the wider social forum, often seen as a condition for survival, and the preservation of identity, construed as equally urgent prescriptions, informs American debates about the depth, meaning and consequences of the cultural assimilation of minorities. The phrase 'melting pot' was coined in the 1910s. It was thought to describe the essentially American and altogether laudable practice of combining norms and practices from different groups in order to create a distinct American political entity as well as a distinct culture. It was assumed that this cultural alchemy would preserve the best of each culture and create an even better one, in the same way as a free market weeds out inefficiency and fosters good practices.

The 'melting pot' ideology emerged more or less at the time when it ceased to be an American reality. Whereas the unification of American groups of different European origins (Scandinavian, English, Irish, etc.) in the course of the nineteenth century more or less corresponded to what the 'melting pot' was supposed to describe, the destinies of groups such as Asian-Americans, Native Americans, Hispanics and African-Americans in the twentieth century were to follow a distinctly separate trajectory. For these groups there was no melting pot, as many liberal critics of American politics observed. These critics often saw the sorry plight of minorities as a straightforward consequence of this failure to mix or assimilate.

However, many members of these minority groups had a diametrically opposed view of the assimilation process. For them, acquiring political leverage and legal protection requires, not their dissolution into larger social membership, but exactly the opposite; an attempt to make their membership of a particular group visible and audible, so that minorities could be counted and allocated political power commensurable to their demographic composition. This change in assimilation patterns (whereby modern assimilation no longer entails acculturation) does not reduce to the general contrast between old groups and newly arrived ones (called the 'old-new' model in sociology). Hence a distinctively American nonmelting pot, where *de facto* cultural similarities are ever-increasing, but social-ethnic groups also maintain strict boundaries and a heightened sense of distinctive identity, and seek an corresponding political influence.

This modern American situation is equidistant from two European political projects that informed the connections between nation and culture. One such project was romantic nationalism. Born in European nations in the eighteenth and nineteenth centuries, this ideology celebrated the ideal of a community united by land, language, and cultural traditions. It suggested that the most 'natural' or most viable political units would correspond to such communities. There was no need to provide specific political recipes for the management of such communities since each cultural tradition already incorporated its own political wisdom, time-tested and therefore appropriate to the nation concerned.

The opposite project was that of the Enlightenment and French Revolution. Here the nation was a *de facto* political unit, with a predefined political ideal (equality and democracy) but no connection to any particular cultural tradition or language. The nation was therefore construed as emerging from the participation of different individuals *qua* individuals. This is the sense of the famous statement of the French Constituent Assembly, requiring that the emancipation of the Jews, while granting them citizenship and making religiously-based oppression illegal, would 'give them everything as citizens, but nothing as a group.' In such a political project there is space for various associations of citizens based on common interests or ideology, but no place for ethnically-defined groups as political participants.

Both European projects seem to have reached the limits of their political relevance by the end of the twentieth century. Romantic nationalism, the foundation stone of many central European nations, flounders in situations characterized by ethnic patchwork, as in the Balkans, and leads to deluded ideologies of domination and the annihilation of the other. Enlightened, supposedly antiethnic nations are reinvested with ethnic and cultural qualities by many participants. This is why many citizens of the Federal Republic in Germany or the French Republic find certain of the cultural practices of Turks or Arabs repulsive or culturally threatening. In both countries political debate now centres on the way distinct ethnic groups could be granted some measure of influence or cultural autonomy without threatening the liberating possibility of participation as a free citizen, with no specific group affiliation. These debates are made more pressing by the expansion of the European Union, with the attendant decrease in the powers of the states and the increase of political influence from regions.

In Europe and other parts of the world such debates are also prompted by concerns over 'globalization.' However vaguely defined, this phenomenon of world-

wide cultural integration and political interdependence is seen as desirable (or inevitable) by many ruling elites and every bit as detrimental (or resistible) by others. From both positions, it seems that even established nations, where cultural and political identities coincide, find themselves confronted with an assimilation process. That is, some of their characteristic political or cultural arrangements are seen as an obstacle to entry into a global economic and political world. So most places become a periphery relative to a center defined as everywhere else.

Historians, sociologists, and political scientists have focused mainly on the social groups concerned, on the interaction between center and gradually assimilated entities. As a consequence, assimilation is often construed, albeit implicitly, as a one-dimensional process, whereby a given group gets closer to the cultural mainstream or maintains its distance from it (or is kept at the periphery). Such metaphors of proximity and distance may not do justice to the multidimensional nature of participation in a large polity. There may be many different dimensions along which a given individual places him- or herself at a particular point relative to a social mainstream. Many African-Americans feel more culturally assimilated to mainstream America than Asian-Americans, yet they are accepted much less in terms of political participation.

To make matters even more complex, it may be insufficient to describe cultural assimilation in terms of explicit concepts and norms. So far, social scientists have focused principally on those notions or preferences that individuals are aware of, and consider to be their distinctive character: their cultural traditions, their language, their common political past. But a cultural unity, a sense of being the same kind of person as others, may also be based on concepts and norms that are not consciously accessible; on ways of acting and even reasoning that are transmitted from one generation to the next without much conscious realization. Experimental social psychologists have documented such subtle cultural differences.

For instance, (white middle-class) American subjects do not react to simple computer animations in quite the same way as Chinese or Japanese subjects. When such animations show a school of fish tightly packed together and another fish at a distance from the group, Americans see the latter as a laudably independent, self-motivated agent. Many Asians, however, tend to see it as pitifully isolated and probably lost. Such results may seem largely explained by explicit ideologies of individualism and self-reliance (in the West) contrasted with group cohesion and solidarity (in the East). Other differences are less easy to interpret, such as a tendency in Asians to look at the overall pattern of a computer display, when Americans are more likely to focus on details and ignore its overall coherence.

Such experimentally-revealed differences do not necessarily mean that socialization in different groups result in fundamentally different cognitive processes. But they do show that assimilating a culture, either that of one's own group or that of a larger polity, cannot be reduced to adherence to explicit norms and cultural concepts. This connects with a concept of culture that is familiar to anthropologists but less so to other social scientists as encompassing, not just explicit norms and habits, but also what goes without saying, the tacit norms and unconscious cognitive habits that structure one's everyday world.

There is still little systematic study of the impact of migration and political assimilation on such elusive cognitive differences. Yet this is a crucial domain of investigation. Social and political interaction between central and noncentral groups may depend on agreement or discrepancies between these tacit norms every bit as much as they depend on explicit differences. Most social scientists are eager to show that assimilation processes require agents, that is, they do not happen outside the social and political projects of various people. It is not, for instance, just American culture, as an abstract entity, that somehow permeates cultural boundaries but actual Americans and members of other groups that join (or do not join) common social projects. Without neglecting this sense of active decision-making on the actors' part, it may be necessary to take into account aspects of cultural inertia that are not affected by people's decisions, because they are not really visible to the actors themselves, yet influence their integration into a wider cultural environment.

Cultural Contact: Archaeological Approaches

The focus of culture contact, as currently defined, is the study of culture change within the context of contact situations involving different cultures. Much of the recent effort in this field has been on early encounters of indigenous peoples with Europeans in colonial contexts. The current archaeological approach integrates lines of evidence from archaeology, ethnography, ethnohistory, linguistics, biological anthropology, and native oral traditions. Beginning with 'acculturation,' the article alludes to subsequent theoretical and methodological trends. While no single theoretical position captures the field, certain ubiquitous issues include: (a) world economy and the intensification of regional exchange and innovations in material culture; (b) demographic collapse, lethal epidemics, and changing natural landscapes; and (c) implications of demographic collapse for social disruption and reformulation including native responses of resistance, domination, and cooperation. A discussion of how issues relating to culture contact articulate with the greater theoretical agendas that dominate anthropology today leads to the recognition of methodological issues or problems as well as future directions involving historical anthropology and an increased interest in the development and negotiation of status hierarchies, ethnic identities, and gender relations in pluralistic colonial communities.

1. Introduction

The focus of culture contact, as currently defined, is the study of culture change or persistence within the context of contact situations involving different cultures and diverse types of interaction. This research has been and continues to be motivated by the overarching and longstanding desire within the field of anthropology to understand how and why culture changes. Much of the recent effort in this field has been on early encounters of indigenous peoples in colonial contexts. Numerous factors were involved in the early exploration and eventual settlement of landscapes all over the world including the discovery and exploitation of resources, the religious or spiritual conversion of Indians, trading, and gaining access to sea routes or ports. In some cases military objectives often necessitated the allegiance of the native population or the use of native peoples to buffer between European military territories. In other cases it was more expedient to use missionaries to control native groups than to establish forts and use military might (Milanich 1995, p. 165). Native encounters with European, African, and Asian peoples in early contact settings can be used to address issues regarding the founding and development of the resultant multiethnic colonial communities.

2. Historical Perspective

As late as 1938 the intensive study of contact between peoples was a 'relatively recent development in the anthropological repertory' (Herskovits 1937, p. 1). One term often used within these studies was 'acculturation.' Herskovits, however, found this word to be 'peculiarly American' and noted that the British had consistently preferred to employ the term 'culture-contact' (Herskovits 1937, p. 2). The subtle differences in these terms mark a trajectory that influences culture-contact perspectives to this day. While acculturation may be taken to refer to the ways in which some cultural aspect is taken into a culture and adjusted and fitted, it also implies some relative cultural equality between the giving and receiving cultures. In 1928 the word 'acculturation' was defined as 'the approximation of one human race or tribe to another in culture or arts by contact.' However, a later edition of *Webster's Unabridged Dictionary* (1934) added the phrase 'to cause or induce a people to adopt the culture of another' (Herskovits 1937, p. 2).

In 1940 acculturation was viewed as a process within a paradigm that saw cultures as 'infinitely perfectable' and in which rates of change will differ in 'so-called primitive cultures' (Linton 1940, p. 468). A sense of the developing colonial and unidirectional emphasis that characterized early culture contact studies might be inferred from a statement made by Malinowski in 1945. 'The study of culture change must take into account three orders of reality: the impact of the higher culture; the substance of native life on which it is directed; and the phenomenon of autonomous change resulting from the reaction between the two cultures' (1945, p. 26).

By 1955 American archaeologists had begun to recognize the complexity of contact contexts and identified eight types of culture contact situations: including intrusive culture, resident culture, site-unit intrusion, and trait-unit intrusion (Woodbury 1955). By 1961 the notions of 'differential change and both directed and nondirected situations' that have since been adopted were being acknowledged by many anthropologists and archaeologists (Spicer 1961).

3. Current Theory and Research

Today, culture contact studies are recognized as being well suited to evaluate and refine theoretical and methodological approaches to culture change and persistence in archaeology. The current archaeological approach subscribes to the potential of multiple lines of evidence by integrating data from archaeology, ethnography, ethnohistory, linguistics, biological anthropology, and native oral traditions. While no single theoretical position captures the field, certain ubiquitous issues include: (a) world economy; intensification of regional exchange and innovations in material culture, (b) demographic collapse; changing natural landscapes and lethal epidemics, and (c) implications of demographic collapse for social disruption and reformulation including native responses of resistance, domination, cooperation, and cultural transformation.

3.1 World Economy and the Intensification of Regional Exchange and Innovations in Material Culture

Many recent archaeological studies of contact contexts have been informed by a colonialist perspective of core–periphery relationships as exemplified in World Systems theory (Wallerstein 1974, Wolf 1982). Wallerstein's world systems theory remains the most influential work in archaeological studies of core–periphery relationships. While these studies have expanded the scope of research, some problems remain. Specific problems with colonialist models include (a) insular models of culture change that treat frontiers as passive recipients of core innovations, (b) the reliance on macroscales of analysis employed in frontier research, and (c) the expectation of sharp frontier boundaries visible in material culture (Lightfoot and Martinez 1995, p. 471). The study of material culture is the unique domain of archaeology and often the influence of material culture on social dynamics is under-rated. Material items are active symbols in broadcasting and even negotiating a person's identity in culture contact situations. However, the impact of introduced materials in these contexts is becoming well recognized. For example, the impact of the introduction of brass and iron kettles by French traders was so great that the cessation of ceramic production among aboriginal populations often occurred in less than a generation (Walthall and Emerson 1992, p. 6). Or, as Hantman suggests, copper could have been a key symbol, if not a source, of power and authority in matters secular and sacred—a critical variable in the dynamics of Jamestown (1990, p. 685). Not only items or categories of materials but architecture, roads, villages, and the spatial distribution of materials and villages on the landscape may reflect or influence similar changes.

3.2 Demographic Collapse, Lethal Epidemics, and Changing Natural Landscapes

Colonists brought with them pathogens that escaped from their original hosts to invade new territory. Because the natives lacked immunity to the introduced viruses and germs, they often succumbed in large numbers (Dobyns 1983, p. 8). Epidemics spread along established trade routes throughout the larger regions, and major outbreaks occurred at varying intervals, some striking at least once every generation. These events often left 'niches' to fill or made inoperative many conventional understandings evolved by large populations (Dobyns 1983). Any respectable theory that attempts to explain the European demographic advance has to provide explanations for the frequent demoralization and often annihilation of indigenous populations, as well as the 'stunning' success of European agriculture in colonialist territories (Crosby 1986).

3.3 Implications of Demographic Collapse for Social Disruption and Reformulation Including Native Responses of Resistance, Domination, and Cooperation

Archaeology has a critical role in addressing change in these contexts of social disruption and reformulation. It is only through analysis of the past that we can assess the precontact social structure, evidence of change, and the accuracy of the ethnohistoric or documentary record. As for native responses, the range of variability available to all people must be attributed to indigenous populations. These would include the possibilities of resistance, domination, and cooperation. For example, sedentary farming societies fit better into the colonial mission system than groups who were not sedentary agriculturalists, and attempts to establish missions among nonagriculturalists was not always successful (Milanich 1995). Revolts, resistance to tribute demands, conscripted labor, and threats to power and status were all potential responses. Brumfiel (1994) has summarized the importance of factional competition in the transformation of societies. These strategies include intermarriage, the creation of exchange partnerships, and the development of work cooperatives.

4. Some Problems and Future Directions

A discussion of how issues relating to archaeological approaches to culture contact articulate with the greater theoretical agendas that dominate anthropology today leads to the recognition of methodological issues or problems. While recognizing the great potential for an archaeology of pluralism, two issues were raised recently about the theoretical models and methodological practices employed in the study of

material culture in multiethnic contexts. The first issue concerned the development of more sophisticated 'contextual' approaches to study pluralism, which can compliment and broaden our current focus beyond artifact-based analyses (Lightfoot 1995, pp. 202–10). The second issue involved the promotion of multiscalar research that may enable archaeologists to address not only macroscale processes of world systems and colonial policies, but also microscale practices of individual intentionality and social action that are critical components of 'encounters' in pluralistic settings (Lightfoot and Martinez 1995, pp. 477–88).

For example, one approach builds on a crucial tenet of practice theory—that individuals will enact and construct their underlying organizational principles and worldviews in the ordering of daily life. By examining the organization of daily life in archaeological contexts—the spatial layout of residential space, the reordering of domestic tasks, the structure of trash disposal—we can critically evaluate the nature and magnitude of culture change and persistence in contact settings (Lightfoot et al. 1998, pp. 216–17).

For other scholars, changes in economic activities are changes in the structure of meaning. Debates over historical process often center on whether internal or external agents are precipitators of historical change. However scholars approach historical processes, they realize now that they were wrong in the past to assume that any culture has been isolated from the rest of the world or that change was unidirectional. Future directions involve issues relating to a redefined 'historical anthropology' and an increased interest in the development and negotiation of status hierarchies, ethnic identities, and gender relations in pluralistic colonial communities.

In summary, the current archaeological approaches to culture contact embrace a 'contextual' and holistic approach that integrates multiple lines of evidence and multiple perspectives.

Cultural Critique: Anthropological

1. Cultural Critique and the Ethnographic tradition

Cultural critique, the use of anthropology to draw critical attention to institutions that readers take for granted, is as old as the origins of the modern discipline. It was a major purpose of Boas' students, especially Margaret Mead and Ruth Benedict. Its antecedents range from modernism to the critical theory of the Frankfurt school and the French surrealists between the wars; and the roots of critique lie in eighteenth-century philosophy.

What is 'cultural critique?' It is to examine the foundations of culture by having recourse to judgment. Judgment in turn is the ability to form an opinion on the basis of careful consideration; beyond

that to discern relations linking particulars to more general principles. Although not indifferent to fact and logic, judgment requires consideration of worth. A judge is respected for his or her wisdom and apparent objectivity, that is for the ability to transcend mere opinion, even by giving expression to universal truth. A cognate expression is critic (which is, after all, derived from the Greek word for judgment). But criticism most often connotes for us the formation of opinions about works of art and the term 'cultural critique' suggests a direct link between anthropology and literary criticism. Indeed, critical anthropology has involved of late a shift in emphasis from life to text, reflecting a trend driven by poststructuralist discourse from the 1970s onwards.

Ethnography has been the dominant form of anthropological enquiry in the twentieth century. It literally means writing about peoples considered to constitute natural units, on the basis of extended participation in and observation of their societies. It arose in opposition to the method that preceded it, evolutionary history. This last sought to explain how the world came to be unified by Western imperialism by postulating a racial hierarchy in which 'our' cultural superiority (having developed a machine technology based on scientific reason) was attributed to biological difference. World War II undermined the credibility of this claim of Western civilization to be founded on universal reason and opened up a space for anthropologists willing to assert the virtues of ways of life previously considered to be 'primitive' and inferior. Bronislaw Malinowski is rightly considered to be the pioneer of a new ethnographic approach stressing the integrity of contemporary exotic cultures. In *Argonauts of the Western Pacific* (Malinowski 1961) he made clear his aim to challenge the assumption that Western economic norms were either universal or inherently superior. Subsequently Edward Evans-Pritchard drew on liberal myths of Saxon resistance to Norman rule to dispute the identification of political order with the state, finding 'ordered anarchy' among the Nuer of the Sudan (Evans-Pritchard 1940).

The academic norm of scientific ethnography was made necessary by anthropologists' drive towards legitimacy as a social science discipline. They eschewed fiction of all kinds. The basis of their truth claims was participant observation, the fact that they had joined the people in some exotic location and shared their life as a means of studying them. Students were encouraged to read the classical monographs as scientific truth. The exercise of judgment was unnecessary, since professional vetting of the empirical object was sufficient guarantee of a monograph's validity. Within this framework of objectivity, ethnography was potentially critical of Western civilization's claim to universality. By stepping out of normal society, ethnographers pointed a sharp light on the assumptions of their readers, showing, for example, that witchcraft accusations made sense or that gifts may be instruments of domination. The general aim of anthropologists at this time seems to have been to discredit the racist assumptions underlying colonial empire. In the USA this trend was associated with a position known as 'cultural relativism': every way of life, however barbarous, has a right to exist and it is not for outsiders to judge it as inferior for any reason.

The founder of modern American anthropology, Franz Boas, was himself committed to educating public opinion (Boas 1929); but his students took this further by setting out to reach a general US audience with the surprising results of their own and others' ethnography. Americans think of their culture as natural, i.e., inevitable; by showing them cultural variation elsewhere they are forced to ask if their own culture is malleable. This perhaps accounts for why Ruth Benedict's *Patterns of Culture* (1934), an impressive collation of cultural variety worldwide, was the anthropology bestseller of all time. Its subtitle is particularly instructive: 'an analysis or our social structure as related to primitive civilizations.' In *Coming of Age in Samoa* (1928), her colleague Margaret Mead's topic was adolescence. Americans think of teenagers' turbulence as the natural result of sexual development; Samoan youth experienced adolescence more peacefully; so maybe they ought to think again about the reasons for teenage behavior. In a comparative work, *Male and Female: A Study of the Sexes in a Changing World* (Mead 1949), Mead piled example on example to demonstrate that the sexual division of labor thought to be natural in Western societies was a special case. It is not hard to imagine how such a book might enter the campaign for female emancipation. Mead has been subjected to savage criticism of late for the inadequacy of her fieldwork and the exaggeration of her deconstructive cultural contrasts. These attacks have come precisely when the cultural critique she pioneered has sought to undermine the premises of scientific ethnography itself, as she never did.

2. *Writing Culture*

Most recently, cultural critique in anthropology has been associated with an American school of ethnographers led by George Marcus. With James Clifford, he published *Writing Culture: The Poetics and Politics of Ethnography* (Clifford and Marcus 1986), a book which has come to be seen as marking the postmodern shift in anthropology. At much the same time, Marcus published, with Michael Fischer, *Anthropology as Cultural Critique: An Experimental Moment in the Human Sciences* (Marcus and Fischer 1999; see also Marcus 1999). The growing prominence of cultural critique has been ascribed to a 'literary turn' associated with the work of Clifford Geertz since the early 1970s (Geertz 1988). Clifford has carved out his own contribution to resolving 'the crisis of representation' in a series of works, notably *The Predicament of Culture*

(1988). Paul Rabinow's *Reflections on Fieldwork in Morocco* (Rabinow 1977) prefigured the critical reassessment of ethnographic method. The journal *Critique of Anthropology* grew out of collaboration between radical anthropologists in Britain, Holland and the USA beginning in the 1970s.

The critique launched by *Writing Culture* had as its focus three aspects of the ethnographic enterprise: poetics, politics (both in the subtitle), and epistemology. By 'poetics,' attention is drawn to the fact that ethnographers make up what they write. Geertz had been more or less explicit about his ambitions as a creative writer for over a decade before. Language, in such a perspective, is never simply descriptive, but persuasive also. If ethnography is literature, the strident assertion by positivists of its factual (nonfictional) basis must be questioned. The 'politics' of ethnography refers to a triadic relationship between anthropologists, their subjects and their readers. The political economy of global inequality must be foregrounded in ethnographic descriptions, and author–reader relations are more problematic than the original formula allows for. Who are the monographs for, and what possibilities for collaboration exist beyond the stereotype of the ethnographer as a lone ranger in a pith helmet? Finally, the status of ethnography as a source of knowledge (epistemology), its methodology and configuration of knowledge as power, are called into question. Cultural critique in these terms examines the very intellectual foundations of modern anthropology.

What then have been the poetic and political purposes of the cultural critics and how effective was their epistemological critique? First, they were Americans who wished to engage more directly with American society. That is, they proposed to carry out ethnographic fieldwork in and write about mainstream activities and institutions. This required developing experimental methods, summed up as 'reflexivity,' the need for the ethnographer to be continuously self-monitoring in the light of feedback from society. Their aim was similar to Mead's in seeking to disturb conventional assumptions about the USA's place in the world. Techniques of authorship proved hard to subvert in practice. Although the boundary between fact and fiction became blurred, few anthropologists have openly embraced the novel as a model. The radical rhetoric of the cultural critics, their attempts to develop new constituencies and forms of collaboration ran up against the continuing dominance of the universities as anthropology's institutional home.

The ideal of the 'citizen ethnographer,' boldly synthesizing fieldwork-based research, critical theory and political commitment at home, remains a somewhat distant goal. If we can no longer read ethnographies as factual truth, how do we acquire the judgment to make sense of them, especially when cultural relativism has told us we should not judge others as the Victorian imperialists used to? Much postmodern writing adopts an ironic tone, and perhaps this is because it straddles unresolved contradictions of this kind. For critics are by definition judgmental, yet convinced relativists have nowhere to stand.

The main controversial aspect of this program is thus its confrontation with the realism, naturalism and objectification inherent in the positivist tradition of scientific ethnography. The traditional premise of ethnography, the study of other cultures for the sake of our own self-enlightenment, became more untenable under postcolonial circumstances. It fell to Marcus and his associates to make explicit the faults of a paradigm that had been unraveling for decades. The value of this American movement is much debated. Although the protagonists have sometimes tried to distance themselves from the 'postmodern' tag, preferring to speak of 'high modernism' or 'reflexive modernity,' cultural critique has been seen by its positivist detractors as evidence of a postmodern collapse into fragmentation, confusion and extreme relativism (Gellner 1992). Others seem to agree that we have entered a postmodern age and that cultural critique is an appropriate response to it.

3. *Other Services of Critical Anthropology*

Cultural critique has not been absent from the other main national traditions of anthropology. Indeed, in France the public's reception of intellectuals has always been readier than was ever the case among the Anglo–Saxons. Moreover, French anthropologists have never embraced a narrow cultural relativism, preferring to keep alive the Enlightenment's legacy of an appeal to universal reason. The recent publication of Marcel Mauss' political writings (Mauss 1997) shows how deep-seated this public engagement was for him. As his principal successor, Claude Lévi-Strauss wrote a popular classic, *Tristes Tropiques*, and exposed to critical view the central institution of French culture, table manners (Lévi-Strauss 1976, 1978). Among contemporary anthropologists, Marc Augé (1995) has successfully bridged the gap between the academy and popular culture, explaining the symbolic significance of Princess Diana's death and other contemporary events to readers of the serious newspapers. Britain produced the only systematic critique of contemporary civilization by an anthropologist so far in Edmund Leach's brilliant BBC lectures, *A Runaway World?* (Leach 1968). His attempt to address general fears concerning the explosion of machine production was premised on the need for his listeners to come to terms with their human potential and for anthropology's scope to match that potential. No one has come close to doing that since.

In the last decades of the twentieth century, feminist anthropology was in the forefront of cultural critique.

Indeed the absence of women from *Writing Culture* provoked a justified response (Behar and Gordon 1995). It was, after all, the women's movement that declared in the 1960s that 'the personal is political' and launched a devastating critique of Western institutions on grounds of the invisibility, exclusion and exploitation of women. These broader criticisms were readily applied to anthropology. An example of the sophistication reached by feminist and post-feminist discourse is Marilyn Strathern's *The Gender of the Gift* (Strathern 1988), where the confounding of Western gender stereotypes in Melanesian cultures is taken as a point of departure for a much wider critique of such core conceptual pairs as individual–society and nature–culture. The 1980s were a decade of deconstruction, what Hegel called 'negative dialectic,' in which the conventional categories of the modern synthesis became confused and discredited. Both inside and outside the academy, this task was performed to a disproportionate extent by women scholars.

Anthropology does not stand alone within an academic division of labor that has recently added 'cultural studies' to its ranks. An enhanced focus on the contemporary forms of cultural production has revived interest in the Frankfurt school of Adorno and Benjamin. Their concern with exposing the uses of culture in masking the contradictions of capitalism remains a powerful one. Perhaps even more relevant to critical anthropology is the work of the West Indian writer, C. L. R. James (Grimshaw 1992, Grimshaw and Hart 1993). In *American Civilization* (James 1993), he identified a growing conflict between vast anonymous bureaucracies and people's aspirations for an extension of democracy into all areas of their lives, an aspiration that could only be met indirectly through the movies and other forms of popular culture. For James, this was a crisis for modern society as a whole, most acutely revealed in the USA; and he addressed it through a critique ranging from Hollywood films and comic strips to psychoanalysis and the classical novels of Herman Melville.

4. *Eighteenth Century Roots of Critique*

As long as ethnographers reached the remotest corners of the planet, their work could claim to be anthropology in the sense of providing the widest possible context of cross-cultural comparison. It is not easy to see what is anthropological about the indigenous critique of American Society, when the term 'ethnography' is also used by geographers, sociologists, and literary critics. The limitations of cultural critique so far could be said to lie in two weaknesses. The epistemological critique of ethnographic method has been somewhat introverted, an in-house discourse maintained by a minor academic profession, when the issues raised are potentially of universal significance. And the aspiration to grasp the human condition in general seems to have been abandoned in favor of competing for public attention in the USA. Both of these deficiencies might be redressed if critical ethnographers examined their roots in the eighteenth-century philosophy that launched modern anthropology, as well as the notion of critique.

This is not the place to explore how Kant developed his original conception of critique, most notably in his great *Critique of Pure Reason*, but also, for our purposes, in the *Critique of Judgment* (see Cassirer 1981 for an inspiring introduction to each). In seeking a metaphysical ground between reason and understanding, Kant emulated Copernicus' revolution, showing how, instead of the object revolving around the spectator, the spectator could be seen as revolving, while the object remained at rest. There are so many echoes of Kantian subjectivity in the anthropological moment of cultural critique. What is missing is the aspiration to a universality of method. This is doubly inexcusable in that Kant invented the term 'anthropology' in its modern sense (Kant 1978). Surely a discipline with the remit of offering knowledgeable guidance on human teleology should not content itself with a jester's role, *épater les bourgeois*.

No one would dispute Jean-Jacques Rousseau's standing as the founder of modern cultural critique. He showed that a critical perspective on society, a refusal to take as inevitable things as they are, requires us to devise new methods of studying and writing about a transitional present. The boundary between fact and fiction has to be blurred if we are to talk about the evolution of possible worlds out of the actual one we live in. In developing a revolutionary critique of politics, education, sexuality and self-identity (*Le Contrat Social*, *Emile*, *La Nouvelle Héloïse*, *Les Confessions*), Rousseau came up with a different genre of writing for each topic.

Critical anthropologists today might emulate his example, were they not forced to justify themselves to the academic bureaucracy. The two discourses that launched Rousseau's career, however, are the principal sources for a renewal of critical anthropology, combining as they do a critique of corrupt civilization with an anthropology whose aim is to redress global inequality. In particular, his *Discourse on the Origins and Foundation of Inequality among Men* (Rousseau 1984), which has inspired anthropologists from Morgan and Engels to Lévi-Strauss, deserves to be seen as the first great work of the modern discipline.

Cultural critique has been an invigorating stimulus to new thinking in anthropology. It is uncertain whether it can flourish while its practitioners remain securely locked up in their academic enclaves. It is time in any case for a return to the universal outlook of the eighteenth-century pioneers.

Cultural Diversity, Human Development, and Education

Humans are a unique species in that they can accumulate experiences in the form of culture, a special medium of life that consists of a set of interrelated and shared artifacts that their offspring can access and incorporate. Human development is thus achieved by incorporating these artifacts into the mind. The human species, more than any other, acquires behavioral characteristics through learning. Moreover, humans organize learning opportunities for their young to socialize or enculturate them in particular ways. Education has emerged from this species-specific tendency (Serpell and Hatano 1997). Hence there should be close, mutually supporting relationships between diverse cultures, differently organized ways of educating children, and correspondingly differentiated courses and products of individual development.

However, two standardizing factors have made the relationships among culture, human development, and education much more complex. First, contemporary cultures, and especially their educational aspects, share a large number of features that are needed to meet the demands of mass production–consumption economies and the values reflecting them. To survive in the present competitive world, most cultures are eager to promote in their children the learning of science and technology, and thus to enhance literacy, numeracy, and a beginning of an understanding of science. As a result, education in the form of institutionalized, basic public schooling has become almost universal across cultures. This form of schooling is, for example, conducted by teachers, who are regarded as specialists and are in charge of choosing their course contents and methods of teaching. The teachers usually rely on didactic methods that require students to manipulate symbols instead of handling real objects in meaningful contexts (Serpell and Hatano 1997).

Second, although the human mind develops by being socialized or enculturated, it has some universal features as a product of the species' evolutionary history. It is now accepted generally that human development is constrained by a set of innate tendencies and preferences, and as a result, there is one human mind, although there are many mentalities. This implies that even diverse cultures may produce a highly similar pattern of individual development. In

this article we will discuss these complicated relationships between culture, human development, and education, taking a few domains of growth as examples.

1. Socialization and Education in Infancy and Early Childhood

It has been universally documented by empirical research that affective relationships between young children and socialization agents enhance the children's susceptibility and tendency to comply with these agents which include parents, siblings, peers, and teachers. A nurturing person to whom a child has attached can induce the child's response to her or his signals, proposals, or demands and convey social influences. In fact, infants earnestly try to acquire information from an attached figure through social referencing when they interpret a situation as being unusual or urgent. Moreover, mothers of securely attached toddlers use less power-assertive and more affective strategies when they interact with their children than do mothers of insecure children. In turn, securely attached toddlers are more compliant with their mothers than are their insecure counterparts.

Although the affect-facilitation principle can be applied to the socialization of children in every culture, the content of socialization must vary between cultures. That is, there are cultural preferences in the goals of child development and also in the patterns of socializing interactions between children and caregivers.

For example, Weisner et al. (1994) investigated children's gender typing in conventional and nonconventional families, and found that the nonconventional parents encouraged their children to develop gender egalitarian values while displaying fewer gender-stereotyped behaviors than did their traditional counterparts. Miller et al. (1997) analyzed narratives directed to a target toddler by family members who were European Americans or Taiwanese. They found that the Taiwanese family members mentioned the past transgressions of the child, treating the transgressions as a didactic resource for conveying the moral standard, while American subjects referred to the past transgressions less frequently and with less seriousness, or they recalled children's past failures as entertainment for the family. Greenfield and her colleagues (e.g., Greenfield 1999) investigated cross-generational changes in the cultural transmission of weaving in a community in Mexico. Their observations indicated that the ecological transition of the society from an agricultural subsistence economy to commercial entrepreneurship over two decades had changed both the goals (the standard of high quality weaving) and the ways of teaching (imitation vs. creation) in this community.

Moreover, educational institutions for young children, nursery schools and kindergartens, have been constructed on every continent under the influence of Western philosophers of education, such as Pestalozzi, Montessori, and Piaget. Through participation in these educational institutions, children obtain knowledge and develop social skills. Some of the goals, tools, and processes of early childhood education are universal across cultures, but others vary owing to historical traditions, customs, and the everyday practices of the peoples of each culture. Through those experiences, children become appropriate successors for each society. For example, Western researchers who observe Japanese preschools are often impressed by the schools' emphasis on cooperation and group-living skills. These researchers speculate that participation in such cultural practices will help Japanese children to develop friendships and an interdependent sense of self, which make them able successors of the so-called interdependent culture (e.g., Tobin 1992).

2. Literacy, Schooling, and Human Development

Formal education in the contemporary world is often construed as a cumulative progression with two broad phases (Serpell and Hatano 1997): (a) the fundamental acquisition of basic literacy skills that are subsequently deployed by the individual, and (b) the acquisition of cultural knowledge and of a higher level of understanding. Thus, much of the initial phase of schooling focuses on the teaching and learning of basic reading and writing. This is because literacy is often construed as a passport to full participation in 'the modern world.'

However, whether the acquisition of literacy skills, both within the community and at the individual level, plays a critical role in human development is still debatable. Although a number of leading scholars in the field assert that literacy establishes a relationship between a word and its referent that is more general and more abstract than in oral communication, such views (called 'the great divide theories') have been criticized because they imply that nonliterate cultures or individuals are primitive or immature. Moreover, it has been demonstrated that the acquisition of literacy skills *per se*, separated from schooling and used in restricted situations, does not produce general cognitive effects. It seems reasonable to assume that orality has its own virtues (Olson and Torrance 1991).

It is reasonable, however, to claim that literacy induces some specific cognitive changes, depending upon what people do with it (Olson 1994). In technologically advanced societies many practices, including administration, religion, and science, require their participants to use the written language, so the acquisition of literacy often enables people to enter one of these practices. This will inevitably enhance the development of the body of knowledge and cognitive skills that are used in the target practice. As in-

formation technology develops further, new forms of literacy (e.g., what is called computer literacy) are now being sought.

Another interesting issue related to the acquisition of literacy in terms of the triangular relationships between culture, human development, and education is how different writing systems are learned differently, and how each culture supports such learning (Harris and Hatano 1999). Writing systems vary widely, even in the contemporary world. For example, as is well known, English is an orthographically irregular language, that is, there is an inconsistent (and, in some cases, arbitrary) relationship between letters and sounds. In contrast, in other languages such as Spanish and Italian, there is a highly regular relationship between sounds and letters. When learning an orthographically regular language, children become fluent readers once they master all the relationships between spelling and sound. It is possible for them to spell any word that they hear and to pronounce any word that they see written down.

There are, in addition, some writing systems in which letters or characters do not represent phonemes but a larger unit. That unit is either a morpheme or a syllable. The best known example of a writing system in which a single character represents a morpheme (basic unit of meaning) is Chinese. To read a logographic orthography such as Chinese, children do not have to segment a spoken word into phonemes to discover the script–sound correspondence. Thus, learning to read the first 100 or so words in these systems is easier than in any alphabetical writing system. However, becoming a competent reader in such a writing system is a very time-consuming process with a large memory load, since it contains a very large number of different characters that cannot easily be broken down into smaller subcomponents as in the case of alphabetically written words. The second type of nonalphabetic writing system is a syllabic system in which each syllable in the language is represented by one character. It is easy for young children to learn to read in the syllabic system of writing because syllables are more readily accessible to awareness than phonemes. Syllabaries in which each character represents a syllable or mora (subsyllabic rhythmic unit) are extensively used in Japan.

For different writing systems, different sets of preconditions are required on the part of the learner. For example, whereas a less sophisticated phonological segmentation strategy is needed for learning Chinese characters than that for alphabets, the ability to discriminate visually complex figures is more critical. Accordingly, different play and study activities for enhancing the development of the relevant preconditions are provided by the cultures. For example, the ability to segment a word into an onset and a rhyme is facilitated by nursery rhymes in English-speaking countries. Similarly, to make up for the difficulty of learning a large number of Chinese characters, the ability to read and write them earns the learner some special respect in the cultures in which these characters are used.

3. *Cross-national Differences in Mathematics Teaching and Learning*

Humans seem to possess some protoquantitative schemata, by which they can count, add and subtract. These schemata serve as the basis for buying and selling, as observed in street mathematics (Nunes et al. 1993). The educational practice of mathematics teaching and learning might be expected to be essentially the same all over the world, wherever schooling is instituted. However, a number of studies have yielded striking differences in mathematical achievements between American and East Asian children. For example, in the first study by Stevenson's group, Chinese and Japanese first-graders clearly outperformed American first-graders. At the fifth-grade level, the difference in performance between the American and the Asian children was even greater—even the highest average score for an American fifth-grade classroom was below the lowest average score of an Asian fifth-grade classroom (Stevenson and Stigler 1992).

There are also remarkable differences in a number of features, both quantitative and qualitative, of the mathematics teaching and learning practices in China, Japan, and the USA. Asian children spend a larger number of hours on mathematics, and are led by teachers more often than their American counterparts. Whereas American teachers have a tendency to ask as many questions as possible, Asian teachers often spend an entire class discussing one or two problems. Also, whereas American teachers often give immediate feedback to students' answers, Chinese and Japanese teachers are likely to ask students to explain their answers and then call upon other students to evaluate their correctness.

These observed differences in the teachers' behavior may be attributed to their different folk-pedagogies as regards the best way for students to learn mathematics (Hatano and Inagaki 1998). They may constitute part of more general cultural beliefs about learning and teaching. Stigler and Hiebert (1999) suggest that, based on a video study of eighth-grade mathematics teaching in Germany, Japan, and the USA, which was part of the Third International Mathematics and Science Study, American teachers believe that the more exercises given, the more smoothly learning will proceed, whereas Japanese teachers believe that students learn best by struggling to solve a problem and also hearing about the pros and cons of different methods.

To summarize, although apparently highly similar public schooling is institutionalized almost everywhere

in the world, the process of actual learning and teaching in mathematics differs even among technologically advanced countries, owing to their different cultural backgrounds. Such differences tend to produce widely different levels of mathematical achievements.

4. *Intervention for Citizenship*

For the creation and continuation of society, every society needs competent members. However, the kinds of knowledge that are required and the extent to which they have to be established depend on various cultural backgrounds, including history, politics, economics, and religion.

In technologically advanced countries, this need has been conceptualized as acquiring citizenship and has provoked relevant research and education. Social scientists and educators are examining whether people, including young children, can develop social awareness through understanding the history, politics, and economics of the society, and also urgent problems such as human rights and environmental issues. It is expected that, as members of society, citizens should recognize these problems as well as be familiar with their entire social system. In addition, they should understand how everyday practices in which they participate relate to other people and other social systems, and know that they are more or less responsible for social events that happen anywhere on earth.

However, it has been documented that it is not easy for ordinary people to acquire accurate societal knowledge. For instance, in his monumental book, Furth (1980) showed that even adolescents, who had supposedly acquired formal operations in cognitive development, could not spontaneously reach the stage of fully understanding social institutions or mechanisms. Moreover, studies on people's understanding of the banking business, as representative of the kind of economic knowledge needed to grasp the present capitalistic world, indicated that adolescents and young adults from middle-class, salaried families in Glasgow, Leiden, and Tokyo possessed only limited knowledge. They developed naive theories about the banking business by borrowing rules from everyday personal interactions that were basically governed by ethical and humanistic considerations (Takahashi and Hatano 1999).

However, it has also been documented that children who are involved in economic activities and live in a highly commercialized area have an enhanced economic understanding. For example, Jahoda (1981) found that children in Harare, Zimbabwe who were working as sellers understood profit-making mechanisms of shops more precociously than did their less-experienced counterparts in Scotland and New Zealand. In addition, it has been observed that people of different social classes develop their own social representations as to social events and systems. For instance, adolescents from middle-class families tend to offer more individualistic explanations for poverty than do their working-class counterparts. Thus, we can assume that formal and informal interventions will advance and elaborate some kinds of societal understandings. In fact, Youniss and Yates (1997) studied how a school-based social activity, i.e., community service experiences at a soup kitchen for the homeless, provoked reflection on poverty, racism, and various social problems among high-school students from a major city in North America. In this case, in a year-long project on social justice, students were both taught in a classroom and required to work four times at a soup kitchen. In Germany, there are many kinds of educational programs for students to learn human rights after Auschwitz. In one project, high-school students cleaned a Jewish cemetery to learn the fate of the Jewish people in Nazi Germany (Rathenow and Weber 1998).

In addition, awareness of inequality and unfairness among the weak in society, i.e., females, children, elderly persons, and handicapped people, has gradually transformed conventional views and beliefs regarding the nature of human beings and human development. For example, Gilligan (1982/1993) pointed out that social sciences have long neglected the fact that females have been socialized and educated to have different voices from males. Although there are no decisive biological differences between the sexes that can rationalize different socialization and education, many studies have indicated that from the birth on, children in almost all cultures are differently socialized and educated through both visible and invisible biased programs of gender typing. Some progressive researchers in Japan have shown by analyzing the content of school textbooks that there are male-dominant biases in both the texts and illustrations.

Furthermore, there are a variety of other opportunities to enhance our societal understanding. For instance, empirical data about the weaker members of society advance people's understanding of human rights. In fact, certain findings have shown that people over 70 years old are, despite the negative image of old age, cognitively and socially competent. This result surely promotes fresh perspectives of successful aging. In addition, narratives about the so-called handicapped may challenge the conventional idea of normality. A book written by a Japanese student who has congenital tetra-amelia, but enjoys an active and satisfying college life, has deeply moved people. Over 5 million copies have been sold. It is reasonable to expect that passing laws and insisting on international treaties that protect women and children will advance people's understanding of the meaning of human rights.

5. Conclusion

Socialization and education are ubiquitous to the extent that people convey knowledge, skills, beliefs, and attitudes. They seem to be based on human species-specific properties. Although we are often impressed by cultural diversity, that is, cultural differences in developmental goals and methods, patterns of human development are also surprisingly similar across cultures. In the era of globalization, these universal aspects of human development should be taken seriously in education as well as in politics and the economy.

Since the end of the Cold War, people have been allowed to identify themselves with ethnic and other local groups within the nation-state and/or with even larger groups extending beyond national borders. To participate and function fully in this complex, hierarchically organized global community, people have to respect other cultures while preserving their own culture. How we can cultivate a sense of global citizenship among children should be a universal task of education.

Cultural Evolution: Ethnogenesis

The term 'ethnogenesis' is an obvious construction between two classical Greek roots, *ethnos* for tribe or nation and *genesis* for birth or beginning, and consequently the word has been invented and reinvented several times. In general, the term has been used over the last two centuries to describe the processes by which tribes, nations, and ethnicities have come into existence in history and prehistory. However, the various major schools of thought, French, Soviet, Central European, ethnohistorical, and sociocultural, have proceeded using different methodologies, and their subject matter has also been somewhat different. Intellectually, ethnogenetic theories have tended to serve as counterpoints to racial theories of human and national origins. More than most scholarly concepts, these theories have frequently been invoked by one side or another in hotly contested political disputes (see *Cultural Evolution: Phylogeny versus Reticulation*).

1. The French Tradition

Probably the first to construct the term ethnogenesis was André-Marie Ampère, the French physical scientist who published his *Essai sur La Philosophie des Sciences* in 1834. In the course of outlining 'all human knowledge,' he created a typology in which the science of ethnology was said to comprise ethnography, geography, and *ethnogénie*. His conception of ethnogenesis was actually quite modern, since he hypothe-

sized that a new ethnic group would usually arise from people of shared descent, or having common beliefs, or occupying a shared territory. But he did not allege, as later theorists did, that these three characteristics necessarily went together.

Several works of history explicitly labeled ethnogenetic were created later in nineteenth-century France, but it is not clear if they were directly inspired by Ampère. Whether or not, a standard method of ethnogenetic research was invented in this period, called the chronological method, which consisted of the following steps: (a) identification of possible ethnic antecedents for modern and recent nations by analyzing and criticizing ancient writings, particularly those in Latin; (b) evaluation of which antecedents were most influential in creating the culture of a descendant nation, and (c) assertion of the cultural primacy or hegemony of certain sets of cultural institutions over others, for example concluding that France is primarily a Celtic nation, or a Roman one, on the basis of language or legal principles.

A good illustration of this methodology is contained in *Les Origines des Aquitains* by Alphonse Castaing, published in Paris in 1885. Taking as his challenge the idea that the Aquitains of southwestern France were originally Basques from the Iberian Peninsula, Castaing mobilized passages from Caesar and Pliny. He identified 'cognates' among the ethnonyms used by classic authors (Galls, Belges, Bretons, Basques, Gascons, etc.) and put the cultural and demographic influences of different immigrations into chronological order. Then he concluded that 'the Aquitains are Gallish, as Caesar declared and as the ancient doctrine admits.'

Another work in the French school is *Ethnogénie Gauloise* by de Belloguet (1872) that emphasizes linguistic evidence. The author concluded that the *langue Gauloise* is 'not Germanic, but entirely Celtic.' Throughout the French school, we find the assumption that every society has a cultural core which can be reliably assigned to just one antecedent. This assumption is analogous to the premise in historical linguistics that every language has a syntactic and semantic core that can reliably be assigned to one and only one language family.

2. *Racial Histories*

It is no accident that French ethnogenetic histories appeared soon after the publication of racial histories by Gobineau and other German authors beginning in 1853. In these racial histories, the French and other European nationalities are cast as imperfect Germans, the results of interbreeding between the Nordic or Aryan 'race' and indigenous Celtic and Slavic peoples. The more general evolutionary theory is that there were originally in antiquity a small number of allegedly 'pure' human races which interacted historically, culturally, and biologically over the centuries to create the distribution of European ethnicities observed in the nineteenth century. In this tradition, which continued through Houston Chamberlain and Herman Wirth, and which finds its ominous climax in the writings of Nazi theorist Alfred Rosenberg, the defined races are said to be not only biologically distinct, but culturally distinct, and each is endowed with a specific level of intellect, and a unique morality and character (Shipman 1994). While Rosenberg emphasized the superiority of the Nordic 'Sun-People,' who he said originated in Atlantis, now sunk between Iceland and Greenland, the Italian Fascists emphasized Roman antecedents for modern Italians, and they alleged that Romans were culturally and biologically superior to Celtic, African, and other especially Mediterranean peoples (Cecil 1972)

These racial histories embodied theories of cultural degeneration that hark back to traditional Christian ideas about the descendants of Shem, Ham, and Japheth, and the wandering tribes of Israel embraced in previous centuries. The general idea is that once upon a time there were clearly defined races in a world where everyone was in their correct place, geographically and socially. But then migration and interbreeding gradually eroded this cultural balance, producing 'mixed races' which were inferior to the originals. These, then, are not theories of cultural evolution, but of cultural devolution, promising that the 'superior' races could reemerge under something like the Nazi political program of segregation and genocide. By contrast, the ethnogenetic theories, with some notable exceptions, have tended to be progressive in content. In a manner analogous to biological evolution, new 'species' of ethnic groups are said to arise continually, pushing aside preexisting ethnicities until the new ethnic formations are in turn pushed aside. Each new ethnic group is supposed to represent a cultural improvement over previous ones, so that overall this process is supposed to propel the human species toward something called 'civilization.'

A prominent but bizarre theory of evolution, explicitly labeled 'ethnogenetic,' emerged in Brazil in the mid-twentieth century. Writing in 1940, Domingos Magarinos argued that the human species evolved in the Central Plateau of Brazil during the late Tertiary. Further, 'languages, alphabets, beliefs, laws, everything originated in Brazil and from Brazil it was diffused to the rest of the world.' As strange as this sounds in light of modern archaeology and palaeontology, such extreme statements call attention to the essentially chauvinist and patriotic nature not only of this book, but of many other essays in the traditions of ethnogenesis and racial history.

3. *The Soviet Tradition*

The Soviet conception of ethnogenesis or *etnogenés* was apparently not derived directly from the French tradition, despite some similarities, but developed in-

dependently from Marxist discussions of 'the national question.' In its Stalinist form, a nation or 'ethnos' was defined as '… a historically constituted, stable community of people, formed on the basis of a common language, territory, economic life, and psychological make-up manifested in a common culture' (Stalin 1975). Under Soviet law, those nations and ethnic groups that qualified for non-Russian ethnic status were supposed to be given certain privileges of language and culture, and to enjoy limited autonomy and sovereignty within the boundaries of the Soviet Union. Over time, these minority groups were supposed to become increasingly Russified, voluntarily losing their own languages and cultures.

Like the French tradition, the Soviet tradition arose to some extent as a response to racial histories. In this regard it is interesting to note that Alfred Rosenberg was resident in Moscow as a student during the 1917 revolution. Contemptuous of Slavic peoples, Rosenberg wrote blueprints in the late Nazi period for a territorially expanded Third Reich in which Russians and Poles would serve as manual laborers for the German master race. Rosenberg alleged that the Slavic peoples, as well as the Lithuanians, Hungarians, Gypsies, Czechs, and other 'inferior races,' had no history of their own, except that which they derived from interactions with more 'advanced' races

After Soviet scholarship was reorganized on a 'revolutionary' basis in 1934, the task of writing official histories for the various component nations of the Soviet Union was split between the discipline of history, which included archaeology, and ethnography, which was increasingly focused on Soviet minorities in Siberia and Central Asia. History was especially entrusted with refuting 'German nationalist' conceptions of European history, and to this end the theory of ethnogenesis was invoked to describe and explain the actual origins of the Russian people (Mehnert 1952)

To refute the 'Nordic' view, Soviet historians denied that the original 'Rus' were from Scandinavia, asserting instead that the ethnogenesis of the Russian ethnicity had been entirely 'autochthonous.' In this view, the ancient Slavic peoples had always lived where they were located in modern times, and were the same as the Scythians of classical times ($\sim$ 500 BC). Most importantly, for political purposes, it was alleged that while the ancient Slavs had interacted with Varengian traders from the north and with literate societies such as Byzantium, they had never been under their domination but had always been a coequal partner in the development of Western civilization

To describe ancient Russian and Soviet history, which became more and more synonymous during the Stalin period, historians utilized the evolutionary periods defined by Marx and Engels: primitive, slave, feudal, capitalist, socialist, and communist. The stages of Russian history and the status of their historical allies and antagonists were also characterized in these terms. Scores if not hundreds of Soviet historians cooperated in this effort, producing hundreds of revisionist and Soviet-flattering books and articles between 1935 and 1990, predominantly in Russian.

While the word ethnogenesis soon faded in Soviet historical studies in favor of a more conventional vocabulary involving 'nation' and 'nationality,' the word and its embodied theory blossomed in Soviet anthropology. Although the terms 'ethnos' and 'ethnogenesis' were proposed for Soviet anthropology as early as 1921 by S. M. Shirokogoroff, the theory did not truly catch fire in the Soviet Union until after World War II. In the meantime, there was a complex jockeying for position among Soviet academic disciplines, and there was the ongoing problem of how to maintain a theoretical and philosophical position within an academic discipline that was compatible with the ever-changing party line of official Soviet Marxism-Leninism (Slezkine 1991).

Practically and philosophically, these problems were solved for anthropology in the late 1950s and early 1960s by Soviet theorist Julian Bromley, who proposed that ethnography (which included what we would call ethnology in English) should focus on the ethnos and especially should investigate the processes of ethnogenesis among small-scale Soviet societies. He defined the ethnos in an orthodox Marxist manner which reflected earlier discussions of the national question, as follows: 'Ethnos (in the narrow sense of the term) can be defined as a firm aggregate of people, historically established on a given territory, possessing in common relatively stable particularities of language and culture, and also recognizing their unity and difference from other similar formations (self awareness) and expressing this in a self-appointed name (ethnonym).' Contrasting the process of ethnogenesis with racial history, he says that ethnogenesis 'shows that all modern peoples trace their origins to a diversity of ethnic components and are mixed in composition, and consequently refutes racist, chauvinist inventions about the "racial purity," "indigenous ancestry," and "national exclusiveness" of certain peoples.' This perspective on the various ethnic groups of the Soviet Union gained official support in the Communist leadership, and resulted in increased approval and support for Soviet anthropology. Essentially, the discipline of anthropology was given the franchise for investigating the social and cultural status of Soviet minorities. Their findings and recommendations concerning the language and culture of over a hundred minority groups often found a sympathetic audience among Soviet bureaucrats entrusted with administering the 27 'republics' and 'autonomous regions' within the Soviet Union.

As leader of the Institute of Ethnography in Moscow, Bromley commissioned hundreds of anthropological field trips throughout the Soviet Union to collect data on language, demography, biology, economics, and culture, resulting in a large number of

publications. Between 1977 and 1982, for example, Soviet anthropologists produced more than 500 books and articles, many of them directly addressed to issues of ethnogenesis. It is no exaggeration to say that during its most active period, anthropologists connected with the Institute produced more pages of ethnogenetic study than the rest of the world before or since. However, because of the Cold War and a lack of literacy in Russian among Western scholars, these publications have not had the academic impact that they might have had under other circumstances.

Ironically, and as a post-Soviet footnote to the era of ethnogenetic studies, the fragmentation of the Soviet Union has seen the use of earlier ethnogenetic theories to deny Russian influences on former Soviet minorities and allies. Recent Romanian historical scholarship, for example, has returned to an emphasis on their Latin roots, minimizing the significance of their historical relationships with Slavic peoples. Peoples of the Caucasus have done the same. And so ethnogenesis is now being used to allege social and even biological 'purity,' purposes opposite to those intended by Bromley.

4. *The Central European Tradition*

Another independent ethnogenetic school of thought developed in the countries of Central Europe after World War II, largely Austrian and mostly published in German. This scholarly florescence was, once again, a reaction against the race-based culture histories offered by Fascist and Nazi historians and pre-historians before 1945. This postwar school of *ethnogenese* tends to consider the same range of problems as the earlier French ethnogenetic tradition, but without as much concern for general theory or for creating an explicit shared definition of ethnogenesis.

The results of these efforts, presented at periodic *Limeskongresses* in Central Europe since 1949 and as part of other activities sponsored by the Austrian Academy of Sciences, constitute an important reconsideration of the origins of all European nations as well as a sprinkling of other societies around the world (Wolfram and Pohl 1990). In their vocabulary and range of interests, this network of ethnogenetic scholars is much more historical and archaeological than it is anthropological. Their implicit evolutionary theories are largely progressive and somewhat Eurocentric. They see 'progress' in terms in increases in social scale, improvements in infrastructure, the development of capitalist democracy, and higher literacy.

5. *Ethnohistory*

In recent decades, ethnogenetic studies of tribal ethnohistory have had a renaissance in the United States, inspired largely by a classic 1971 article by William Sturtevant. Taking his cue from Soviet scholars, Sturtevant used the concept to describe the separation of the Seminoles from the Mvskoke Creeks in the period 1780–1820, and he defined ethnogenesis simply as 'the establishment of group distinctiveness.' In his writing, he has elaborated this simple definition to include distinctiveness in territory, economy, and political structure.

In the hands of American scholars such as Nancy Hickerson and Ernest Burch, ethnogenetic theory has lost much of its political baggage and become a tool for doing ethnohistory, a hybrid field between history and ethnology which analyzes tribal and ethnic histories during that shadowy period between prehistory and history, where there exist only cursory and distorted ethnographic descriptions. During the period of Spanish colonialism, for example, Hickerson uses Spanish documents to show how the so-called 'Jumanos' underwent two centuries of migrations from Mexico to Canada and a series of ecological revolutions and basic ethnonymic transformations before emerging on the Central Plains as the 'Kiowa Indians' in the early nineteenth century. On a more limited time scale, Ernest Burch and his colleagues have shown how a group of Athapaskans in Alaska were ethnogenetically transformed into 'Eskimos' between 1860 and 1880 (Hill 1996).

6. *Sociocultural Approaches*

In 1962, American sociologist Lester Singer once again reinvented the word 'ethnogenesis' to describe 'the process whereby a people, that is an ethnic group, comes into existence.' This theme, and the word, was picked up by other sociologists and some sociocultural anthropologists for the study of ethnic or national minorities within complex societies. Independently, Belgian anthropologist Eugeen Roosens has developed his own brand of ethnogenetic studies, addressing himself not only to tribal societies but to European immigrant minorities. His work, like that of sociologists, is more clearly inspired by theories of ethnicity than of ethnogenesis, since it considers only a shallow time depth and is not much concerned with evolutionary theory.

7. *Remaining Issues*

Currently, the global spectrum of ethnogenetic studies ranges from the strictly humanistic to the thoroughly scientific. On the humanistic side, historians and some sociologists are largely indifferent to the task of defining general principles of ethnogenesis. The more politicized scholars of ethnogenesis, in fact, often assert that the processes that produced their particular nation or ethnic group were absolutely unique. At the other end of the spectrum, prehistorians, ethnohistorians, and ethnologists of a scientific orientation are very much preoccupied with developing and refining theories of ethnogenesis that are consonant with and

in fact are constituent parts of general evolutionary theory. From the great volume of data already in hand and still being collected, specific and elaborate scientific theories of ethnogenesis, clearly articulated with evolutionary theory, are sure to emerge.

The most imminent current problem for ethnogenetic scientists, however, is determining how many processes of ethnogenesis there might be, and characterizing the differences among them. Perhaps there are some aspects of ethnogenesis that are universally typical of the process, no matter what its scale or geographical location, just as there are recurrent features of millenarian processes and political revolutions. Once these ubiquitous features are accounted for, the more significant problem for theories of cultural evolution is whether the remaining unique or variable aspects of ethnogenesis can be placed in some kind of chronological order, or otherwise seriated in some unilinear or multilinear and universal sequence. If they can, then ethnogenesis can be counted among the most important processes of cultural evolution.

Cultural Evolution: Overview

Cultural evolution is one of the most hotly debated of all concepts in the social and behavioral sciences. There are many reasons for the debate, but some of the most important issues stem from the divergent answers of scholars to three basic questions.

1. What is Cultural Evolution?

First, there is debate over what the expression 'cultural evolution' refers to. What is it that evolves? This domain of debate is hardly surprising since 'culture' itself is notoriously difficult to define and delimit. Historically, however, the issues here cluster around two main schools of thought. One school follows a broad, holistic definition of cultural evolution that includes changes over space and time in the combined cultural and social systems of a human population. This definition covers big terrain, including both people's values, ideas, and beliefs—the ideational phenomena of cultures—as well as the organization and structure of societies (as reflected in the size and centralization of polities, the degree of stratification, level of social integration, and so on). This school looks for either universal tendencies across vast expanses of space, time, and human experience—so-called 'general evolution'—or for variable trajectories of change within particular societies or groups of societies— 'specific evolution.' Credible examples of this approach include Johnson and Earle (1987) and Sahlins and Service (1960). Today, the first school is commonly called 'social evolution' (see *Social Evolution: Overview*).

The other school takes a narrower definition of cultural evolution and focuses on the dynamics of change in the ideational systems of populations. This school attempts to trace the history of ideas, values, and beliefs that are held by groups of people, and to ask what processes have guided the historical trajectories of change in these phenomena? What processes have made certain ideas and beliefs prominent, in the sense of being widely held and acted on within a group, and others ephemeral or unimportant? This school is sometimes described by analogy: if one regards the cultural system of a human population as a collection of socially transmitted texts in the minds of culture bearers then one can ask, what is the social history of these texts? How were they written and rewritten, and by whom? What are the main processes and actors that

have historically edited the texts? And so on. Such questions today are at the heart of this school of cultural evolution, sometimes called 'evolutionary culture theory' (Durham 1990, 1992). This second school, focused on socially-transmitted information in human populations—though not exclusive of socially-conveyed information in nonhuman populations (see, for example, Bonner 1980, Heyes and Galef 1996, Wrangham et al. 1994)—is the topic of the remainder of this entry.

2. *In What Sense Do Cultural Systems Evolve?*

A second question in cultural evolution concerns the meaning of 'evolution' itself, another one of those words that can mean many different things (see *Evolution, History of*). Curiously, the word 'evolution' has had two quite different categories of meanings as it applies to the study of culture change. First, the term has referred to predictable trajectories of change in the social and cultural properties of human populations. In this category, evolution has been taken to mean stage-wise progression from earlier to later forms through regular transitional steps. This meaning of evolution is especially prevalent in the unilinear trajectories (e.g., from simple to complex, from sexual promiscuity to the conjugal family, from savagery to civilization, etc.) of the 'classical evolutionists' of the nineteenth century (e.g., John Lubbock, Henry S. Maine, John F. McClennan, Herbert Spencer, Edward E. Tylor—reviewed in Stocking 1987). A similar meaning of the term is also found among so-called 'neo-evolutionists' of the twentieth century (including Leslie White, Julian Steward, Elman Service, and Kent Flannery), who commonly propose parallel, multilinear trajectories of change (reviewed Sanderson 1990). Because these arguments, old and new, feature the changing social organization of populations, again they are more commonly called 'social evolution' today (see *Social Evolution: Overview*).

The second category of meanings for cultural evolution features a close analog of Darwin's original definition, 'decent with modification,' only as it applies to the cultural (ideational) features of distinct populations. Here the focus is on transformational change either as (a) one cultural system changes over time and space; (b) one cultural system differentiates into two or more distinct systems; or (c) two or more cultural systems merge into one new one. The first of these transformations (a) is also called cultural 'microevolution'—change within a given cultural system over time. The second and third transformations, (b) and (c) together, comprise what is sometimes called cultural 'macroevolution'—that is, pattern and process in the diversification (or homogenization) of new cultural systems either through the division (branching) of one system or the fusion (reticulation) of two or more cultural systems. Because new ideational systems often emerge through the formation (whether by fission or fusion) of new and distinct 'ethnic groups,' readers interested in cultural macroevolution see *Cultural Evolution: Ethnogenesis*; *Cultural Evolution: Phylogeny versus Reticulation*. The remainder of this article focuses on cultural microevolution.

3. *What Causes Cultural Microevolution?*

This third question, what causes change within a given cultural system over time, is an area of active research and discussion in the social sciences. The question entails at least two main areas of contemporary debate. The first debate concerns the nature of the elements of which cultural (ideational) systems are composed—the so-called 'units of culture.' If cultural systems are composed of socially transmitted information, so the argument goes, then what exactly are the dimensions and properties of the information under conveyance? Are cultural phenomena best modeled as fairly uniform little pieces or 'particles' during social conveyance? Or is it more accurate to view cultures as interconnected systems or hierarchies of information that do not readily 'chunk' into uniform small pieces during social transmission? This productive, ongoing debate (reviewed in Weingart et al. 1997) has spawned what might be called another school of cultural evolution theory—the 'meme' school, or 'mimetics.' Mimetics considers cultural systems to be little more than aggregations of 'cultural viruses' that human (or nonhuman) minds as their hosts (see *Memes and Cultural Viruses*). The debate has been useful for drawing attention to several interrelated questions, all without clear answers at the time of writing. If cultural histories are replete with 'viral outbreaks,' have culture carriers evolved a diversity of immune (protective) responses? If so what are these immune systems and how do they work? Are they effective enough to prevent people's thoughts and actions from being governed by 'selfish memes?' To the extent that cultural evolution favors selfishness on the part of cultural entities, genetic and cultural evolution are predicted to show divergent tendencies (Durham 1991). How often does this occur, in what contexts, and with what outcomes? The implications are clearly substantial for the social sciences: there is a pressing need for more good work in this area.

The second big area of debate concerns alternative models and processes for understanding the 'editing activity' of cultural microevolution. The challenge that has emerged from this debate is to identify that process or processes that are akin to Darwin's 'main motor' of biological evolution, natural selection. Looking across the vast expanses in space and time of cultural conveyance in human populations (or nonhuman), what process or processes have served as 'editor in chief?' Also, does the role of 'editor in chief' vary in predictable ways by circumstance, as defined by ecological, sociopolitical, and economic conditions? A wide range of different approaches have

appeared in recent years to answer these questions; useful views and reviews include Cronk (1999), Durham et al. (1997), see also *Cultural Evolution: Theory and Models; Genes and Culture, Coevolution of*.

One good way to summarize some of today's leading models, but by no means the only good way, is according to the models of other processes that inspired them. One approach, for example, called an 'epidemiology of representations' (Sperber 1996), draws its inspiration from models and theories governing the spread of contagious disease in host populations. It regards cultural systems as 'contagions of ideas' that spread through human population under the guiding influence of ecological and psychological conditions. In this epidemiological model:

> All the information that humans introduce into their common environment can be seen as competing for private and public space and time—that is, for attention, internal memory, transmission, and external storage. Many factors affect the chances of some information being successful and reaching a wide and lasting level of distribution, of being stabilized in a culture .... The most general psychological factor affecting the distribution of information is its compatibility and fit with human cognitive organization. (Sperber 1996, p. 140)

The approach has much to recommend it: certainly many cultural phenomena spread 'horizontally' (between peers) within societies, like fads and fashions; certainly the success of contagious cultural elements depends to some extent on their psychological appeal or attraction; and surely cognitive processes in individual minds actively transform the 'contagion' as it spreads. The challenge to this approach remains to illustrate by theory and example the relative force of psychological attraction compared to other forces, and to produce convincing empirical examples across a spectrum of cultural phenomena (for one example, see Boyer 1994).

A second approach uses the term 'coevolution' to develop a model of cultural evolution that is explicitly parallel to, though different from, Darwinian theory in biology (Durham 1991). The model views human populations as having two 'inheritance systems,' one genetic and one cultural. Each form of inheritance is conceptualized as having its own channel of information transmission, one consisting of genes passed along via reproduction and the other consisting of ideational phenomena (ideas, values, beliefs) passed along via social transmission. Each form of inheritance is subject to a variety of processes producing change over space and time. In the genetic channel, these processes include the familiar Darwinian foursome: mutation, migration, drift (chance fluctuations), and differential reproduction or 'natural selection.' In the cultural channel, coevolutionary theory proposes the roughly analogous processes of innovation, diffusion (with or without migration), cultural drift, natural selection (cultural change via differential reproduction), and cultural selection (change through value-driven decision making by culture carriers). Durham's formulation (1991, p. 198) emphasizes the role of human beings as decision makers:

> Provided they are given both a range of options and an opportunity to choose, people can participate in the transmission process as selecting agents. In other circumstances, where options and choice are largely pre-empted [by power relations], cultural evolution may still be guided by human decisions—that is, by the imposed decisions of powerful individuals or groups. But either way, culture changes under 'human' direction; people, not 'nature' do most of the selecting.

The strengths of this approach are several: it builds social structure and asymmetrical power relations into the evolutionary dynamics of cultural change; it emphasizes key similarities and differences with biological evolutionary theory without overly 'Darwinizing' cultural dynamics; and it provides a ready explanation for the culturally-guided directionality so characteristic of cultural evolution. In Durham's view, the most important values governing the decision-making processes are previously evolved 'cultural' values. Further the framework has particular value in analytical applications (see Durham 1992). While not as quantitative as other models, it has been useful in more and more thorough empirical analyses than the other formulations.

The third approach was also the first historically, and the most quantitative (see also *Cultural Evolution: Theory and Models*). Taking its main inspiration from Mendel, mixed with influence from Darwin and epidemiology, the approach focuses on the cultural transmission process and the ways in which the context of transmission (who teaches, who learns) produces evolutionary change in cultural systems (Cavalli-Sforza and Feldman 1981). Quantitative models have been proposed for three different contexts of social transmission: vertical (meaning from parents to offspring), oblique (from nonparents of one generation to offspring in the next), and horizontal (among peers of the same generation). The models predict, among a variety of other things, that vertical transmission is generally most conservative in its evolutionary effects (i.e., causing least change from generation to generation) while horizontal transmission promotes relatively rapid evolutionary change—a finding nicely corroborated in a later empirical studies (see, e.g., Hewlett and Cavalli-Sforza 1986). These baseline models have been modified and extended to include conformity effects, continuous traits, and group-level selection (see discussion in *Cultural Evolution: Theory and Models*). Similar transmission models developed by Boyd and Richerson (1985), also drawing inspiration from Mendel, emphasize various forms of 'bias' that can result from variability in the context of social transmission. In 'indirectly biased transmission,' for example, individuals are viewed as adopting for

themselves the cultural variants that are used or exhibited by 'successful' individuals whom they emulate. Boyd and Richerson show how this biasing mechanism can lead to the unstable 'runaway' cultural evolution of highly exaggerated features (such as growing huge yams or participating in elaborate tattooing, in the examples they offer). In 'frequency dependent biased transmission,' individuals adopt for themselves the most common or most popular cultural variant in a population, a process that readily leads to conformist effects. An interesting result of conformist transmission is that it may increase the magnitude of intergroup differences, potentially contributing to differential rates of group-level survival and propagation (i.e., group selection, see Boyd and Richerson 1985, Chap. 7).

In a further extension of so-called transmission models, Feldman and Cavalli-Sforza, and Aoki after them, proposed a combination model that allows genetic and cultural transmission to produce joint 'genophenotypes' which can then be used to model coevolutionary dynamics (see *Genes and Culture, Coevolution of*). Recently, Laland et al. (2000), building on Durham (1991), have added self-induced habitat change, or 'niche construction,' to the interactive processes of biological and cultural evolution. The schema formally recognizes the way that cultural processes produce long-lasting habitat modifications, thus providing a kind of 'environmental inheritance' that permits human beings to 'co-direct our own evolution.'

In conclusion, one may fairly state that theories of cultural evolution themselves continue to undergo rapid evolutionary change. Their potential value to social science is substantial, particularly if they eventually help to bridge the intellectual gap between biological and social sciences. Further theoretical developments will surely contribute to the bridge, but good empirical analyses and longitudinal case studies will probably be even more persuasive. At the time of writing, theories of cultural evolution remain surprisingly peripheral to mainstream social science. Hopefully that, too, will change.

W. H. Durham

Cultural Evolution: Phylogeny versus Reticulation

Why do human cultures and languages form patterns of differentiation through time and across space, and how do such patterns form? Why do language families and archeological cultures exist? Application of biological concepts such as 'phylogeny' (evolutionary history of a genetically-related group of organisms) within the anthropological, archeological, and linguistic disciplines might seem a little unwarranted since culture is transmitted through both Mendelian (phylogenetic) and Lamarckian (reticulate) processes (Boyd and Richerson 1985, Cavalli-Sforza and Feldman

1981, Durham 1991). Thus, the transmission of cultural knowledge and language from generation to generation cannot be precisely equated with genetic inheritance in terms of mechanism. But the terms phylogeny and reticulation can have direct value in understanding the creation of many historical and ethnographic situations.

For instance, since AD 1600 , societies have developed in the UK, North America, and Australasia, which clearly share some degree of common history (phylogeny). This is evident in the almost universal use of the English language, in the direct biological ancestry of many inhabitants of these regions from a British source, and in many aspects of material culture which originated in ways of doing things widely current in Britain between approximately AD 1600 and 1850. These societies in North America and Australasia originated historically via a process of colonization and early political control emanating from the British Isles. Similar generalizations can be made about the spread of Iberian culture, language, and biology through much of Central and South America.

At the beginning of the twenty-first century, it is quite obvious that by no means all of the cultural and biological patterning found in these regions is of a circumscribed British (or Spanish, or Portuguese) origin. Indigenous peoples have contributed, as have migrants from other regions. Cross-cultural borrowings abound and occur continuously, forming a network of horizontal transmission, which in this article is termed reticulation.

Thus we have two conceptual directions of transmission for the elements of both cultural and biological patterning—vertical (phylogenetic or descent-based) and horizontal (reticulative or interaction-based) (Bellwood 1996a, Dewar 1995, Mace and Pagel 1994). Naturally, in a real-life situation such as the modern USA it is impossible to untangle the inherited from the borrowed in an overall sense and to present the results in the form of a statistical statement. To attempt to do so would in any case be futile. These are simply concepts, which allow us to model the formation of cultural patterns through time, essentially to understand the main trends of history.

It might seem obvious that cultures at any given time will reflect variation from both ancestral and borrowed sources. But there is one very significant implication of the concept of cultural phylogeny. In those situations where common ancestry is demonstrable for the member units within widely spread entities, such as language families, major religious complexes, or highly specific style repertoires within archeological complexes, we are obliged to infer dispersal of an ancestral configuration (such as a 'protolanguage') from a homeland region. This is especially the case where the entities concerned are of very broad extent. Explanations which involve the convergence of genetically unrelated units into a single entity such as a language family do not work in these large scale, sometimes transcontinental, situations which extend beyond the ranges of regional communication networks.

The linkages between phylogeny and dispersal can therefore become extremely important in explanations for particular long-term and large-scale patterns in human prehistory. Any evidence for fairly rapid and far-flung dispersal will obviously militate against an explanation for cultural patterning expressed in terms of gradual evolutionary change at a constant and uniform rate. By its very existence, phylogenetic patterning carries significant implications favoring a punctuated trajectory for cultural evolution, focused on periodic episodes of dispersal and change alternating with trajectories of relative equilibrium (Bellwood 1996b; Dixon 1997).

It is important in this regard, however, to differentiate between spreads of people, languages, and other aspects of culture. Ethnographic and historical records offer examples of situations where patterns of biological, linguistic, and sociocultural variation do not correlate at all, or correlate only slightly. On the other hand, they can sometimes correlate with almost 100 percent precision, as in the early stages of population expansion into new territories. Whole populations already *in situ* geographically can adopt new languages and cultural forms through contact-induced change (Ross 1997), whereas at the other extreme whole populations can colonise new territories with closely correlated physical attributes and cultural characteristics.

In terms of human prehistory, it is important to remember the significance of scale. On a small scale, the inhabitants of a village or small river basin could, and indeed have in many historical and ethnographic examples, adopt a new language and undergo genetic change due to intermarriage with members of an outsider, perhaps of higher status, group of people. Ethnic groups can also 'fuse' under situations of depopulation or outsider-imposed stress, as has happened very frequently in the period of tribal shrinkage which history offers us in the form of the 'ethnographic present' (Atkinson 1989, Moore 1994, Nicolaisen 1977–78).

But, on a much larger scale, a chain-reactive process of language and cultural shift of this kind will not explain why, for instance, related languages are spoken over vast regions of the earth in the form of major language families such as Indo-European, Austronesian or Uto-Aztecan (see Fig. 1 in *Archaeology and the History of Languages*). These language families had reached their outer geographical limits before the beginnings of written history, and no historical processes such as military conquest or mass media persuasion can hope to explain them. They are records of major human dispersals, spreading foundation languages and archeological cultures. Many undoubtedly owe their existences to population increase and dis-

Figure 1
Phylogeny and reticulation in time and space perspective. (NB: A diagram such as this cannot hope to replicate the full complexity of cultural evolution in any real- life situation. It is intended as a schematic model only.)

persal consequent upon the regional beginnings of agropastoral food production (Renfrew 1997). But this is not true for all, since many languages such as English and Spanish have spread over vast distances in recent historical times and can also be regarded as potential foundation languages for future language families. Comparative linguistics and ethnohistory also reveal some excellent examples of large-scale hunter-gatherer dispersal in the form of the Eskimo-Aleut and Athabaskan language families in North America.

The point to be reinforced is that wherever phylogenetic relationships can be demonstrated to exist between the members of an array of languages or cultures (including archeological cultures), then dispersal of an ancestral complex must be inferred. Whether or not this ancestral dispersal directly related to a movement of actual people is something which must be decided on a case-by-case basis. In the case of extremely widespread phylogenetic entities, population movement to some degree can hardly be denied. In addition, most language families clearly spread relatively quickly in overall chronological terms. From internal evidence and archeological correlations, most reached their geographical limits in 4,000 years or less (for example, between 2,000 and 4,000 years from origin regions to outer limits in the cases of Indo-European and Austronesian). Speed of dispersal, in this regard, relates directly to the intensity of punctuation.

The comparative linguistic record can also provide clear structural evidence for rapid dispersal, especially when the component language subgroups within a family do not share any unique linguistic innovations which allow them to be subgrouped phylogenetically above the individual subgroup level (but still below that of the language family as a whole). 'Descent trees' created to show the structure within such language families will be extremely rake-like, rather than tree-like with many successive branches. In such cases, claimed for instance for several of the major Austronesian subgroups of Southeast Asia and the Pacific (Pawley 1999), there is a strong likelihood that the resulting pattern reflects an initial history of very rapid and far-flung dispersal, followed by a formation of independent subgroups, each sharing a common ancestry in the initial dispersal but all reflecting an independent history thereafter.

Direct demonstration of rapid dispersal can also be identified in the archeological record, as for example when a particular aspect of artefact style and decoration too complex to reflect functional selection alone

is distributed very widely in a short time. Examples include the Olmec stylistic complex which spread through Mesoamerica after 1250 BC (Sharer and Grove 1989), the Early Neolithic Linearbandkeramik cultural complex which spread through central Europe about 5000 BC (Bogucki 1996), and the Lapita cultural complex with its distinctive and elaborately decorated pottery which spread through the western Pacific about 1000 BC (Kirch 1997). In contextual terms it is apparent that these dispersals of material culture correlated with dispersals of people and perhaps language, even though the nature of the archeological record does not allow this to be stated as more than a logical possibility rather than a demonstrated fact. A parallel with the linguistic diversification of language families from a common source also comes in the archeological record when very widespread complexes such as those mentioned above are followed by a breakdown of widespread homogeneity into regional diversity, this diversity becoming more marked over time.

Finally, reasons for dispersal in any given historical situation are probably knowable, even if they are often heatedly debatable. Clearly it is important to distinguish between populations who dispersed into territories devoid of prior human inhabitants and those who moved into already-settled areas. In both situations the inception of a successful trajectory of dispersion/colonization would obviously have required the acquisition of some form of advantage allowing demographic growth and range expansion. In the case of many of the examples discussed above the advantage seems to have been the acquisition of systematic agriculture, but the whole story is of course far more complex. The initial human colonizations of empty continents like Australia (60,000 years ago) and the Americas (15,000 years ago) must also have led to the dispersal of phylogenetically-related languages and cultures, of which some faint traces might still survive in present cultural patterns.

1. Some Examples of Phylogenetic Studies of Archeological and Ethnographic Cultures

The ethnographic and archeological records are replete with examples of cross-cultural contact via trade, warfare, and intermarriage, indeed by 'diffusion' and gene flow in their many forms. Past humans have been just as interested in communicating with their neighbors, whether as friends or foes, as have recent ones. But evidence that ethnographic and prehistoric cultures form phylogenetic arrays indicative of dispersal is not always so obvious once one moves beyond the evidence from comparative linguistics (Mace and Pagel 1994). Normally, teasing out of the nonlinguistic aspects of the pattern requires attention to details from archaeology and biological anthropology, assisted of course by information from comparative ethnology and, where relevant, historical records and oral tradition (e.g., Flannery and Marcus 1983, Romney 1957).

As a case study, a debate has emerged in recent years amongst anthropological scholars working in the islands of Polynesia. Polynesians form a population of many island societies in the great triangle bounded by Hawaii, Easter Island, and New Zealand, including Tonga and Samoa, with a few additional 'Polynesian Outliers' existing to the west amongst the larger islands of Melanesia. That Polynesian languages share a common ancestry is not in doubt, but beyond language the explanations for the Polynesian cultural pattern are more contested. Two recent perspectives on the Polynesians—the 'phylogenetic' and the 'reticulative'—can be counterposed.

The archaeologists Kirch and Green (1987, 2001) have presented Polynesia as a 'phylogenetic unit' of closely related cultures, languages, and peoples all sharing a common origin derived from the settlement of the Tongan, Samoan, and other nearby Western Polynesian islands by Lapita populations at about 1000–800 BC. Working from the archeological and linguistic records, Kirch and Green suggest that the Polynesian societies of ethnographic times formed a closely related set in terms of material culture, social organization, biological phenotype, and most importantly, language. Societies so related can be conceived as something akin to the genus of biologists—a group of 'species' defined as a group through possession of certain uniquely shared features (synapomorphies in biological terminology). From this perspective, Polynesian societies all share a single origin, and since that period of origin have differentiated due to a wide range of historical processes reflecting both internal change and external contacts with other societies both inside and outside Polynesia. Because Polynesian societies are geographically so clearly bounded by sea, and because archaeology and linguistics lead us to believe that only Polynesians ever inhabited Polynesia prior to European contact, the region obviously lends itself ideally to such a phylogenetically oriented historical perspective.

But not all agree entirely with a phylogenetic perspective. The archaeologists Terrell et al. 1997 (see also Terrell and Welsch 1997) take a tangentially opposed and rather more reticulated viewpoint, pointing out that ancient Pacific Island (including Polynesian) societies were never isolated and would always have maintained some degree of contact between different regions. Virtually all archaeologists would agree with this statement in simple form, because of course the archeological, linguistic, and genetic records carry widespread evidence of trade, borrowing, inter-marriage, and so forth between different island populations. But the reticulative perspective is taken further by Terrell and his colleagues to draw the conclusion that interaction will erase any recognizable traces of cultural phylogeny (see also Moore 1994).

For these scholars, the phylogenetic ancestry of cultures is generally unknowable, and thus cannot contribute to an understanding of cultural history. In addition, as they rightly point out:

> We need to be wary about thinking that history and diversity in the Pacific can be reduced to a few grand moments of genesis and immigration. (Terrell et al. 1997, p. 175)

The perspective offered in this entry agrees that a masking of phylogenetic history can occur in cases where actual creolization has taken place, in the form of mixing between two cultural entities of entirely different origin and ancestry. Such intricate mixing on the level of material culture is believed to have occurred, for instance, in some of the Austronesian- and Papuan-speaking societies of lowland New Guinea (Welsch et al. 1992, but see also Roberts et al. 1995 for a contrary view). But when 'like meets like,' as would generally have been the case in Polynesia where all cultures shared a recent common origin, then erasure of all traces of phylogenetic relationship becomes much harder to imagine. Even in the case of lowland New Guinea, the fact that the Austronesian and Papuan languages have not in themselves generally become creolized tells us something about the strength of cultural, especially linguistic, transmission through time, and from generation to generation.

2. *Future Research Prospects*

At the beginning of the twenty-first century, there is widespread interest in the prospects of combining linguistic, archeological, and genetic perspectives on the human past. Elsewhere in the Old World a main supporter of a dialog has been the archeologist Colin Renfrew in his writings on Indo-European languages (Renfrew 1987) and broader macrofamily relationships (Renfrew 1992a, 1992b). Renfrew's position, like that of Bellwood for Austronesian (1996a, 1996b, 1997) and that of geneticist Luca Cavalli-Sforza (Cavalli-Sforza and Cavalli-Sforza 1995) for world populations in general, is that the prehistories of large scale ethnolinguistic populations can be approached from the independent, but overlapping perspectives of genetics, archaeology, and linguistics. The basic model here focuses on a homeland concept, followed by phylogenetic descent to the present through a dispersive sequence involving mainly fissions and divergences, albeit constantly tempered with the results of interpopulation contact. But as Bateman et al. (1990) point out, in discussing the problems of reconciling biological and linguistic phylogenies:

> Such phylogenies are likely to be 'noisy,' reflecting complicating factors such as hybridisation, the less constrained evolution and competitive displacement among cultural traits, and the fact that the contemporaneity of human gamodemes and languages cannot be assumed. (Bateman et al. 1990, p. 13)

An attempt is made finally to encapsulate some of the cultural trajectories and differing opinions discussed above in the form of Fig. 1. This diagram highlights both divergent and convergent evolutionary situations, which should be regarded as overlapping possibilities rather than as absolutely separate processes. Divergent situations include the following: (a) Cultural divergence following the break-up of a communication network; (b) Large-scale operation of the above as a result of the foundation by dispersal of a new phylogenetic unit (e.g., the dispersal of the foundation dialect chain for a major language family). Situations of convergence or amalgamation include the following: (c) Periodic cultural reconvergence of traditions already related phylogenetically; (d) Absorption of some elements of a cultural dispersal (e.g., language, food production system) by indigenous populations, usually in peripheral locations with respect to the source of the cultural dispersal (i.e., the indigenous dominates the exogenous). Such absorption can then be followed by renewed dispersal; (e) Assimilation with no continuing separate cultural identity of the assimilated tradition (i.e. the exogenous dominates the indigenous); (f) Two-way interaction (the middle road between absorption and assimilation). Also to be taken into account is; (g) Cultural extinction, normally as a result of environmental problems, naturally or humanly stimulated, sometimes also reflecting strong assimilation (concepts such as pidgin and creole formation in linguistics are not considered here since they are held to belong mainly to recent episodes of colonial population translocation).

Four other processes are shown schematically in Fig. 1: (a) Generation to generation transmission of cultural traditions through time; (b) Schematic horizontal representation of interaction (reticulation). Reticulation is continuous and universal; (c) The relative potential for population growth (rapid during population dispersal); (d) The period during which the breaking-up of a cultural network, resulting from the foundation dispersal of a future phylogenetic unit, will give rise to separate cultural traditions.

The aim of the diagram is, in part, to indicate that human prehistory cannot be purely regarded as a process of local evolution through all time, but that major episodes of dispersal of the foundation cultures for future phylogenetic arrays punctuate the mesh of gradual reticulate ethnogenesis. Without such dispersals there could be no major language families, and none of the rapid and large-scale spreads of early agricultural economies and cultural complexes which we read from the archeological record in many parts of the world.

Cultural Evolution: Theory and Models

More than 150 definitions of 'culture' have been proposed in the literatures of anthropology, archeology, sociology, and other disciplines. Most of these have been made with a rationale that is neither predictive nor quantitative, but rather descriptive and/or comparative. In the following account, the article will take as culture those aspects of thought, speech, behavior, and artifacts that can be learned and transmitted. This process of transmission may include the action of genes but may also purely cultural and will therefore produce results that are, in general, different from those of models in evolutionary biology. The transmission may involve any or all of imprinting, conditioning, observation, imitation, or direct teaching.

Cavalli-Sforza and Feldman (1973, 1981) developed a quantitative theory for the cultural transmission and evolution of traits within populations. Such traits may be discrete valued or take values in a continuum. The idea here was to seek laws or principles that could explain observed levels of variation or estimated rates of change in a manner analogous to (but, of course, different from) those that have proven useful in evolutionary biology.

Durham (1991) has argued that the use of 'cultural traits' as the units of cultural transmission 'pits nature

against nurture.' But if one simply uses 'traits' as units, then there is no implication as to how the trait is determined. This determination is defined by the model of transmission, which may be purely cultural, purely genetic, or some combination of these (Feldman and Cavalli-Sforza 1976, 1979). In principle, Durham's alternative 'ideational units' are amenable to the same kind of quantitative analysis as that originated by Cavalli-Sforza and Feldman.

Boyd and Richerson (1985, p. 36) exclude 'behavior and the products of behavior' from the definition of culture because 'behavior is contingent upon both patterns of thought and feeling and environmental circumstances.' In following the example of Geertz (1973, pp. 44, 143–6) this exclusion would, if observed religiously, prevent most reasonable measurement and hence quantitative inference about cultural transmission and change. Many of the examples used by Boyd and Richerson, however, do actually involve behaviors as either the transmitted entity or the way in which the hypothesized entity is revealed and transmitted. Formally, at least, the structure of the theory in Boyd and Richerson (1985) is very similar to that of Cavalli-Sforza and Feldman (1973, 1981) and Feldman and Cavalli-Sforza (1976).

Units of cultural transmission have been assigned a variety of names beyond the 'trait' designation originally used by Cavalli-Sforza and Feldman (1973) and Feldman and Cavalli-Sforza (1976). Dawkins (1976) introduced the term 'meme,' which he later defined as a unit of information that is conveyed from one brain to another during cultural transmission. Lumsden and Wilson (1981) use the term 'culturgen' because they require that such traits are processed through 'genetically determined procedures that direct the assembly of the mind.' Each of these terms has disadvantages: 'meme' conveys a sense of imitation or involuntary allocation to memory, while 'culturgen' places too heavy emphasis on the 'gen,' and we know very little about which, or how many genes might be involved in human information processing. If a term is necessary, the recently introduced term 'seme' advocated by Hewlett et al. (2001) is attractive, with its connotations of semantics, signal, and communication.

1. Types of Cultural Transmission and their Consequences

Consider individuals in a large population at time t, where t is on a scale of generations, and generation t represents the parents of generation $t+1$. It is often useful to assume that these generations are non-overlapping with generation t physically replaced by generation $t+1$. Of course, for culturally transmitted entities, this may not preclude a contribution of generation t to generation $t+2$, for example. It is usually assumed that the population is censussed after cultural transmission has taken place. In the simplest models, the sexes are not distinguished, and each instantiation of the cultural trait may be regarded as taking a value from a set C, say.

Table 1
Transmission of a dichotomous trait

Marriage			Offspring probability**	
Mother	Father	Frequency*	0	1
0	0	$x_0^2+mx_0x_1$	$b_{00,0}$	$b_{00,1}$
1	0	$x_0x_1(1-m)$	$b_{10,0}$	$b_{10,1}$
0	1	$x_0x_1(1-m)$	$b_{01,0}$	$b_{01,1}$
1	1	$x_1^2+mx_0x_1$	$b_{11,0}$	$b_{11,1}$

* The subscript t for the parental generation is suppressed. $x_0+x_1=1$.
** $b_{ij,0}+b_{ij,1}=1(i,j\in\{0,1\})$.

1.1 Vertical Transmission

If an offspring's probability of acquiring trait l in C depends on the traits j and k of its parents, we may represent the set of such transmission probabilities or rates as $\Gamma=\{\beta_{jk,l}\}$. Given the frequencies of each representation of the trait in the parental generation at time t, $\{x_{i,t}\}$, Γ determines $\{x_{i,t+1}\}$ and the sequence of frequency vectors $\boldsymbol{x}_0, \boldsymbol{x}_1, \ldots, \boldsymbol{x}_t \ldots$ fully describes the evolution of the trait. Marriage between a pair of parents may occur at random, or we may assume, as is likely for many culturally transmitted traits, that individuals of the same trait value prefer to marry one another. This is called 'assortative' mating and occurs with probability m, say. An example of a dichotomous trait, that is one for which C contains the elements 0 and 1, is given in Table 1.

Then, if we write x_i' for the frequencies in the offspring, that is, generation $t+1$, we have

$$x_i' = x_0^2B+x_0C+b_{11,0}+mBx_0(1-x_0) \qquad (1)$$

where $B=b_{00}-b_{10}-b_{01}+b_{11}$, $C=b_{10}+b_{01}-2b_{11}$.

Iteration of Eqn. (1) produces the complete evolutionary trajectory for the population frequencies of this trait. Note that $b_{00,0}=1, b_{01,0}=b_{10,0}=\frac{1}{2}, b_{11,0}=0$ would be the expected transmission rule if 0 and 1 were genetic alleles of a sexual haploid biological organism. The closer the bs are to these values, the more the dynamic resembles a purely genetic evolutionary trajectory. But the system shows interesting flexibility; for example, if the probability that an offspring is unlike its parents is high enough, a cyclic trajectory results (Feldman and Cavalli-Sforza 1976).

Within the framework of vertical cultural transmission, the parameters $\{\beta_{ij,k}\}$ may be disaggregated into separate additive contributions from each parent, although other partitions are conceivable. Estimation of these transmission parameters, for example under an assumption of equilibrium, is possible from familial correlations such as father–offspring or sib–sib correla-

tions, while m is usually measured as the correlation between spouses. However, this may be biased by marital convergence.

Empirical studies designed to assess the importance of vertical transmission of everyday preferences among Stanford University students revealed that only religious and political attitudes were strongly vertically transmitted. Spousal correlations among the designated parents of these students were reasonably high, suggesting a moderate value for m (Cavalli-Sforza et al. 1982). Among the Aka pygmies, an African group of hunter-gatherers, however, vertical transmission of many customs was estimated by Hewlett and Cavalli-Sforza (1986) to be strong.

Evolution under long-continued vertical transmission should be conservative relative to that expected under other modes of transmission in the sense that change over generations is restricted by the extent of parent–offspring concordance. In particular, the more closely $\{\beta_{ij,k}\}$ resembles a genetic transmission system, the slower will be the evolution. In fact, an exactly genetic transmission structure, in the absence of other forces, results in no temporal change at all. These points will be revisited in connection with continuous traits.

1.2 Horizontal and Oblique Transmission

Suppose that after vertical transmission the frequency of trait variant i in the population at time $t+1$ is $x^V_{i,t+1}$ and suppose that this particular variant, once acquired, cannot be lost. Then, in analogy with epidemic models of disease transmission, we suppose that individuals of type j (different from i) who did not acquire i by vertical transmission contact those who did and are converted to i at rate f_{ji}, the rate of horizontal transmission. It is usual to assume $0 < f_{ji} < 1$. Then, after this transmission the new frequency of i is $x^H_{i,t+1}$ with

$$x^H_{i,t+1} = x^V_{i,t+1} + \sum_{j \neq i} x_{i,t+1} x_{j,t+1} f_{ji} \tag{2}$$

If the trait has only two variants 0 and 1, for example, then

$$x^H_{0,t+1} = x^V_{0,t+1} + f_{10} x^V_{0,t+1}(1 - x^V_{0,t+1}) \tag{2a}$$

in which form the logistic nature of the dynamic becomes obvious.

Within the population, horizontal transmission will generally result in more rapid evolution, that is faster change in the frequencies of trait variants, than vertical.

Horizontal transmission modeled by Eqn. (2) occurs between members of the same demographic cohort. If the transmitters are in generation t (or earlier) and are not the parents of the acquirers of the trait, then we have oblique transmission. In most cases, oblique transmission will have similar consequences to same-cohort transmission, with a slight delay. However, an important special case of oblique transmission we have termed 'one-to-many' or 'teacher-type' transmission, which, in the strongest case, entails that a single individual at time t transmits to all individuals at time $t+1$. This results in exceptionally rapid evolution equivalent to the kind of cultural inbreeding often associated with modern mass media.

An important case of horizontal transmission is often called 'cultural diffusion.' The term generally applies to the trajectory of new cultural variant, an alternative to one that already exists and is dominant in the population. It can apply to the spread of the new variant within a single population or, if the population consists of several subpopulations between which there is some communication, it can refer to the spread across the collection of subpopulations. A logistic dynamic is often observed for the change in frequency of the new variant as it diffuses (e.g., Rogers 1995). An important question for many anthropologists is whether this diffusion may occur in the absence of migration of the people who carry the trait, and it is this case for which the term cultural diffusion is often reserved. On the other hand, if people move and carry their variant of the trait with them, and this variant diffuses with its carriers, the term 'demic diffusion' is commonly used. Distinction between these is usually difficult to make, but if genetic data are available that suggest a cline or gradient in allele frequencies from a putative source population of the human migrants (Cavalli-Sforza et al. 1993), then it might be reasonable to infer that demic diffusion has occurred.

The empirical basis of the conversion parameters $\{f_{ji}\}$ in Eqn. (2) has been the subject of extensive sociological analysis. Rogers (1995) introduces the notion of awareness-knowledge, which is information that the new variant of the trait exists. Then there is the adoption phase, in which the decision to adopt may depend critically on local history of the variant, on the education level or economic status of earlier adopters vis-à-vis the decision-maker. Clearly, for the dynamics to be interpretable, simplification of the large number of parameters involved in these details is necessary. Hence the choice of $\{f_{ji}\}$.

It is possible to incorporate the idea of reinforcement through repeated transmission in both vertical and horizontal cases simply by iterating recursions Eqn. (1) or Eqn. (2) a number of times within a generation and censussing after this number of repeated operations. The rate of change across the new census points will be faster than that due to a single iteration per generation.

1.3 Group Effects and Conformity

The pressure on individuals within a population to adopt a belief or perform a task in a certain way may be affected by how many others in that population

believe or act in that way. The result is that the transmission parameters, instead of being constant as in Eqns. (1) and (2), become functions of the frequency (or possibly frequencies). That is, for the dichotomous trait with horizontal transmission, f_{10} in Eqn. (2a) might be an increasing function of $x^V_{0,t+1}$ when $x^V_{0,t+1}$ is large enough. This would amount to a pressure to conform to the majority. Boyd and Richerson (1985, Chap. 7) point out that this can accelerate the rate of cultural evolution. If the frequency-dependent transmission operates in different directions in different places, because of chance effects of environmental differences, this kind of conformity may also augment geographical differences between isolated groups. Applications to economic theory in terms of norms and preferences that are regarded as cultural entities have been initiated by Bowles (1998).

1.4 Innovation

In biological evolution, the ultimate source of all variation is mutation, nondirected random changes in the DNA that may or, more often, may not result in functional change in the organism. The equivalent for a cultural trait is the appearance of a new cultural variant, an innovation. The fate of an innovation within a population depends on its rules of transmission, which in turn may depend on a host of structural features of the trait itself. The analogue to the genetic phenomenon epistasis, which measures interaction between variants of different genes, is an example of a structural feature, but others would bear little relationship to the structural features that affect the fate of biological mutations. For example, stylistic variation in tool manufacture or behaviors that are coerced economically or by direct force would fall into this category.

In terms of the transmission law of Table 1, if $b_{00,1} > 0$ or $b_{11,0} > 0$ an innovation has occurred in the offspring of the first or fourth matings, respectively. On a more general scale, an analogue to the infinite alleles models of population genetic theory (Ewens 1979, Chap. 3) is more appropriate to describe the stochastic dynamics of innovations, although this is an area that has had little formal study.

2. Continuous Traits and Linear Gaussian Models

If the trait under study varies continuously, then the transmission scheme is more difficult to represent. It is usual to represent the values of an offspring's trait as X_{t+1} and to specify that it is a weighted average of two randomly chosen parental values augmented by a random term:

$$X_{t+1} = b_m X_{m,t} + b_p X_{p,t} + \varepsilon \qquad (3)$$

where b_m and b_p are maternal and paternal weights, and ε is the error random variable with zero mean and variance σ^2. Recursion (Eqn. (3)) corresponds to vertical transmission, and it is easy to include correlation between the parents (that is, assortative mating) as well as a kind of oblique transmission. The latter may be represented as a group effect g:

$$X_{t+1} = (1-g)[b_m X_{m,t} + b_p X_{p,t}] + g\bar{X}_t + \varepsilon \qquad (4)$$

where $\bar{X}$ is the mean of the trait at generation t.

Several features of the dynamics resulting from models like Eqns. (3) and (4) are worth noting. The existence of a group-effect constrains the variance within the population (Cavalli-Sforza and Feldman 1981). If a number of groups are considered, however, within each of which transmission occurs as in Eqn. (4), then the variance, V_t, of the average across groups relative to the original group mean increases linearly with time: $V_t = kt\sigma^2$, where k depends on g, b_m, and b_f.

Linear models analogous to Eqn. (3) or (4) allow correlations between relatives to be computed rather simply, especially under Gaussian assumptions for the trait distribution. Indeed, the most widely used framework for studying familial aggregation of quantitative characters represents the genetic contribution to the character as a linear factor complementary to a linear environmental factor. With appropriate assumptions on the genetic term, variances and covariances between relatives can be computed that mimic those calculated under the simplest genetic hypotheses (Fisher 1918). Controversy remains, however, about which joint linear model of genetically transmitted, culturally transmitted, and nontransmitted contributions to traits that aggregate within families is appropriate (Feldman and Otto 1997), while few attempts to use nonlinear representations have been made.

3. Natural and Cultural Selection

Most intuition about the effects of natural selection on genotypes comes from an interpretation of fitness as a relative probability of survival from fertilized egg to adult. However, a considerable body of experimental evidence (reviewed by Lewontin 1974, Chap. 5) suggests that differential fertility, sexual selection, and frequency-dependent effects are more important than differential survival abilities, although the former are more difficult to measure experimentally and to analyze theoretically. Despite these difficulties, it is reasonable to view natural selection on biological variation in terms of differential reproduction and survival. More details on the components of selection may be found in Hartl and Clark (1997, Chap. 6).

For cultural variants, natural selection on a trait may be understood in the same Darwinian way. To the

extent that the variants of a trait affect the reproduction or survival of their carriers differentially, the frequencies of the variants will change over time accordingly. By contrast, cultural selection refers to differences in the rates of transmission of the cultural variants. As examples, such differences may be manifest in the rates at which individuals become aware of the alternatives or in the decision processes leading to the adoption of one or other of the alternatives. The results of cultural selection will be changes in the frequencies of the cultural variants in a population over time. One obvious difference from natural selection is that cultural may act within a generation rather like an epidemic (Rogers 1995). The parameters that summarize the process of cultural selection are the vertical, horizontal, or oblique transmission rates previously defined.

One area of theoretical debate concerns the possibility of conflicts between cultural and natural selection acting on the same variant of a trait. Thus, for the cultural trait of fertility, the variant whose carriers adopt fertility control (e.g., via contraception) is at a clear disadvantage in natural selection but has spread, especially in developed countries, by virtue of its advantage in cultural selection. Other examples are discussed by Cavalli-Sforza and Feldman (1981), Boyd and Richerson (1985), and Durham (1991). The debate, which cannot be settled with standard experimentation, centers on whether natural and cultural selection should act in the same direction most of the time. Alternatively, should the process of natural selection during human evolution have generally shaped cultural transmission in such a way that those variants favored by cultural selection are adaptive in the Darwinian sense?

A second contentious topic in debates about selection on a cultural trait concerns the role of group selection in the maintenance of variants which, within a group, are individually disadvantageous. Two kinds of models have been considered; in one there is extinction and recolonization of groups according to a stochastic process. If the probability of extinction of a group decreases with increasing frequency of the individually disadvantageous trait, then competition between the groups may preserve the disadvantageous trait. The usual example used for such analyses is altruism (e.g., Boyd and Richerson 1985, Chap. 7; Uyenoyama 1979). Maintenance of such a trait by extinction-type group selection is much less likely than by graded group selection, in which extinction does not occur but the expected relative contribution of a deme to the whole set of demes increases with the frequency of the altruist (Uyenoyama 1979). In the latter formulation, after reproduction there is redistribution of individuals to subgroups according to a stochastic process whose outcomes depend on the numbers of the disadvantageous types (Cohen and Eshel 1976). In other models, fluctuating environments in each of the subpopulations have been shown to allow group selection to occur under more general mixing conditions (Uyenoyama 1979). As pointed out by a number of authors, there are great similarities between these theories of group selection, and the Shifting Balance Theory of genetic evolution due to Sewall Wright (1931, 1935, 1948). On balance, there is a recent trend towards accepting the efficacy of an appropriately formulated model of graded group selection in maintaining traits that are individually disadvantageous, whether culturally or genetically transmitted. In particular, frequency-dependent cultural transmission, for example of the conformist type, may amplify differences between groups, thereby increasing the strength of group selection relative to that of natural selection within groups (Boyd and Richerson 1985).

4. *Some Metatheoretical Considerations*

Since around 1965, three main theoretical frameworks have formed the basis for the study of behavioral evolution and, in particular, human behavioral evolution. The first is kin selection theory, the second is evolutionary game theory, and the third is gene–culture coevolutionary theory.

Kin selection theory is due to W. D. Hamilton (1964) and is based on the idea that genetic alleles whose effect is disadvantageous on a carrier may be preserved if that carrier acts to increase the survival rate of other carriers of those alleles. These other carriers will most likely be relatives of the first carrier—hence the name 'kin selection.' By the mid 1970s, this theory had been extended beyond its original insect and animal boundaries to include human behaviors. In this process, the position that a wide array of behaviors would generally be genetically determined and adaptive, came to be called sociobiology (Wilson 1975).

During this period, the application of game theory, the second framework, to animal and human behaviors also became widespread. Here, in pairwise interactions for example, each individual was thought to optimize its behavior relative to the alternatives the other could adopt. The notion of optimization became prevalent in discussions of behavioral evolution (see, e.g., Parker and Maynard Smith 1990). Such treatments did not consider evolutionary dynamics as processes of frequency change but as processes of maximization of functions chosen by the investigator, usually to represent a measure of fitness.

Although such traits as altruism may well have a culturally transmitted basis, they have generally been studied in the theoretical literature using genetic models. Gene–culture coevolutionary theory was introduced as an alternative to the two former frameworks by Feldman and Cavalli-Sforza (1976). By allowing each individual a phenogenotype, the investigator is free to incorporate transmission mech-

anisms, selection functions, and dynamics that span the spectrum from purely genetic to purely cultural. Besides the obvious gain in flexibility to describe the evolution of behaviors, this framework also permits a natural statistical analysis of correlations between relatives *à la* Fisher (1918). The advantage here is that nongenetic effects are modeled more realistically than is possible using standard linear regression theory. In the coevolutionary dynamics with vertical cultural transmission, an association measure between the cultural and genetic variants is important and the order of magnitude of this association as a function of the comprehensive transmission rule can be derived. More details on the connections between these theories and the following examples can be found in Feldman and Laland (1996).

5. *Examples of Gene–Culture Evolutionary Theory*

The evolution of lactose absorption was shown by Aoki (1986) to be well understood as a case of gene–culture coevolution. Here the gene in question is an autosomal dominant with lactose absorption the dominant phenotype at this locus. The cultural dichotomy is the presence or absence of a history of dairy farming. The frequency of lactose absorbers in populations with dairy traditions often reaches over 90 percent, while in those populations without such a tradition it is typically below 20 percent. In modeling the joint evolution of the gene and the custom of dairying, both natural selection due to increased nutrition provided by milk and the cultural transmission of milk use, are affected by the genotype at the lactose absorbing locus. Analysis of this coevolution suggests that the fate of the absorption allele critically depends on the rate of vertical transmission of milk use. If this rate is very high, then a significant fitness advantage to absorbers can shift the frequency of the dominant allele to high frequencies in as few as 300 generations.

The spread of agriculture into geographical areas previously occupied by hunter-gatherers has been a fruitful subject for students of genetic and cultural history. Aoki and Shida (1996) used a reaction-diffusion process to model the spread of farming. Their analysis included a horizontal transmission process converting hunter-gatherers to farming as well as different intrinsic growth rates for initial farmers, converted farmers, and hunter-gatherers. Their analysis produced conditions under which farming would advance at a constant rate and, in addition, a gene frequency cline would simultaneously form. This elegant study represents a major advance over the earlier proposal of Ammerman and Cavalli-Sforza (1971), which was based on R. A. Fisher's famous model for the advance of an advantageous gene (Fisher 1937).

A third example of gene–culture coevolution concerns the well-documented cultural bias against daughters in South and East Asia (Das Gupta 1987, Tuljpurkar et al. 1995). Under the assumption that a preference for sons is vertically transmitted, Kumm et al. (1994) studied how this transmission might affect the evolution of sex-determining genes. They showed that if parents act to increase the proportion of sons, irrespective of the biologically set sex ratio among their children, and if they compensate for lost daughters by having further children, the sex ratio will evolve to be female-biased. On the other hand, if parents try to achieve a desired sex ratio among their children and in so doing have fewer children than impartial parents, the primary sex ratio will become male-biased.

Cultural Expression and Action

Attention to action in the sociological study of culture (and in the social sciences more generally) typically has meant taking the individual as a theoretical starting point. Max Weber (1968, p. 3) defined 'social action' as follows: 'We shall speak of "action" insofar as the acting individual attaches a subjective meaning to his behavior—be it overt or covert, omission or acquiescence. Action is "social" insofar as its subjective meaning takes account of the behavior of others and is thereby oriented in its course.' Cultural and structural accounts of action are often contrasted, but action theorists have been interested in precisely how structural constraints and cultural meanings interact. A focus on culture and action also points toward questions of how culture affects action, rather than toward the interpretation of culture for its own sake.

The focus on action raises a set of important questions around which this article is organized. (a) What kinds of meanings or cultural elements shape action? (b) How are meanings brought to bear on action? (c) What is the relation between consciously articulated symbols and implicit, unarticulated practices in guiding action? (d) What is the best way to conceptualize the relation between culture and social structure? (e) Are there cultural 'logics' and if so, how do they operate? (f) How is culture organized differently, such that it may have differing effects on action, at different levels of social organization?

1. *Kinds of Meanings*

What *kinds of meanings* or cultural elements shape action? There are several candidates for the key component of culture that influences action, each with different implications for the shape that influence will take. Max Weber attempted to understand the subjective meanings that governed action, focusing on the effects of particular, historically specific *ideas*. Thus, he argued, the beliefs of Calvinist Protestants, or Hindu mystics, or Confucian officials had consequences for the ways they acted. Ideas are not the only influence on action, but they provide its premises: 'not ideas, but material and ideal interests directly govern men's conduct. Yet the "world images" that have been created by "ideas" have, like switchmen, determined the tracks along which action has been pushed by the dynamic of interest' (Weber 1946 [1922–23], p. 280).

The difficulty with Weber's formulation, however, comes in specifying how ideas actually guide action. Weber had emphasized that ideas such as religious doctrines channeled actors' motives by defining the ends or goals of action and shaping beliefs about relevant means. Thus Western religious traditions, positing a powerful personal God who is creator and judge, conceive of individual salvation as something to be earned by active conduct in this world. Many Eastern religious traditions conceive divinity as immanent in reality, and their adherents seek to merge with the divine through contemplative or mystical practices (Weber 1993). In Weber's most famous example, *The Protestant Ethic and the Spirit of Capitalism* (Weber 1958), Protestant anxiety about salvation, channeled through the Calvinist doctrine of predestination, produced powerful motivations for

disciplined work in a calling. Later theorists, however, noted that belief systems could and did support diverse lines of action, that people in fact hold a variety of often inconsistent or poorly-integrated beliefs, and that even civilizations Weber thought to be otherworldly and mystical develop disciplined, rational economic activity.

Ideas are rarely coherent or consensual enough to account for the paths actors take (see Wuthnow 1987, Skocpol 1985), although Swidler (1986) has argued that such consistent, intense, effective ideologies are more common in 'unsettled' historical periods. Indeed, even John Calvin, who for Weber epitomized rigorous submission to the logic of ideas, adapted his doctrines continuously to his vision of how the Genevan community should be ruled (see Walzer 1973). Furthermore, the Protestant ethic of anxious, disciplined self-scrutiny long outlasted Calvinist doctrine, casting doubt on the causal centrality of Calvinist ideas in themselves.

Talcott Parsons, reinterpreting Weber's work along with that of Emile Durkheim, focused not on particular, historically contingent ideas, but on broad, general *values* which he felt characterized whole societies. Such values as individual achievement or equality provided the core goals that motivated both individuals and societies. Parsons (1937, 1951) developed a voluntarist theory of action which described actors making choices in a situation. While he understood that there were many noncultural constraints on action, ranging from the biological nature of the human organism to characteristics of individual psychology, and to constraints and opportunities provided by power or wealth, he saw the distinctive contribution of sociological analysis as study of the cultural values and norms that shaped what people sought and the means they thought legitimate.

Parsons' formulation raised numerous questions among them are: to what degree cultural values are shared; what values are and where they are located (how they can be observed); how they are internalized in individuals; and how they constrain individual thought and action. Some critics argued that 'values' had no independent standing as causal elements in human action, since the only evidence for the existence of values that purportedly guided action was the action itself (Cancian 1975). Others objected to an overly deterministic theory which, despite the metatheoretical commitment to 'voluntarism' saw individuals as constrained by socially imposed norms and values such that no real choice was possible (Wrong 1961).

Other theorists question the image of individuals as choosing their actions one at a time in order to attain their ultimate ends, in favor of broader but looser conceptions of how culture shapes human action. Geertz (1973) emphasizes the *ethos* of a people, especially the mood or tone of their collective life, the emotional attitudes engendered by their ritual practices, and the experience of the world encouraged by their artistic styles, their everyday practices, and their sacred symbols. He still sees a role for 'world view,' but he does not seek to draw direct links between cultural beliefs and action, nor to trace social choices to shared, overarching values. Swidler (1986) argues that not values but styles, skills, and habits (culturally cultivated capacities) are the most direct cultural influences on action. She argues that individual actors do not usually start with culturally defined goals or values (as Weber and Parsons had assumed) and then build lines of action around them. Rather, actors are constrained by their culturally learned styles, skills, and habits, and they tend to adopt goals or values which are compatible with those cultured capacities. By locating cultural influence in skills and habits rather than in ultimate values or ideas, Swidler allows for the possibility that cultures contain many diverse elements, some of which may be contradictory, so that culture should be thought of as a 'tool kit' upon which actors draw, rather than a coherent set of ends or values.

New ways of thinking about culture have become important since the 1980s as concepts of *discourse* and *practice* have replaced the older interest in ideas and values. The term discourse, although it sometimes designates symbolic communication as opposed to embodied practices, usually means a transpersonal ordering of symbols and meanings which sets the terms within which particular things may be said. In this usage the term points away from action theory and actors altogether. A discursive system does not exist in the mind of any particular actor and does not depend on any one user (see Wuthnow 1987). Nonetheless it presumably constrains what actors can think, say, and do, although the precise nature of these constraints is not made clear. The emphasis on practice (Bourdieu) or practices (Foucault), as Ortner (1984) suggests, envisions culture as both deeper (embodied in unconscious habits rather than in consciously held ideas and values) and more fraught with power and conflict than earlier approaches had recognized. Practice theorists have stressed the active, strategic agency of social actors (their 'resistance') while also emphasizing their subjection to dominant discourses and practices.

A more recent challenge to action theory comes from a revitalized social constructionist perspective (see Berger and Luckmann 1967) which reintroduces culture as a general set of *cognitive rules and recipes* in terms of which agents, institutions, and structures are constituted. John Meyer and his collaborators (Meyer 1983, 1986, 1987, Meyer et al. 1997) locate culture in the 'environment' of cognitive rules and recipes that define the world, rather than in the consciousness of individual actors. They argue that the major effects of culture are to define institutional structures (such as nation states, organizations, or such institutions as schooling) rather than to guide individual action

directly. (On the contrasts between Parsonian understandings and Meyer's 'new institutionalism' see DiMaggio and Powell 1991.) Thus, in the examples favored by Meyer and his collaborators, nation states are constituted according to global rules imbedded in the international system; organizations are created according to schemas constituted within nation states; and individuals themselves are constituted according to rules imbedded in a global culture of 'human rights,' citizenship, and the rationalized Western account of the sources and purposes of economic growth and progress. Rather than offering an alternative explanation of how culture affects action, such neo-institutionalist approaches dismiss the explanation of individual and collective action as uninteresting. Neo-institutionalist theory has offered a broad description of changes in the contemporary world system, while remaining vague about the mechanisms by which institutional rules and recipes emerge, change, or decline, or the concrete processes involved in their adoption, alteration, or rejection by particular groups or actors.

2. *How Culture Is Internalized*

The second major question for any theory of action is *how cultural elements come to govern action*. Do they become internalized, and if so how? Weber assumed that cultural ideas operate by channeling human motives (for health, wealth, salvation from suffering) along lines suggested by a world view. Weber assumed that world views were offered by religious and ideological entrepreneurs, but that once the ideas had become established they constrained people by shaping what they thought was real, what they thought was possible, and what they thought desirable. Parsons (along with collaborators such as Freed Bales) developed a complex Freudian theory of family dynamics to explain how values are internalized in individuals through socialization. The most innovative contribution along these lines has been that of Pierre Bourdieu (1977, 1984). Bourdieu sees human actors as active strategists, not following cultural rules, but manipulating rules to their own advantage. Nonetheless, the skills needed to manipulate a cultural code, according to Bourdieu, require a deep process of internalization during which people in essence internalize their own position in the social structure. Thus the conditions for agency—a fluid mastery of a system of social meanings—are the conditions for being dominated by its criteria of evaluation. Bourdieu sees culture not as values but as cultural skills and capacities, particularly the skills that allow innovative performances within established cultural patterns. Bourdieu incorporates a notion of social constraint into the heart of his model of the actor as active, strategic, and innovative, by arguing that culture becomes deeply internalized, not in the mind as values, but in the body (or rather 'bodily schemas') as *habitus*: as a system of 'transposable dispositions' which make 'possible the achievement of infinitely diversified tasks, thanks to analogical transfers of schemes permitting the solution of similarly shaped problems' (1977, p. 83). For Bourdieu the *habitus* marks one both because the whole set of internalized bodily dispositions, tastes, and habits are particular to one's social location, but also because learning to manipulate the social world means internalizing it and its standards.

Randall Collins (1981, 1988) has also sought to understand how relations of power and status inequality are reproduced at the micro level of personal interaction. His model, however, depends less on internalization and more on exchange. Collins argues that every interaction leaves actors either enhanced or diminished emotionally, so that those in powerful or high-status roles dominate interactions and find that each interaction increases their emotional reserves, while those in subordinate positions lose out and experience themselves as less vital or powerful. Bourdieu and Collins thus both show how elements of social structure (particularly power and inequality) are incorporated directly into the person at a visceral or bodily rather than an intellectual level.

Hans Joas' *The Creativity of Action* (1996) offers a rich description of action that does not require the presumption of an autonomous, goal oriented actor who chooses actions in a situation that is somehow external to his or her action. Joas reconstructs pragmatist social theory to show how sociality, physicality, and intentionality are inherent in human action: 'vague dispositions toward goals which are constantly at work even when we have not set ourselves any immediate goals, are located in the personal body of the human being…Situations do not trigger our actions, but nor do they merely provide the terrain on which we carry out our intentions. Our perception of the situation is predefined in our capacities for action and our current dispositions for action' (p. 161).

3. *Discourse and Practice*

What is the *relation between articulated discursive elements and implicit, unarticulated practices* in guiding action? Are the meanings that shape action primarily ideas and symbols, or are they embodied practices—habitual ways of acting not necessarily guided by conscious thought? Michel Foucault (1965, 1978, 1983) has argued that discourse and practice reinforce each other. New institutional practices, such as asylums that separate the sane from the mad, make plausible the associated discourses and their ways of categorizing human beings. Practices, such as that of confession in the church or the segregation of lepers in the Middle Ages, persist to form the basis of related practices (psychoanalysis; the insane asylum) and their associated discourses in later historical eras. At the same time, new kinds of knowledge—what Foucault (1980) calls 'power/knowledge'—such as the academic

disciplines that study, analyze, and categorize human behavior, the biological organism, or social formations—provide the bases for new practices, which in turn make the categories plausible. John Mohr and Vincent Duquenne (1997) have mapped the mutual constitution of categories and practices, showing how categories of the poor are constituted by welfare agencies' practices, and agencies' practices are defined by the categories of the poor they treat. Mohr and Duquenne also demonstrate how this structure of mutually constituted practices and categories changes over time.

Some scholars have tried to disentangle the causal role of discourses and practices. Richard Biernacki (1995) has argued that the differing ways labor was constituted as a commodity in Germany and England (in Germany employers purchased labor time, while in England they purchased the labor embedded in commodities) had profound effects on both thought and action. The cultural constitution of labor shaped the design of factories, the ways foremen behaved, and the ways workers went out on strike, as well as the contrasting intellectual perspectives of Marx vs. the British political economists. Yet, he argues, this profound difference in the nature of labor as a commodity was not a matter of differing ideas or discourses about labor, but of the 'silent practices' which reproduced the differing ways labor was constituted as a commodity, independently of how men and women tried to think about their experience. In particular, the ways factory owners and workers negotiated wages, with German workers and managers contending over compensation for workers' labor time, while British workers and owners fought over the price of cloth of different qualities, reproduced differing understandings of the nature of labor. These patterns emerged in turn out of the practices for mobilizing labor that were available to owners at the start of the industrial era. These different understandings of labor as a commodity ended when, during World War I, governments suspended wage negotiations and thus interrupted the arena of practice in which these differing forms of labor had been reproduced.

Dobbin (1994) also privileges practice over discourse in arguing that nations base their industrial policies on cognitive models of the sources of order and progress. These models in turn are based on understandings of national sources of political order. While neither study resolves the question of the relationship of practice and discourse, they suggest additional ways of thinking about how culture constitutes patterns that in turn constrain social action.

4. *Culture and Structure*

What is the relation between *culture and social structure*? The fourth problem raised by any theory of action is that of the relation between the cultural influences on action and the influence of what are sometimes called 'structural' or 'material' factors. This problem is an old one in the social sciences, from Marx's insistence that ideas were the product not the determinant of material realities to Max Weber's discussion, quoted above, of the ways 'material and ideal interests' govern men's conduct. For many decades, sociological debate revolved around how to weigh 'material' vs. 'ideal' influences on action, or somewhat later, the relationship of 'culture' and 'social structure.' Talcott Parsons developed the most sophisticated solution of this problem in its original Weberian form in his 'cybernetic' model of action (see Alexander 1983 for a fuller discussion). Parsons proposed paired hierarchies of factors that 'condition' vs. 'control' action. Conditioning factors are necessary but not sufficient conditions for action, such as being alive or having the material capacity to act—high in 'energy' but low in 'information.' Controlling factors, like ideas, culture, or the genetic code, are high in information but low in energy. High-energy factors determine the capacity for action, but the high information factors—a person's ideas, an architect's plans, or a chromosome's genetic structure—convey the information necessary actually to guide action.

Recent theories have sought to re-examine or eliminate altogether the distinction between culture and structure in theories of action. The most important effort along these lines is that of William Sewell Jr. (1992), drawing on Bourdieu (1971) and Anthony Giddens (1984). Bourdieu noted that structure itself has to be reproduced, and argued that culture plays a role in that reproduction. Giddens introduced the idea that structures are 'dual,' constituted simultaneously by 'schemas' which are 'virtual' and material resources which are actual. This formulation maintains the distinction between material and ideal, but instead of seeing them as separate factors in action, sees them as something like matter and form in the ancient Greek sense, in which entities do not acquire their properties unless matter is given form through cultural meanings. In this formulation, structures themselves become cultural artifacts whose creation, reproduction, and meanings are constituted by cultural schemas. At the same time, schemas are instantiated only when they structure some set of material resources, if only print on a page or sound waves in air.

Sewell (1992) advances Giddens' discussion in several ways. First, he follows Giddens in noting that schemas are transposable from one context or situation to another, but he makes this one of the crucial foundations for an argument about human agency. Each transposition of a schema to a new context (even the reproduction of a structure in a new time or place) is a creative adaptation in new circumstances. Second, cultural schemas are 'polysemic' or 'multivocal' so that each time a schema is abstracted from its current embodiment and reproduced, there is human agency involved in interpreting or reading the schema-bearing

structure. Indeed, Sewell's most powerful idea may be that structures themselves are 'read' like texts for the schemas they encode, and that such readings may vary. Third, any instantiation of a schema may produce unpredictable material outcomes, and those outcomes themselves may then be read as embodying an altered schema. Fourth, unlike material resources, human resources always involve some element of agency since human beings attribute meaning to their action and retain some measure of control over their capacities and commitments.

The notion that culture 'constitutes' social structure has become something of a truism, but Sewell has begun to explore the sense in which it is true. His conception of structure still covers an extraordinarily wide range of phenomena, from handshakes, to capitalism, to nation states, but he is right to point to the cultural schemas that organize and order each of these structures, and which at least potentially make possible their transformation. If existing structures are read for the cultural schemas they instantiate, this also suggests how material transformations, whatever their source, can constitute a new cultural text.

The most creative use of this framework is Sewell's (1996) paper on the transformation of structures during the French Revolution. By analyzing the 'event' of the fall of the Bastille as it unfolded over a period of weeks, Sewell shows how an intense collective crisis transformed social meanings. This transformation was made possible by the possibilities of existing patterns of symbolic meaning (the fact that the 'people' ['*le peuple*'] could mean both the crowd or rabble and the legitimating foundation of the nation), but the new meanings emerged only in an intense, public ritual where new symbolic meanings could be validated by public enactment. Sewell also shows the role of material resources in establishing a new schema. He argues that the popular violence at the Bastille was retrospectively redefined as legitimate revolutionary fervor only when the National Assembly, in the days following July 14, 1789, recognized that the people had saved the Assembly from the King's National Guard. Thus the revolutionary transformation of structure resulted from the agency of actors caught up in an intense, fraught, consequential public ritual, but the reproduction of those transformed meanings also depended on their material consequences.

5. *Coherence and Cultural 'Logics'*

There is wide disagreement about *how coherent* cultural systems are. Are they 'systems' at all, and if so, in what sense? One challenge for those who argue that cultural systems have their own logic is to specify what a cultural logic is, how it operates, and how it constrains thought and action. Alexander (Alexander and Smith 1993), along with anthropologists such as Schneider (1976) and LeVine (1984), have insisted on cultural coherence, while Swidler (2001), DiMaggio (1997), and others have seen culture as being more disorderly and unsystematic. Sewell (1999) has argued that culture is necessarily a system in the analytic sense of semiotic codes whose meanings are inter-related. Any concrete culture, however, is made up of many different codes which may be inconsistent, partial, or conflicting.

Theorists who insist on culture's coherence rely on the notion of a 'cultural logic' as the link between culture and action. But sociologists who use the idea of a cultural logic have done little to define, or even to examine explicitly, what cultural logics are, and how they constrain action. Weber (1946) argued that world views had greater influence on action as they became more rationalized and thus had stronger, more inescapable logical implications. Bellah (1964) developed powerfully this idea in his analysis of 'Religious Evolution,' arguing that as symbol systems became more differentiated and coherent, and as specialized institutions for generating and transmitting religious meanings emerged, those meanings had greater independent leverage over action. But logical-deductive coherence is not the only, nor the most plausible, candidate for describing how cultural meanings might actually be organized. Levi-Strauss and his followers have described binary oppositions as the fundamental organizing principle of all cultures, while Clifford Geertz has insisted that each culture's logic is distinctive. Such a notion of unique logics might seem to vitiate the notion of a 'logic' altogether, except that Geertz (1973, pp. 133, 399, 405–8) frequently describes a kind of existential logic in which some ways of experiencing the world are compatible with, or even require, others.

Other theorists have proposed narratives as organizing cultural logics (see Turner 1974, Ortner 1989); still others have seen cultural logics as arising from institutional patterns (Friedland and Alford 1991, Swidler 2001). The anthropologist Bradd Shore (1996) has argued that cultures contain multiple, intersecting logics (see also Friedland and Alford); Pierre Bourdieu (1990) has argued that when people seek to solve urgent problems, the logic of practice brings to bear all sorts of contradictory schemas. If there are many overlapping or intersecting cultural logics, do actors just pick and choose among them? Are some more compelling than others? Or do 'external factors' determine when and how cultural logics are constraining? Some notion of a cultural logic or logics seems essential for understanding how culture influences action. But existing approaches leave unresolved problems of how cultural logics operate and how or when they are brought to bear on action.

6. *Levels of Analysis*

For those who accent the multiplex, incoherent, and conflicting aspects of culture, one challenge is to specify the contexts that organize meanings and

sometimes bring them to bear in a consistent way on action. Swidler (2001) points to the incoherence of actual cultures, both the variety of cultural resources available (the opposing adages of conventional wisdom; platitudes vs. the cynical knowledge of insiders; competing voices in the political arena; contradictory messages in the media) and the confused, often contradictory aspirations and understandings of individuals. She argues that to explain when and how cultural meanings constrain action, one needs to specify the contexts or institutions that sometimes bring culture to bear in a consistent way on action, even when it remains incoherent or incomplete in the minds of individuals.

The key to analyzing problems of culture and action is to differentiate levels of analysis—to see that culture may be organized differently at different levels of social organization. On the one hand, individual actors draw on repertoires of cultural meanings to construct lines of action which allow them to navigate the wider social space. At the same time, contexts external to actors (such as public arenas, institutional demands, or even publicized social codes) may structure meanings and thus influence action, independently of whether culture is deeply incorporated into the actor. Swidler (1995) offers the example of polarized public meetings as contexts in which cultural meanings may become organized coherently, so that voicing an opinion one held yesterday may 'mean' something very different today; public debate may reorganize ideas around new 'logics'; and actors may find themselves constrained by the public ordering of ideas they personally do not hold.

Some social meanings may be anchored in established social practices, without those practices themselves being linked to larger cultural logics. Asking what anchors cultural meanings raises the question of why culture is sometimes much more fluid, negotiable, and transformable than at other times. Biernacki (1995) has shown that practices such as those of wage negotiations between owners and workers in England vs. Germany were enduring and were capable of organizing wide domains of thought and action, yet had no necessary logical tie to other social patterns. Sewell (1999) has suggested that the state is in the business of imposing order on cultural meanings, attempting to produce a more unified cultural logic in the public arena.

7. Collective Action Schemas

The basic paradigms that describe logics of collective action (that is, the mobilization of a community outside institutionalized channels) may have a distinctive logic that is not necessarily homologous, and does not necessarily change in rhythm with more institutionalized patterns of culture and action. In essence, the schemas that guide collective action are a kind of social 'default option'—what everyone knows that everyone else knows that everyone knows. Such schemas of collective action may endure through many institutional transformations because they are not created by routine social experience and they always depend on simultaneous, public knowledge to establish new patterns. Dramatic public ritual events, like those Sewell (1996) has analyzed, may redefine paradigms for collective action, while the culture that undergirds ordinary strategies of action may remain largely unaffected (see Swidler 1992).

The Weberian theory of action saw culture as shaping social life by shaping the ideas and thus channeling the motives of individual actors. Later theorists of action have attempted to find a tighter linkage between the individual and the social—sometimes, like Parsons, seeing the individual as a carrier of consensual social values; sometimes, like Sewell and Swidler, emphasizing again the autonomy of individual actors. Practice theory attempted to solve the relation of actors to social structure by seeing social structure itself as deeply, unconsciously internalized. But understanding how culture is organized in actors' minds, bodies, and experiences is not sufficient for a full theory of culture and action.

Recognizing that culture is organized, and organized *differently*, at multiple levels may help to specify the autonomous causal role of culture, taking account of the agency of actors while acknowledging separate processes through which external contexts bring culture to bear on action. Such an approach would take cultural meanings seriously while analyzing the contexts that bring culture to bear on action, the situations that organize or reorganize meanings, the schemas that encode logics of collective action, and the institutional demands that reproduce cultural supports for action.

Cultural Geography

Cultural geography is a subdisciplinary category that is credited as being 'perhaps the most ambiguous term in the discipline's lexicon' (Price and Lewis 1993). There are two reasons for this ambiguity. First, the term 'culture' is often not defined; there is simply an 'easy coupling with geography in which both refer to a general sensitivity to issues of context, difference, and the local' (Barnett 1998, p. 631). Second, there has been a proliferation of cultural geographical approaches since the 1980s: 'the revival of cultural geography in a radically new form was one of the most striking [disciplinary] developments of the 1980s' (Gregory 1994, p. 98).

1. *The Berkeley School*

The term 'cultural geography' can be traced to nineteenth century German scholarship, but is thought to have been introduced into American geography in the 1920s by Carl Sauer (Price and Lewis 1993). Sauer, his colleagues in the geography department at Berkeley, and their students dominated American cultural geography until the 1980s. (This is not to say that this was the only strand of 'traditional' cultural geography. For a contemporary overview of a broader range of traditional cultural geographies, see Foote et al. 1994). Sauer (1925) framed cultural geography in opposition to environmental determinism, which he criticized for subjecting the diversity of cultures to a monocausal, nomothetic theory. Sauer instead advocated historical synthetic accounts of human interaction with natural environments. For Sauer, landscape study was an exercise in historical reconstruction that sought to show how a particular cultural group, working on and through the natural landscape, enacted a cultural landscape. The relevant unit of observation was the cultural region, defined as an area over which a functionally coherent way of life dominated. Much of Sauer's fieldwork was located at the US/Mexican border, and he explored the border as a cultural, rather than a physical divide. In the prologue to his important book, *The Early Spanish Main*, Sauer wrote that: 'the same mountains and desert, pine forest, and woodlands, scrub, and grasslands extend north and south; the difference is the people and their ways' (Sauer 1966, p.V). Members of the Berkeley School explored a range of themes in mostly rural locations: the migration of human groups and the process of adapting a familiar culture to a new land; the domestication of plants and animals; the development, intensification, and dispersion of agriculture; ancient cultivation systems; and the genesis and diffusion of cultural traits and material culture (e.g., folk housing). (For fuller accounts of the Sauerian tradition, see *Ecology, Cultural*; *Cultural Landscape in Geography*; *Cultural Landscape in Environmental Studies*.)

1.1 *Recent Assessments of the Berkeley School*

In the early 1980s, as new approaches to cultural geography were developed, a (contested) critique of the Berkeley School emerged. Berkeley School cultural geography was charged with conceiving cultural groups and regions as unities, and deploying a superorganic concept of culture that invested agency in culture rather than individuals. Power relations were given short shrift (Duncan 1980). The accuracy of this critique has been disputed (Price and Lewis 1993) but, even among those who accept it, there is now a renewed appreciation of the cultural ecology tradition that grew out of the Berkeley School. Crang (1998) draws attention to the ways in which Sauer bound the material and social, viewing crop species and gene pools, for example, as 'material expression and embodiment of social processes and knowledge' (p. 16). Willems-Braun (1997, p. 705) acknowledges the significance of studies of pre-contact indigenous cultural transformation of nature; they offer important tools for those who wish to disrupt the equation of 'native' and 'nature.' Even the disdainful treatment given to the Berkeley School's preoccupation with establishing cultural hearths deserves reconsideration; Woods (1998), for example, deploys the notion of cultural hearth in relation to 'blues epistemology' as an indigenous knowledge. Woods insists that the US south, in particular the Mississippi Delta, is the center of African American culture and that its 'lands, rivers, streams, air, plants, and animals … must be restored to their sacred status' (p. 290). This is an empirical and strategic claim, which he poses in opposition to white writers who focus on the degradation of African American culture and thus the necessity for cultural assimilation. 'Not only is working-class African American culture not broken and deviant, it is a powerful world culture held together, and expanded, by repeated blues movements' (p. 289). The Mississippi Delta must be understood as a 'Mecca', and African American blues culture as a model for sustainable communities.

2. *New Cultural Geographies*

Recent tendencies toward accommodation mute a sense of subdisciplinary transformation that existed in the late 1970s and 1980s, when a new generation of cultural geographers began to engage with a diverse range of philosophical traditions, and social and cultural theories. In some ways paralleling Sauer's rejection of nomothetic theory, humanistic geographers positioned themselves against spatial science and drew upon phenomenology, existentialism, and symbolic interactionism to recover the role of individual agency in the construction of place and cultural meanings (see *Humanistic Geography*). Hist-

Figure 1

orical materialism, and then an increasingly diverse array of cultural theories have also been drawn upon, such that the subdisciplinary—indeed disciplinary—boundaries of cultural geography are now exceedingly blurry. Some of this history and excitement can be organized around the themes of representation, power, and cultural identity.

2.1 Representation

The linguistic turn of the 1980s was felt throughout the social sciences and humanities; in cultural geography it focused attention on the landscape as text and the politics of the representations that geographers produce (i.e., on the culture of geography).

2.1.1 Landscape as text. There is a long tradition of 'reading' the landscape in cultural geography. Peirce Lewis (1979, p. 12), for example, described the landscape as 'our unwitting autobiography.' Since the 1980s, however, the metaphor of landscape as text has been pursued more rigorously through a fuller engagement with literary and cultural theory, for example, in Duncan's (1990) study of the Kandyian Kingdom in early nineteenth century Sri Lanka. Duncan describes how the king of Kandy concretized two intertwined discourses on kingship through a massive city-building program, in an attempt to secure his political power; this landscape transformation was then interpreted differently by the king, nobles, and peasants, through the lens of the two key texts. The story, then, is of intertextuality, of the interplay of discourses enacted in landscape and texts.

This textualization of landscape has itself been criticized, less in relation to Duncan's specific empirical application than as a general theory of landscape interpretation. It is criticized for erasing process (Gregory 1994), for over-emphasizing the coherence of texts and landscapes, and for suppressing traces of non-human others: 'it treats the landscape as a blank page that only human actors can read and write upon' (Demeritt 1994, p. 170). Nevertheless, the metaphor has been reworked, for example around the notion of theatre and the script, to draw out the open, performative possibilities of text—partly structured and partly improvised. Gregory (1999), for example, writes about the scripting of Egypt in the nineteenth century by a growing tourism industry. European tourists not only read voluminously when traveling down the Nile (Fig. 1), the guidebooks also provided stage directions for transforming *dahabeeah* (floating barges) into 'secure viewing platforms' (e.g., English travelers were advised to bring 60 yards of chintz as a means of effecting this), and the remains of ancient Egypt were literally and materially staged as an 'extended exhibition.' It is this attention to the materiality and spatiality of writing, in this case travel writing, that distinguishes the work of cultural geographers (Duncan and Gregory 1999).

2.1.2 Landscape and maps as ways of seeing. Humanistic geographers of the early 1980s were drawn to the textual metaphor; Cosgrove (1985) entreated them to pay closer attention to the visual, as a way of understanding one of their key, though untheorized, concepts, that of landscape (see *Cultural Landscape in Environmental Studies*). In Gregory's (1994, p. 98) assessment, this recognition of the 'conceptuality' of landscape is one of the 'cardinal achievements' of the revival of cultural geography in the 1980s. Cosgrove traced the emergence of landscape as a visual ideology, as a way of seeing, in fifteenth and sixteenth century Europe. The discovery of linear perspective enabled a realist illusion of space: 'Landscape is thus a way of seeing, a composition and structuring of the world so that it may be appropriated by a detached individual spectator to whom an illusion of order and control is offered through the composition of space according to the certainties of geometry' (Cosgrove 1985, p. 55). This way of seeing coincided with and supported a transition from feudalism to capitalism, and new social relations with nature, and land as property.

What landscape paintings achieve aesthetically 'maps, surveys, and ordnance charts achieve practically' (Cosgrove 1985, p. 55); this recognition has led to a critical reassessment of another of geographers' representational forms: the map. The assumed link between reality and representation has been broken, and maps are now read as 'mechanisms for defining social relationships, sustaining social rules, and strengthening social values' (Harley 1992, p. 237), in short, as technologies of power. Harley has used deconstructive methods to read a simple road map, specifically a map of the State of North Carolina. He begins his interpretation at the margins of the map—for example, with the pictures of points of interest (that include a Cherokee woman making beaded jewelry, and a sand dune), a ferry schedule, and a message from a state official—to argue that the map does more than help ordinary motorists find their way. Through the marginal, mundane notes, and images, the map constructs a mythic geography: a landscape full of points of interest; it affirms State sovereignty; and it sustains the American 'love affair' with the car. Maps are such effective technologies of power because they 'operate behind the mask of seemingly neutral science' (Harley 1992, p. 238) (see *Cartography*; *Cartography, History of*).

2.1.3 Other ways of seeing. Cultural geographers have sought to unmask this neutrality through their own representations; one of the most adventurous has been Pred (1995,) who experiments with font size, repetition, and montage to engage us in (re)cognizing European modernities. In his essay on the Stockholm Exhibition of 1897, Pred invites the reader to participate in the 'phantasmagorical dream' of the exhibition by leading us through a tour of endless lists of commodities and visual pleasures. This description is jostled by fragments of quotations from cultural theory, newspaper and government reports, and personal anecdote. Rather than being declarative and closed, Pred's analysis emerges through a series of unanswered questions. An unlabeled cartoon (Fig. 2) is

repeated incessantly, its interpretation shifting in juxtaposition to different portions of the text. We eventually learn that it is a cartoon of the extensive looting that took place at the close of the exhibition. We more fully understand Pred's repetition of the cartoon when he asks, in closing the essay, whether the looting—which was largely erased from official history—is not in fact an overdetermined metaphor for the exhibition. Pred's experiments in montage are an effort to 'force discordant fragments to 'whisper' and 'shout' at each other in polylogue' (1995, p. 26) in order to re-present contemporary commodity society.

2.2 *Material and Symbolic Geographies as Technologies of Power*

It should now be clear that power and politics have been central concerns for contemporary cultural geographers (Jackson 1989). Landscapes not only express social relations, they are also an important means of enacting them. And landscapes, like maps, are such effective technologies of power because they tend to naturalize these relations (Cresswell 1996, Mitchell 1996). Pred (1995), for example, understands Stockholm's exhibitions as training grounds for citizen-consumers. The exhibition of 1897 afforded visitors new perspectives on the city: 'Spy on others without their knowledge. Observe restaurant customers shamelessly flirting with waitresses … Be titillated in these and other ways while simultaneously (re)learning the lessons of modern power, of panoptical bureaucratic power … Be reminded that the power of the State lies not so much in its ability to rally police or locally stationed troops at points of actual or potential disturbance, as in the ability of its constituent agencies to keep an eye on, to maintain bureaucratic surveillance over, each and every subject' (p. 61). By the 1930 exhibition, the geography lessons are quite different. The dominant architecture does not enable a bird's-eye view; it is a 74-meter advertising mast that gathers the crowd around the commodity: 'A mast to command all, to be seen from below … a mast to be dwarfed by, to integrate one with the everyday masses, to instill a sense of solidarity' (p. 122). Cultural geographies organize people in space so as to communicate and effect social relations.

Considerable attention has been given to the various geographies that constitute colonial relations, in the past and in the 'colonial present' (see *Postcolonial Geography*). Sparke (1998), for example, traces the multiple material and symbolic geographies deployed by the Canadian State to extinguish two First Nations—the Wet'suwet'san and Gitksan—claims to sovereignty and land rights in an extended 374-day trial in 1987. The geographies include the relocation of the trial from Smithers (a small community in the heart of the claimed territory) to Vancouver, a distance of over 1200 kilometers, that imposed costs on many of those testifying for the First Nations, removed those testifying from their support networks, and placed the trial squarely within the metropolitan 'center.' This material geography, among others, was supplemented by symbolic ones, for example, instances of ridiculing First Nations' counter-maps, in which they translated House songs of territory into map format. The lawyer representing the Canadian federal government dismissed these maps: 'The place names, the names of creeks, rivers, and hills and all the other features, are none of them geographic names, they are Gitksan names' (Sparkae 1998, pp. 474–5) (see *Law and Geography*). Ironically, when these maps of traditional boundaries of Gitksan and Wet'suwet'-san territories were introduced in court, they were labeled, by the presiding judge, as 'the map that roared,' and Sparke argues that they did indeed roar in profoundly disruptive ways. It is this potential for resistant, transgressive, and transformative 'roaring,' and for the eruption of social conflict in and through conflicting claims to space, that captures considerable interest among cultural and social geographers (Cresswell 1996).

2.3 *Cultural Identity and Place*

A persistent theme for cultural geographers has been cultural identification with place (see *Place in Geography*); in the 1970s, humanistic geographers reactivated concerns about attachment to place, (sub)-cultural variations in use of and meanings attributed to places, and alienation in modern, bureaucratized landscapes such as suburbs (see *Humanistic Geography*). The latter concern also permeates a now vast literature on the 'disneyfication' of urban space, leading to the criticism that a romantic nostalgia for authentic landscapes runs through it (see *Postmodern Urbanism*).

What is newer is a profound unease about the bounding of cultural identity and place. This unease is tied to the ways that claims to territory function as mechanisms for social exclusion and control (see *Territoriality: Geographical*). In an early attempt by a cultural geographer to engage with Said's analysis of Orientalism, Anderson (1991) argued that the creation of Chinatown as a space apart in early twentieth century Vancouver was constitutive of Chinese people as a race. It is not only that Chinatown 'expressed' racist sentiment or racial ideology; the definition of Chinatown as unhygienic (marked, for example, by listing it as a separate entry in public health records—it was the only neighborhood to be listed in this way) and a place of vice (which altered police practices in ways that produced more crime; see *Crime, Geography of*) was part of the process of racializing Chinese people as 'other' than Canadian. Using the psychoanalytical concept of abjection, Sibley (1995) fur-

ther explores the compulsion on the part of dominant groups to 'purify' space. Designating a group, such as gypsies, to a marginal, polluted place is quite literally part of the process of marginalizing the group (see *Social Geography*; *Ethnic conflict, geography of*; *Locational Conflict (NIMBY)*).

Mitchell (1995) traces this concern back to the concept of culture itself, arguing that it is a modernist concept, integrally tied to notions of otherness: 'culture is a concept to stop flux in its tracks, creating stability and "ways of life" where before there had been changes and contest. The idea of culture demanded a mapping of boundaries and edges, the specification of a morphology: culture had to become a bounded object that ultimately differentiated the world' (p. 107). He urges geographers to resist conceiving culture as an ontological entity, and to focus instead on the work done by the idea of culture. In whose interests is the idea of culture deployed? Who has the capacity to define cultural boundaries?

These concerns have led to attempts to conceive of identities that exceed fixed boundaries; for cultural geographers this also entails imagining the spaces in which this might happen. A striking example of such an exercise is Law's (1998) discussion of one bar in Cebu City in the Philippines. Law criticizes the discourses currently used by Western feminists and non-governmental health organizations to frame sex workers in the Philippines (as either victim or economically empowered), in part because sex workers are unable to recognize themselves within them. She draws on her ethnography of one bar to represent both dancers and their male, mostly Australian, customers in more nuanced terms. This involves conceiving shifting relations and identities so as to render neither dancer nor customer as powerful or powerless. The space of the bar is more than a backdrop to this ambiguous dance of identities and power relations; it is the liminal space in which it can happen. By pursuing the spatialities of hybrid, mobile identities, geographers have a good deal to contribute to a more free-floating discussion in cultural studies. In Law's case, she offers a cultural representation that might lead to more effective communication between dancers and health organizations around HIV/AIDS education (see *AIDS*, *geography of*).

Attempts to rethink the relations between identity and place have been provoked also by the realizations not only that cultural identities are multiple and shifting, and that multiple identities inhabit the same place, but also that places are open and unbounded. The global flows through the local, in terms of financial capital, commodities, ideas, and migration of individuals and households (see *Globalization: Geographical Aspects*). The attachments that individuals may feel to multiple places (captured by the term polylocality) enrich and complicate increasingly multi-cultural locales. Tensions arising from multi-culturalism often become manifest as landscape conflict. Ley (1995) has written an exemplary case study of one such conflict over the transformation of the affluent neighborhood of Shaughnessy in Vancouver. Shaughnessy was built in the early twentieth century, by mainly foreign-born English immigrants, to the standards of conservative English landscape tastes. This English theming has little cultural salience for ethnic Chinese immigrants who have come to Vancouver in increasing number since 1980 from nations in the Pacific Rim. Ethnic Chinese elites have rebuilt parts of Shaughnessy along a different landscape aesthetic, and the construction of what have been called 'monster houses,' sometimes necessitating the removal of trees, has been hotly contested by the old, Anglo-identified elite. Ironically, this elite—themselves immigrants or descendents of immigrants—deployed the rhetoric of roots, nature, and preservation to naturalize their claims to place and to convey their deeply-held sentiment for the landscape. A strength of Ley's analysis is that he conveys the old elite's topophilia, love of place, and the integrity and intensity of their griefing for a lost landscape, while simultaneously problematizing their exclusive claims to an urban—indeed national—space, and drawing out the interwoven colonial histories of the Anglo and Chinese elites. Ultimately, Ley makes an incident involving the felling of two sequoias on a residential lot speak to the problem of constructing a homogeneous national citizen in what has been identified as the first 'postmodern' State (Canada). This movement between scales, and the demonstration of the interwoven construction of scale, are features of the best contemporary work in cultural geography (see *Scale in Geography*).

3. *Beyond Dualisms*

If Sauer defined the cultural against environmental determinism, and humanistic geographers defined the cultural against economism, recent theorizing disrupts both sets of implicit dualisms, leaving Matless (1996, p. 380) to ask: 'Is "cultural geography" then a nonsensical term?' Rather than nonsense, it is gaining a new sense in relation to, rather than in opposition to, nature and economy.

3.1 *Nature and Culture*

Geographers have drawn from Bruno Latour and Donna Haraway to interrogate the assumed duality between nature and culture (Demeritt 1994, Mitchell 1995, Matless 1996, see *Nature–Society in Geography*). There are two issues at stake. First, the division between nature and culture enforces the view that humans are the sole social agents. An artifactual understanding of nature pluralizes agency; cultural geographers are now willing to consider that we live in a livelier world in which nonhuman actors also have

agency. The notion of agency has been reworked, away from that of a conscious and controlling self, to one of having effects. Second, conceptualizing the boundary between nature and culture as a social construction has opened up a rich set of investigations around both the production of the boundary and slippages across it. Anderson (2000), for example, examines the ways in which racial ideology has been interwoven with discourses of animality and nature, and Emel (1995) argues that the eradication of wolves in the USA has been underwritten by norms of masculinity.

3.2 Economy and Culture

The lines between economy and culture are no less blurry. Economic development is increasingly about culture, whether it be in the form of tourism or the redevelopment of urban areas for the purposes of spectacle and consumption (see *Postmodern Urbanism*). Access to jobs and job performances are interpreted as cultural phenomena. Economic theory, models, and methods are being read for the ways in which they are structured by metaphor (see *Economic Geography*). Gibson-Graham (1996), for example, argues that recent discussions of the globalization of capitalism function through the metaphor of rape (see *Globalization: Geographical Aspects*). Drawing on feminist attempts to conceive a perspective on rape in terms other than victimization, Gibson-Graham entreats us to imagine possible economic futures that exceed the 'rape' of capitalism.

The spirit of the Gibson-Graham analysis, of conceiving of non-violent trespass, is perhaps a good note on which to end. Cultural geography is currently extremely lively, no longer operating as a bounded sub-discipline but as a critical perspective on the production of boundaries and processes of differentiation.

Cultural History

It is not easy to define 'cultural history' in its specificity. Should it be done by designating objects and practices whose study would constitute the very nature of this

history? The risk is great, therefore, of failing to draw a definite and clear line between cultural history and other histories: for instance, the history of ideas, the history of literature, the history of art, the history of education, the history of media, or the history of sciences. Should we, consequently, change perspectives and consider that all history, whatever its nature—economical or social, demographic or political —is cultural, insofar as the most objectively measurable phenomena are always the result of the meanings that individuals attribute to things, to words and behavior? In this fundamentally anthropological perspective, the problem is not so much to define the particular sphere of cultural history, differentiated from that of its neighbors, but rather avoid an imperialist definition of the category.

Between these two stumbling blocks, the road is narrow. From there, the course followed in this article consists of marking the shifts that have characterized the historiographical practices designated, in their time or subsequently, as belonging to cultural history.

1. *The History of Mentalities*

The very lengthy genealogy of cultural history generally stops at a certain number of precursors: the historians of the nineteenth century (Michelet, Burckhardt), Voltaire's, *Siècle de Louis XIV*, the legal practitioners of the 'perfect history' during the sixteenth century, even Herodotus himself. The course is not without illusion, measuring the 'anticipations' of certain precursors according to a posterior state of historical science. So as to avoid this trap, it is preferable to limit the research to the twentieth century and to follow the different faces taken by the historiographical projects which intended to focus on the phenomena left aside by the classical forms of political, economical, or social history. The history of mentalities was the first amongst them.

1.1 The Founders of the Annales and the History of Mentalities

Unlike a given idea, the paternity of the category of the 'history of mentalities,' insofar as it indicates a particular area of history, is not to be attributed to the founders of the *Annales* Lucien Febvre and Marc Bloch. It is the invention of Robert Mandrou and Georges Duby at the end of the 1950s. The expression appears for the first time in the title of a university course in 1956 with the election of Robert Mandrou in the 6th Section of the Ecole Pratique des Hautes Études to the chair of 'Social History of Modern Mentalities', while at the same time, Georges Duby was opening a seminar on 'medieval mentalities' at the University of Aix-en-Provence. In 1961, when Robert Mandrou published his book *Introduction à France, Modern*, he presented it as a response to the 'requests formerly made by Lucien Febvre in favor of the history of collective mentalities' (while using another notion as the subtitle of the study, 'psychological history' which was also dear to Febvre). Thus, designated as the inspirer of this new form of history, Lucien Febvre, in fact, had rarely used the exact term 'mentality,' preferring the adjective 'mental' added to words like 'equipment,' 'material,' but above all 'tool,' or even, in the plural form, 'habits' and 'needs.' In 1942, in the *Problème de l'incroyance au XVIe siècle: Religion de Rabelais* he characterized the 'mental tools' by expressing two essential statements: that the ways to perceive and reason are neither invariable nor universal, and that there is no continuous and necessary progress in the succession of mental tools. The book makes an inventory of the instruments and conceptual categories which are the different supports for thinking: first, the state of language, with its vocabulary and syntactic particularities, the tools and the languages available in the operations of knowledge, and finally the value and the credit attributed to each sense. From there, the conclusion: 'So close to us in appearance, the contemporaries of Rabelais are already distant by all their intellectual properties. And even their structure was not ours.' In each time, the ways of thinking and feeling outline in a specific way the limits between nature and the supernatural, or between what is possible and impossible.

Paradoxically, Lucien Febvre, taken to be the father of the history of mentalities, uses the term less often than Marc Bloch who uses it as much in the *Société féodale* (where we encounter 'mental atmosphere' or 'religious mentality') as in *Apologie pour l'histoire ou le métier d' historien*. He prefers 'sensitivity' that defines the subject of 'historical psychology' which seems for him the only capable way of avoiding the culpable anachronism which equips men and women of the past, not only with knowledge and conceptions which were impossible for them, but also with feelings and emotions that were unknown to them. Febvre stigmatizes such an error in *Amour sacré, amour profane: autour de l'Heptaméron* (1944) by concluding: 'In fact, a man of the sixteenth century should be intelligible not in relation to us, but in relation to his contemporaries.'

In his book of 1961, Robert Mandrou does not dissociate the study of the mental tool from that of sensations, emotions, and passions which make up the mentality. Without separating these two dimensions, he distinguishes the common elements to all men (and women) in a shared time and place and those that are particular to each generation, to each profession, to each social group, or to each class. For him, 'all historical psychology, all history of mentalities is social history.' We should, therefore, once the common mental tool has been identified, describe 'the mental horizons which are characteristic of the dif-

ferent social groups.' The 'history of mentalities,' or of the 'visions of the world,' another term often used by Mandrou, was thus strongly anchored in the differences between social classes, defined more by the unity of life style and the feeling of belonging than by a strict economical determination.

1.2 The Golden Age of the History of Mentalities

From the 1960s onwards, the notion of mentality imposes itself to designate a history whose object is neither ideas, nor socioeconomical realities. This 'French' history of mentalities reposes on a certain number of ideas more or less shared by those who practice it (see Le Goff 1974). In the first instance, the object of the history of mentalities is defined by Le Goff as the opposite of that of classical intellectual history: 'The level of the history of mentalities is that of everyday life and the automatic, which is what escapes individual subjects as it shows the impersonal content of their thoughts.' These ideas, which result from the conscious elaboration of a singular spirit, are therefore opposed to mentality, always collective, which regulates, without them knowing, the immediate perceptions of social subjects. Such an expression is not very far off the definition of collective representations in the tradition of the sociology of Durkheim as the accent is placed on the contents or the methods of thinking which result from the unconscious incorporation of unknown determinations in each member of a community, which set up their common manner of classifying and judging. Now, the second characteristic underlined by Le Goff: the possibility that the history of mentalities or the historical psychology 'link themselves to another important trend of historical research today: quantitative history.' Having as subjects collective, automatic, and repetitive actions, the history of mentalities should and must be serial and statistical. It is part of the heritage of the history of economies, populations, and societies that, on the horizon of the major crisis of the 1930s, followed by the mutations after the war, constituted the most innovative field of historiography. When, in the 1960s, the history of mentalities and the historical psychology defined a new, promising, and original area of study, they did so often by recapitulating the methods which ensured the conquests of socioeconomical history: the techniques of regressive statistics and the mathematical analysis of series.

From the importance given to series, and therefore to the establishment and treatment of homogenous data, repeated and comparable at temporal regular intervals, two consequences follow. The first is the privilege given to massive sources, widely representative and available over a long period, for example, the inventories after death, wills, library catalogues, legal archives, etc. The second consists of the attempt to articulate, according the braudelian model of different times (long term, conjuncture, event), the long period of mentalities which often resists to change, with the short period of brutal ruptures or of rapid transfers of belief and sensitivity.

The withdrawal of witchcraft as a criminal act in France during the seventeenth century (see Mandrou 1968), the transfer of attitudes before childhood or death (see Ariès 1964, 1977) or the dechristianisation of France during the second half of the eighteenth century (see Vovelle, 1973) illustrate the articulation of the different periods of the history of mentalities. In each case, the problem lies in understanding how, in the long-term stability of mental structure, an essential transfer occurs: thus, the transformation of the representations of the world in the mileu of magistrates, the invention of childhood, and the concealment of death, or the indifference towards devotion practices, moral injunctions, and catholic beliefs.

A third characteristic of the history of mentalities in its golden age lies in its ambiguous way of considering connection to society. The notion seems, in fact, dedicated to erasing the differences in order to find the categories shared by all the members of a same era. 'The mentality of a historical individual, a great man, is exactly what he has in common with other men of his time' writes Le Goff (1974), adding, as examples, 'it is what Caesar and the last soldier of his legions, Saint Louis and the peasant of his domains, Christopher Columbus and the sailor all have in common.' Amongst all the practitioners of the history of mentalities, Philippe Ariès is no doubt the one who made the greatest attachment to such an identification of the notion as 'common feeling' or 'general feeling.' The recognition of the 'archetypes of civilisation,' shared by a whole society, does certainly not signify the cancellation of all differences between social groups or between clerics and laymen. However, these differences are always considered inside a long-term process which produces representations and behavior which become common. Postulating the fundamental unity (at least tendentious) of the 'collective unconscious,' Philippe Ariès reads the texts and images, not like demonstrations of individual peculiarities, but in order to 'decipher, beyond the will of authors or artists, the unconscious expression of collective sensitivity,' or to 'find, beneath the ecclesiastic language, the ordinary set of common representations which are obvious' (see Ariès, 1975). The sensitivity and the collective gestures which are disclosed should be understood at the cross-roads of biology and the mental, at the meeting point of demographic realities (birth, death, etc.) and psychological investments (the forms of self-consciousness, the representations of life after death, the feeling of childhood, etc.). With Philippe Ariès, mentality refers to 'currents of the deep' which govern, without them necessarily being aware of it, the most essential attitudes of men and women of a same period.

For other mentality historians, more directly located in the heritage of social history, the essential elements lie in the link between the differences between the ways of thinking and feeling and social differences. Such a perspective organizes the classifying of mentality facts into divisions established by the analysis of society and then the superposition postulated as necessary between social boundaries that separate groups or classes and those which differentiate mentalities. This social cutting out is no doubt the most precise trace of the dependence of the 'history of mentalities' in relation to social history in French tradition. It was possible to understand it at a global and macroscopic level—and so in research aiming to characterize a mentality, a religion or a 'popular' literature, opposed finally to that of the dominant or the elite—or in a more fragmented way, in reference to the hierarchy of conditions and professions. However, in both cases, the study of mental horizons reproduces the divisions proposed by the history of societies.

1.3 History of Mentalities or Historical Psychology?

Mentalities, sensitivities, visions of the world: the unstable plurality of vocabulary indicates, at the same time, both the difficulty in defining objects of a new historiographical approach and the will to link, in the same perspective, intellectual and psychological categories.

When Alphonse Dupront proposes, in 1960, at the International Congress of Historical Sciences at Stockholm, to constitute historical psychology as a whole discipline within human sciences, he gives it a maximal extension as it must be 'the history of values, mentalities, forms, symbolics, myths.' Such a definition reduced the distance established by the founders of *Annales* between mentality and ideas, as the latter participate fully in 'collective mentality' of men of a period. The ideas, perceived through the circulation of words which designate them, situated in their social rooting, considered in their affective and emotional load as much as in their intellectual content, therefore become, just like myths or values, one of those 'collective forces via which men live their time,' one of those elements which Dupront, in words borrowed from Jung, called 'collective psychic.' An expression exists there which, while claiming to be loyal to the project of the *Annales*, surpasses the old oppositions by giving a fundamental psychological definition of mentality and by reintroducing the ideas in the exploration of the collective mental.

Such a perspective (without the word 'mentality') appears in the work of Ignace Meyerson whose importance, perhaps underestimated today, was central for the renewal of historical studies of Antiquity—in particular his book *Les Fonctions psychologiques et les oeuvres* of 1948. A first relationship lies in the assertion of the fundamental historicity of mental categories and the psychological functions. It is this essential historicity of psychological objects which allows Meyerson to define it as a 'historical anthropology': 'The psychological functions have a history and they have had different forms throughout this history. Time and memory have a history. Space has a history. Perception has a history. The person has a history.' The work of historical psychology does not, therefore, consist of finding different modalities or expressions of functions considered as stable and universal. It attempts to understand, in their discontinuity and their singularity, the emergence and the economy of each of these functions. In this way, by applying the perspective of Meyerson to the question of the person in ancient Greece, Jean-Pierre Vernant writes: 'There is not, there cannot be a model person, exterior throughout human history, with differences, variations according to places, transformations due to time. Research should therefore not establish if the person, in Greece, is or is not, but should research what the ancient Greek person is, how he is different, in the multiplicity of his features, of today's person' (see Vernant 1965).

On the other hand, Ignace Meyerson radically modifies the location and comprehension of the mental and psychological categories. To their immediate, existentialist, phenomenological grasp he opposes their knowledge based on symbolical forms, works, and acts in which they are objectivized. Analyzing psychological functions via productions (institutional, religious, legal, aesthetic, linguistic) allows for the rupture with the idea of universal and abstract men, and with the universalization of a particular form of the personality.

1.4 Success and Criticisms of the History of Mentalities

How can one explain the infatuation, of historians and readers, in France and outside France, for the history of mentalities, whatever be the designation, in the 1970s and 1980s? No doubt because such an approach allowed for, in its very diversity, the introduction of a new balance between history and social sciences. Contested in its intellectual and institutional superiority by the development of psychology, sociology, and anthropology, history coped by annexing the topics of the discipline which questioned its domination. The focus then moved towards objects (systems of belief, collective attitudes, ritual forms, etc.) which, until then, belonged to the neighbors but which fully entered into the program of a history of collective mentalities.

Adapting to the approaches and analysis methods of socioeconomical history while transforming the historical questionnaire, the history of mentalities (in its widest definition) was able to occupy the front part of the historiographical scene and constitute an effective response to the challenge launched by social sciences.

However, there were many critics of its principles and methods. The first came from Italy. In 1970, Franco Venturi denounced the obliteration of the creative force of new ideas for the benefit of simple 'mental structures' 'lacking dynamism and originality' (see Venturi, 1970). Some years later, Carlo Ginzburg magnified the criticism (see Ginzburg 1976). He refused the notion of 'mentality' for three reasons: first, for its exclusive insistence on 'elements which are inert, obscure and unconscious of a determined vision of the world,' which lead to reducing the importance of rationally and consciously expressed ideas; second, for the 'interclass' character which unduly assumes the sharing by the whole society of the same 'mental equipment'; and lastly, for the alliance with the quantitative and serial approach, which, all together, reifies the contents of thought and attaches itself to the most repetitive expressions and ignores singularities. Historians were thus invited to privilege individual appropriations more than statistical distributions, to understand how an individual or a community interpreted, according to its own culture, ideas and beliefs, and texts and books circulating in their society.

In 1990, in the book with the provocative title, *Demystifying Mentalities*, Geoffrey Lloyd, historian of Greek philosophy and science, hardened the indictment once again. The criticism lies within the two essential principles of the 'history of mentalities': on the one hand, allocating to a whole society a stable and homogenous set of ideas and beliefs; on the other hand, considering that all thoughts and all conducts of an individual are governed by a unique mental structure. The two operations are the very condition allowing a mentality to be distinguished from another and permitting the identification within each individual of the mental tool shared with his contemporaries. However, such a way of thinking erases, in the repetitions of the collective, the originality of each singular expression and it encloses within an artificial coherence the plurality of belief systems and ways of reasoning that a same group or a same individual can successively mobilise.

Lloyd therefore proposed to substitute for the notion of 'mentality' that of 'styles of rationality' whose use depends directly on the contexts of discourse and the domains of experiences. Each of them lays down their own rules and conventions, defines a specific form of communication, supposes particular expectations. This is why it is quite impossible to bring back the plurality of methods of thinking, knowing, and arguing to a homogenous and unique mentality.

The case was well pleaded but is it really justified? On one hand, the history of mentalities did not only detain the single globalizing definition of the notion, as it inherited it from Lévy-Bruhl, author in 1922 of *La Mentalité primitive, ou des psychologues* (Charles Blondel, Jean Piaget, and Henri Wallon). If Lucien Febvre surely was tempted by the 'interclass' definition of mentality—in particular in *Le Problème de l'incroyance au XVIe siècle*—and Philippe Ariès after him, Marc Bloch and Robert Mandrou were very attentive to the social differences which command, in a same society, different ways of thinking and feeling, or diverse visions of the world.

On the other hand, French historians have not always ignored the possible presence, within the same individual, of several mentalities, distinct or even contradictory. Le Goff strongly expresses it: 'The coexistence of several mentalities at a same time and in a same spirit is one of the delicate but essential elements of the history of mentalities. Louis XI, who, in politics, revealed a modern 'Machiavellian' mentality, in matters of religion revealed a very traditional superstitious mentality.'

The critical examination of the contributions and limits of the 'history of mentalities' should neither reduce the diversity of it nor simplify the expressions of it.

2. *From the History of Mentalities to Cultural History*

The path of the history of mentalities is, therefore, made up of paradoxes. While it claimed to be clearly differentiated from other historical practices, it was never able to define clearly and unanimously its objects, methods, and concepts. It was during the years when it underwent the most criticism and when expression itself retreated for the benefit of other categories that the multiplication of works which explore the topics it designated were seen. It is no doubt due to the plasticity of its definition and the diversity of its uses that this history, omnipresent and inaccessible, was able to durably characterize a form of *historiographical* work. It is, therefore, no longer possible today, in a time when the notion of 'cultural history' has become dominant, even sometimes supreme. This is what must now be examined.

2.1 *An Impossible Definition*

The difficulty in defining cultural history lies fundamentally in the even larger difficulty in defining what the object 'culture' itself is. The innumerable meanings of the term can be diagrammatically distributed into two families of meaning: one which designates the works and gestures which, in a given society, avoid economical or symbolical urgencies of daily life and are submitted to an aesthetic or intellectual judgement, and one which aims at ordinary practices through which a community, whichever community it may be, lives and thinks out its relations to the world, to others, or to itself.

The first order of meanings leads to building the history of texts, works, and cultural practices like a history with two dimensions, as Schorske suggests:

'The historian seeks to locate and interpret the artefact temporally in a field where two lines intersect. One line is vertical, or diachronic, by which he establishes the relation of a text or a system of thought to previous expressions in the same branch of cultural activity (painting, politics, etc). The other is horizontal, or synchronic; by it he assesses the relation of the content of the intellectual object to what is appearing in other branches or aspects of a culture at the same time' (Schorske 1979). We must, therefore, consider each cultural production in the history of its genre, discipline, or field as well as in context of its relationships with the aesthetic, or intellectual productions and the cultural practices which are contemporary to it.

The latter leads to the second family of definitions of culture. It strongly relies on the meaning that symbolical anthropology gives to notion—and in particular Geertz: 'The culture concept to which I adhere [...] denotes an historically transmitted pattern of meanings embodied in symbols, a system of inherited conceptions expressed in symbolic forms by means of which men communicate, perpetuate, and develop their knowledge about and attitudes towards life' (Geertz 1973). It is, therefore, the entirety of languages and of the symbolical actions of a community which constitute its culture. From there, for historians, the attention is transferred to collective expressions where a cultural system is expressed in a paroxysmal way: rituals of violence, rituals of passages, carnivalesque festivals, etc. (Davis 1975, Darnton 1984).

What the different approaches try to consider today is the paradoxical articulation between a difference—the one by which all societies, in varying methods, separated a field characterized by particular experiences and delights—and subordination—those which make the aesthetic and intellectual invention possible and intelligible by noting it in the social world and in the symbolical system particular to a time and a place.

2.2 *Plurality of Practices, Common Questions*

According to historiographical traditions and heritage, cultural history favored different objects, fields, and methods. Making an inventory of it is an impossible task—and partially futile as it would cause repetition of the assessments presented in the numerous articles of this encyclopedia. More significant, perhaps, is the pinpointing of the common questions to these very diverse approaches.

A first stake is the necessary articulation between singular works and common representations. There are several ways to conceive this: by concentrating on the particularities of each social space where works develop and circulate (guilds, the court, the academies, the market), by situating them in relation to texts and ordinary practices with which they are in 'negotiation' (to use a term which is dear to 'New Historicism'), or, using Elias's method, by understanding how aesthetic conventions refer to psychological economy and structure of personality in a time and a place.

A second question, very widely shared, lies in the relationships between popular and learned culture. The ways of perceiving them can be dealt with by using two large models of description and interpretation. The first, trying to abolish all forms of cultural ethnocentrism, treats popular culture as a coherent and independent symbolical system, which is organised according to irreducible to logic, that of well-read culture. The second, concerned remembering the existence of relationships of domination and inequalities of the social world, understands popular culture by its subordination and its weaknesses compared to the culture of the dominant. Therefore, on the one hand, popular culture is considered as a symbolical independent system, enclosed within itself, and on the other, it is entirely defined by its distance opposed to cultural legitimacy. For a long time, historians fluctuated between these two perspectives. Then, the work carried out on religion or literature treated as specifically popular and the construction of an opposition, repeated through time, between the golden age of a free and vigorous popular culture and the times of censorship and constraints which condemn it and dismantle it. Distinctions that are so clear are no longer accepted without doubts today, which leads us to consider all the mechanisms which cause internalization by the dominated to be of their own illegitimacy and expressions via which a dominated culture manages to save something of its symbolical coherence. The lesson is valuable for the confrontation between the elite and people in the old Europe (Ginzburg 1966, 1976) and for the relationships between the dominated and the dominant in the colonial world (Gruzinski 1988).

A final challenge for cultural history, whatever be the approaches and objects, lies in the articulation between practices and discourse. The questioning of ancient certainties took the form of a 'linguistic turn' which reposed on two essential ideas: that the language is a system of signs whose relationships themselves produce multiple and unstable meanings, beyond all intention or all subjective control; that 'reality' is not beyond discourse but is always built by discursive practices (Baker 1990).

Opposed to such a position, numerous are the historians who, following the distinctions proposed by Foucault between 'discursive formations' and 'non-discursive systems' (see Foucalt 1969) or by Bourdieu between 'practical sense' and 'scholastic logic' (see Bourdieu 1997), marked the difference between the logic of practices and that which governs the discursive production and which underlined the irreducibility between the reality which was (or is) and the discourse which intend to organise it, censure it, or represent it.

The fundamental object of a history attempting to recognize the way in which social actors give meaning

to their practices and discourse is, therefore, found in the tension between the inventive capacities of individuals or communities and, on the other hand, the constraints and conventions which restrict—more or less tightly according to the position that they occupy in their domination relationships—what is possible for them to think, express, and do. The acknowledgment is valid for well-read works and aesthetic creations as well as for ordinary practices—which is another way of expressing the double definition of the objects of cultural history.

Cultural Landscape in Environmental Studies

The concept cultural landscape has at least two meanings. It refers both to an empirical object of analysis, and to an approach to studying that object. Cultural landscape as an object of analysis refers to the material–cultural expressions of human modifications of 'nature' as they appear on a particular surface of the earth. The cultural landscape is generally thought to include all of the elements of the built environment (e.g., buildings, roads), as well as land-use patterns. In this usage, cultural landscape is juxtaposed with natural landscape, although the distinction between the two is problematic (hence the quotes). By contrast, the concept of landscape used in ecology tends to be more focused on nature and natural processes instead of the emphasis on culture and cultural mechanisms that forms the basis of the concept used in geography and the social sciences more generally. The cultural landscape as an approach, generally refers to an interpretive and inductive strategy for understanding the meaning of those cultural expressions, as opposed to a more scientific and deductive approach. These two meanings have an intertwined history, although the former meaning (object of analysis) preceded, and led to, the second. This essay is not divided into two parts, but rather how and why the different meanings emerged and often converged are pointed out (when relevant).

Introduced into American geography in the early twentieth century, the importance of the concept cultural landscape has waxed and waned in relation to the shifting contours and contexts of the history of the social sciences, expressed primarily in the discipline of geography. It has taken on diverse meanings, been subject to rigorous criticisms, and emerged in the late twentieth century as a vital and politically-charged concept. This essay traces the changing interpretations and uses of the concept 'cultural landscape,' before analyzing contemporary and future trends.

1. Historical Development

American geographer Carl Sauer's influential essay 'The Morphology of Landscape,' originally published in 1925 (1963), provided the first formal introduction of the concept of the cultural landscape into American social science, and laid a foundation on which it would build for the next 50 years. Partly in reaction to the methodological and philosophical flaws of what had become the reigning paradigm in geography—environmental determinism—Sauer attempted to situate human-environment relationships more firmly as a science by putting forward the concept of the cultural landscape as its distinctive object of analysis. Sauer posited a natural landscape, comprised of land forms,

climate, waterways, and vegetation, that was acted upon by human cultures to create a cultural landscape, composed of material expressions of population density and mobility, housing plan and structure, production, and communication. In his now famous phrase: 'The cultural landscape is fashioned from a natural landscape by a culture group. Culture is the agent, the natural area is the medium, the cultural landscape is the result' (Sauer 1925, p. 343). To make clear his position vis-à-vis environmental determinism, Sauer explicitly stated that nature is only important in that it provides the raw material that people use to fashion the cultural landscape: 'The shaping force, however, lies in the culture itself' (Sauer 1925, p. 343). So by positioning landscape studies in this way, Sauer was putting forward an empirically verifiable object of analysis (the cultural landscape), and was shifting the explanatory variable away from nature to culture. Sauer's 'Morphology of Landscape' proved particularly influential in American geography, partly because he drew on German and French traditions which at the time were thought to be more sophisticated in conceptualizing human–environment relationships, and partly because he provided a core concept that gave geography its own object of analysis distinct from other disciplines. For the next 30 or so years, the concept of the cultural landscape as advanced by Sauer was central to the emerging discipline of geography in the USA, and to human–environment studies more broadly. Sauer and the students he trained at the University of California at Berkeley formed a particularly influential group of geographers, and the methods and approaches they used to study cultural landscapes, influenced by the anthropology of A. Kroeber and R. Lowie, became almost paradigmatic.

As former students and others attempted to 'operationalize' Sauer's ideas in the 1930s and 1940s, two distinct trajectories became evident: the first stressed the enumeration of elements of the cultural landscape in order to delineate homogenous regions, while the second stressed spatial and temporal processes that created the cultural landscape. The first trajectory, often referred to as chorology, or areal differentiation, offered a way of studying the cultural landscape systematically by enumerating its various elements, looking for similarities in forms and structures (morphology), and deducing from this analysis areas or regions. The second interpretation looked at a particular cultural landscape as the end result of a set of spatial and historical processes. The significant spatial process in Sauer's approach was that of diffusion—the movement of people, ideas and things across space—and the historical processes referred to the role of cultures in transforming a 'natural' landscape into a cultural landscape. For example, geographers in the 1930s to 1960s studied the origins and diffusion of agricultural patterns, house types, and fences (Zelinsky 1973), while others reconstructed sequences of past cultural landscapes leading up to the present-day, and outlined the transformations from a so-called 'primitive landscape' to a 'cultural landscape.'

As these studies matured, the two trajectories became more divergent. The delineation of regions on the basis of cultural landscape elements (the first trajectory) moved away from the focus on cultural landscape elements, and more to the systematic analysis of spatial patterns. The quantitative revolution that swept through the social sciences in the 1960s was taken up by the disciplines more focused on cultural landscape, leading to diminished attention. The term 'cultural landscape' retained its currency for those who emphasized historical processes, and those who continued to use the three-dimensional definition of cultural landscape (the second trajectory). In these studies, the concept of the cultural landscape as an object of study and as an approach to that study converged. In other words, researchers concerned with outlining and analyzing how, over time, culture groups shaped their landscapes, and how cultural landscape forms can be interpreted as indicators of cultural norms, looked to historical and interpretive methods to answer their questions. Their emphasis on the particularities of landscapes, and of its three-dimensional qualities, was not amenable to abstract, generalizable models. The subfield of cultural geography coalesced around these studies and approaches, with the concept of cultural landscape forming an integral component.

Sauer and the students he had trained at Berkeley dominated these studies of the cultural landscape. Fred Kniffen at Louisiana State University and Wilber Zelinsky at Penn State University were particularly prolific, publishing articles on a range of cultural patterns from the New England Barn to the Covered Bridge. Kniffen presented a conceptual framework for these studies in his publication 'Folk Housing: Key to Diffusion' (1965), while the statements put forward by Phillip Wagner and Marvin Mikesell (also Sauer's former students) in their introduction to the edited collection *Readings in Cultural Geography* (1962) provided a firm definition of the concept: 'This term comprehends both the distinctive features that serve to set a region apart and those not confined to a particular region but occurring there. The cultural landscape, then, connotes the geographic content of a determined area, or a geographic complex of a certain type, in which the choices made and changes worked by men as members of some cultural community are manifested' (10). By the 1960s, the term cultural landscape had become synonymous with idiographic studies of the 'content of a determined area,' and formed a central tenet of the subfield of cultural geography.

2. *Criticisms and Reconceptualizations*

Criticisms of cultural landscape as the object of analysis for cultural geography were first given voice

by an Australian geographer Harold Brookfield. In his 1964 article, he questioned why cultural geography was limited to a study of the visible material elements of culture, and argued that only by examining issues on the 'human frontiers,' that is, those that are concerned with social, cultural, political factors, could geographers ever hope to answer the how and why of landscape patterns (Brookfield 1964). A variant on this theme was taken up in 1980 by geographer James Duncan, in a penetrating philosophical critique of the use of the superorganic form of explanation in cultural landscape studies and cultural geography more broadly. According to Duncan, these studies were fundamentally flawed since their explanations relied on a reified notion of culture that assigned it 'ontological status and causative power' (Duncan 1980, p. 181). By so doing, culture writ large could be said to explain landscape patterns, overlooking any in-depth analysis of the workings of cultural processes, and foreclosing the possibility of individual agency. Duncan's critique was particularly aimed at studies of vernacular material culture, studies that had relied on a fairly naïve understanding of 'folk' cultures to explain landscape patterns. According to Duncan, these studies provided rather sweeping explanations of patterns, but not in-depth understanding of process. As a result of such critiques, and of the quantitative shift in geography, the discipline that most focused on the topic, the concept cultural landscape as object of analysis and as approach was marginalized throughout the 1970s and 1980s.

This is not to say that the concept was moribund. Some of the most compelling cultural landscape studies were published during this time—essays that implicitly asked and answered questions that went beyond Brookfield's 'human frontiers' and that included human agency and cultural processes in their explanations. J. B. Jackson had begun publishing such essays in the 1950s in his journal *Landscape*, and throughout the 1960s and 1970s scholars from a range of disciplines including architecture, history, landscape architecture, urban planning, and geography, contributed provocative writings to the journal. Jackson was very influenced by the French school of landscape history that looked at the cultural landscape as the embodiment of a *genre de vie*—that is, of an economic, social, and moral order. For example, in distinction to the studies of vernacular house types that were used to delineate cultural regions, Jackson (1952) saw the house as the most significant element in the cultural landscape because it was the most tangible symbol of a people's way of life. In this way, the cultural landscape was not simply the passive imprintment of a society, but was an active expression, both reflecting and expounding the economic, social, and moral order of a group of people. Scholars such as Grady Clay (1980) took up this idea and generally applied it to the urban built environment at large—that is, to the way everything from street patterns to commercial buildings could be 'read' as statements about the way of life of the people responsible for building them. Even in disciplines seemingly unrelated, such as literary criticism (Conron 1973) and photography (Corner and MacLean 1996), scholars explored the idea of the cultural landscape as a potent visible symbol of a particular way of life.

Reconceptualizing the concept cultural landscape as a symbol opened it to new arenas of analysis and new methods. Geographer Donald Meinig, in the influential group of essays he edited, *The Interpretation of Ordinary Landscapes* (1979), spoke of the cultural landscape as 'a panorama, a composition, a palimpsest, a microcosm' (6), and argued for historical methods of analysis. For geographer Marywn Samuels (1979), the cultural landscape could be thought of as the physical manifestation of innumerable, individual decisions, and its interpretation could take the form of a 'biography,' with scholars outlining the contexts in which those individual decisions had been made. Drawing on a large range of writings, from religious studies to American literary criticism, geographer Yi-Fu Tuan (1974) undertook a sustained examination of human meanings expressed in cultural landscapes, and human experiences and responses to those meanings. For Tuan, the cultural landscape was more than the sum of material artifacts; it was full of psychological, religious, aesthetic, and moral meanings that people had given to it, and it evoked those meanings to other people. For these scholars, cultural landscape studies offered a way to explore cultures and societies beyond what was offered by the quantitative work on spatial patterns that dominated the discipline at the time.

A different sort of reconceptualization of cultural landscape began in the UK in the 1980s. Heavily influenced by the cultural materialism of Raymond Williams, cultural and social geographers reconceptualized the cultural landscape as the expression of, and a constituent force within, the complex social, economic and political structures that characterize cultures. In *Social Formation and Symbolic Landscape* (1984), British geographer Denis Cosgrove took on the idea of landscape as a particular way of seeing, and positioned that way of seeing within its European historical context, making clear its connections to the 'real historical world of productive human relations' (2). Cultural landscapes were seen not only as the result of human labor, but also as cultural products that 'expressed and supported a range of political, social and moral assumptions' (1). In distinction to a strict Marxist view, the culture of cultural landscapes was not seen as divorced from the 'real' world of socio-economic formations and thereby dismissed as unimportant, but was instead regarded as an integral component of that world.

This infusion of cultural materialism into cultural geography brought new life to the concept of cultural landscape. In a statement that set the way for a reconstituted 'new' cultural geography (in distinction

to the 'old' or Sauerian school), Denis Cosgrove and Peter Jackson (1987) positioned the cultural landscape concept prominently, and offered a 'new' way of interpreting that 'allows us to disclose the meanings that human groups attach to areas and places and to relate those meanings to other aspects and conditions of human existence' (96). Their suggestions of two such approaches to interpretation—using the metaphor of text to conceptualize the cultural landscape so that it could be 'read' as a social document, similar to what Clifford Geertz had proposed in anthropology; and using the art historian's notion of iconography to interpret the cultural landscape as a set of visual images that can be interpreted at various levels of significance—was highly influential in the work on cultural landscapes that would follow in the late 1980s and 1990s. But perhaps more influential was their shifting of the agenda of cultural geography, and by implication of cultural landscape work, away from its emphasis on rural, historical studies of fixed and homogenous places, to the urban, contemporary scene, and to the contested nature of its production. In Cosgrove's and Jackson's words, the new cultural geography should be 'interested in the contingent nature of culture, in dominant ideologies and in forms of resistance to them (1987, p. 95). These statements removed the stigma that had been attached to cultural landscape studies—as benign, but irrelevant work done by antiquarians in remote and unimportant places—and highlighted the importance of the cultural landscape, as both object of analysis and approach, in the poststructural, politically charged atmosphere of the 1980s and 1990s social sciences. With the 'cultural turn' that had taken hold in the social sciences, the concept cultural landscape was suddenly relevant and trendy.

3. *Current Usage*

The two approaches suggested by Cosgrove and Jackson—landscape as text and the iconography of landscape—have generated a host of empirical studies. Both approaches were borrowed from the humanities (iconography from art history and 'text' from literary criticism), and drew on what could be called a postmodern stance on interpretation, i.e., that the meanings that can be drawn from analyses of landscapes are never straightforward, nor are they unchanging. 'Instead of providing a transparent window on a "real" world,' Cosgrove and Jackson argue, cultural landscapes, like 'images and languages are now regarded as a sort of sign that presents a deceptive appearance of naturalness and transparence concealing an opaque, distorting, arbitrary mechanism of representation, a process of ideological mystification' (1987, p. 98). Influenced by the writings of such scholars as Jacques Derrida and Michel Foucault, practitioners began to see the cultural landscape as a representation (not a mimetic expression) of time and place-specific, contested cultures. The 'cultural turn' in the social sciences brought an awareness that landscape was, in the words of W. J. T. Mitchell, 'a medium of cultural expression' (1996, p. 4). But because landscape, 'does not easily accommodate political notions of power and conflict, indeed it tends to dissolve or conceal them,' the role of the researcher is to explore and reveal its 'duplicity' (Daniels 1989b, p. 196). For example, Daniels' essay on the landscape of Georgian England points out how the 'typical' landscape representation of the time—the tradition of the picturesque—served both to engage some of the political and economic problems of early nineteenth-century England, at the same time that its imagery served to 'obscure social and economic issues' (1989a, p. 73).

Drawing on similar poststructuralist assumptions about interpretation, but with insights gained from psychoanalytic theory and film criticism, feminist geographer Gillian Rose (1993) criticized the 'iconographic' cultural landscape school for its implied masculinism. Rose argues that despite the progressive aim of these new cultural landscape studies, they embody an approach that by definition is implicated in power relations and oppression of women. That approach is one of an objective viewer, coded in Western thought as masculine, 'gazing' at and thereby in power over, a 'feminized' scene or cultural landscape. These implied power relations make problematic any appreciation of or pleasure derived from the actual viewing of landscapes as image. Catherine Nash (1996) countered this criticism by showing how understanding the particular contexts of viewing and creating cultural landscape images can subvert or 'unsettle any easy claim of oppression in any act of seeing or visual representation' (152). Her analysis of two landscape images created by women that utilize traditional landscape genres, but intentionally conjoin landscape with images of the male body, shows how 'to view body as land or land as body has no essential meaning, yet neither can it ever be innocent' (167).

In a different vein, but still informed by feminist theory, Heidi Nast (1996) 'reads' the cultural landscape of the Kano Palace in northern Nigeria circa 1500 to reveal its active role in constituting and replicating the gendered and sexual politics of its time. By reading the changing cultural landscape of the Kano Palace in relationship to changes in Islam, sexual practices, and gender roles, Nast shows how spatial evidence like cultural landscapes can be used to interpret the past worlds of people who were excluded from power, and therefore were unable to leave any written record. Similarly, Lynn Stewart (1995) reveals how the cultural landscapes of Plantations in antebellum American South reinforced the legal codes that gave all eminent rights to the white land owners. However, Stewart also shows that within this oppressive landscape slave men and women were able to

create their own social spaces that allowed for self-expression and at times forms of transgression.

Others have taken an iconographic and textual approach to studying cultural landscapes within a postcolonial framework. Rod Neumann (1995), for example, examines how the British importation of ways of seeing landscape was integral to their imperialist efforts at the turn of the century. The British appropriated lands for national parks in east Africa by constructing them as landscapes as consumption, free of human labor and visually satisfying, in distinction to the lands they developed for agricultural production. By remaking African land into one that satisfied an English landscape tradition where production and consumption were spatially separated, the British undermined indigenous land rights and land-use practices, a 'phenomenon inseparable from the recasting of African society' (1995, p. 153). In a related fashion, Jane Jacobs (1996) takes a postcolonial look at the changing meaning of cultural landscapes both at the 'heart' of British imperialism—the City of London—and at its peripheries—Aboriginal land claims in Australia. She argues that the power relations of nineteenth-century imperialism endure and are evident even in our postmodern cities, and that these relationships are articulated and negotiated through debates about the meanings of cultural landscapes.

4. Future Directions

If the existence of debate is any indication of intellectual currency, then the concept cultural landscape will certainly enter the third millennium as a vital part of the geographic discipline and the social sciences more broadly. Recent controversies have centered on the 'correct' way to interpret and think about cultural landscapes—whether analyses have moved too far beyond materialist explanations (Mitchell 1997), and the degree to which 'cultural' explanations incorporate the political, economic, and social (Schein 1997). These debates signal that the concept is politically charged, both in the sense of it serving as a focal point of political debate among academics, but more importantly, as it has now come to be seen as a key concept in our understanding of power relations and potential challenges to power. Whether it concerns the actual material production and transformations of cultural landscapes, or the ongoing re-interpretations of its meaning, the cultural landscape will be a key source for understanding dominant ideologies, and challenges to them. The cultural landscape embodies and expresses relationships of power along all of its axes—of gender, sexuality, 'race,' class, ethnicity, disability, age—and future research lies in explorations of these power relations as they are constituted by, and reflected in, cultural landscapes, and to the ways that a cultural landscape approach and subject matter can help us understand and articulate challenges to those power relations.

Cultural Landscape in Geography

1. *The Concept*

The term, 'cultural' landscape is a scientific concept that has acquired an array of distinct meanings over time as it developed in geography and spread to other scholarly disciplines. This multiplicity of meanings has vastly enriched contemplation of the relation of humans to their earthly environment, but not without ambiguity and periodic confusion. It has entered the scientific literature of many languages, most notably Dutch (*kulturlandschap*), French (*paysage humanisé*), German (*Kulturlandschaft*), Italian (*paesaggio culturale*), Japanese (*bunka-keikan*), Russian (*landshaftovedeniye*), Spanish (*paesaje cultural*), and Swedish (*kulturlandscapet*). A cultural landscape is the successive conversion over time of the material habitat of a sedentary human society responding with growing strength and variety to the challenges of nature, the society's own needs and desires, and the historical circumstances of different regions in different times.

The cultural landscape, as part of the noösphere or human environment (in contrast to the Earth's physiosphere, containing, among other things, the natural landscape), is an objectivization of socially organized and environmentally interactive humankind. It represents, therefore, a transformation of human thought into physical matter, a vast and complex assemblage of natural materials shaped by human struggle, con-

flict, cooperation, and ingenuity. It includes a heritage of valued material possessions passed selectively from generation to generation, representing unique societal assets.

The cultural landscape keeps its resident societies fairly rooted in place for varying periods of time, sometimes millennia, because of the continuous labor it assimilates in construction and reconstruction, as well as the collective psychological associations it inspires. Sometimes, this rootedness withstands major historical upheavals. Continuity or repetition of human occupation produces historical stratification (see Fig. 1), making the cultural landscape an invaluable multidimensioned source of cultural knowledge, aside from written documents, inviting interpretation from numerous perspectives. It consists of an extraordinary variety of human settlement forms providing for livelihood, shelter, and cultural sustenance superimposed on the land surface. These include buildings of all kinds, fields, fences, gardens, roads, bridges, factories, quarries, and a host of special land uses, plantings, and structures in rural and urban settings. Variations in age, design, social provenance, and symbolism are practically infinite, but in any given area generally fall into discernable patterns.

With the historical growth of societies, and their progressive integration in broad-scale territorial entities, specialization has created a diverse array of functional types of cultural landscapes, nested within a regional geographical matrix spanning the landmasses of the globe. Few parts of the contemporary world fail to exhibit cultural landscapes, many of them of great intensity in relation to the encompassing natural environment. Figure 2 presents the example of England and Wales, in which landscapes have been classified by two criteria: (a) general physio-economic characteristics highlighting their dominant vegetation and land use appearance, and (b) rural settlement forms, highlighting degrees of nucleation or dispersal and village layout.

The concept has affinities with other constructs: landscape is related to but not identical with nature; it is a scene, but not identical with scenery; it is around us, but not identical with environment; related to but not identical with place, and related to but not identical with region, area, or geography (Meinig 1979, pp. 2–4). For many, the interest lies in the study and explanation of the landscape itself; for others, in the way we look at it, given human ideas, attitudes, and aesthetics.

Numerous mental constructs of landscape in general have evolved over time, and the cultural landscape is implied in nearly all of them. The most important meanings can be grouped as follows: (a) the pictorial representation of an earthly scene by an artist (usually, that taken in at a glance from one point of view); (b) the sensory impression of the everyday environment; (c) the outward appearance of a district or region; (d) the natural condition of an area; (e) the cultural imprint of a region; (f) the total character of a region; (g) a

bounded territory; (h) a political-legal territorial entity (now rare, but historically significant); (i) an areal or distributional extent of a particular feature or characteristic; and (j) a 'geo-ecosystem' and an interaction system (Schmithüsen 1976, pp. 74–6, Leser et al., 1995, p. 346). In modern times the term landscape has gained popular metaphorical usage as (k) a stretch of abstract intellectual territory, as for example in the 'inner landscape' of the mind or the 'political landscape.'

2. *Historical Development*

The scientific term 'cultural landscape' came into use at the end of the nineteenth century in Germany, but its emergence rests upon a long history in which the primary term, landscape, evolved numerous meanings, many of which endured for long periods, some down to the present. The history of the specialized scientific term also mirrors shifts in understanding and popularity, and today the term enjoys wide currency in both scholarly discourse and general use.

2.1 *The Prehistory of the Scientific Concept*

The graphic depiction of landscapes for symbolic purposes is almost as old as human society, being known from the Assyrian, Egyptian, and Minoan cultures during the second millennium BC. From Greek vases in the sixth century BC to frescoes and pictorial mosaics of the Roman Empire, landscape motifs appeared with frequency. The word for landscape appeared in Chinese literature around 1000 BC by the fusion of the signs for mountain and river, and stylized landscape renderings entered Chinese art during the Han period (202 BC–220 AD).

In the western world, the word, landscape, emerged in various Germanic forms during the post-Roman period, including an ancient Frisian form 'lant-sceap,' and generally meant area, territory, tract of country, or historically constituted district. European art first depicted stylized landscape elements as scenic background for religious subjects during the thirteenth century, and in the following century for local historic figures, as with the Tuscan hill towns in Simone Martini's fresco of Guidoriccio da Fogliano painted in 1328. By the fifteenth century, Dutch, Italian, and German art of the Renaissance began to incorporate direct field observation, exemplified by the work of Jan van Eyck, Leonardo da Vinci, and Albrecht Dürer. Now came realistic portrayal of scenes from nature and social life, and even landscapes without people. In this era, just as printing made its appearance, usage of the word, landscape, shifted to the new scenic painting, which focused on the content of localities, there being plenty of synonyms to sustain the territorial meaning. The new graphic portrayals strengthened the use of the German word *Landschaft* in its meaning as picture, physiognomy, or character of an area. By 1480, European maps joined pictures as representations of regions, with da Vinci and Dürer equally skilled at both.

The age of exploration spurred rapid development in the scientific quality of maps as representations of geographical areas and their contents, particularly with the abstract addition of place names. The sailor-soldier Hans Staden in 1557 was seemingly the first to incorporate '*Landtschafft*' in a book title, referring to the contents of a region seen during his adventures in Brazil. By 1598 landscape became the 36,963rd word added to the English vocabulary (Finkenstaedt et al. 1970). During the eighteenth century geographers became seriously interested in scientific regional description, with an emphasis on physical features and the interrelationship between creative forces. However, through the works of Alexander von Humboldt (see *Hebb*, *Donald Olding* (1904 – 1985)) and Carl Ritter, there was no explicit scientific concept of landscape as such.

2.2 *The German Scientific Tradition: Systematization, Hegemony, and Near-collapse*

German geographical thought in the decades following the deaths of Humboldt and Ritter in 1859 centered on the scientific advance of physical geography grounded in systematic field observation. Ferdinand von Richthofen developed the concept of 'chorology,' understanding regions and places through their interconnectedness in the context of the earth's surface as a whole, an approach carried further by Alfred Hettner. Friedrich Ratzel developed an 'anthropogeography' based heavily on the relations of physical earth conditions and human movements. In sharp reaction to these perspectives, with their basis in method rather than subject matter and their potential over-reliance on environmental explanation, Otto Schlüter (1906) proposed a focus on *Landschaftskunde* (landscape science) as a more grounded study of the interrelations of things in particular areas. Attention to the visible features of the landscape, both natural and cultural, he felt, would give geography distinctive subject matter and logical structure. Nonobservable features would be relevant only to the extent that they helped explain the visible landscape. The approach would be evolutionary and permit study of both the *Naturlandschaft* (natural landscape) and the development of the *Kulturlandschaft* (cultural landscape) as the human modification of the original *Urlandschaft* (the wild landscape at the outset of human colonization).

Schlüter's concept was widely adopted, thanks in part to the spread of an 'objective-realistic' world view in central Europe, and by the 1930s it dominated the practice of German geography. But there was strenu-

ous debate over its limitation to evidence observable in the field, and the role of nontangible and moveable features, such as social customs and trade, and, indeed, the precise way in which the term *Landschaft*, with its multiple historical meanings, should be used. Awkwardly, the concept validated the idea that *Landschaft* is made up of manifest, visible phenomena while at the same time signifying a homogeneous area or region: thus, a region is more than a mere mental construct, it is a concrete reality. Nevertheless, Schlüter is considered to have founded modern cultural geography, and was the first to raise the landscape-forming activity of man to a methodological principle. The cultural landscape could now be examined from the standpoints of its morphology, physiology, and developmental history, just as the visible phenomena of nature in the build of the landscape as a whole. This gave human geography the same systematic order as physical geography (Waibel 1933). Siegfried Passarge wrote extensively on the topic, particularly at the world scale, which brought him international attention.

By World War II most German geographers subscribed to the scientific *Landschaft* concept whether they included or excluded nonmaterial features in their studies, exemplified by Schlüter's own master-work on the early settlement landscapes of central Europe published during the 1950s. *Kulturlandschaften* rode high in the saddle of German geography and the idea of cultural landscapes diffused elsewhere in European geography. This philosophical hegemony in Germany would persist well into the 1960s, when it fell sudden victim to a widespread reformulation of geography as the science of man's spatial organization (a paradigm shift initiated in Anglo-American geography), and suffered as a result greatly reduced popularity (Schmithüsen 1976).

The concept survived, however, particularly in the shrunken subfield of historical geography, and in recent times has made a dramatic comeback under new impulses to reunite physical and human geography through frameworks such as geoecology, dynamic human-environment systems, and landscape synthesis (Neef 1967, Hard 1973, pp. 15–181, Leser et al. 1995, pp. 34–355). In this light, the cultural landscape is seen as the highest level of integration of anthropogenic geofactors. It includes the study of cultural landscape elements, cultural areas, cultural landscape organization, cultural landscape cells, cultural landscape making and landscape change (Leser et al., 1995, pp. 332–3).

2.3 *Diffusion of the Concept*

The German scientific concept of the cultural landscape found receptive minds elsewhere in European geography during the course of the twentieth century, usually as an explicit theoretical importation grafted on to related indigenous ideas. As a result it has broadened and mutated to fit intellectual and historical conditions in different major language areas, as a few cases will illustrate.

French geography in the early twentieth century was concerned with the *genre de vie* of small regions *pays*, led by Vidal de la Blache, who saw landscape as the physical domain, set alongside 'civilisation.' But Schlüter's concept was quickly adopted by Vidal's student Jean Bruhnes, and a tradition of interpreting *paysage* emerged, through Pierre Deffontaines, Roger Dion, Marc Bloch, to Augustin Berque (1995). Berque discriminates between civilizations with and without landscapes (a distinctly French notion), the former necessitating the existence of specific vocabulary for landscape, a descriptive literature, landscape painting, and a culture of garden design. Italian geographical concern with landscape existed already in the late nineteenth century, but applied to physical scenery and aesthetic responses to it. During the 1930s the German landscape debates seeped into Italian geography and fluoresced ultimately in the writings on *paesaggio antropogeografico* of Aldo Sestini, Lucio Gambi (*paesaggio umano*), and later writers on *paesaggio culturale* such as Silvio Piccardi (1986).

German thought on the cultural landscape made a particular impression on American geography through Carl O. Sauer, who soaked it up as a student in Chicago before World War I. His (1925) essay, 'The morphology of landscape,' belatedly reflected this influence. Later Sauer would favor culture history over landscape as the central pursuit of human geography, but his many students were to extend American geographical contributions to cultural landscape research well into the 1970s. Richard Hartshorne (1939, pp. 145–74), siding with Hettner, sharply attacked this focus for the discipline, favoring instead relative location, as expressed in 'areal differentiation,' and thereby helped mute wider interest in the cultural landscape for some decades. J. B. Jackson (1997), however, a lay geographer who founded *Landscape* magazine in 1955, attracted a devoted following within and beyond geography for his unabashed passion for understanding cultural landscapes. Wilbur Zelinsky, David Lowenthal, Peirce F. Lewis, and Donald W. Meinig (1979) have since been prominent in the field.

British geographers were strikingly disinterested in the German concept of the cultural landscape during most of the twentieth century—perhaps monolingualism and two world wars took a toll—notwithstanding Robert E. Dickinson's (1939) introduction to the German literature. Vaughan Cornish, a British lay geographer, had broached the issue of landscape aesthetics earlier, but it was H. Clifford Darby's (1940) approach to historical geography which provided an intellectual home for British thinking about the cultural landscape, with his emphasis on major transformations—draining fens, clearing woodlands, reclaiming heaths. Cultural landscape research was well embedded in British geography before the historian

William G. Hoskins published his landmark *The Making of the English Landscape* (Hoskins 1955, Muir 1999).

In human geography elsewhere in Europe—Scandinavia, the Low Countries, Spain and pre-communist Eastern Europe—the cultural landscape as defined in Germany became a generally accepted, if not always core, concept by mid-century. Only in Russia, under Soviet conditions, did the concept find little favor, landscape science being defined as a physical domain to assist natural resource mobilization. In Latin America, Africa, and Asia, the cultural landscape concept also gained some currency, often under the rubric of historical geography. Australia and New Zealand followed British precedent.

Most effort in the history of the concept of the cultural landscape has been given to it as an objective, concrete reality, seeking means to define, measure, and interpret its morphology, functional structure, dynamics, and meaning as a physical reflection of variable culture across the face of the earth. That both this concept and its subject matter serve also as social constructions, with consequences for scientific objectivity as well as, more profoundly, for understanding the social meanings of landscape over time and place, has been examined intensively only since the 1970s or 1980s. This shift coincides with the rise of poststructuralism and postmodernism in the social sciences and humanities worldwide. Although the new perspectives have individual precedents, even among the German writing of the 1920s and 1930s, most of the recent scholarship has been introduced in the British and American literature. While extensive research continues unabated in many of the long-established spheres of study, suggesting its continued value, less attention tends to be paid now to the relations between human societies and the physical environment, and more to the subjective aspects of the concept, particularly the mind-states and collective visions of human actors in and interpreters of landscape making through the ages.

2.4 Landscape as Social Construction

Landscape may be regarded as 'a way of seeing,' and an ideological one, not just an image or an object; a sensibility dating to the Italian Renaissance (Cosgrove 1984, 13). Therefore, the art-forms used to represent and symbolize landscapes, as well as the artifice of the landscapes themselves, over time and space are laden with their own significance. From this vantage point landscape can be seen to reflect the unequal distribution of social and political power, where the forces of production are slyly obscured and the struggles and achievements of the less powerful hidden, patterns demonstrably starker in autocracies than democracies.

Scholarship in this vein has focused on the culturally-produced imagery of landscape and treated it, for the most part, as an essentially closed circuit of cultural invention, visualization, marketing, and social contest seen from a largely aspatial communications perspective. Whatever the ground truth of the specific earth landscapes being represented at the time are or may have been remains conspicuous by its absence and seeming irrelevance, and would be difficult anyway to include (see, for example, Daniels's 1993 study of paintings and national identity). The analytical substance here is not the concrete realm of the objective landscape, but rather the mental realm of world-view, perceptions and stereotypes, values and aesthetics, symbolism and semiotics, project and discourse (e.g., Duncan 1990).

It is in this subjective domain of landscape interpretation that British and American geographers, in particular, over the last two decades have explored interdisciplinary terrain with vigor, starting with art history. They have found common ground with scholars in other social sciences and the humanities, who were discovering simultaneously the role that 'space' plays in the problematics of culture (for further discussion of this conceptual arena, see *Cultural Landscape, in Geography*; *Cultural Landscape in Environmental Studies*).

3. Interdisciplinary Interest

Cultural landscapes are so intimately intertwined with the human societies inhabiting them as to have attracted increasingly interdisciplinary attention. But not all disciplines have put direct value on the cultural landscape concept, so the interest has been uneven, bypassing some social and behavioral sciences while including some in the physical and biological sciences and humanities.

Long before the scientific concept of cultural landscape, liberally-educated geologists and naturalists such as Archibald Geikie in Britain and George Perkins Marsh in the United States wrote about the aesthetic character and educative value of landscapes. This interest has returned in modern times with the environmental movement and finds expression in landscape ecology and historical ecology.

In the social sciences beyond geography, historians were first sensitized to landscape through Hoskins in the 1950s. Since then landscape history has become a popular pursuit in Britain and continental Europe (Hoskins 1955). In America, historical interest still emphasizes the human actors in relation to individual landscape elements (such as parks) rather than the artifact's complex organization. Landscape history has drawn in archaeologists interested in scales beyond that of the 'site,' and the British lead is now matched by similar interest in Europe and elsewhere. Anthro-

pologists have also recently discovered landscape as a 'place' context for relating community studies to broad patterns of cultural transfer. In the behavioral and medical sphere, landscape perception has been recognized as a component of environmental psychology (Porteous 1977) and mental health (Gesler 1992).

In the humanities, landscape representation has long been a fixture in art history, and more recently has been tied to landscape aesthetics and environmental values and behavior more generally (Tuan 1974, Appleton 1975, Penning-Rowsell and Lowenthal 1986). Cultural landscapes have also found a place in architectural history with the belated recognition of the importance of vernacular forms (Brunskill 1981). Landscape as a theme in literature is ancient, and affective landscape description in 'regional' literature of long standing. Recently, as metaphor, it has gained new attention in cultural studies. Linguistics and folklore have periodically contributed significantly to cultural landscape history.

4. *A Semiautonomous Field*

Over the last century cultural landscapes have spawned a burgeoning interdisciplinary scientific and scholarly literature. Their study, however, has not attained disciplinary autonomy, although it exhibits many features of an independent field: distinct scientific organizations devoted to its furtherance, dedicated publication series, public policy relevance, and in some countries an avid lay following. The less-than-autonomous status of the field reflects perhaps the extreme diversity of landscape's physical and social character, the diversity of analytical skills brought to its elucidation, and the fragmentation of managerial entities relevant to its management. Besides, disciplinary associations remain strong and vital. Geography is still the source of much, if not most, conceptual thought applied to cultural landscapes, and as a spatially-integrative discipline remains well placed to assimilate and interpret the diverse findings of landscape research on all fronts. Archaeology, history (particularly art, architectural, and landscape design history), and geoecology bring essential questions and methods to the subject.

The investigative research literature of cultural landscape studies is supported by at least a dozen international scientific journals, foremost among them being *Landscape, Landscape History, Landscape Research, Landscape Journal, Ecumene*, and a new entry *Landscapes*. Dedicated research groups exist, such as the Landscape Reseach Group, the Society for Landscape Studies, the Vernacular Architecture Forum, the Society for Commercial Archaeology, and many others. And some large-scale research programs have yielded remarkable publications on such subjects as the multinational, multivolume *Historic Towns Atlas*, the Swedish Ystad Project (*The Cultural Landscape During 6000 Years in Southern Sweden*) and an entire volume of the National Atlas of Sweden devoted exclusively to the nation's cultural landscapes (Vol. 13), and the *Atlas of the Irish Rural Landscape*.

5. *Other Uses of the Concept*

Since the 1950s studies using the cultural landscape concept have gained relevance beyond academia in the arena of public policy, education, and business. Detailed survey-driven documentation studies, consisting of cultural resource inventories (organized in GIS/geographic information systems), along with regional interpretation of the cultural landscape features past and present support two key social-environmental enterprises: the design professions such as architecture (building traditions) and landscape architecture (land planning and design), and activities that come under the rubric of *landscape management*. These include environmental conservation and protection (national parks, urban open space), historic preservation (cultural parks, open air museums, ornamental gardens, historic districts), and general regional planning (especially of transportation, land use, recreation and tourism). For purposes such as these techniques of landscape assessment (or appraisal, evaluation), including land and structure classification, surveys of landscape aesthetics (measuring visual complexity, 'quality,' and preferences), and landscape impact analysis—all ultimately grounded in theories of cultural landscape history, dynamics, and perception—provide wide-ranging applications of this fundamental, integrating concept in the social and behavioral sciences.

Cultural Policy

The study of cultural policy is concerned with the instruments (legal, administrative, economic) through which governments provide, regulate, and manage cultural resources and the uses to which they are put. The objectives that are pursued by these means can be divided into three broad, but overlapping, categories—the symbolic, the social, and the economic. In exploring these objectives and the political rationales on which they rest, this article examines the history of their development as concerns of government, and the varying interpretations they have received in different political regimes and philosophies.

1. Cultural Policy and State Symbolism

The cultural policies of contemporary governments are most evidently continuous with those of earlier political systems when supporting cultural activities that symbolize the virtues of a particular nation, people, or political system. The most obvious precursor for these concerns consists in the use of the arts as instruments of state policy associated with the absolutist monarchies of early modern Europe. These were characterized by two contrasting orientations. The first aimed to weaken the nobility by involving its members in a socially demanding and economically debilitating cultural life centered on the court. The second aimed to symbolize the principles underlying the political order through a public theater of power (statues, processions, palaces) which magnified the king's potency so as to incline his subjects to obedience. Culture, here, symbolizes sovereign power with a view to enhancing its effects.

If this connection between sovereign power, culture, and the arts of governing was most fully developed in France, it was given a new interpretation during the French Revolution. This consisted in the role that was developed for the arts, and culture more generally, of symbolizing the more abstract form of sovereignty that was now vested in a democratic citizenry (McClellan 1994). In this new conception—evident in the policies developed for the Louvre as much as in the debates over language policies, public monuments, and architecture—culture served as the means through which a democratic citizenry made its own power as a sovereign people manifest to itself. But it also allowed that citizenry to exercise a direction over itself through the ideals—of, for example, heroism and sacrifice—the citizen was exhorted to emulate.

These relations between the arts, culture, and sovereign power have undergone a number of mutations in the subsequent development of the rationales underlying state support for specific kinds of cultural provision. The logic underlying continuing state patronage of the art forms that had been most closely linked to court society—ballet, theatre, opera, and the art museum—remains one of forging particular forms of elite sociability, bonding the powerful through shared rituals and symbols. The evidence in all societies where relevant studies have been conducted shows that participation in these cultural institutions is mostly limited to elite social strata (Bourdieu and Darbel 1991). Their role in symbolizing a cultural distinction between such strata and the generality of the population plays an important part in the cultural dynamics of class societies. This is, therefore, an aspect of government involvement in the cultural sphere that

is often regarded as in conflict with the democratic principle of equal cultural entitlements for all citizens which, in the postwar period, has become a guiding principle for cultural policy development.

Government support for more spectacular cultural forms, as a means of symbolizing the power of a particular people or nation, has remained an enduring aspect of the cultural policies of modern polities. The festivals of the French Revolution constituted a symbolic use of public space which, in making a citizenry visible to itself, disputed the earlier symbolism of royal processions. The subsequent development of participatory forms of public spectacle—international exhibitions, national celebrations, and spectator sports—has yielded a range of contexts in which a people is made visible to itself and its virtues celebrated in ways which pit them in competition with other nations, races (the prime cases being Nazi Germany or fascist Italy), and political regimes (especially during the Cold War).

Important questions of publicness concerning the forms in which the identity and qualities of a people, citizenry, or nation are to be represented are at stake in these festival, celebratory, and commemorative forms. The relations between the policy structures and processes through which these matters are resolved and the perspectives of political constituencies organized in terms of relations of race, class, gender, or religion have played a crucial role here in redefining both who gets to be counted as citizens and the exemplary virtues that are held up as models for their emulation. A continuing history connects those who criticized the revolutionary festivals for a public iconography of womanhood which portrayed women as mere helpmates to a republican brotherhood of men to late nineteenth-century feminist criticisms of the male-centered norms of publicness associated with international exhibitions and museums. And there is a continuing history connecting both of these to contemporary debates centered on the adequacy of the forms of representativeness—whether in terms of gender, race, or religion—that are to be aimed for in major forms of national commemoration or celebration. The debates occasioned by Georges Pompidou's *grands projets*, by Aboriginal engagements with Australia's 1988 bicentennial celebrations, or by Britain's Millennium Dome are all cases in point. As such, they illustrate how ways of making power manifest inherited from an earlier political regime based on a singular source of authority are imbued with a more contested content as a consequence of their relations to a civil society that is plural and divided.

2. *Acting on the Social*

As well as investing in culture to symbolize power, modern governments have also invested in culture as itself a power that is capable of bringing about changes in conduct and ways of life. These are not entirely different functions. Debates concerning how best to symbolize a citizenry—how best to present to them their collective power and virtue—have been concerned centrally with reinforcing some kinds of conduct and changing others. The early modern period, however, also saw the development of an orientation toward culture that, although it had precedents in earlier forms of pastoral power, represented a new departure so far as secular forms of cultural administration were concerned. This consisted in the role that was accorded culture in the *Polizeiwissenschaft* (science of police) of the seventeenth and eighteenth centuries. This aimed to bring a new order to the social body in place of that which had characterized the relationships between different estates in the old social order with its clear rules regarding the forms of behavior, dress, duty, and demeanor appropriate to particular stations in life. It thus concerned itself with ways of life both negatively and positively: negatively in prohibiting particular kinds of behavior (for example, public drunkenness), and positively by providing the cultural means through which problematic forms of conduct might be transformed through programs of self-improvement. An early nineteenth-century Prussian regulation puts the point well:

> In their capacity as 'Polizei' authorities of the land the governments are charged with the care and well being of our loyal subjects, in positive as well as negative aspects … . Governments therefore have supervisory powers in matters of public improvement, education, and culture (Knemeyer 1980).

Within the emerging class dynamics of nineteenth-century industrial societies, such conceptions, when translated into the programs of liberal government, typically split the field of culture into two. On the one side, the culture of the working classes presented itself as ways of life that needed to be acted on, often with varied aims in view (combating political sedition, inducing habits of thrift and sobriety), as a means of re-forming the social. On the other, the rational and improving culture that had once formed a part of the bourgeois public sphere (Habermas 1989) appeared in a new historical guise as an instrument of government, providing the means whereby individuals might be led to transform their own conduct (Minihan 1977).

This was the general impetus behind the nineteenth-century development of public libraries, museums, art galleries, concert halls, and public schooling through which, in Europe, governments undertook to make cultural provision for the population as a whole. It was, however, the needs and aspirations of government, rather than any sense of democratic cultural rights of the kind that had been asserted during the French Revolution, that supplied the rationale for this provision. Government action in the cultural sphere was based on the expectation that the improving influence of a rational, enlightening, and elevating

culture would lead, through the accumulation of thousands of individual acts of self reform, to a transformation of working class ways of life and, consequently, a re-ordered social body. The guiding principle of state cultural provision in this period accordingly was focused mainly on leading 'the people' away from cultural activities and traditions that were popular with subordinate social strata and towards greater participation in elite cultural forms that had received the official sanction of state approval.

It is not until the 1930s that questions concerning the responsibility of governments for maintaining and promoting popular pastimes, traditions, and ways of life came centrally to the fore. The contexts in which this occurred were often nationally specific: the development, in the context of the New Deal in the United States, of community-based cultural programs (Harris 1995); the programs of leisure-time organization (*dopolavoro*) of fascist Italy; and the role of the Popular Front in France in opening up a new politics of popular leisure (Looseley 1995). These tendencies were continued in the Second World War which, if it was 'the people's war,' also brought the question of the people's culture—and its role in maintaining their morale—to the fore in new ways that made it increasingly imperative for democratic governments both to know about popular ways of life and to nourish them so that they might thrive. This trajectory toward more democratic understandings of the concerns of cultural policy has been continued throughout the postwar period, although by no means consistently or without reversals. Indeed, exceptions to this tendency have often been institutionalized as the administrative apparatuses established to develop government support for art, culture, and leisure have reflected the lingering influence of older elite values. The histories of the Arts Council in Britain and the Australia Council are cases in point. In both cases, the criteria of excellence that have guided their allocations of funds have been at odds with their obligation to meet the cultural needs of all sections of society (Hawkins 1993).

The predominating tendency of the period since the 1960s has been to call into question these socially exclusive conceptions in favor of more democratic conceptions of the range of cultural tastes and values governments should support (see *Cultural Policy: Outsider Art*). While these criticisms initially centered on questions of social class, feminist criticisms brought questions of gender to the fore in the 1970s while, since the 1980s, questions of race and ethnicity have tended to displace the importance that was earlier accorded social class. The responses to these pressures have varied. The cultural policies developed by Jack Lang as a member of Francois Mitterand's governments provided an influential model in the 1980s in view of the accent they placed on the values of pluralism and democracy (Looseley 1995). The cultural policies developed in Australia under the Labor governments of Bob Hawke and Paul Keating were also innovative in developing cultural policies that recognized the diverse needs of a society with a history of culturally varied migration and an indigenous population with highly distinctive cultural needs and traditions.

The recognition and promotion of cultural diversity—now the major international leitmotif of cultural policy discourse, and one actively promoted by UNESCO (World Commission on Culture and Development 1995)—is not, however, simply a matter of recognizing cultural rights. On the contrary, programs of cultural diversity are now central components in the governing strategies of modern polities. They supply a means for acting on the social—by celebrating cultural diversity, and marshalling a variety of legal and moral sanctions against racist forms of conduct—that is widely accepted as crucially important for managing the relationships between ways of life in contexts where the mix of peoples is increasingly diverse (Gunew and Rizvi 1994).

However, these tendencies are neither universal nor irreversible. The policies and politics of ethnic cleansing are a testimony to the continuing influence of monocultural approaches to managing the relationships between peoples with different ways of life that had characterized earlier forms of racism. The new right's criticisms of political correctness in the United States have also challenged cultural diversity policies. The links that had earlier connected cultural access policies to social justice principles are now also weaker in Europe where policies based on the logic of social inclusion often fail to acknowledge the relevance of social class to either social or cultural distributive issues.

3. *Culture and Economic Development*

Whatever the importance of the social and civic issues associated with cultural policies, these are now eclipsed by the economic significance of the cultural and media industries. This is not entirely new. Tourism has played a role in the calculations that have guided investments in large cultural infrastructures since the eighteenth-century spa movement and the museum and exhibition boom of the nineteenth century. The industrial issues at stake in the development of new communications technologies have also been clear from the outset: witness the variety of legal and technical barriers developed in Europe to combat the dominance of American cinema.

However, the economic aspects of cultural policy have assumed an altogether unprecedented significance in the closing decades of the twentieth century. There are a number of reasons for this. Some have to do with the demise of more traditional industrial sectors and the increasing importance of cultural industry development to the employment strategies of

once prosperous industrial regions. Some have to do with the changing relations of work and leisure, resulting in increased effective demand for cultural activities. This is reflected in the increasing role accorded cultural tourism as a means of attracting visitors to particular tourist destinations. But the key driving force over the 1980s and 1990s has consisted in the intersections of a number of technological developments that have revolutionized communications in ways that have affected profoundly all aspects of the cultural and media sectors of advanced societies (Collins and Murroni 1996). The role of computing and the Internet in the development of the 'information economy,' and the convergence of these with new developments in television and telecommunications, have been especially important.

The cumulative effect of these developments has been to forge a stronger connection between cultural policies and economic policies. This is especially evident in contexts where local or national cultural industries are threatened by the more global pattern of cultural flows associated with the new international media order. In France, Australia, and Canada the case for government investment in cultural industries— for example, film and popular music—has been urged as a means of retaining a viable base for their future expansion in the face of American and British imports. The same rationale lies behind policies that restrict the amount of foreign content that can be broadcast on radio or television, or regulations limiting foreign ownership of media. However, it is also clear that, in these cases, the considerations at stake are not only economic. In view of their role in circulating not merely economic value but also cultural values and meanings, viable cultural and media industries are seen as necessary for maintaining and developing nationally, regionally, or locally distinctive heritages and identities. In other contexts, however, economic and cultural considerations may be in tension with one another and in need of mediation. The requirement that tourism policies should be 'culturally sustainable'—that is, not be promoted to an extent that will detract from the quality of the specific culture or way of life of a particular locality—is a case in point.

Here too, then, questions of ways of life and the relations between them are at stake. The same is true of the increased interest in questions of intellectual property associated with the new media. A part of the concern here has been with the extent to which intellectual property regimes developed in an earlier media environment can provide for sufficient security of title to sustain the viability of investment in cultural forms whose reproducibility opens up the prospects of their free circulation via the Internet. A second area of distinctive concern, however, has been with the intellectual property protocols that are needed to mediate the relations between specific cultural producers and the marketplace in ways that do not prejudice the cultural traditions of the former. The debates that have accompanied the use of the Internet to market the art of the indigenous peoples of Australia, Canada, and New Zealand are a case in point, comprising a subset of a broader group of policy questions concerning the relations between new media and indigenous cultures (Michaels 1994).

Considerations of this kind, however, do not address what is perhaps the most important issue associated with the new media order: the increasing division between 'information rich' and 'information poor' societies. The fact that there are few, if any, international mechanisms that are capable of addressing this issue underlines the extent to which cultural policies remain, in the main, the instruments of national governments.

4. *Culture, State, and Civil Society*

The development, over the eighteenth and nineteenth centuries, of these different kinds of governmental involvement in the cultural sphere has occasioned debate concerning the extent to which such involvement is justified and the means through which it is most appropriately exercised. These questions are rehearsed, in the specialist literature, in assessments of the respective virtues of the different models of support for culture that have been developed in connection with different political regimes and philosophies. These range from the view, prevalent in the United States and Japan, that the role of government should be purely facilitative, regulating cultural and media markets by legal and fiscal means to provide the conditions in which the arts and culture might flourish, to the assumption of direct responsibility for funding and directing cultural activities associated with communist regimes.

The main point at issue in these debates concerns the relations between state and civil society that different kinds of state action in the cultural sphere entail. Within the formulations of the science of police, the allocation of a responsibility to the state for the cultural well being and development of the population formed part of a more general program of government in which the state was to become involved directly in the administration of all aspects of life. There is a significant continuity between these formulations and the approaches to the administration of culture associated with communist regimes of the mid-to-late twentieth century in their aspiration to replace market mechanisms by means of a cultural plan developed by state functionaries in the light of officially-sanctioned criteria of aesthetic and political excellence. This construction of the relations of culture and government entails a denial of the autonomy of civil society as a realm separate from the state. Instead, in the cultural policies of communist regimes, the institutions of civil society, including those of culture, are inte-

grated into the state in order that the citizen might be molded directly in accordance with cultural ideals endorsed and supported by the state. This integration of the institutions of civil society and of the citizen into the state was also a characteristic of fascist cultural policies: the *dopolavoro* was a clear assault on the autonomy of Italian working-class culture and an attempt to integrate it into the state where it could be subjected to more direct forms of regulation (De Grazia 1981).

In western democracies, the role of liberalism and its criticisms of the totalizing aspirations of the earlier science of police have given rise to a different set of relations between state, culture, and civil society. Within liberal conceptions of government, the autonomy of civil society is to be not so much respected as constructed, organized as a zone of rights and freedoms on which the activity of government must not trespass. This has meant that cultural policies that have aimed to bring about specific changes of conduct have done so in ways which have accepted the independence of civil society. This has entailed fashioning cultural resources into means of acting on the social that work indirectly, through the agency of the citizen's voluntary activity rather than via state imposition, and at a distance in the sense of accepting the autonomy of the social as a realm of behaviors and relationships that exist independently of the state.

These principles of liberal government have been a constant feature of the cultural policies of the United States, Britain, Canada, France, and Australia. However, their implementation has been, at different historical moments, either muted or modified in view of the expansion of the state's functions associated with its role in the provision of social welfare and, since the Second World War, corporatist strategies of economic management. They have, however, come into the ascendancy once again with the phase of neoliberalism inaugurated by the Thatcher and Reagan administrations and subsequently greatly assisted by those accounts of globalization which suggest that the global flows of both culture and capital now exceed the regulatory capacities of national governments. The process of rolling the state back out of the lives of its citizens has resulted in a tendency to reduce the levels of direct government funding and support for specific forms of culture in favor of the operation of private cultural markets and corporate or philanthropic forms of sponsorship. In these circumstances,'audience development' has become the policy buzzword of the 1990s. At the same time, where government funding remains a significant factor, new relations of competition have been fostered to make the institutions of public culture more responsive to the effects of market forces. This has been most notably true of the restructuring of the British broadcasting industry over the period since the 1990 Broadcasting Act (Goodwin 1998). Taking a broader perspective, however, perhaps the most significant changes in the relations of state, culture and civil society at the close of the twentieth century are those evident in China where new forms of cultural consumption associated with the development of new cultural markets now increasingly take the place of state-provided culture.

However, if the policy catch phrase of the 1980s and 1990s has been deregulation, this tendency has not gone unchallenged. Indeed, the consequences of deregulating the culture and media industries have often been sufficiently problematic to lead to more-or-less instant demands for their re-regulation. There is, however, no escaping the historical shift that is entailed in a policy discourse that now sees the state's cultural role primarily in terms of the exercise of its regulatory capacities rather than as itself directly a significant agent of cultural production.

Cultural Policy: Outsider Art

Within the broad framework of public policy, government support of culture varies from one nation to another. In authoritarian or totalitarian regimes culture is usually a tightly controlled instrument of ideology, in liberal democracies expenditures of public funds are justified on other grounds, for example, the role of culture in strengthening civil society. Until recently, cultural policy has traditionally been concerned with art forms whose standing was uncontested. The art genre that has come to be known as 'outsider art' is of particular interest because of its divergences from either of these historic patterns. It serves as the focus of this article.

1. Introduction

1.1 Construction of the Outsider Art Genre

(a) The term 'outsider art' has been used to signify the art of the 'insane' or more generally the creations of certain kinds of untrained artists. Its main components, noted from the late nineteenth century on, consist of works by mental patients, children, and 'primitive' peoples from cultures outside of Western civilization. Recently, the genre has been enlarged by the cultural creations of what are usually thought of as self-taught creators considered marginal to or marginalized by their society: naïve artists, folk craftsmen or women, urban or rural isolates, hobbyists, the homeless, prison inmates, institutionalized elderly (Zolberg and Cherbo 1997).

(b) In the last quarter of the twentieth century, outsider works began to gain fame, to the monetary and symbolic benefit of their owners. Works are exhibited in museums, featured in art magazines, and analyzed in books that detail and assess their quality. In the process, a 'tradition' of outsider art has emerged centered upon certain canonic works that sell for extraordinary prices. In contrast to what are classified as professional artists, outsider artists are generally believed to be unaware of their artistry, not promoting their own career, but spontaneously following their creative impulse (Becker 1982). They become known largely through the discovery and *marketing* practices of art dealers, gallery owners, art critics, scholars, museums, and government agencies (Ardery 1997).

(c) At one extreme, their creators inhabit a world of isolated naïves, whose works take shape as the result of personal visions (Becker 1982). At the opposite, as inmates of total institutions (Goffman 1961), they gain access to the possibility of creation when it is offered by their keepers. It is the latter who select what merits public display. A third class of canonical outsider art is 'primitive' art, a form whose meanings derive from completely different societal and cultural traditions. It was through convenient misunderstandings of their origin and significance that primitive art was lumped together with the works of the 'insane,' adult naïves, and children (Zolberg 1997, 53–72).

1.2 State and Market in the Making of the Genre

(a) Outsider art flourishes or languishes depending upon the political regime and the art market in which it comes to light. The complexity both of art and of its context makes it necessary to clarify the nature of their interactions by tracing the genre's institutional and structural foundations. The institutions and policies of governments play a part, but government policies, vital as they are for fostering or inhibiting culture, can seldom determine cultural outcomes. Their importance lies in the fact that they set the conditions under which their creation and dissemination may take place. In liberal states where commercial processes are permitted and fostered, the power of the art market is at least as decisive as is governmental policy *per se* in providing gatekeepers, agencies of reward, recognition and legitimation.

(b) The principal question is whether, how, and with what consequences the public sector came to enter into the domain of outsider art. Equally important is the role of art market structures and processes. Although this combination of domains has not been directly drawn together into a unified analysis, it appears that together these gatekeeper agencies and groups are engaged in the discovery as well as construction of new forms of outsider art.

2. The Social Construction of Outsider Art

2.1 An Aesthetic Response to Modernization

(a) Interest in outsider art is an aspect of attempts by observers and scholars to grasp the meaning and impact of modernizing trends in society. Theorists who laid the groundwork for understanding the phenomenon came at it from various perspectives and disciplines, though, with the exceptions of Max Weber (Gerth and Wright 1946) and Georg Simmel (Wolff 1950), they generally did not refer explicitly to the arts.

One of the most influential formulations was that of Ferdinand Toennies, whose analysis of the growing dominance of modern society over what he perceived as a declining communitarian rural life world, summarizes a widespread unease prevalent among many nineteenth-century intellectuals (Toennies 1963). Cultural opinion leaders such as William Morris and his followers tried to overcome what they saw as the cold ugliness of industrialization and its products by reverting to medieval inspiration for design, and work organization based on handcraft. Forms and genres that they associated with folk culture appealed to their romantic sensibilities and, for some, their socialist ideas.

(b) An imagined peasantry and its way of life was not the only victim to the seemingly inexorable march of modernization. Integral to much nineteenth-century longing was a search for 'authenticity' in contrast to the 'artificiality' of urban civilization. Seemingly embodied in artistic creations of children and of asylum inmates, authenticity was sought by therapeutically oriented scholars of the 1920s. Hans Prinzhorn, for example, a leading proponent of the artistry of the mentally ill (Prinzhorn 1972) was not alone in his appreciation of their gifts. Walter Morgenthaler, a physician in a Swiss institution, publicized the achievements of one of the first major outsider artists to be 'discovered,' his patient, Adolph Wölfli (Morgenthaler 1992).

(c) The third principal form of outsider art, works by non-Western peoples, has a very different source and trajectory. It entered European consciousness through nineteenth- and twentieth-century colonialist imperialism, when much of it was rarely recognized as art, but rather as superstitious fetishes or indications of the innate childishness of primitive people. These interpretations provided additional justification for European domination, since they intersected with conventional stereotypes, and rationalized the claim that colonialism would elevate the subjects to a civilized state. Primitive artistry was 'discovered' largely in the early twentieth century when, spearheaded by *avant garde* artists (Cubists, Fauvists, Expressionists), these works were re-interpreted in appropriate aesthetic terms (Vogel 1988). It was not long before other artists, art historians, and critics turned their attention to this blossoming genre (Zolberg 1997, 53–72).

2.2 Intellectual and Scholarly Perspectives on Outsider Art

(a) English critic Roger Cardinal (1979), French *avant garde* artist Jean Dubuffet (1988), art historian and museum curator Robert Goldwater (1986), historians and critics John MacGregor (1989), Michel Thévoz (1976) and many others have provided a multifaceted scholarship on these works. Anthropologists, psychologists, and sociologists have contributed their understandings: Howard Becker (1982), Sander Gilman (1982), James Clifford (1988), Anne Bowler (1997), Vera Zolberg (1997), Julia Ardery (1997). Several of them perceive affinities between outsider art and genres and works of 'maverick' artists (Becker 1982) of the turn of the century *avant garde* movements (Bowler 1997, Tuchman and Eliel 1992, Hall and Metcalf 1994).

(b) While interest in outsider genres parallels concerns about modernization, technology, and anxieties about ecology, free-floating concerns are insufficient to account for the burgeoning of interest in these genres. Without the creation of aesthetic institutions dedicated to state building, and their transformation with the rise of art markets, it is difficult to imagine the emergence of outsider art as an admired genre.

2.3 Structural Context for Recognition

(a) The modern system of public institutions and agencies (the academic system), which had been enacted by nation states, became the authoritative gatekeeper in establishing and maintaining artistic status hierarchies. Exclusionary and narrow in their definition, academic establishments were eventually sufficiently shaken by challenges from successive waves of *avant garde* art movements (Poggioli 1971) to be obliged to open themselves to new styles. This came about largely as they faced competition from the private sector of an emergent, free-wheeling, commercial dealer system (see, for example, *Fine Arts*).

(b) Psychotherapy converged with the rise of *avant garde* art movements. Resulting imagery was interpreted as spontaneous expressions of outsiders who were seeking a visionary experience. To these unschooled, apparently spontaneous creations of institutionalized mental patients and children, were added tribal arts of Africa, the southern Pacific (Goldwater 1986), and rustic Europe.

(c) By the latter half of the twentieth century, as the 'insider' art worlds of academies and of dealer systems became increasingly open to stylistic and genre innovations, official and conventional art categories were transformed. This was true as well for unconventional *avant garde* artists, whose claim to standing as arbiters of fine art was challenged by even more unconventional expression that rejected pure aestheticism and linked their creation to other domains. Barriers between high and low art, art and politics, and art and religious rite, art and emotional expression, art and life itself are repeatedly breached. Art historians, aestheticians, social scientists, and policy makers face complex challenges when they try to delineate what is Art, what it includes or excludes, whether and how it is to be evaluated, and the relative importance to assign to different genres (DiMaggio 1987). These uncertainties are directly implicated in controversies

about how and whether governments should provide official support for more recent kinds of artistic creation, and their dissemination to larger audiences.

3. *Public Policy and the Arts*

3.1 *Pitfalls of Public Culture*

(a) In recognizing certain forms of culture as symbolically significant, the state confers official approbation and respect. France very early established a sphere of official cultural policy for the glorification of the state (Mesnard 1974). The French example influenced much of western Europe and left a durable heritage on its former colonies. Inevitably, officially recognized cultural forms were viewed as hierarchically superior to those receiving support from other sources, whether religious, provincial, or commercial (see, for example, *Fine Arts*). Integration into its ranks gains artists public or private patronage rather than leaving them dependent on commercial forces.

(b) While most liberal national governments recognize and support some art forms, rarely is the institutional structure of support as centralized as in authoritarian or despotic regimes. Nazi Germany suppressed the principal forms of outsider art and their creators. Under the dominance of their leaders' racist beliefs and eugenicist pseudoscience, the state's agencies used their apparent kinship with the stylistic and philosophical orientations of *avant garde* forms (Expressionism) to justify official suppression of both (Barron 1991). Labeling the art of vanguard artists and the art of the mentally ill, the naïve, and African works as 'degenerate,' the Nazi regime persecuted and frequently murdered artists, and sold their works abroad or simply destroyed it.

(c) The relationship of outsider art to contemporary political agendas in most other societies is considerably more benign. Thus, in relatively liberal regimes outsider art forms have come to be associated with heart-warming outcomes of social work or psychotherapy; some have come to be regarded as having aesthetic value in their own right. It is in this process that they have become incorporated into the gallery system.

3.2 *Cultural Policy US Style*

(a) European nations, with their feudal and monarchical traditions, have emulated the French structures of official academic art, though rarely in as centralized a form (Corvisier 1978). Even in a nation as divergent from European traditions and, in particular, from state centralization, as the USA, France's reputation as patron of the arts was admired by artists. This is understandable, since in contrast to France, nineteenth century US artists found themselves dependent upon a market for their livelihood, or at best on insufficiently appreciative patrons (Morgan 1978, p. 71). For many US politicians, however, far from being the touchstone, France was an anti-model. Not only was an official culture incompatible with the distrust of the state that pervaded US political thought (Kammen 2000), but the arts were thought of as a private pleasure in whose support the state had no right to disburse public monies (Meyer 1979).

(b) It is not surprising that cultural subsidies are a relatively new development in the USA. Prior to the Great Depression of the 1930s, it had been confined, as in other nations, to visual and aural forms of relatively routine expressions of national sovereignty: designs for currency, the official seal, military uniforms, postage stamps, architecture of government buildings and monuments, and musical compositions for military bands and a national anthem. For the most part, designs were made by civil servants in the course of their duties or, later, by commissions to artists or architects as needed. The spurt of activity generated by New Deal art programs was unprecedented. Not surprisingly, they were justified not so much on the ideal of artistic creation, but on the practical ground of generating jobs for unemployed artists.

(c) With a preference for fairly popular styles to appeal to an unsophisticated public, most New Deal artists, composers, and writers worked largely in the most recognizable fine art forms: painting (Marling 1982), and background music for documentary films. In addition, writers were commissioned to produce regional guide books, in part to enhance the appeal of distant or isolated US regions for prospective tourists. The New Deal supported scholars and serious amateurs, who collected and recorded music in rural areas among agricultural people, fishermen, small town churchgoers, and prisoners in chain gangs. Beside research in outlying areas, the New Deal employed musicians and artists to teach in schools and settlement houses, as well as adapting some art forms to therapeutic ends (McDonald 1969). The preservation of folk music, arts, and crafts echoed the search for authenticity by artists, writers, and musicians. Perhaps inadvertently, by preserving folk music, the federal government helped nurture one of the classic genres that later came to be incorporated into the domain of outsider art.

(d) Recognizing the connections between certain art forms and the groups which are their source, the Natiojnal Endowment for the Arts (NEA) seeks out originality in the relatively uncontroversial domain suitable to school curricula: 'folk arts, storytelling, and historic preservation' (NEA 1999). Since it is the principal federal agency charged with providing support for the arts, its artistic selections are likely to lend high visibility and legitimacy to the creative activities it embraces. Its budget, originally handled on a national level, is now partially allocated among state and local arts agencies in all 50 states and possessions, for grass roots groups, and especially for educational projects.

4. Artistic Genres Multiplied: Boundary Blurring

4.1 Cultural Contradictions or Expansion of Civil Society?

(a) As important as official government agencies may be in recognizing new art forms, public policy alone does not account for the rise of outsider art. It is only one ingredient among others, of which the most important are art market initiatives. Although therapists played a vital part in recognizing the creations of their patients, the discovery of outsider art hinged on collectors, dealers, and scholars in the context of an expanding art world. These developments were vital to broadening the domain of the arts more generally, including the entry of new collectors. This is indicated by the growth of interest among African–American collectors in African tribal art as well as in works by African–American artists (Halle 1993). The exclusionary definition of art proposed by some of the most influential philosophical estheticians and buttressed by the academic system has ceded to one more sensitive to nuance, process, and inclusivism: not high vs. low but high and low; not insider vs. outsider but insider and outsider; not art vs. politics but art and politics. These boundary blurring innovations are seen by some as a danger, indications that much of the Western world has entered a period of 'cultural declassification—an unraveling and weakening of ritual classifications.' The discomfort that this may create is expressed by the sociologist Daniel Bell, who regrets this symptom of the decline of the fine arts into no more than the impermanence of fashion. He takes it as a sign of an esthetic malaise because of a 'disjuncture of culture and social structure' (Bell 1996). Other sociologists, such as Paul DiMaggio, see declassification from a more dispassionate standpoint, as a predictable result of the intimate relation between them. DiMaggio attributes it to a combination of factors, among which the most salient are the transformation of local upper classes into a US elite, anchored in organizations and less in community; an increase in the influence of commercial principles of classification as popular culture industries expand; the emergence of relatively autonomous and competitive high culture art worlds; the growth of mass higher education; and changes in the US state (DiMaggio 1987, p. 452).

(b) While an air of elitism still clings to the arts, both artists and the public they seek have expanded to the point where earlier conceptions of exclusivity seem to many to be in need of revision. To some degree, this was driven by the new challenge of the 1960s when abstractionism was confronted by Postmodernism. In Andreas Huyssen's analysis, Postmodernism challenged the *avant garde* autonomous fine art sphere, which had preserved traditional strictures of uniqueness and originality from the illegitimate importations of technology. In challenging this position, certain artists launched a revolution that brought the techniques of mass media into the domain of the fine arts. No longer would the quasi-sacred realm of fine art be clearly distinguished from that of commerce. Instead, it came to include everyday consumer goods, on the same level as the aura-laden fine art to which Walter Benjamin had directed his attention (Benjamin 1969). In the process, they blurred the line—the Great Divide—between fine art and commercial art (Huyssen 1986, Cherbo 1997). Moreover, makers of prints, color lithographs, and photographs that reproduce unlimited numbers of copies were not content to be mere adjuncts for reproducing already acknowledged works of art. Instead, they claim these media of design and advertising are themselves Art. Upholders of the older, exclusive *avant garde* ideals became the chief detractors of Postmodernism. Their efforts were largely in vain: the day of clearcut boundaries between fine and other art forms had passed.

(c) Postmodernism has another side that is closely connected to the make up of societal membership. Although the situation varies considerably from one nation to another, in many the exclusion from the esthetic core of certain art forms on the basis of their creators' categorical memberships—based on gender, race, class, status, or socially defined handicaps—have gained attention of policy makers and scholars. Since art worlds are embedded in, and encompass a part of, the social fabric, it is not surprising that the tensions and demands of under-represented groups and their art works are revealed in them. These forms of the Postmodern turn have implications for all the arts, but outsider art may be the most salient because it reveals the multitude of domains in which different forms of artistic excellence are recognized.

4.2 The Triumph of the Transitory

(a) The dynamic of modernism was centered on the very dismantling of a guiding canon, the blurring of the boundary between a governing center; and recurring waves of outsiders struggling to become insiders. In the 'tradition of the new' art could be intended or unintended, made by either professionals or nonprofessionals (Rosenberg 1964). Unexpectedly, however, vanguard innovations beginning in the last decade of the nineteenth century, for better or worse, did so much violence to the renaissance and enlightenment heritage underlying the cultural structure of the arts, that it was altogether reasonable to characterize their effect as constituting 'the shock of the new' (Hughes 1981). Startling as it was at the time, that shock did not in itself immediately destroy the consensus surrounding the fine arts. A century later, however, the visual and aural revolution heralded at its outset has thrown into question the very idea of a high aesthetic realm. The range and density of artistic

change have reached their apogee in the form of a permanent revolution.

(b) The existence of outsider art implies an insider art, one in which a canon serves as a focus around which artistic products and their makers are evaluated. But it is difficult today to identify a canon that governs art as opposed to non-art. Without an autonomous domain of fine art based on a consensus of aesthetic standards and criteria, in a world in which anything can potentially be art, it is to be expected that outsider art is not more likely to be excluded than a potentially infinite variety of other genres. This does not imply that artistic recognition no longer exists, but that recognition and legitimation are no longer identifiably situated in a single institution such as an academy. Rather, they inhabit a domain composed of a plurality of gatekeepers—organizations, influential individuals, publications, media, popular and commercial or elite and scholarly, each of which may be local, national, or international in reach. Insider–outsider distinctions have become multidimensional; they are matters of degree rather than of kind. Recognition may be founded on the fame and glamour of stardom, commercial success based on sales, critical or scholarly appreciation, depending upon the trajectory of creation and reception.

(c) No longer hemmed in by a single canon governing fine art, competing groups promote forms or styles that they identify as their own. Shifting power centers support claims to validity to a wide range of outsider activities and mentalities (Huyssen 1986, p. 218). In the process, the European autonomous sphere of fine art has come to exist as one cultural structure among several. The artistic tradition in which both integrated professional artists and mavericks furthered their own creativity and success (Becker 1982) has also enabled the arts to become available for other purposes: for therapists using art, music, or theatrical performance for prisoners, the elderly, the ill, to improve their sense of self worth or to reinforce a sense of ethnic identity (Zolberg and Cherbo 1997). However, this does not exclude the probability from an administrative perspective that the arts may be a means of social control in custodial institutions. What is clear is that the dynamic of insiders and outsiders extends beyond the bounded art world of objects that may be bought and sold, that gain or lose value. The conjunction of government programs with agendas not specifically intended to construct this genre, and commercial forces that capitalize on the spending power of an enlarged clientele with empathy for authenticity and spontaneity, have played a role in creating this genre.

V. L. Zolberg

Cultural Property and Ancestral Remains, Repatriation of

Repatriation refers to the return of objects of cultural heritage to the living descendants of their creators. This seemingly simple concept is made enormously complex by the emotional, legal, and political environment in which claims for repatriation take place.

1. *Heritage of the Group or of Humanity?*

This environment is conditioned by the historical interplay of two basic human desires: (a) the urge of individuals to give meaning to their lives through their sense of belonging to a special group; and (b) the fascination that human beings have for the ancient and the exotic, the beautiful and the bizarre, and the unknown and the faraway.

People declare their group identity through physical objects that symbolize the special relationships they share. Ultimately, these objects take on an almost mythical significance with the possession and curation of them considered essential to the physical well being and the spiritual continuity of the group. Throughout history, conquerors in recognition of the importance of such objects have mutilated or destroyed them and confiscated them as lasting reminders of conquest and subjugation.

Thousands of objects have been removed from their homelands as souvenirs. Explorers and travelers have filled the museums of Europe and America. A global tourist industry has enabled people everywhere to participate in a culture of humanity-at-large, a shared world heritage. Western European countries, inspired by the art and literature of the classical world, helped both to create and to disseminate this composite heritage of humanity. Objects from the ancient Mediterranean region now grace the halls of museums worldwide.

These influences created an appreciation of other cultures and sometimes a better understanding of them. Unfortunately, what is seen by Europeans and Americans as appreciation and understanding is often interpreted as domination, exploitation, and appropriation by many indigenous people and former colonial subjects. However, these two versions of heritage are not antithetical. One may appreciate the cumulative global human achievement and at the same time participate fully in one's chosen group.

2. *Setting the Stage for Repatriation*

The exploration that introduced exotic people and their cultural property to Europeans spawned a period of economic expansion, imperial conquest, and colonial exploration. European explorers and conquerors brought home strange and beautiful objects from all over the world. Among these objects were often the very physical symbols that maintained the social, political, and spiritual identity of the subjugated. Objects were acquired as the booty of war, legitimate diplomatic and personal gifts, honorable and forced purchase, and outright thefts. Many were the motives for transferring objects of cultural heritage from their homelands to the museums and private collections of the conquering nations: aesthetic desire, religious fervor, military vengeance, international competition, commercial greed, imperial arrogance, cultural ig-

norance, and racial intolerance (Greenfield 1996, Messenger 1999).

During the last half of the twentieth century, the demand for antiquities increased dramatically. The clandestine looting of protected archaeological sites, the widespread theft of antiquities, and the illicit trade in cultural property aroused the conscience of officials and politicians, as well as the anger of indigenous people, archaeologists, and private citizens. Efforts to control this looting of world cultural heritage resulted in the 1970 UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export, and Transfer of Ownership of Cultural Property. Several major art-importing countries, for example, the UK, are not yet signatories to it.

The twentieth century also saw the breakup of the colonial empires and the emergence of new nations eager to recover the physical symbols of their cultural identity. Tribal groups with long memories and functioning cultures began to seek the return of their cultural property. Those politically conscious groups that had already lost their cultural heritage attempted to recreate it through repatriation.

Tourism became a critical component of world economy and tribes and nations alike wanted to have their cultural symbols available for tourists to see. The great European and American museums that displayed the shared global heritage were reluctant to disperse their collections through repatriation. Some of the objects involved, such as the Elgin or Parthenon Marbles in the British Museum and the Venus de Milo in the Louvre, had become 'national treasures' of great importance to the heritage of their new homelands.

3. *International Repatriation*

The return of cultural property at the international level has been carried out for a long time. After Alexander the Great conquered the Persians in 331 BC, he forced them to return the Tyrannicides sculptures they had removed when they defeated Athens in 480 BC. The idea that cultural property was not the booty of conquest was present in European treaties of the twentieth century. It was established in international law when France was required in 1815 to return the art taken by Napoleon. The laws of different countries are often contradictory, making the resolution of claims complex and difficult, but the main problems are not so much legal as moral. Who owns the past? Who curates the cultural property? Who controls the cultural heritage?

Despite these problems, many repatriations have been carried out internationally, especially since World War II. At least a dozen countries have returned cultural property to more than 30 nations, from the Icelandic literary treasures returned to Iceland by Denmark, to the human skeletons turned over to the Australian Aborigines by the University of Edinburgh, and the Lydian Hoard sent back to Turkey by the Metropolitan Museum of Art. However, other international claims continue to be controversial and unresolved, the most celebrated of which is the Greek effort to retrieve the Parthenon Marbles from the British Museum (Greenfield 1996, pp. 42–90).

4. *Domestic Repatriation*

Although restitution of cultural property at the international level attracts a great deal of attention, the most important developments in repatriation have taken place in domestic or internal national contexts. Beginning in the 1960s, indigenous people in the USA, Canada, and Australia documented losses of cultural heritage and made claims for the return not only of their cultural property but also of the bones of their ancestors. They made these claims using the legal and political processes available to citizens in their countries.

In the USA, the creative tension between the national culture and minority groups is not unlike that between the heritage of all humanity and that of ethnic groups. Just as in the global situation, special groups of American citizens take part in the national culture without giving up their cultural identity. American Indian activists had two additional advantages. First, after World War II, the USA began to recognize the rights and needs of its minority citizens and to celebrate its cultural diversity. Second, American Indians are not just another minority group. They have a special status as domestic sovereign nations within the American legal system, continuing the British colonial practice of dealing with Indian tribes on a government-to-government basis. Building on this special status, Indian leaders in the Native American Rights Fund and the National Congress of American Indians insisted that Indian citizens had a right to the control of their cultural heritage and that the bones of their ancestors deserved proper and respectful treatment.

During the national debate on these issues, many tribal groups provided examples of past mistreatment and injustices, the loss of cultural property through warfare, theft, and deceit, and especially the indignities caused by the storage of the bones of their ancestors in museums. In general, the members of the public, increasingly aware of the many injustices suffered by Indian people, especially during the westward expansion of the nation, supported their claims. In 1990, the Congress, influenced by this public support, passed the Native American Graves Protection and Repatriation Act (NAGPRA).

A complex and comprehensive piece of legislation, NAGPRA requires that museums receiving federal assistance inventory their American Indian holdings, report them to appropriate tribes, consult with the tribes, and respond to requests for repatriation of

human remains and associated grave goods, sacred objects, and objects of cultural patrimony. Some museum professionals feared that NAGPRA would cause them to lose all of their Native American materials. Some archaeologists predicted the end of research on American Indian cultures. Biological anthropologists expressed concern that skeletons would be reburied without scientific analysis. This concern is a continuing problem because lineal descent is often difficult to demonstrate and cultural affiliation for remains from remote time periods cannot be assumed solely on the basis of geography. In practice, the requirement that museums and Indian tribes consult with one another has been a powerful mechanism for building positive relationships. The consultations have led to highly productive new working arrangements characterized by considerable good will and cooperation. In sum, although there are still some issues to be resolved, NAGPRA is working reasonably well, as are comparable laws in other countries (Bray and Killion 1994, Mihesuah 2000, Swidler et al. 1997).

5. *Basic Principles*

The various historical, political, legal, and emotional contexts in which the removal and redistribution of cultural property have taken place make each case unique. Case by case analysis is necessary to establish ownership, the method of acquisition, the nature of the cultural property, and the significance of it to the claimants.

Concepts of property differ from one culture or country to another. However, answering the ownership question is often difficult, especially in international situations, because of the secrecy surrounding transactions, the lack of regulation of the art marketplace, and the questionable practices frequently employed. Purchase of an object 'in good faith' from a 'rightful owner' is meaningless unless the place of origin, the means of acquisition, and the subsequent history of the object are known. Fraudulent documentation designed to legitimize stolen and smuggled objects, not only clouds the ownership but also compounds the ethical issues (Messenger 1999).

NAGPRA has been successful because it eliminates problems of acquisition and ownership. The NAGPRA focus is on the nature of the object and its significance to the claimant. If an object fits the statutory definition, is culturally identified with the claimant group, and is significant to that group, it is eligible for repatriation. The question is not the legality of current ownership, but the appropriateness of the proposed repatriation.

Although there may always be problems of definition, cultural affiliation, legality, and even morality, the basic principles for dealing with repatriation claims are clear. Experience shows that these principles work reasonably well, especially when applied in a climate of good will and mutual trust and respect. The USA has facilitated the international return of cultural property through innovative use of its criminal law and has transformed domestic repatriation by creating a new legal framework that allows its American Indian citizens to reclaim with dignity the cultural and spiritual traditions of their heritage.

The right of a people to possess their symbolic cultural property and to control their cultural heritage underlies the very concept of repatriation. Repatriation is neither an effort to go back to the past nor an attempt to redress past injustices. Rather, it is an opportunity to start again in a new relationship based on mutual trust and respect. Such relationships are now the norm in the southwestern USA, where American Indians, anthropologists, and curators have been in close contact for more than 100 years. They have discovered how to talk and listen to one another, how to disagree and compromise, and how to learn from one another. Out of this experience has come the kind of trust and respect that has made possible meaningful consultations, ethical decisions, and successful repatriations.

Cultural Psychology

1. *Cultural Psychology: What Is It?*

A major aim of the discipline called cultural psychology is to document variations in modes of (and ideals for) 'normal' psychological functioning across ethnic communities. One assumption of the discipline—the premise of non-uniformity—is that there is a substantial portion of the psychological nature of human beings that is neither homogeneous nor fixed across time and space. Cultural psychology seeks to document the protean cultural aspects of human

psychological nature. The discipline can be defined as the study of the distinctive mentalities of particular peoples (Balinese Hindus, Satmar Hasidim, Chinese Mandarins) (see Boesch 1991, Geertz 1973, Greenfield and Cocking 1994, Markus et al. 1996, Miller 1997, Shweder 1991, Shweder and LeVine 1984, Shweder et al. 1998).

Cultural psychology can thus be distinguished from the study of general psychology, which is the study of mental structures and processes that are so widely distributed as to characterize the normal psychological functioning of all human beings (or perhaps even non-human primates as well). Research in cultural psychology has, for example, systematically corroborated the special status accorded to the defense of female 'honor' in the mentality of many Southern American white males (Nisbett and Cohen 1995). Research in cultural psychology has authenticated the claim that there is a positive sense of empowerment and a feeling of virtue associated with 'modesty' and the attitude of 'respectful restraint' in the psychology of women in some regions of the contemporary non-Western world (Menon and Shweder 1998). Such feelings of power and goodness associated with 'modesty' contrast with ideas about (and ideals for) psychological functioning constructed in the contemporary Anglo-American cultural region. Research findings in cultural psychology thus raise provocative questions about the integrity and value of alternative forms of subjectivity across cultural groups.

A second assumption of cultural psychology is that many mental states (and some mental processes) are best understood as by-products of the never-ending attempt of particular groups of people to understand themselves and to make manifest their self-understandings through social practices (Bruner 1990, Geertz 1973, Wierzbicka 1993, 1999). That might be called the premise of self-reflexive social construction. Whether one studies Inuit Eskimos or Anglo-American middle-class urban liberals, the aim in cultural psychology is to spell out the implicit meanings (the goals, values, and pictures of the world) that give shape to psychological processes (Briggs 1970, White and Kirkpatrick 1985). The aim is to examine the patchy or uneven distribution of those meanings on a global scale and to investigate the manner of their social acquisition, for example by means of participation in the symbolic practices, including linguistic practices, of this or that tradition-sensitive cultural group.

2. *The Mental States of 'Others'*

One of the several aims of cultural psychology is to develop a language for the comparative study of mental states that makes it possible to understand and appreciate the mental life of 'others.' 'Others' refers to members of some different cultural community who by virtue of life-long membership in that group ascribe meaning to their lives in the light of wants, feelings, values, and beliefs that are not necessarily the same as one's own.

Cultural psychologists are interested, for example, in cultural variations in the degree to which feelings are constructed as 'emotions.' Anna Wierzbicka (1999) has suggested that while all normal human beings have 'feelings' (e.g., pleasure and pain, arousal and serenity) many of the 'emotions' lexicalized in the English language are not universally available in the mental life of people around the world. There has been much research in cultural psychology into the character of the particular emotions (Ifaluk 'fago,' American 'happiness') that are salient or important in different types of social worlds (Lutz 1988, Kitayama and Markus 1994, Shweder and Haidt 2000).

Cultural psychologists are interested as well in population-based variations in social cognition, moral judgment, and the sources of personal fulfillment or life-satisfaction in different social groups. For example, they have studied the origin, significance, and place of 'filial piety' and the 'social motivation to achieve' in some East Asian populations (Yang 1997). They have investigated the self-empowering aspects of ascetic denial and other forms of sacrifice among high-caste women in South Asia (Menon 2000). They are concerned to document the divergent meanings and distinctive somatic and affective vicissitudes of such experiences as 'loss' (or 'success,' or of 'not getting the things you want,' etc.) for members of different cultural communities. It is in the pursuit of such research questions that they have discovered replicable cultural differences in reports about the quality of the experience of 'loss' (and 'gain'). In comparison to majority populations in northern Europe or the USA, majority populations in Samoa and China are more likely to react to apparent 'loss' with feelings such as headaches, backaches, and other types of physical pain than with feelings such as sadness or dysphoria (Levy 1973, Kleinman 1986). Cultural psychologists also seek to document differences in modes of thought (e.g., analytic vs. holistic) (Nisbett et al. in press), in self-organization (e.g., interdependent vs. independent) (Markus and Kitayama 1991) and in moral judgment (e.g., reliance on an ethics of autonomy vs. an ethics of community vs. an ethics of divinity) across different types of groups (Shweder et al. 1997).

In most of its research the field of cultural psychology has been pluralistic in its conception of 'normal' psychological functioning and interdisciplinary in its conception of how to go about studying the origin, meaning, and social role of particular mental states on a worldwide scale. The field draws together anthropologists, psychologists, linguists, biologists, and philosophers in its study of the diverse, yet potentially effective, modes of psychological functioning that have been produced, and socially endorsed, in different cultural traditions, and have

made those cultural traditions possible. Indeed, cultural psychology is sometimes described as the study of the way culture and psyche 'make each other up.'

3. The Tenet of Psychic Pluralism

Taken together, the premise of non-uniformity and premise of self-reflexive social construction sum up to a principle that is at the heart of the discipline of cultural psychology. This is the tenet of psychic pluralism, which states that the study of 'normal psychology' is the study of multiple psychologies, and not just the study of a single or uniform fundamental psychology for all peoples of the world. Cultural psychology is thus the study of the way the human 'mind' (understood to consist of an inherently complex, heterogeneous collection of abstract and/or latent schemata) can be transformed, and made functional, in a number of different ways, which are not equally distributed across time or space. Hence the slogan, 'one mind, many mentalities: universalism without the uniformity' (Shweder et al. 1998) which is meant to give expression to goals of a discipline aimed at developing a credible theory of psychological pluralism.

Cultural psychology can also be understood as a project designed to critically assess the limitations and incompleteness of all uniformitarian versions of the idea of psychic unity. Alternatively put, cultural psychology is the study of ethnic and cultural sources of diversity in emotional and somatic functioning, self-organization, moral evaluation, social cognition, and human development. It is the study of population differences in the things people know, think, want, feel, and value, and hence are customarily motivated to do, by virtue of life-long membership in some recognizable group that has a history and a conception of its own destiny. 'To be a member of a group,' the eighteenth-century German romantic philosopher Johann Herder argued, 'is to think and act in a certain way in the light of particular goals, values and pictures of the world; and to think and act so is to belong to a group' (Berlin 1976). Although the field of cultural psychology has many ancestral spirits (Giambattista Vico, Wilhelm Wundt, Wilhelm Dilthey, Edward Sapir, Ruth Benedict) and some very prominent contemporary advocates (Jerome Bruner, Michael Cole, Clifford Geertz, Jacqueline Goodnow, Patricia Greenfield, Shinobu Kitayama, Hazel Markus, Richard Nisbett, Hazel Markus, Anna Wierzbicka), Johann Herder is justly claimed as one of the original cultural psychologists, although he was probably not the first. For an account of the historical development of the field, see Jahoda (1991) and Cole (1996).

4. Culture and the 'Custom Complex'

One of the contributions of cultural psychology is to revive a conception of 'culture' that is both symbolic and behavioral. In the history of twentieth-century anthropological thought, the idea of culture was variously defined, either behaviorally (as patterns of behavior that are learned and passed on from generation to generation) or 'symbolically' (as the categories, beliefs, and doctrines that organize, rationalize, and justify a way of life). In research on the cultural psychology of a particular cultural community, the notion of 'culture' usually refers to community-specific ideas about what is true, good, beautiful, and efficient that are made manifest in behavior. To qualify as 'cultural' those ideas about truth, goodness, beauty, and efficiency must be socially inherited and customary; and they must actually be constitutive of different ways of life, and play a part in the self-understanding (including the self-criticism) of members of the community.

Alternatively stated, the concept of 'culture' as used in cultural psychology refers to what Isaiah Berlin called 'goals, values and pictures of the world' that are made manifest in the speech, laws, and routine practices of some self-monitoring group. These are sometimes also called 'cultural models' (D'Andrade 1995, Shore 1996). Cultural psychologists thus engage in the interpretive, symbolic, or cognitive analysis of behavior. They assume that actions speak louder than words and that 'practices' are a central unit for cultural analysis. Thus, what John Whiting and Irvin Child (1953) once referred to as the 'custom complex' is a natural unit of analysis or starting point for a study in cultural psychology.

Whiting and Child introduced the idea of a 'custom complex' in 1953 but the basic idea was not really taken up and carried forward until the rebirth of cultural psychology in the 1980s and 1990s. According to Whiting and Child, a custom complex 'consists of a customary practice [for example, a family meal, arranged marriage, animal sacrifice, a gender identity ceremony involving circumcision] and of beliefs, values, sanctions, rules, motives and satisfactions associated with it.' There are many labels that have been placed on this type of unit of analysis (a 'custom complex,' a 'life space,' a 'habitus'). Whatever the label, this is the type of unit of analysis that makes it possible to conceptualize cultural psychology as the study of the way culture (ideas about what is true, good, beautiful, and efficient made manifest in practice) and psyche (what people know, think, feel, want, value, and hence choose to do) afford each other realization, and thus 'make each other up.'

5. An Example of a 'Custom Complex': Genital Surgeries in Africa

A rather dramatic but highly illuminating example of a 'custom complex' is the 'circumcision ceremony' or 'genital surgery' that is customary for both boys and girls in many East and West African ethnic groups. In

the countries of Sierra Leone, Mali, the Gambia, Ethiopia, Somalia, the Sudan, and Egypt genital surgeries are culturally endorsed and popular for both males and females, and receive high approval ratings from the vast majority of men and women in the general population. Human rights advocacy groups in Europe and in the USA have criticized the practice. Nevertheless, the most comprehensive and rigorous review of the medical and demographic literature on African genital surgeries suggests that widely publicized claims about the severe and negative consequences of the custom for health, sexuality, and childbirth are quite inaccurate, and deserve to be discounted (Obermeyer 1999). In a recent manuscript on the cultural psychology of male and female circumcision among the Kono people of Sierra Leone, Fuambai Ahmadu, who is both a 'native' and an anthropologist, has written as follows (Ahmadu 2000, p. 301).

> It is difficult for me—considering the number of these ceremonies I have observed, including my own—to accept that what appear to be expressions of joy and ecstatic celebrations of womanhood in actuality disguise hidden experiences of coercion and subjugation. Indeed, I offer that most Kono women who uphold these rituals do so because they *want* to—they relish the supernatural powers of their ritual leaders over against men in society, and they embrace the legitimacy of female authority and, particularly, the authority of their mothers and grandmothers.

Among the various goals, values, and pictures of the world (the cultural psychology) that make this practice meaningful and satisfying for those men and women for whom it is a 'custom complex' are the following:

(a) A culturally shared belief that the body (especially the genitals) of both males and females are sexually ambiguous until modified through surgical intervention. According to this picture of the world the foreskin of a boy is viewed as a feminine element and masculinity is enhanced by its removal. Similarly the clitoris is viewed as an unwelcome vestige of the male organ, and Kono females (for example), as described by Ahmadu, seek to feminize and hence empower themselves by getting rid of what they perceive as a dispensable trace of unwanted male anatomy.

(b) A culturally shared aesthetic standard in terms of which the genitals of both women and men are viewed as ugly, misshapen and unappealing if left in their 'natural' state. For many African men and women the ideal of beauty is associated with a sexual anatomy that is smooth, cleansed and cleaned (shaved) and free of all 'fleshy encumbrances.'

There is of course much more to be said about the beliefs, values, sanctions, rules, motives, and satisfactions associated with female (and male) genital surgeries in Africa. Nevertheless, in the light of these and other culturally endorsed reasons a genital surgery is experienced as an improvement of the body in many East and West African ethnic groups (Ahmadu 2000).

The cultural psychology of the culturally endorsed practices of any particular community is likely to result in a depiction of 'other minds' that is unsettling, astonishing, or at least surprising for those whose goals, values, and pictures of the world are characteristic of the cultural psychology of some other group. Radical divergence in the moral evaluation of particular 'custom complexes,' such as 'circumcision,' is itself an important topic for research in cultural psychology. Indeed, the cultural psychology of moral evaluation is currently an active research area. Moral concepts (e.g., human rights, justice as equality) privileged in some sections of society and in some regions of the world are not necessarily the moral concepts that are most salient and important in other sectors of society and regions of the world (Shweder et al. 1997).

6. *Cultural Psychology: What It is Not*

The tenet of psychic pluralism and the emphasis on 'goals, values, and pictures of the world' as a source of psychological differences between cultural communities distinguishes cultural psychology from other fields of study (such as 'cross-cultural psychology' and 'national character studies') with which it should not be confused.

6.1 *It is Not Cross-Cultural Psychology*

Research in cultural psychology proceeds on the assumption that psychological diversity is inherent in the human condition, and that culture and psyche are interdependent and 'make each other up.' It should be noted in passing that any theory of psychological pluralism would lack credibility if it staunchly denied the existence of any and all universals. Indeed, as should be obvious, cultural psychology presupposes many psychological universals (e.g., feelings, wants, goals, ideas of good and bad, of cause and effect, of part–whole relationships, etc.). However, the search for and the privileging of things that are uniform across all peoples is a project that goes under other names, for example, general psychology or perhaps even 'cross-cultural psychology.' (See Schweder 2000 for a discussion of cross-cultural psychology, partly recapitulated here.)

Some of the goals of cross-cultural psychology (which I am contrasting with cultural psychology) have been described by Segall et al. (1998). One goal is 'to generate more nearly universal psychology, one that has pan-human validity' and to attain 'a universally applicable psychological theory.' A second closely related goal is to 'keep peeling away at the onion skin of culture so as to reveal the psychic unity of mankind at its core.' It is for that reason that cross-cultural psychology (not to be confused with cultural psychology) can be viewed as a vigilant cousin of

general psychology; for they both share the same uniformitarian goals. Such goals give a distinctive character to cross-cultural psychology, and they help explain why all of the following kinds of activities are typical of research by cross-cultural psychologists and distinguish it from research by cultural psychologists.

Thus one of the aims of cross-cultural psychology is to determine the boundary conditions for generalizations generated in Western laboratories with Western (mostly college student) subjects, generalizations which, prior to critical examination by cross-cultural psychologists, have been presumptively interpreted as fundamental or 'natural' and universalized to the whole world. The aim here for the cross-cultural psychologist is not to represent the distinctive cultural psychology of particular peoples. This aim does not result in research focused on differences in the way members of different communities perceive, categorize, feel, want, choose, evaluate, and communicate that can be traced to differences in salient community-based 'goals, values, and pictures of the world.' Rather the aim for the cross-cultural psychologist is to make sure that the hoped-for universal psychology is truly universal and to throw out any claim that only holds in the Anglo-American world. This is an extremely useful corrective for the tendency of Western psychologists to overgeneralize their findings, but it is not the same as undertaking a project in cultural psychology.

A second aim of cross-cultural psychology is to establish comparability or equivalence for measuring instruments across different populations. Often the goal here is to try to show that people in different cultures really are alike, and that any reported differences in performance were due to noise, or inappropriate measuring instruments, or bad translations, or misunderstandings about the way to ask and answer questions. The instincts of a cultural psychologist run in quite a different direction. For a cultural psychologist (not to be confused with a 'cross-cultural psychologist') the 'noise' is interpreted as a signal about true differences in cultural meanings (goals, values, and pictures of the world), and not as something to eliminate or overcome. Indeed, cultural psychologists are likely to worry if one's measuring instruments travel easily and well from university classroom to university classroom around the world and display the same psychometric properties here and there. They may suspect that one has not really landed in a truly different culture at all. This is because 'peeling away the onion skin of culture so as to reveal the psychic unity of mankind at its core' is not what cultural psychology is about.

A third major aim of cross-cultural psychology is to focus on 'independent variables' of the cultural environment (for example, nucleation of the family, literacy vs. non-literacy) that are thought either to promote or to retard psychological development. In such research 'development' is almost always defined in terms of universal norms for cognitive, emotional, or social functioning (e.g., Piaget's notion of 'formal operational' thinking or Ainsworth's notion of healthy 'attachment'). Cultural psychology is primarily concerned with the elaboration and discovery of alternative or plural norms for successful psychological development, which is another way it can be distinguished from cross-cultural psychology (LeVine 1990).

6.2 *It is Not National Character Studies*

Attempts to characterize whole populations in terms of generalized dispositions (e.g., authoritarianism, Apollonianism, high need for achievement) went out of fashion in psychological anthropology in the late 1950s and early 1960s. This happened for several reasons but largely because looking for variations in types of personality traits to explain differences in cultural practices or custom complexes (and vice versa) turned out to be something of a dead end. It was discovered that if one tries to describe individuals within and across cultural communities in terms of general dispositions or traits of character, then within-group variations typically exceed between-group variations. It was discovered that hypothesized 'modal personality' types typically characterize only about a third of the population in any particular cultural group.

A major insight, although a fragile one, of recent work in cultural psychology is that it is better to represent and interpret human behavior the way sensible economists do rather than the way personality trait theorists do. That is to say, it is better to think about behavior as emanating from 'agency,' and to analyze it as the joint product of 'preferences' (including goals, values, and 'ends' of various sorts) and 'constraints' (including beliefs, information, skills, material and social resources, and 'means' of various sorts). This avoids the hazards of dispositional approaches in which behavior is interpreted as the by-product of mechanical forces pushing both from inside (in the form of 'personality traits') and outside (in the form of 'situational pressures'). Ultimately, a fully successful piece of research in cultural psychology must avoid nominal dispositional categories such as 'holistic vs. analytic' and render behavior intelligible in terms of the particular goals, values, and pictures of the world that motivate and inform the 'domain-specific' behaviors and routine practices of specific intentional agents. To do otherwise is to reify cultural stereotypes and fall into some of the traps of the past.

7. *The Future: Going Indigenous*

The field of cultural psychology that has re-emerged on the North American and European scene during the past 20 years is quite similar to an intellectual

movement that has grown up in the non-Western world and is increasingly known as 'indigenous psychology.' One of the most eminent theoreticians of this movement, Kuo-shu Yang, the Taiwanese psychologist, lists several ways to 'indigenize' psychological research. Here are four of Professor Yang's virtues for the aspiring indigenous psychologist of China (Yang 1997):

(a) 'Give priority to the study of culturally unique psychological and behavioral phenomena or characteristics of the Chinese people.'

(b) 'Investigate both the specific content and the involved process of the phenomenon.'

(c) Make it a rule to begin any research with a thorough immersion into the natural, concrete details of the phenomenon to be studied.

(d) Let research be based upon the Chinese intellectual tradition rather than the Western intellectual tradition.

Those are some of the virtues that define 'cultural psychology' as well, although it remains to be seen how many of us can live up to such demanding standards. Even today with the rebirth and renewal of cultural psychology not all research actually begins with fieldwork or with 'a thorough immersion into the natural concrete details of the phenomenon to be studied.' All too often research still starts with a published finding from some Western laboratory, which is then subjected to critical examination by means of various attempts at replication with populations from other societies. But things are changing. Given the increasingly international and interdisciplinary character of collaborative scholarship in cultural psychology one looks forward to more and more research that keeps faith with Kuo-shu Yang's high ideals.

R. A. Shweder

Cultural Relativism, Anthropology of

Relativism, which may be taken in most general terms as the awareness of the presence and importance of the perspectival in judgement and understanding, is generally understood as a philosophical problem and a hobgoblin of the pretensions to generalization and universalization of thought characteristic of the intellectual classes. But much if not all that has been taken up and intellectualized by these classes was first found among the folk as part of their lore. Anthropologists and folklorists can readily confirm this observation, for in practically any book of proverbs will be found axiomatic observations which are relativistic in import. People are usually aware from their domestic everyday experience of the difference of perspective and the relativity in understanding between men and women, the old and the young, the parent and the child, the slow and the quick. We might observe that it is philosophers and theologians who have lived among absolutes and have worked to impose them, while in 'the practice of everyday life' the common people characteristically live among relatives. Lately, philosophers have been increasingly taking cognizance of that practice and its implicit perspectivalism if not relativism.

In philosophy, to be sure, there has been a long tradition of relativistic thought. The Sophists' cultivation of the contestatory rhetoric of community life and community organization is often taken as relativistic in implication and action, and Hume's (1975) skepticism about general observations including any universal moral principles is surely relativistic in spirit. Kant's view of the constructed nature of the metaphysical and Hegel's historicism are instrumental in the development of the more radical relativisms found in Marx and Nietzsche. Modern-day pragmatism continues this perspectivalism, whether in the works of Foucault (1979), Derrida (1993) or Rorty (1989). These scholars focus, respectively, on knowledge as conditioned by power, knowledge as conditioned by rhetorical or textual construction, and knowledge as conditioned by social solidarity. Such views have steadily and perhaps definitively been undermining overarching claims to metaphysical universals. It has certainly given rise, in respect to moral philosophy, to a 'rational relativism.'

Anthropology, a discipline mainly emergent since the mid-nineteenth century, has not been immune to these philosophical developments and the crisis of representation and legitimation they usher in. Indeed, it has become, through its various arguments for cultural and linguistic autochthony, a central player in the relativism/universalism wars. The interest of anthropologists, particularly in the issue of cultural relativism, derives first from ethnographic field experience of the variable proverbial wisdom of local life lived on the ground, as it were, or from the fact that anthropologists usually work comparatively across cultures and, therefore, across cultural and language perspectives, or from the long interest in anthropology in the difficult problem of universal human rights. Philosophy, understandably, has reacted by exercising pointed critique of the *incoherence* of anthropological relativism—it is inescapably self-refuting and it undermines its own truth claims—and the *perniciousness* of anthropological relativism—it undermines philosophical commitment to the improvement of thought.

The anthropology of Franz Boas is generally seen as the fountain head of cultural relativism in American anthropology. Although originally a physicist, Boas was increasingly cautious both about universalization of things human and the hierarchization of human groups which often accompanied such practice. His chief intellectual opponent was classic evolutionism, with its invidious ranking of societies on a scale from savagery to civilization. His chief popular opponent was racism, or in its benign form, the Civilizing Mission. Indeed one of Boas' few popular books, in an otherwise vast oeuvre—*The Mind of Primitive Man* (Boas 1938)—attacked 'racial determinism,' that is,

the association between biology and 'personality' (by which he meant behavior in the broadest sense). He did this by focusing on the shaping force of culture upon behavior and understanding (that is, upon 'mind'). In this book, therefore, itself preceded by any number of lectures and papers dating from the late-nineteenth century, Boas early laid the ground work for the 'cultural relativism' of his students, although this was not a term he employed to any extent.

There are several other classic stimuli to relativistic views in the Boas oeuvre. In 'The study of geography' (Boas 1887), while resisting geographical determinism, he stimulated thinking on methodological relativism by pointing to two different and justifiable approaches to field data, the nomothetic or law-seeking and the idiographic or descriptive, each of which, differently attuned to local circumstance, gave different yet necessary understandings of the field data. It may be said, particularly in postmodern times, that although increasingly convinced by the 'structuring power of tradition,' Boas in his emerging relativism never abandoned entirely the universalist hope of the scientific mission and method and the seeking, however cautiously, of lawful generalizations.

Cultural relativism in its strong form is identified with two of Boas' foremost students, Ruth Benedict and Melville J. Herskovits. In her widely read *Patterns of Culture*, Benedict (1934) took particular aim at universalist notions of the normal and abnormal. This argument was made effective through its arresting portraits of three cultures, Pueblo, Dobu, and Northwest Coast Indians, whose characteristic behaviors, abnormal from a Western perspective, are portrayed as normal from the local perspective.

Benedict repeatedly resisted ethnocentric and provincial views of the normal and argued a 'Great Arc of human possibility' (Benedict 1934, p. 34) of which no culture could take full advantage and on which every culture had to make its particular choices. It was Melville Herskovits, however, who most directly framed the issue of 'cultural relativism' in his general text *Man and His Works* (Herskovits 1948), and whose collected arguments could be posthumously published as *Cultural Relativism* (Herskovits 1972).

None of the Boasians, including Herskovits, were out and out relativists in the epistemological sense that they gave up on the possibilities of discovering universals beyond the fact of cultural relativity. In all their writings there appears the promise of those eventual discoveries. They are all to be considered, rather, methodological and moral relativists whose main aim was to resist ignorance of and moral superiority towards other cultures, and exploitative intolerance of them. The aim was to increase mutual respect and tolerance in the world. Herskovits argued, however, that such cultural relativism was not derived from any kind of moral philosophy, but rather from the empirical anthropological observations on diversity by field-working anthropologists. Nevertheless, he struggled with many dilemmas of philosophical type in his 'cultural relativism': negotiating the universal and the particular, the practical and the ethical, the 'is' and the 'ought,' anthropological science and anthropological humanism, the cross-cultural and the within-cultural view, the applied and the philosophical. His strategy was to convert these dilemmas, which arise from the fate of the field-working man or woman of science finding himself or herself inescapably situated in the fold of philosophy, into the revelatory paradoxes of anthropological practice (Fernandez 1990).

The heyday of 'cultural relativism' in the USA—in the sense of seeking to define a durable doctrine in the face of persistent assault from various moral philosophies on the one hand and philosophies of science on the other—were the decades of the mid-twentieth century, the 1930s through the 1960s. Subsequently, however, some notable contributions to this enduring issue have come forth together with a contemporary challenge to relativistic thought: the human rights movement. Marshall Sahlins (1976), although not espousing 'cultural relativism' in its paradoxical sense of moral obligation to defend diverse local moral orders, nevertheless conducted a compelling argument against the culture-free universalization, mainly among economists and political economists, which accepts utility interests as the dominant principle in practical reasoning. In the 1980s, a notable argument developed over relativism and the role of culture in determining reality principally among three anthropologists: Renato Rosaldo, Clifford Geertz and Melville Spiro.

Rosaldo (1989) addresses the impact on older notions of the stable truths and dispassionate objectivities of classic social analysis made by awareness of both the anthropologist and his or her informants as 'positioned (and repositioned) subjects' recurrently engaged in an ongoing dramatic process of 'relational understanding.' In such a process truth becomes a very moving target only perspectivally to be apprehended, if at all, and in any case best interpreted by narrative analysis firmly set within and not beyond cultural contexts. While not espousing a straight-line cultural relativism, he notes and resists the return of a 'nostalgia' for the authoritative, often imperious, truths of objective social science—a nostalgia often expressed in an attack on a stereotyped notion of relativism.

This strategy of skepticism has also been that of Geertz, the central player in the interpretive approach that puts the play of perspectives at the center of anthropological inquiry. In 1984 he offered an intricate argument, exemplified in the double negative of the title of the article, 'Anti–anti relativism' (Geertz 1984). He takes to task the resurgence of absolutist interests in affirming some metaphysical or, what is the same, very physical, that is to say biological, realities behind the influence of cultural and language differences. This search for 'nature's own vocabulary,' and the security

of objective biological truths on this side of culture, truncates what anthropology is all about, and Geertz questions the kind of 'hearty common sense' that simply ignores the diversity of lifeways plentifully evidenced in the anthropological archive. While written in defense of that broadly rather than narrowly humanizing knowledge of diversity laboriously acquired by anthropology, Geertz neither directly espouses in any direct way the moral commitments present in an earlier 'cultural relativism' nor denies the probability that on the other side of culture there may be some universals to discover.

In defense of the possibility of scientific, which is to say universal, measurability and explanation across cultural boundaries, Spiro (1986) develops a useful contrast between three types of cultural relativism: descriptive (that there are important empirical differences between cultures), normative (that evaluative judgement of the norms expressed in these differences are always relative to cultural contexts and hence not generalizeable) and epistemological (that culture determines what we know and how we know it). Spiro accepts descriptive relativism and the perspectivalism it reflects, and the cautions of field methods it enjoins. He rejects the strong form of normative relativism, which argues against any possibility of cross-cultural judgement of human practices, as well as epistemological relativism in general, which would argue both for ontological incommensurability between cultures and for the irrelevance or perversity of the discovery of biological and psychological commonalities in humankind. It has been the tendency, he argues, in the fin-de-siècle age of textual hermeneutics, to espouse an immoderate form of epistemological relativism; something that the earlier cultural relativists, although committed to descriptive and moderate normative relativism, never did. The consequence is simply to deny the possibilities of an explanatory science of humans anchored in a valid and verifiable logic of discovery, with all the implications for professional authority that such a denial of principled comparative inquiry entails.

In the 1990s, an important area of challenge to cultural relativism arose in the argument for universal human rights. At first glance, cultural relativism would seem to be an impediment to such universalization of a value. Indeed, oppressive states proclaiming state sovereignty over their citizens often claim justification in 'cultural relativism.' This defense begs the question for all concerned of cultural boundaries within states, which is to say the question of the definition of culture and its boundaries in a pluralizing, globalizing world. That the relation between cultural relativism and universal human rights need not be taken as inevitably oppositional is seen in recent efforts on the part of the Human Rights Commission of the American Anthropological Association, to posit a species-wide disposition to create culture and cultural difference, and the corresponding right to such creation and such difference as long as it does not impose on that right in others (American Anthropological Association 1998, Turner 1997). There may remain problems with this enlightenment argument, as theory and practice, but it effectively moves the debate away, as for example does Geertz' argument before it, from a simple and fruitless opposition in which one or another pole of the debate is confined to a demonic reading. Also, it preserves the practical and methodological aspects of cultural relativism as a posture of critical inquiry.

In reviewing this century-long argument over relativism in the social sciences, we may note several principal points. First, there is the tendency for stereotypic views of the opposite argument to emerge, with the consequence that the opponent's views are trivialized and simplified. Second, strong and moderate forms of cultural relativism in its various aspects (descriptive, normative and epistemological) must be distinguished if the argument is to obtain to any clarifying power. Third, the methodological aspect of cultural relativism and its importance, in its descriptive and normative aspect, as a posture of inquiry must be recognized for those, mostly but not exclusively anthropologists, who have chosen to work in other cultures. Fourth, the discussion of cultural relativism is inevitably related to one's definition of culture and particularly cultural boundedness. Fifth, it must be recognized that the logics of inquiry differ significantly between the sciences and the humanities. Hence the discussion of relativism is itself relative to what disciplinary faculty is anchoring and being evoked in the discussion. Sixth, there is a politics of relativism which is inevitably present—the Boasian relativists, for example, were pronouncedly egalitarian, pluralist, and anti-authoritarian in their values. Relativism has been a recurrent irritation, a valuable provocation, and a useful restraint on imperious inquiry in the academy, and has produced over this long period some of the most interesting arguments about just how individual scholars and researchers with different agendas working in different cultures with differing worldviews are to come together and engage in productive and fair-minded inquiry. Without the gadfly of relativism, the horsemen of social science, galloping through their agendas of investigation, might well be more roughshod, less discriminating, less insightful, and less empathetic beings.

Cultural Resource Management (CRM): Conservation of Cultural Heritage

Cultural resource management is the practice of conserving and preserving cultural heritage. Cultural resources include archaeological, historical, architectural, and engineering properties, and associated artifacts and documents. Also included are museums, archives, archaeological parks, shipwrecks, cultural landscapes, religious sites, as well as traditional lifeways and languages. (Knudson 1986, pp. 400–2, King 1998, pp. 5–9). These resources represent the cultural heritage of individual peoples and nations, and collectively, they represent the heritage of the world. Cultural resources reflect finite periods of time, or ephemeral cultural traditions. Once destroyed, they are gone forever. Economic development, looting, international trafficking in stolen artifacts, and natural erosion destroy thousands of cultural resources every year (Cameron 1997). For this reason, the primary management goal is preservation *in situ*.

The term 'cultural resource management' is used mostly in the United States by archaeologists working for federal and state agencies or for private firms contracting with such agencies (Fowler 1982, Green and Doershuk 1998). Heritage management is a similar term used in many parts of the world (McManamon and Hatton 2000). Heritage management and cultural resource management can be used interchangeably.

1. *Value of Cultural Resources*

People value cultural resources for present and future uses (Lipe 1984). They are tangible links to the past allowing people to experience and relate directly to their history, and hold an evocative power sometimes lacking in documentary sources. Heritage properties have symbolic values for nations and ethnic groups because they represent a common history and identity, as well as cultural and spiritual norms. The process of deciding which cultural resources to preserve and monumentalize is therefore frequently contentious and politicized (Tunbridge and Ashworth 1996).

The aesthetic value of cultural resources, especially architectural properties, provides incentive for the reuse of historic buildings long after original uses are no longer economically viable. The preservation of the historic core of nineteenth-century business districts in the United States is a priority because of the perceived aesthetic value of early buildings. The aesthetic appeal of architectural ruins around the world is a primary reason for their continued preservation.

Cultural resources have informational value. Archaeological sites provide the only record of human achievement for much of history. At best, written documents cover events of only the past 5,000 years and only in a few parts of the world. In some parts of North America written records represent a scant 200 years. Government and business records, newspapers, diaries, etc., are fragile and subject to loss due to natural events, deterioration, neglect, and intentional destruction. Also, official records provide information primarily about dominant cultures and leaders. For these reasons the physical evidence in historic and archaeological sites may be the only record of many past human activities, even in relatively recent times, and their destruction results in an immeasurable loss of information.

Cultural resources have economic value resulting primarily from their associative and aesthetic values. People want to visit heritage sites. Tourism is one of the largest industries in the world, and heritage tourism is one of the largest sectors of the industry. For many countries, such as the United Kingdom and Jordan, tourism is a major part of the economy. In the United States, cultural resources support a billion-dollar industry in the State of New Mexico alone.

2. *Legal Protection*

Cultural resources are the tangible links to the cultural heritage of the world. For this reason, UNESCO and the International Council on Monu-

ments and Sites (ICOMOS), a private organization advising UNESCO, have produced charters establishing standards for preservation (US/ICOMOS 1999). Two foundational documents guiding heritage management at the international level are the 1964 Venice Charter adopted by ICOMOS, and the Convention Concerning the Protection of World Cultural and Natural Heritage signed by 158 nations, and adopted by UNESCO in 1970. UNESCO also manages the World Heritage List, which recognizes cultural and natural sites of world significance, and the World Heritage Fund, providing financial assistance for various preservation projects.

Despite international interest in preserving heritage resources, most cultural resource management is conducted under the laws of individual nations or local divisions within nations. Laws have been established to protect cultural resources threatened by economic development projects, urban sprawl, vandals, looters, and neglect. In addition, nations must make a multitude of complex decisions regarding these issues. Governments must determine the ownership of individual artifacts and collections; oversee excavation permits and arrange for the use and care of resulting artifacts and records; mediate controversial issues such as the excavation of graves and human remains; allocate responsibility for funding archaeological excavations or restoration projects in advance of construction projects; and determine the extent of involvement of various interested parties, such as indigenous peoples, in the processes of decision-making. Not all countries of the world have laws and regulations dealing with these issues, and some issues are more important in one country than another. Legal traditions and history invariably affect the law. For example, in Mexico the State asserts ownership of all prehistoric artifacts. United States law reflects strong traditions safeguarding private property. Only artifacts located on federal land are federally owned, and private landowners retain the ownership of materials found on their land.

3. *Management Requirements*

Knowledge is crucial in managing cultural resources. Agencies need to know where the resources are, which are significant, why they are significant and to whom. Plans for their preservation must be developed. If sites are threatened by dams, roads, water systems, or buildings, planning statutes usually require agencies or various units of government to address the impact of such projects. Nongovernmental corporations or organizations are frequently required to assess the effects of their projects on cultural resources or pay to have this work done. Accurate information is also crucial to protecting sites from looting and vandalism. Cultural resource inventories and evaluation studies should be conducted by appropriately trained specialists, such as archaeologists, architectural historians, historians, and anthropologists. Thus, an inventory of significant cultural resources is the primary basis for management decisions.

Many countries have developed criteria to determine which cultural resources are significant, and these criteria vary from country to country. In the United States, properties as young as 50 years old are evaluated, while in Jordan only properties older than AD 1750 need be considered. The range in kind and type of significant properties also varies from place to place. Some countries consider only archaeological and historic properties, while others include sacred and traditional cultural sites, and even contemporary expressions of culture such as festivals and dances. Government agencies usually make decisions concerning significance, but even if a country does not have a formal evaluation procedure, someone must decide which resources are ultimately important and worthy of mitigation or preservation (Thompson 1982).

Once an inventory is obtained, it is necessary to determine which resources are threatened and need immediate consideration. It is a sad fact, but not all sites determined to be culturally significant can be preserved. Developing priorities for action is usually a process of give and take between those with preservation interests and others primarily working toward economic development. When properties can not be preserved, appropriate mitigation measures must be developed. The type of mitigation adopted depends on the type of cultural resource effected. Archaeological sites are usually excavated, or sometimes buried for protection. Architectural and engineering properties are documented through photography, photogrammetry, measured drawings, and the salvage of individual architectural features. When feasible, architectural properties can be moved to new locations. It is difficult to develop satisfactory mitigation measures for the religious or sacred properties often important to traditional communities. Hard decisions have to be made about whether such controversial projects will be completed as planned, or moved to another location.

Cultural resources in national parks and other protected areas may not be threatened by economic development projects, but they still need active management to prevent deterioration. The site of Petra in Jordan is a good example. Petra is famous for massive sandstone architecture and for water-control systems built by the Nabataean Arabs before Roman occupation. These famous architectural elements are continually eroded by wind-driven sand and rain and will disappear if not conserved. Jordanian conservation scientists are actively developing methods to preserve the site. Around the world, even in protected areas, limited financial resources dictate preservation priorities.

Another important element in the management of cultural resources involves the care of archaeological

and museum collections, archives, and documents. Great expense is involved in providing state-of-the-art, climate-controlled, and safe environments for storage, processing, and use of such collections. The conservation of paper, metal, and other perishable artifacts is a science in itself. Heated debates arise around the world about the appropriate distribution of artifacts. Many countries such as Guatemala and Turkey have increasingly strict laws about the transport and use of artifacts, and many European countries with colonial traditions and large archaeological collections from the Middle East and elsewhere are facing various questions of repatriation (Herscher 1998). The establishment and funding of curation facilities are part of this debate, as well as being crucial to the availability of knowledge and resources to future generations.

Traditions concerning historic and prehistoric cultural artifacts and human remains differ widely among the cultures of the world. Such belief systems must increasingly be taken into consideration in the formation of cultural resource management policies, as well as in national and international law. In some countries indigenous peoples have insisted on the repatriation of human remains and associated funerary objects, and other objects of cultural patrimony (Jones and Harris 1998). A satisfactory balance between the interests of the broader society in cultural resources and the needs of individual communities has not yet been reached, and these are among the most controversial issues facing heritage managers today (Suagee 1999). Conflicts are exacerbated in countries with recent histories of social injustice, and otherwise routine decisions are fraught with emotion. Animosities can be allayed as governments take responsibility for the legal protection of various rights and as peoples are forced to deal amicably and respectfully with each other's goals and beliefs. Consultation between government bodies and local communities is essential to the success of preservation efforts.

4. *Tourism and CRM*

The management of archaeological parks, museums, and historic districts for tourism is a significant part of cultural resource management. Tourism offers many opportunities for the preservation and restoration of heritage properties around the world, and because of the economic benefits of tourism, many individual communities and national governments are developing properties for tourists. The correct manner of development (Boniface 1995), the authenticity and quality of interpretative presentation (Bruner 1994), and the type and use of restoration methods are hotly debated issues. The tourist infrastructure, as well as interpretive facilities like trails and museums, can negatively impact on the very cultural resources and landscapes tourists want to visit. The plan to build a gondola to transport tourists to Machu Picchu in Peru is a case in point. In addition, when the interests of local communities are not considered, conflicts can be expected.

5. *Public Support and Education*

The preservation of cultural resources is dependent on the support of the general public. The charters of UNESCO and ICOMOS stress that the success of local and national preservation initiatives are dependent on programs educating the public about the value of cultural resources. Heritage education in the public schools is required in many countries to foster a preservation ethic and pride in national heritage. Governmental organizations and professional societies often cooperate in publicity campaigns to combat looting. In those parts of the world where sites of general interest represents a cultural heritage different from that of the contemporary inhabitants, education about the values and economic uses of these resources is especially important. For example, Roman and Byzantine ruins in modern Islamic countries and Native American sites in the United States are often more valued by foreign visitors and national governments than by local communities.

The varieties of cultural resources in the world and the multiplicity of values attached to them make cultural resource management a complex practice. The preservation of cultural resources in the face of economic development, population growth, looting, and world conflicts requires integrated legal tools and protection policies at all levels of government, as well as trained professionals to implement them.

Cultural Rights and Culture Defense: Cultural Concerns

Although cultural rights are sometimes regarded as the least developed category of human rights, they are unquestionably a part of international human rights law. Cultural rights have been highly controversial because their protection sometimes requires that other human rights be limited. There is substantial debate about the proper interpretation of cultural rights, about which individuals are entitled to invoke them, and about what obligations governments have to enforce these rights.

Cultural rights are significant because culture is an intrinsic part of individual and group identities. Not only does culture exert a crucial influence on the formation of the identity of individuals, but it also helps perpetuate ethnic groups. It is important to appreciate the status of cultural rights in law and politics.

1. The term 'Culture'

In order to interpret cultural rights, it is first necessary to define the term culture. There are many different notions of culture including 'high culture' which refers to museums, operas, and the like, 'popular' or 'mass' culture which means comic books, films, pulp fiction, and 'traditional' culture, which can be construed as a way of life. While some commentators who analyze cultural rights have in mind 'high culture,' most of the discussion focuses on so-called 'traditional culture.' Of the multitude of definitions of culture, a particularly useful one was devised by the Canadian Commission for UNESCO, the United Nations agency responsible for the protection of culture:

> Culture is a dynamic value system of learned elements, with assumptions, conventions, beliefs and rules permitting members of a group to relate to each other and to the world, to communicate and to develop their creative potential (1997).

Culture differs from society inasmuch as culture is an abstraction, whereas society is the collection of individuals in the community.

When culture is analyzed in the context of cultural rights, it is usually used as a synonym for a way of life. Culture encompasses many aspects of life including attire, child rearing practices, diet, marriage customs, politics, religion, death rituals, and so on. In short, culture is constituted of the many and diverse folkways of ethnic groups. One attempt to delineate the many facets of culture is found in the Human Relations Area Files compiled at Yale University. Although some contend that projects which aim at documenting cultural practices risk 'freezing' them in a particular moment in time, cultural theorists invariably acknowledge that cultures are dynamic systems.

2. Cultural Rights

A major question has been whether cultural rights should be conceptualized as individual rights or group rights. Theorists, many of whom come from individual rights traditions, associate group rights with utilitarianism and worry that recognizing group rights may lead to the denial of individual rights. In reality, however, rights which have historically been considered bona fide individual rights such as religious freedom require the existence of a group. While this issue has generated much debate, there is no reason why the right to culture cannot be conceived of both as an individual and as a group right. Insofar as cultural rights include rights to language and religion, it would be difficult to deny the essential group nature of such rights. Moreover, even if the right to culture were an individual right, it could still come into conflict with other individual rights.

Ordinarily, individuals and peoples exist in cultures without having to think self-consciously about the protection of their traditions, most of which are not controversial. It is only when their way of life is threatened by a dominant political system that ethnic minorities are compelled to assert a 'right to' culture.

In this sense cultural rights represent a legal means by which minorities can shield themselves from intervention by the dominant political apparatus, which is normally the state. Governmental intrusion is a manifestation of cultural hegemony, or the imposition of the dominant culture by elites on ethnic minority groups.

Intervention by governments is not an infrequent occurrence as there is a widespread presumption that cultural minorities should become assimilated. When the folkways of a minority group clash with the standards of the dominant system, the expectation is that the members of the minority group should discard their customs. This is sometimes expressed in the form of a proverb: 'When in Rome, do as the Romans do.' However, shedding their folkways may not be a simple matter as individuals are often strongly motivated to follow their cultural traditions. Sometimes they may face a dilemma as failure to comply with the folk law can lead to divine retribution or social ostracism. These individuals either violate the state law and face the consequences in the official legal system or else comply with state law and face dire consequences within their customary law systems.

3. *The Cultural Defense*

If individuals do, in fact, have cultural rights, this implies that there is a duty on the part of governments to allow their cultural practices. This obligation is not an absolute one, though, and cultural rights will be allowed unless a more important, countervailing reason requires that they not be protected. The challenge, naturally, is to distinguish which are valid reasons for overriding traditions and which are not.

Most of the time governments decide that cultural traditions are not permissible because they threaten public health, safety, or morals. If individuals refuse to discontinue the practices, asserting that they have a right to follow their traditions, they may face criminal prosecution. In these circumstances, ethnic minority defendants may invoke what has been called the 'cultural defense.' Such a defense, while not formally recognized by any legal system, sometimes operates to acquit or to mitigate punishment. The core idea behind the defense is that individuals who act under cultural imperatives should be considered less culpable under the law than those who act in the absence of such an imperative. In order for judges to evaluate the extent to which a defendant's cultural background affected his or her behavior, they must consider cultural evidence relating to the offense. The chief difficulty in many cases is the tendency of courts to exclude cultural evidence as irrelevant.

Supporters of the cultural defense favor its adoption in order to ensure the consideration of evidence and to demonstrate genuine commitment to cultural pluralism. The cultural defense would also guarantee more equal treatment for cultural minorities in a legal system whose standards are based on the values of the dominant culture. Advocates contend that the cultural defense would result in condign punishment for ethnic minorities.

Opponents worry that if culturally motivated offenses go unpunished, this will undermine the deterrent function of the law. They often contend that anarchy will reign supreme if each individual can decide with which particular laws he or she will comply. The defense is criticized for giving special rights to minorities. This puts the victims of culturally motivated crimes at a disadvantage, and is therefore unjust.

The presentation of cultural evidence does not commit the court to accepting the argument. The evidence might not establish the existence of the tradition, that the ethnic group had this tradition, or that the defendant was influenced by the tradition when violating the law. The defense merely ensures that the information is treated as admissible in court. To the extent that cultural rights are guaranteed as part of human rights, the argument is that individuals should be entitled, at the very least, to present evidence about their cultural background in a court of law.

4. *Scholarship on Cultural Rights*

The early scholarship on cultural rights was sponsored by UNESCO through symposia designed to clarify the meaning of culture and cultural rights. In 1950 UNESCO published *Freedom and Culture* which was its first attempt to develop the idea of cultural rights. In 1970 UNESCO sponsored a meeting of experts on cultural rights in Paris to discuss the government responsibilities for sacred places, monuments of cultural significance, and language preservation programs. As a great deal of emphasis was placed on cultural property, the meeting dealt with the relationship between individuals and cultural objects.

The Interdisciplinary Institute of Ethics and Human Right at the University of Fribourg, Switzerland held a colloquium on cultural rights in 1991. The Council of Europe held the Eighth International Colloquy on the European Convention on Human Rights in Budapest in 1995 on the theme 'Cultural rights: universal, individual, and legally enforceable individual rights.' In 1998 the International Conference on Cultural Policies of Development met in Stockholm, Sweden to evaluate governmental programs designed to ensure that individuals in all communities can exercise the rights guaranteed by Article 27.

In academic circles two parallel scholarly literatures emerged on the subject of cultural rights, one in political theory, and the other in international law. Political theorists in the Western tradition analyzed the question of whether cultural rights are compatible with liberalism. For the most part political philosophers worry that the acceptance of cultural rights will lead to 'balkanization,' thereby undermining the unity

of the state. The leading proponent of the view that cultural rights can be reconciled with liberalism is Will Kymlicka, a Canadian scholar. His writings underscore the importance that belonging to a community represents to most individuals.

Despite the fact that his work is generally considered to offer the staunchest support for cultural rights, his defense of cultural rights has been criticized for being too limited. First, Kymlicka advocates the protection of cultural rights only in societies which are said to be structured along liberal lines. His theory does not provide cultural rights for immigrants who have chosen to move and thereby give up their culture; only minorities long residing in a state and indigenous peoples can legitimately make claims to cultural rights. His interpretation of cultural rights concentrates mainly on language rights and representation rights. Critics such as Chandran Kukathas have noted that his theory provides minimal protection for cultural rights.

Other leading theorists such as Bhikhu Parekh have attempted to create theories which afford greater protection to cultural rights. In his elaborate scheme advocating 'a principle of dialogical consensus,' Parekh proposes having a minority spokesman who will engage in a dialog with representatives of the majority about cultural practices which clash with 'operative societal values.' It is the duty of the spokesperson to explain how the tradition is authoritative, central to the way of life of the ethnic minority group, and in general, desirable. If it is not feasible to persuade the majority representatives of the value of the tradition under debate and it offends an 'operative societal value,' the ethnic minority must give it up.

Many feminist theorists reject the proposition that cultural rights deserve legal protection because of their concern that protecting these rights will undermine gender equality. Although their work is often framed as a critique of multiculturalism, e.g., Ayelet Shachar, these analysts are essentially denying the validity of the notion of cultural rights.

Generally speaking, most of the commentary on cultural rights in Western political theory is concerned with ways to limit the scope of application of the rights. When cultures do not imprison those who seek to exit, particularly women wishing to flee from oppressive customs, there appear to be fewer objections to the protection of cultural rights. Their objections do not appear to apply to the numerous traditions which have no connection to gender.

In the field of international law, James Anaya has provided a comprehensive analysis of the cultural rights of indigenous peoples. A more general theoretical treatment is that of the late Sebastian Poulter whose brilliant scholarship is extraordinarily important. In Poulter's view, a cultural tradition which violates human rights should not be permitted. According to Poulter, however, if a government, by prohibiting a tradition, is violating human rights, then that tradition should be permitted. His framework has been criticized for presuming the validity of international human rights standards as a basis for determining the validity of traditions and for evading the question of when cultural rights, which are human rights, are superseded by other rights.

5. *Formal Guarantees in Legal Systems*

Few national legal systems officially guarantee a right to culture. The extent to which cultural rights are protected depends on whether or not general principles of law such as religious freedom, equal protection, and freedom of association are interpreted to encompass cultural traditions. Because lawmakers are elites from the dominant culture, they tend not to construe abstract principles in such as way as to benefit ethnic minorities. One sign of the preference for monoculturalism is the widespread preference for single official language policies in many countries.

From time to time, minorities challenge public policies which they regard as unwarranted intrusions into their way of life. For example, in France the Muslim community objected strenuously to the ban against wearing the *hijab* or headscarf in French public schools. The national controversy was known as *L'Affaire des Foulards*. The policy was justified because it ensured the separation of church and state, the integration of foreigners into French society, and gender equality. Some women's groups in France thought the Muslim religious garb, the scarf, symbolized the subordination of women. Eventually, after litigation, the Education Minister relented, allowing the children to wear their religious attire to school.

In the United States indigenous peoples have challenged development projects which would undermine their way of life. In *Lyng vs. Northwest Territory* 1987, tribes argued that the construction of a highway through Chimney Rock would desecrate sacred sites. As part of an environment impact study, the government hired an expert who advised against building the road because of its devastating effect on the tribes. Despite the admonition, the government proceeded with the project, undeterred. The US Supreme Court ruled that the burden on the religion was incidental, not the purpose of the development, and that religious minorities have to accept some burdens.

Difficulties in domestic litigation generally have to do with the question of what counts as the 'authentic' culture or whether a specific practice is 'traditional.' In order to determine the authenticity of cultural traditions, there is the related issue of who is the legitimate representative of the group. Sometimes, indigenous people find offensive the practice of consulting 'experts' or scholars rather than leaders of their communities. Even when the groups themselves are the source of information, it is not always obvious which

person from within the group speaks for the group. Two examples show the practical difficulties in litigating cultural rights claims.

In France the government made an exception to its animal slaughter law to permit Orthodox Jews to slaughter animals in accordance with religious law so that they could consume the meat. France empowered the Central Rabbinical Committee to handle the implementation of the policy. However, one group of Orthodox Jews, concerned that the method employed for the ritual slaughter of animals was not guaranteeing that the meat was sufficiently pure or *glatt*, sued France, challenging its delegation of authority to the Central Rabbinical Committee. After French courts ruled against the group, it appealed to the European Court of Human Rights, where it lost as well.

The Hindmarsh Bridge Island litigation in Australia also shows the dynamics of intragroup tension. A group of aboriginal women objected to a proposed bridge between the Australian mainland and Hindmarsh Island because they claimed it would jeopardize their way of life. The island was ostensibly used for secret women's business, and their customary law supposedly prevented them from divulging information about the nature of the business. During the litigation another group of aboriginal women held a press conference denying the veracity of this claim, saying there was no such 'secret women's business.'

In contrast to domestic litigation which relies on abstract principles interpreted to apply to culture, in international law explicit protections for culture can be found. Among them are the International Covenant on Economic, Social, and Cultural Rights, particularly Article 15, the Declaration on the Rights of Persons Belonging to National or Ethnic, Religious, and Linguistic Minorities (1992), the Framework Convention for the Protection of National Minorities (1995), and the European Charter for Regional or Minority Languages (1992). In addition, there are related documents such as the Draft Declaration on the Rights of Indigenous Peoples and the Declaration on the Elimination of All Forms of Intolerance and of Discrimination Based on Religion or Belief (1981). Cultural rights are covered not only by human rights treaties, but also by instruments concerned with safeguarding cultural heritage such as Convention Concerning the Protection of the World Cultural and Natural Heritage (1972).

To date, the most important cultural rights provision is Article 27 of the International Covenant on Civil and Political Rights (ICCPR), a treaty ratified by virtually all countries in the world. This provision is not subject to any reservation (except for France's), which enables a government to avoid obligations under the article. Article 27 provides:

> In those states in which ethnic, religious, or linguistic minorities exist, persons belonging to such minorities shall not be denied the right, in community with the other members of their group, to enjoy their own culture, to profess and practice their own religion, or to use their own language.

However, Article 27 cannot serve as a guide to determine the substantive meaning of cultural rights under international law because it has been interpreted in only a few situations. As of 2001, the provision has been applied mainly to protect sacred land, the right to hunt animals, and language rights.

Although it is widely referred to as a 'minority' rights provision, it is often invoked in cases involving indigenous peoples, many of whom do not consider themselves to be minorities, subordinate to a state. Some members of indigenous groups object to its application in their cases. Article 27 has also been criticized for being formulated as an individual right and as a negative right. These criticisms may be unwarranted: first, the provision can be invoked by individuals or groups; second, if communities only need to invoke a juridical right to culture when governments threaten to halt their practices, it makes sense that the provision was expressed in negative terms: 'governments shall not deny … .' Moreover, because there was some question about the nature of government obligations for the protection of cultural rights, the Human Rights Committee, which enforces the ICCPR, issued a policy statement interpreting Article 27, known as General Comment 23(5), stipulating that governments take affirmative steps to enforce cultural rights.

One of the best-known disputes in international law in which cultural rights were invoked was the celebrated Lovelace decision which was based on Article 27 of the ICCPR. Sandra Lovelace was a Maliseet Indian who married outside the tribe, thereby losing her tribal status (if a male Maliseet Indian married someone not belonging to the tribe, he would not lose his status). After her divorce, she was unable to rejoin the band as a fully-fledged member. She sued unsuccessfully in the Canadian courts and subsequently filed a complaint with the Human Rights Committee. Although she challenged the sexist membership rule, alleging that it violated human rights law and the tribe defended itself by invoking the right to self-determination (Article 1 of the ICCPR), the Human Rights Committee decided that she had been denied the right to enjoy her culture in her community. Interestingly, this case stands for the proposition that women also have a right to culture!

In the final analysis, the main challenge in international human rights jurisprudence is how to evaluate the relative importance of cultural rights vis-à-vis other human rights. This is known as the hierarchy problem. There are rights conflicts between treaty regimes, for instance between Article 27 and provisions of the Convention on the Elimination of All Forms of Discrimination Against Women which require governments to abolish all traditions that interfere with gender equality. The UN appointed Mrs

Halima Embarek Warzazi as Special Rapporteur on Traditional Practices Affecting the Health of Women and Children. Her studies recommend the elimination of traditions with adverse consequences for women and children. For the most part, fundamental rights conflicts within the United Nations system have not been resolved to date.

6. Theoretical Issues

Regardless of whether or not domestic and international legal systems afford adequate protection to cultural rights, the right to culture may be important because abstract principles require it. Appeal can be made to many principles to justify the recognition of cultural rights; among these are identity, freedom, and tolerance.

If culture is intrinsically linked to the formation of identity, then any general notion of individual or group rights requires that culture be protected. To the extent that democratic systems are committed to the principle of noninterference by the government, intervention in the absence of a serious threat would be illegitimate. The notion of freedom would appear to compel the acceptance of cultural rights. Finally, the idea of tolerance is widely considered an important one in liberal democracies. Although tolerance has somewhat pejorative connotations, i.e., 'putting up' with practices with which one disagrees, allowing the flourishing of diverse cultural traditions is consonant with this principle.

Even if the right to culture is established as a fundamental right, it remains to be seen how much importance it has vis-à-vis other human rights. The hierarchy question is likely to occupy the attention of scholars interested in the nature and scope of cultural rights.

Cultural Studies: Cultural Concerns

This article attempts to describe that complex contemporary social formation: Cultural Studies (CS). A single thesis organizes the argument. Contemporary CS exists within competing fields of discourse. This discourse, as Carey (1997b) argues, is moving in several directions at the same time (see Frow and Morris 2000, Striphas 1998). This has the effect of simultaneously creating new spaces, new possibilities, and new formations for CS, while closing down others.

Thus, a process of containment is occurring, even as this interdisciplinary field expands globally (*Public Culture* 1988, Frow and Morris 2000, Alasuutari et al. 1998, Hartley 1998). There are those who would marginalize CS, equating it with Marxist thought, and chastising it for not paying adequate homage to Sociology's founding fathers, including Weber and Durkheim (Long 1997). Others would seek a preferred, canonical, but flexible version of the project (see Grossberg 1997a, 1998). Within this framework (see Grossberg 1997a), there are attempts to establish a set of interpretive practices fitted to specific projects. For Grossberg (1997a, pp. 248-261) these practices, or interpretive principles involve a self-reflexive, interdisciplinary project which always detours through theory. This version of CS maintains a commitment to political praxis and radical contextualization, including anti-reductionist, anti-essentialist ontologies. Still others would ironically equate CS with identity politics and critical readings of popular culture. Some would critique the formation from within, distinguishing semiotic, political economy, empiricist, and material approaches to the field's subject matter (Fiske 1994). Still others challenge CS to take up the problems of feminism, gender, racism, colonialism, and nationality (Ferguson and Golding 1997).

1. *The Origins and Definitions of CS*

Ferguson and Golding (1997) observe that 'Few would dispute that CS' 'myths of origin' were made in Britain, and that their 'founding fathers' were Raymond Williams, Richard Hoggart and E. P. Thompson, and subsequently Stuart Hall.' The legacies of these figures is enduring, and includes a commitment to a Marxism without guarantees, a rejection of positivism and functional social theory, and a conception of culture that is political. But on beginnings and origins, Hall (1980) is quite firm, 'there are no absolute beginnings and few unbroken continuities … What is important are the significant breaks.'

The culture in CS is not aesthetic, or literary, it is political, and located in the domain of the popular or the everyday (Storey 1996). The object of study is how culture, as a set of contested interpretive, representational practices, embraces and represents 'a particular way of life, whether of a people, period or a group' (Williams 1976). Popular, everyday cultural practices are treated as social texts. It is understood that nothing stands outside textual representation. Texts, however, involve material practices, structures, flows of power, money, and knowledge. Popular culture is conceptualized as a site of constant negotiation, consent, and resistance. Meaning is always contextual, structural, and anchored in historical processes (Hall 1996b). Cultural processes, in turn, embody class, gender, and racial divisions and relationships. These relationships involve the exercise of power.

1.1 *The Circuits of Culture*

A complex interpretive process shapes the meanings things have for human beings. This process is anchored in the cultural world, in the 'circuit of culture' (du Gay et al. 1997) where meanings are defined by the mass media, including advertising, cinema, and television. This process is based on the articulation or interconnection of several distinct and contingent processes (du Gay et al. 1997). In the circuits of cultural meaning five interconnected processes, representation, identification, production, consumption, and regulation, mutually influence one another (du Gay et al. 1997).

Objects and experiences are represented in terms of salient cultural categories. These categories are connected directly to social and personal identities. These identities are attached to representations of family, race, age, gender, nationality, and social class. These objects and identities are in turn located in an ongoing

political economy. A political economy is a complex, interconnected system. It structures the production, distribution, and consumption of wealth in a society. It determines the Who, What, When, Where, Why, and How of wealth and power in everyday life; that is, who gets what income, at what time, in what places, for what labor, and why?

This economy regulates the production, distribution and consumption of cultural objects. It does so by repeatedly forging links between cultural objects (cars, clothing, food, houses), their material representations, and the personal identities of consumers as gendered human beings (see discussion below). To summarize, an understanding of these five processes leads researchers to examine how cultural objects are represented in the media and in everyday popular culture. Scholars then move from this level of analysis to studies of those social identities that are attached to the cultural object, asking, at the same time, how is this object 'produced and consumed, and what mechanisms regulate its distribution and use' (du Gay et al. 1997). An instance is given in those moments when a cultural fad, a style of dress, or a hairstyle seemingly sweeps across an age or gender group. New and old identities are attached to the use of the object that is produced for consumption by a small number of manufacturers who regulate price and distribution.

2. *The Narrative Turn*

This concern for language and meaning has been called the narrative or discursive turn in CS. This turn implies greater interest in language, discourse, discursive practices, and the argument that meaning is contextual (Hall 1996a). This narrative turn moves in two directions at the same time. First, CS scholars formulate and offer various narrative versions or stories about how the social world operates. This form of narrative is usually called a theory, for example, Freud's theory of psychosexual development. Second, scholars study narratives and systems of discourse, arguing that these structures give coherence and meaning to the world. A system of discourse is a way of representing the world. A complex set of discourses is called a discursive formation (Hall 1996a). The traditional gender belief system in American culture, with its focus on patriarchy and a woman's place in the home, is an instance of a discursive formation. Discursive formations are implemented through discursive practices, for example, patriarchy and the traditional etiquette system.

Systems of discourse both summarize and produce knowledge about the world. These discursive systems are seldom just true or false. In the world of human affairs, truth and facts can be constructed in different ways. Consider this question, 'Are those Palestinians who are fighting to regain a home on the West Bank of Israel freedom fighters or terrorists? (Hall 1996b). The very words that are used to describe these individuals prejudge and evaluate their activity. Freedom fighter or terrorist are not neutral terms. They are embedded in competing discourses. As such they are connected to struggles over power, that is who has the power to determine which term will be used? As Hall notes, 'It is the outcome of this struggle which will define the "truth" of the situation.' Often times it is power 'rather than facts about reality, which makes things "true"' (Hall 1996b).

Power produces knowledge (Foucault 1980). Regimes of truth can be said to operate when discursive systems regulate relations of power and knowledge (Hall 1996b). The traditional gender belief system, which regulates the power relations between men and women in this culture is such a regime. In these ways discursive systems affect lives.

2.1 *Experience and its Representations*

Of course it is not possible to study experience directly, so CS researchers examine representations of experience, interviews, stories, performances, myth, ritual, and drama. These representations, as systems of discourse, are social texts, narrative, discursive constructions. The meanings and forms of experience are always given in narrative representations. These representations are texts that are performed, stories told to others. Bruner (1986) is explicit on this point, representations must 'be performed to be experienced.' In these ways researchers deal with performed texts, rituals, stories told, songs sung, novels read, dramas performed. Paraphrasing Bruner (1986), experience is a performance.

2.2 *Assessing Interpretations*

The politics of representation is basic to the study of experience. How a thing is represented often involves a struggle over power and meaning. While scholars have traditionally privileged experience itself, it is now understood that no life, no experience can be lived outside of some system of representation (Hall 1996c). Indeed, 'there is no escaping from the politics of representation' (Hall 1996c).

This narrative turn suggests that researchers constantly are constructing interpretations about the world, giving shape and meaning to what they describe. Still, all accounts, 'however carefully tested and supported are, in the end "authored"' (Hall 1996a). CS explanations reflect the point of view of the author. They do not carry the guarantee of truth and objectivity.

The narrative turn leads scholars to be much more tentative in terms of the arguments and positions they put forward. It is now understood that there is no final or authorized version of the truth. Still, there are criteria of assessment that should be used. Researchers are 'committed to providing systematic, rigorous, coherent, comprehensive, conceptually clear, well-

evidenced accounts, which make their underlying theoretical structure and value assumptions clear to readers...(still) we cannot deny the ultimately interpretive character of the social science enterprise' (Hall 1996a).

3. Diversity and Constraint

The open-ended nature of the CS project creates a perpetual resistance against attempts to impose a single, umbrella-like paradigm over the entire project. There are multiple CS projects, including: the articulation model of the Birmingham school, and the work of Stuart Hall, Paul Gilroy, Lawrence Grossberg, and their associates (du Gay et al. 1997, Grossberg 1997a, 1997b); Black British CS (Baker et al. 1996); the conjunctural, resistance perspective of Fiske (1994); feminist, ethnographic projects connected to the British and Frankfurt schools; American CS versions located in communication studies (Ferguson and Golding 1997), which work through pragmatism back to the arguments of McLuhan, Innis, Ong, and Dallas Smythe (Carey 1997a, 1997b, Denzin 1995); the African-American, prophetic, postmodern, neopragmatic marxism of West (1992); the empiricist, neofunctional American cultural sociology project which draws on the work of Bourdieu and Parsons (see Schudson 1997); a Chicana/o, Latina/o model that elaborates and then departs from the Birmingham approach (Chabram-Denersesian 1999); a critical, CS pedagogy (McCarthy 1998); Canadian and Australian CS models which focus on policy and public culture and attempt to de-Anglocize the British model (Blundell et al. 1993, Frow and Morris 1993); a Black feminist cultural criticism (Hooks 1990); an American-based, ethnographic, critical CS model centered on a resistance postmodernism; and more recently a transnational CS focused on the critical, ethnographic study of public culture and the flow of cultural forms and cultural representations from one site to another (*Public Culture* 1988).

The generic focus of each version of CS involves an examination of how the history people live is produced by structures that have been handed down from the past. Within these traditions, culture is treated as a verb, a process, and a place, always in motion, where meaning and situated identities connected to race, class, and gender are created and performed (du Gay et al. 1997). A shared emphasis on international cultural and social processes unites these various programs. This shared focus moves in four directions: (a) the 'detour through theory' (Hall 1992, Grossberg 1997a), linked (b) to the politics of representation, the circuits of culture (Hall 1996a), and the textual analyses of the media, literary, and cultural forms, including their production, distribution, and consumption; (c) the ethnographic, qualitative study of these forms in everyday life and the analysis of the social and communication processes that they shape and define; (d) the investigation of new pedagogical practices that interactively engage critical cultural analysis in the classroom (Grossberg 1997a). Each of these versions of CS is joined by a threefold concern with cultural texts, lived experience, and the articulated relationship between texts, materiality, and everyday life. Within the cultural text tradition some scholars (Fiske 1994) examine the mass media and popular culture as sites of resistance where history, ideology, and subjective experiences come together. These scholars produce critical ethnographies of the active audience in relation to particular historical moments. Other scholars read texts as sites where hegemonic meanings are produced, distributed, and consumed. In the feminist ethnographic tradition, there is a postmodern concern for the social text and its production (see Denzin 1997).

These models see culture as a series of ongoing interactional practices, conversations, talk, ways of acting, and representing the meanings of experience. Any cultural practice is significant because it is an instance of a cultural practice that happened in a particular time and place. This practice cannot be generalized to other practices, its importance lies in the fact that it instantiates a cultural practice, a cultural performance (story telling), and a set of shifting, conflicting, cultural meanings (Fiske 1994).

The researcher strategically selects sites for interpretation that constitute the intersection of texts and interacting individuals. Interactional specimens are extracted from these sites, written off from the conversations and actions that occur within them. This model always work upward and outward from the concrete to the larger set of meanings that operate in a particular context. It offers glimpses of culture in practice, setting one set of practices and meanings off against others that may compete in the same situation (Fiske 1994). The concept of structure is critical. In interpretive CS structure is a set of generative (often hegemonic), interactional, and cultural practices that organize meanings at the local level. Critical emic inquiry guides this process, the researcher seeks to understand a subject (or class of subjects) within a given historical moment. Sartre's (1963) progressive–regressive method is employed. A variant on the pragmatic emphasis on the consequences of acts, this method looks forward to the conclusion of a set of acts. It then works back to the conditions, interpretations, and situations that shape this decision. By moving forward and backward in time subjects and their projects are located within culture as a set of interpretive practices.

4. In Conclusion: The Calling of CS

Frow and Morris (2000) observe that contemporary versions of CS have been shaped by encounters between diverse feminisms, ethnic and critical race studies, gay, lesbian, and queer studies, postcolonial

and diasporic research, and with indigenous people's scholarship. These interactions produce a sensitivity to culture in its multiple forms, including the aesthetic, political, anthropological, performative, historical, and the spatial. Thus, there are collections and essays in Australian-Asian CS, Asian-Pacific CS, Latin-American, Mexican, and Chicana/o CS, as well as Black-British, Irish, British, Spanish, Italian, Nordic, and African CS.

At the same time, students of CS wrestle with the multiple meanings of such key terms as identity, place, globalization, the local, nationhood, and difference. These terms are debated constantly in the media, played out in arenas defined and shaped by the new information and communication technologies. CS scholars examine how meanings move between and within various media formations. This yields studies of Madonna, Elvis, the Gulf War, Anita Hill, the memory-work of museums, studies of tourism, shopping malls, and so on. In such work it becomes clear that culture is a contested, conflictual set of practices bound up with the meanings of identity and community.

The disciplinary boundaries that define CS keep shifting, and there is no agreed standard genealogy of its emergence as a serious academic discipline. Nonetheless, there are certain prevailing tendencies including: feminist understandings of the politics of the everyday and the personal; disputes between proponents of textualism, ethnography, and autoethnography; continued debates surrounding the dreams of modern citizenship.

But of course CS is a discursive category, its meanings are established in and through rhetorical and material practices. Nonetheless, the *sine qua non* of CS is irrefutable. A core belief defines the project, the understanding that scholars have a commitment and a responsibility to record and analyze, and register the meanings of 'the great events of our time for the benefit of future generations' (Nelson and Gaonkar 1996). This is the calling of CS.

Cultural Studies of Science

'Cultural studies of science' marks a loosely amalgamated, multidisciplinary research field drawing from history, anthropology, feminist theory, sociology, and philosophy of science. Its participants emphasize that scientific practices are historically situated, meaningful patterns of interaction with the world. Cultural studies offer an interpretive, critical engagement with scientific practices, rather than an explanation of their outcome. Cultural studies are situated within the 'cultures of science' that they investigate, and are responsive to what is at stake in the ongoing development of scientific practices.

1. The Place of Cultural Studies within Science Studies

Cultural studies of science first emerged in the late 1980's and early 1990's in response to debates between proponents of internalist history and philosophy of science, and adherents of the 'Strong Program' in the sociology of science. These debates concerned how best to explain the content of scientific knowledge, either by appeal to rational norms or as the outcome of particular social interactions. The stakes in these debates over explanatory strategies seemed to concern the authority of scientific claims, their relation to the natural world, and the normative stance of the explanation itself. With respect to scientific authority, philosophical accounts typically vindicated the acceptance of scientific claims or research programs as rationally warranted or reliable, whereas constructivist sociological work emphasized the contingency of scientific work and the impossibility of rationally foreclosing alternative interpretations. Meanwhile, scientific realists argued that scientific claims were accountable to the world as independent of human language, experience, or social practice, while antirealists (including both sociological constructivists and philosophical empiricists and historical rationalists) insisted that the sciences could never reach beyond our categories, practices, and norms. Finally, classically normative accounts of science aspired to assess the adequacy of scientific practices according to philosophical norms, while philosophical and sociological naturalists proposed primarily to describe (and perhaps explain) how the sciences actually proceed.

Work in cultural studies proceeded differently, in ways that rejected assumptions shared by most participants in these debates between internalists and social constructivists (assumptions that are also implicit in classic works of social history, such as Forman 1971 or Shapin and Schaffer 1985, that are otherwise thematically congenial to cultural studies). First, cultural studies are strongly antiessentialist about the sciences: there are no goals, methods, products, or norms belonging to science as such. Such antiessentialism undercuts the explanatory projects of both internalist philosophical histories and of a programmatic social constructivism, which are committed to accounting for the sciences as knowledge-producing activities (where 'knowledge' is a distinctive kind of product, either rationally warranted, causally reliable, or socially authoritative belief). The sciences are historically evolving practices, such that past and present practice cannot fix their nature, significance, aim, or 'content.'

Cultural studies also find no clear boundaries between scientific content and its social context. Both philosophers and sociologists have identified the shared commitments and norms of scientific communities as the locus of their divergent explanatory projects. Cultural studies have instead emphasized both an 'internal' heterogeneity that belies any presumption of community within a scientific field, and an active traffic in meanings and material across any supposed boundaries between scientific communities and their social or cultural contexts. This absence of community-defining consensus also exemplifies a more fundamental issue: cultural studies take the subjectivity of scientific knowers to be part of what needs to be understood rather than as an explanatory resource. Neither the natural body, the rational faculties, or the social identity of a scientist can be taken for granted as the locus or source of agency and belief. Prosthetic embodiments, narrative re-enactments, discursive interactions, and the affordances of material surroundings instead constitute knowing subjects through scientific practices, rather than accounting for practices as the doings of human agents/believers.

The opposing positions in the realism debates thereby dissolve. The question whether human knowers can ever get beyond the confines of their mental or social representations in order to be accountable to natural objects presupposes the autonomous intelligibility of mental or social representa-

tions. Cultural studies take scientific practices to be always already materially engaged and discursively articulated, so that there is no confinement within experience, language, theory, or social world to be transcended. On the contrary, experience, language, theory, and social forms themselves only take on determinate form through ongoing patterns of 'intra-action' in the material world (Barad 1996 coins this term to avoid the connotation that 'interactions' involve agencies definable apart from their interaction). But the same is true of 'nature,' whose objects and capacities only acquire determinate articulation in phenomena, ongoing patterns of 'material-semiotic' intra-action (Barad 1996, Rouse 1996, Haraway 1999).

The dispute between normative and naturalistic (descriptive) approaches to scientific practices also turns out to share false presuppositions. Cultural studies agree with naturalists that there can be no standpoint 'outside' of ongoing scientific practices from which to articulate norms to which they are accountable. Yet they disagree that science studies must therefore simply describe (and perhaps explain) the norms that function within those practices. The normative accountability of scientific practices is not a determinate fact or regularity about them (or about scientific 'communities'), but is instead constitutive of their intelligibility to practitioners and interpreters alike.

Scientific practices only make sense in terms of what is at issue and at stake in those practices. Yet these issues and stakes are themselves contested within the practice, and its interpretation. Cultural studies are not neutral descriptions of what scientists do, but interpretive construals of those doings that may thereby partially reshape the field of subsequent practice. In that respect, cultural studies are continuous with scientific work, which likewise reinterprets what is at issue and at stake through re-enacting the practices it participates in (Rouse 1996).

Cultural studies thereby articulate dynamic, expressive conceptions of meaning, knowledge, and power, which contrast sharply with the standard approaches to these phenomena within philosophy and social theory (Rouse 1996, 1999). On such accounts, meaning is not a property of utterances or actions; the term 'meaning' instead articulates the ways in which such performances inferentially draw upon and transform the field of prior performances in which they are situated. Knowledge is, likewise, not a theoretically coherent kind of representation; the term 'know' is used expressively in ongoing practices of assessing, attributing, relying upon, and contesting understanding and justification. Power, in turn, is not a substantial component of social interaction, something possessed and exercised by some agents, and lacking for others. The term expresses the ways in which one action aligns with others over time to affect the field of subsequent possible activity: 'power' articulates the connections between causal efficacy and intelligibility. Cultural studies of science thus expressively articulate the semantic, epistemic, and effective roles of scientific practices.

2. *Prominent Themes*

The preceding account offers a broadly philosophical interpretation of the aims and commitments embodied in the wide range of historical, anthropological, and sociological investigations that exemplify cultural studies of science. Typically, however, these commitments are expressed through detailed studies of particular practices, performances, or institutions rather than as explicit philosophical theses. A representative list of prominent work in cultural studies of science would include work directed toward particular laboratories, field sites, and other settings (e.g., Haraway 1989, Heath 1997, Traweek 1992, Biagioli 1993), images, models, and metaphors (e.g., Bono 1995, Haraway 1992, Keller 1995, Martin 1994, Daston and Park 1998), and machines and procedures (e.g., Barad 1998, Galison 1997, Rheinberger 1997, Daston and Galison 1992), all of which involve patterns of exchange between scientific settings and other sites of meaning-articulation. These topics have been marked as productive foci of inquiry not because they are relatively localized or self-contained, but because they have been productive nodes in the circulation and transformation of meaning, knowledge, and power around potent and often contested issues.

'The body' has been among the most prominent of these issues taken up in detailed work by cultural studies scholars, perhaps in part because of their insistence upon the embodied, materially interactive dimension of scientific practices. Attention has been directed toward bodily disciplines and skills (both as constitutive of scientific knowing, and as impositions upon who or what is to be known); toward prosthetic extension or reorganization of bodily engagement with the world (including the immunological internalization of the boundary between bodily self and external others); toward bodies as raced and gendered, and otherwise differentially marked (Heath 1997, for example, takes up the distinctive bodily markings and significations of Marfan's Syndrome); toward animal bodies, microbial 'bodies,' and their complex material-semiotic relations with human embodiment; and toward various processes and apparatuses of bodily reproduction. Along with 'the body,' other meanings partially constitutive of scientific knowing have also become issues for cultural studies of science. Authorship and authority, objectivity in its multiple contested deployments, the construction of professional and disciplinary identities within and around the sciences, and the affective dimensions of scientific understanding (e.g., wonder, anxiety, love, empathy, and various forms of humor) have been among the epistemically

significant issues that have provided a focus for cultural studies of science. Cultural studies have also been attentive to many of the ways in which the objects of scientific understanding have been meaningfully articulated. Genes, organisms, cyborgs, blood, information, life, matter, viruses, origins, secrets, foundations, environment, and ultimately nature in its significant differentiation from culture, society, artifact, and history have been prominent themes in both scientific practices and cultural studies of science.

In rejecting global legitimations or critiques of science as justified knowledge, social consensus, empirically reliable methods, cultural tradition, or approximately true theories, cultural studies of science have attempted to set aside the project of accounting for what science really (essentially) is, or how science is actually done, in favor of participatory engagement with specific scientific practices. The sciences are not regarded as optional practices (or belief-systems), of which it could even make sense to be for or against, credulous or skeptical, as a whole. Scientific practices are integral to the formation of a field of intelligible possibilities for action and self-understanding, partially constitutive of any conceptualization of who we are and what our situation is. To engage successfully in cultural studies of science is to clarify, and thereby partially transform, that field of possibilities and our involvement within it. Ultimately, the stakes in cultural studies of science are located in the notion of responsibility. To whom, to what, and in which respects are the sciences and science and technology studies responsible? How might such responsibility be exercised, and even partially fulfilled, through scientific research in particular settings, and through cultural studies of specific scientific or technological practices? What criteria or concerns should govern the assessment of responsible and irresponsible science and science studies? With these questions in mind, cultural studies become not simply a specifiable and in-principle exhaustible domain of academic inquiry, but an ongoing project of responsible engagement within the cultures of science.

Cultural Variations in Interpersonal Relationships

Interpersonal relationships refer to all kinds of social interactions. In the social sciences, and particularly in psychology, the positive side of interpersonal relation-

ships has been studied under such rubrics as attachment, friendship, couple and marital relationships, close relationships, and social networks. The negative side of interpersonal relationships has been highlighted through studies of aggression, conflict, loneliness, alienation, and so forth. This article focuses on positive interactions and relationships.

1. *Commonalities and Differences Across Cultures*

It has been universally documented that in every culture, human beings need other people from the cradle to the grave, because they are social by nature. Humans develop interpersonal relationships with multiple significant others, such as family members, friends, teachers, romantic partners, and respected persons throughout their lives. Moreover, research indicates that through interpersonal interactions, people receive emotional support, enjoy their lives, and learn. That is, it has been found that interpersonal relationships not only enhance the quality of life, but also are essential for human beings to maintain a basic level of functioning.

At the same time, it is widely observed that the nature of at least some interpersonal relationships varies with cultures and subcultures, because each culture in which people participate encourages and sometimes discourages certain social behaviors. For example, in some cultures, for instance, among modern, white, upper-middle-class males, articulating the need to have close relationships is suppressed; these men are encouraged to be emotionally independent of others. In this culture, in comparison with females, men are inhibited from expressing the need to have close relationships.

2. *Attachment Relationships in Infancy*

The onset of interpersonal relationships is clearly observed in the infant–caregiver affective bonds, that is, attachment relationships. Around the first birthday, infants everywhere are upset when they are separated from their primary caregiver, usually the mother. Bowlby (1969/1982), who proposed attachment theory, observed that many of the human infants' behaviors are organized for maintaining proximity to a caregiver, and hypothesized as an evolutionary principle that infants are biologically predisposed to stay close to their mothers for survival. According to Bowlby and his colleagues, an attachment is a special type of affective bond with a specific person who is not interchangeable with anyone. Attachment theorists view an attachment as a highly evolved behavioral system that produces the felt-security state in the infant, that is, the belief that an attachment figure will efficiently respond if he or she asks for help (see *Attachment Theory: Psychological*).

The quality of attachment to the mother among infants and young toddlers is assessed by a series of episodes in a laboratory, known as the Strange-Situation procedure (Ainsworth et al. 1978). The basic rationale of this procedure is that the quality of attachment is observed when the infant is placed under mild stress. As the procedure was originally designed for mother–infant pairs from American white middle-class families based on their child-rearing practices, this mild stress is induced by encounters with an adult stranger and by being left alone in the unfamiliar laboratory. By the procedure, infants are classified into one of three main patterns of attachment: secure (B-type, 67 percent in the original sample); anxious/avoidant (A-type, 21 percent); or anxious/resistant (C-type, 12 percent).

This procedure, constructed in a particular society, has been applied without adaptation to a wide variety of cultures on almost every continent, and sheds a unique light on cultural diversity in child-care practices. Based on meta-analysis of 2,000 classifications in eight different countries, van IJzendoorn and Kroonenberg (1988) identified samples whose ABC distributions were different from those reported by Ainsworth and others. These unexpected findings, all from outside North America, opened the door to further research aimed at understanding the differences.

For example, in Bielefeld, a city in northern Germany, a majority of toddlers were identified as A-type (52 percent), although they had no apparent psychopathological difficulties (Grossmann et al. 1985). In contrast, both in Sapporo, a city in northern Japan (Takahashi 1986), and in a traditional Israeli kibbutz (Sagi et al. 1985), a larger number of the toddlers were classified into C-type (32 and 34 percent, respectively) than in the original American sample. Takahashi (1990) pointed out that the appropriate level of stress in the procedure must vary with everyday child-care practices. That is, as the Japanese have long shared a belief that any stress for young children disturbs their healthy development, young children are virtually never left alone. In that culture, the procedure, especially the infant-alone episode, was so stressful that some of the Japanese children and also their mothers were pushed from B-type to C-type by the procedure. However, what triggered strong stress in kibbutz-reared toddlers was the appearance of a stranger. Sagi and his colleagues maintained that everyday kibbutz child-care practices that were very different from those of conventional families must have combined to produce the difference. The Grossmann et al. suggested that the toddlers in northern Germany were so strongly encouraged to be autonomous and discouraged from staying close to the mother that the children avoided interacting with the mother even in the experimental procedure.

3. Interpersonal Relationships in Lifespan Development

Attachment theorists have focused mainly on the dyadic affective relationships between infants and their primary figure, usually the mother. However, the relationships highlighted by the attachment are too limited to describe real-life experiences in interpersonal interactions, for at least the following two reasons (Takahashi and Sakamoto 2000).

First, it is often observed that, in every culture, humans from birth interact with not only the focal, attached figure, but also with other persons, such as the father, siblings, grandparents, and peers. It is well documented that through expansion of social arenas from family to other social institutions, i.e., day-care centers, schools, and workplaces, humans continuously expand and change their interpersonal relationships. Second, humans need others who fulfill different kinds of psychological functions, not only those crucial for survival, which have been focused on by attachment theorists, but also peripheral but enjoyable functions, such as receiving information and knowledge from, sharing experiences and emotions with, and giving nurture to, others. It may reasonably be assumed that human beings need multiple significant others concurrently, because it is difficult for even the most important figure to fulfill all of the psychological functions required by individuals.

In fact, there is plenty of evidence that shows the differentiation of psychological functions among multiple significant others. The multiple interpersonal relationships are described under the rubrics of social networks, social support networks, or personal frameworks of social relationships (see *Social Relationships in Adulthood*).

Kahn and Antonucci (1980) asked their subjects to map important persons in their lives and to classify them into three concentric circles, because they had hypothesized a hierarchical social network based on the image of a convoy that surrounds a person over time. This hierarchical network questionnaire, applied to every culture, has universally revealed that people, from young children to elderly persons of both genders, designate about 10 figures in their convoy. Moreover, in every culture, the percentage of family members mapped in the inner circle is higher than that of nonfamily members, and the figures who are placed in the inner circle provide higher proportions of all kinds of support, such as confiding, reassurance, and caring, whereas figures in the outer circle lend mostly peripheral support. Until the end of life, human beings maintain their own convoys, although the size of the social network decreases and the main figure changes with age. These studies have successfully made a rough but clear sketch of the universal nature of social relationships consisting of multiple figures.

At the same time, there have been many studies that indicate that social contexts affect interpersonal behaviors and relationships. However, careful, methodological examinations are needed before we can accept that they reveal real cultural differences in interpersonal relationships. First, differences in cross-cultural research may reflect response styles more than the differences in human relationships across cultural groups. For example, contrary to popular notions of interdependence, it is reported that American people at every stage of life from adolescence to old age exhibit their affective needs towards others more strongly than do their Japanese counterparts (Takahashi and Ohara 1997). In Taiwan, people are more reluctant to describe interpersonal relationships positively to an investigator, a third person, than are their white American counterparts (Miller et al. 1997). Second, observed differences could be due to people's different interpretations of terms and tasks. The concept of friend is a good illustration (Krappmann 1990). A cross-cultural comparison of friend relationships suggested that the connotation of the term 'friend' among Japanese elementary-school children was wider than that among German peers. The German children selectively nominated nine friends on average, whereas the Japanese students named most classmates as friends (mean = 23), and refrained from excluding any agemates from their group of friends if they had no appropriate reasons to be excluded. This attitude towards agemates among the Japanese children was attributed to the culture in the schools, where children were trained to establish 'nice' relationships with all of their agemates (see *Cross-cultural Psychology*).

To overcome these response biases, in a cross-cultural study between Japan and the USA, our group made relative comparisons between the two cultures. Instead of direct comparisons of the scores of each of five significant figures (i.e., mother; father; friend; romantic partner/spouse; and child), distributions of the dominant figures (that is, those who were assigned the highest score by each individual) were compared between the cultures. Both commonalities and diversities emerged. In both countries, the parents were rarely assigned the dominant role from adolescence on; rather, a same-sex friend—and later a romantic partner—was consistently and highly rated. Also, in both cultures, parents rated their child very highly when the child was grown-up. However, the number of family-dominant participants was larger among the Japanese than their American counterparts.

4. Individualism vs. Collectivism

Social and behavioral scientists may be tempted to attribute the observed cultural variations in interpersonal relationships to more global cultural differences in values and orientations, such as individualism vs. collectivism, or independence vs. interdependence (e.g., Markus and Kitayama 1991). In

such a dichotomous framework, cultures in the West, typically in North America, are supposed to encourage people to be more independent of others than cultures in the East, typically in Japan. However, some researchers have questioned the validity of such a dichotomy. For example, Takano and Osaka (1999) reanalyzed 15 empirical studies performed in the framework of individualism vs. collectivism, and concluded that the research did not provide sufficient evidence for the dichotomous classifications of cultures.

5. Conclusion

Thus, cultural and subcultural comparisons that respect the native group's perspective advance our understanding of not only differences among people's social relationships, but also the universal nature of human beings and their social relationships with others. Moreover, longitudinal research within each culture will help our understanding of how social and historical factors cause changes in social relationships. Another important challenge for future researchers is to investigate social relationships beyond close and intimate others. Globalization highlights the growing necessity for research concerning positive social relationships with unfamiliar people.

Culture and Economic Development: Cultural Concerns

Economic development presupposes not just the existence of formal institutions like property rights and a rule of law under which buyers and sellers can exchange goods in markets, but also certain norms or social values that promote exchange, savings, and investment. Thus, there is a cultural dimension to economic behavior. Culture has been given a wide variety of definitions, but it will be used here to signify the informal shared values, norms, meanings, and behaviors that characterize human societies. Just how important the cultural component of development is has long been a subject of controversy within the social sciences.

1. The Controversy over Culture

Modern neoclassical economics tends to downplay the importance of culture to development. Economists make the simplifying assumption that human beings are rational utility-maximizing individuals, and that such maximizing behavior is largely invariant across different human societies. The standard economic growth model pioneered by Robert Solow looks only at inputs of capital and labor; more recent so-called 'endogenous' growth models emphasize the role of

technology. From this perspective, culture constitutes at most a kind of residual factor that one appeals to when other explanations fail.

Sociologists, on the other hand, have tended to believe that cultural norms pervade economic life and that the latter cannot be understood apart from them. (Granovetter 1985) Emile Durkheim, for example, argued that the markets described by economists themselves presuppose shared norms (e.g., that people exchange goods rather than trying to rob and murder one another), and that sociology therefore looks to a deeper level of causation than economics. Max Weber (1930) pointed out that the economist's assumption that raising the piece-rate would increase output had the opposite effect in certain peasant societies, since workers, valuing leisure over accumulation, would be able to quit work earlier in the day. His life's work centered on showing how the emergence of the modern economic world depended on a prior shift in cultural values having to do with Protestantism. He in effect stood Marx on his head by arguing that what the latter labeled ideological 'superstructure' was in fact a key shaper of the means of production.

Today, the impact of culture on development tends to be studied more by economic sociologists than by economists. The one important exception to this generalization are development economists, that is, economists who specialize in the problems of growth in less-developed, premodern, or non-Western societies. They tend to see that many behaviors that can be taken for granted in the US or Western Europe, e.g., that public officials will not be grossly corrupt or incompetent, are not necessarily prevalent in other societies (Harrison 1992).

2. *History of the Development of Economic Sociology*

2.1 *The Weber Hypothesis*

The *locus classicus* of studies of culture and development is Weber's *The Protestant Ethic and the Spirit of Capitalism*, first published in 1904. Weber argued that the Calvinist doctrine of predestination, rather than inducing quietism, led believers to seek to demonstrate their status as elect by engaging in commerce and worldly accumulation. According to Weber, Puritanism created a work ethic—that is, the valuing of work for its own sake rather than for its results—and demolished the Aristotelian–Catholic doctrine that one should acquire only as much wealth as one needed to live well. In addition, it enjoined on its believers moral behavior outside the boundaries of the family, which was crucial in creating a more impersonal system of social trust.

The Weber thesis was controversial from the moment it was published, with figures like R. H. Tawney, Ernst Troeltsch, and Talcott Parsons weighing in. Various scholars argued that Weber was wrong empirically about the superior economic performance of Protestants over Catholics; that Catholic societies had started to develop modern capitalism long before the Reformation; that it was the Counterreformation rather than Catholicism *per se* that led to economic backwardness; and that the shift towards modern notions of accumulation was a more rational process than Weber believed. In the end, however, most scholars believe that Weber essentially was correct, given the delayed development trajectory of virtually all Catholic countries when compared with their Protestant counterparts.

2.2 *The Decline of Cultural Explanations*

At the same time, Weber's work gives us reason to be cautious about applying cultural explanations for economic development too readily. The German sociologist's other great work on culture and development was his study that was translated as *Confucianism and Taoism* (Weber 1951). Weber was seeking to answer the question why capitalism arose first in the Protestant West rather than in other societies. He argued that Confucianism created an environment hostile to capitalist development: while it was a rational ethical system, it emphasized the 'sib' or kinship as the primary source of social relatedness and thereby promoted economically inefficient nepotism. Japan, according to Weber, was even less suited than China to produce modern capitalism. In light of the astonishing economic performance of Japan, China, and other Confucian societies in East Asia after World War II, one is forced to conclude that the obstacles to development in that part of the world had much more to do with politics and inappropriate institutions than any specific cultural factor. Weber was in fact correct in pointing to the centrality of kinship as an organizing principle in Chinese society—businesses have been and continue to be family centered—but greatly overestimated the impact this would have on aggregate growth.

Following Weber, there were a number of studies up through the 1950s that emphasized cultural variables in economic development. Werner Sombart in *The Jews and Modern Capitalism* (1911) argued that Jews possessed the same cultural characteristics pointed to by Weber that were conducive to capitalism. A similar argument was for Japan by Robert Bellah, who argued that Buddhist sect founded by Ishida Baigan in the sixteenth century supported a functional equivalent of the Protestant work ethic.

Towards the middle of the twentieth century, authors including Everett E. Hagen, W. Arthur Lewis, and David C. McClelland all argued in different ways that certain less-developed societies lacked cultural characteristics (such as McClelland's 'achievement

orientation') that constituted obstacles to development. The 'modernization theory' popular in American social science during the early postwar period tended to see traditional cultures in a negative light, and to regard contemporary Western societies as models to which they needed to aspire.

This kind of argument fell out of favor during the next generation for a number of reasons. The first was the charge of ethnocentrism: many culturalist arguments tended to assume uncritically that social norms rather than institutions or structural conditions were responsible for lack of development, and that Western cultural values were superior to non-Western ones. This period saw the rise of neo-Marxist doctrines like *dependencia* theory that pointed to the structure of the world economy as the source of underdevelopment.

But a second strand of criticism came from orthodox economics. Cultural factors are, methodologically, very difficult to measure and to disentangle from other kinds of variables. As the Weber example above indicates, Asian underdevelopment could be explained not just by culture, but also by political conditions, poor economic policy, weak institutions, global economic conditions, and a host of other factors. Those promoting culturalist interpretations usually had no empirically convincing way of demonstrating that cultural factors were indeed as important as they claimed. Given that culture tends to change relatively slowly, it would seem very implausible that Asia's rapid rise in the second half of the twentieth century should be due primarily to cultural factors.

2.3 The Revival of Cultural Interpretations

In the 1980s and 1990s there has been something of a revival of culturalist interpretations of development. Part of the impetus for this came from within economics itself, with the rise of the subdiscipline of the so-called 'new institutional economics' associated with economic historian Douglas North. The new institutionalists recognized the importance of norms in economic life; according to North (1990), 'institutions' (i.e., formal or informal rules) were critical in reducing transaction costs and thereby promoting economic efficiency. Without agreed rules concerning property rights, for example, there could be no modern economic world as such since innovators would not have the incentive to take risks or make investments. While they often seek to give rational, maximizing accounts of the origins of institutions, institutional economists as a group are much more aware of the importance of history, culture, tradition, and other so-called 'path dependent' factors in shaping economic behavior.

The second reason for the revival of interest in culture and development was the experience of transitional economies in the late 1980s and 1990s, as well as observation of the so-called 'Asian Miracle.' Following the collapse of communism, many Eastern European and Soviet successor states set up formal market institutions, along with other institutions associated with developed market democracies such as democratic constitutions and electoral systems. Countries like Poland, Hungary, and the Czech Republic made the transition from centrally-planned to market-oriented economies relatively easily. Others, like Russia and Ukraine, had a much more difficult time; institutions were weak and levels of corruption were high. It seemed to many people unlikely that the difference in transition outcomes was simply the result of differing designs of formal institutions, particularly since the outcomes largely followed what one would have predicted on the basis of cultural factors (i.e., the degree of Westernization of each country prior to communism). As a result, many of the economic policy practitioners in international financial institutions like the World Bank and the IMF began to look towards cultural factors as key variables explaining successful transition strategies.

Similarly, rapid economic growth in Asia spawned many theories of how development there was driven by uniquely Asian cultural characteristics like a work ethic or deference to state authority. As noted above, Asian growth is better explained by institutional factors, and much of this cultural theorizing was undercut to some extent by the Asian economic crisis of 1997–1998.

3. Culture and Economic Behavior

In the large literature on culture and development, cultural factors are said to affect economic behavior in at least four ways: through its impact on organization and production, through attitudes towards consumption and work, through the ability to create and manage institutions, and through the creation of social networks.

3.1 Culture and Production

There is a large literature on 'organizational culture,' which studies norms and behaviors characteristic of individual organizations or even subunits within organizations. Organizational culture varies substantially across national cultures (e.g., the organization of a Japanese factory compared with a British one; see Dore 1973), but also between regions, sectors, or even companies within a single sector. Firms can be more or less hierarchical, open to outside influences, flexible in decision-making, and the like, for reasons having less to do with their formal organization than the informal norms that characterize them.

Social classes are also characterized by distinct social norms that give them differing characteristics with respect to class solidarity, attitudes towards money making and education, and the like. One argument for Britain's relative economic decline in the twentieth century, for example, had to do with the absorption by the English middle class of upper-class values that disdained practical education and technology.

3.2 Attitudes towards Consumption and Work

In addition to the classic literature on the work ethic, there has been substantial writing on the so-called 'culture of poverty,' a phrase coined by Oscar Lewis in the 1960s to characterize the failure of the poor in Latin America to take advantage of work opportunities. This term was used extensively in the debate over poverty and welfare in the US, where observers like Daniel P. Moynihan and William Julius Wilson argued that poverty was the result not just of structural problems in the economy, but of dysfunctional social behaviors that had taken on a life of their own among the 'underclass.' Other studies have focused more on the culture of the rich rather than the poor, observing that different elites can place different relative valuations on work and leisure, leading to conspicuous consumption in some cases and frugality and reinvestment in others.

3.3 Culture and Institutions

Many economists correctly point out that the differences in economic performance from one society to another are better explained by differences in institutions and in the policies undertaken by those institutions than by cultural factors. This is not, however, the end of the story, because culture also affects the ability of societies to create and properly manage institutions. For example, in the postwar period Japan, South Korea, and other East Asian countries employed industrial policies, in which the state rather than the market allocated credit to national industries, to encourage economic growth. Not all societies, however, are capable of building East Asian-style economic planning bureaucracies. Such institutions are especially vulnerable to rent seeking and capture by narrow societal groups; to make industrial policy work, planning bureaucracies have to be shielded from undue political influence and overt corruption. Similar institutions created in Latin America, Africa, and other parts of the world proved much less effective than their East Asian counterparts. While effective industrial policy is partly a matter of institutional design, it is also influenced heavily by culture—for example, expectations of corrupt behavior on the part of public officials, bureaucratic professionalism and esprit de corps, levels of education, etc.

3.4 Social Networks

The final broad category of ways in which culture is said to affect economic behavior is in the formation of social networks. In a short essay titled '*The Protestant Sects and the Spirit of Capitalism*,' Weber pointed out that in addition to the work ethic proper, sectarian Protestantism of the sort found in the US encouraged commerce by promoting networks of trust among the members of each sect. Early Protestantism enjoined its members to behave morally not just towards fellow believers, as was the case with many other religions, but towards all human beings. This kind of moral universalism, combined with the propensity of sectarian denominations to organize themselves congregationally (i.e., from the bottom up rather than hierarchically), meant that business could be transacted across a much broader range of people than in other cultural systems. The differing impact of cultural values on networks of social relations is the basis for the concept of social capital, discussed in the following section.

4. Social Capital

One of the most important headings under which the issue of culture and development has been discussed in the 1980s and 1990s has been that of 'social capital' (Putnam 1993). Social capital consists of norms or values shared among a group of people that promote cooperation and trust among them; like physical and human capital, social capital is a source of wealth. While the term 'social capital' was put into general circulation by sociologist James S. Coleman in the 1980s (Coleman 1988), the concept underlying it has a long intellectual history. Alexis de Tocqueville noted in *Democracy in America* that the American propensity for civil association was key to the success of American democracy, since it permitted the society to organize itself without the help of centralized, hierarchical authority. Edward Banfield in his classic ethnographic study *The Moral Basis of a Backward Society* coined the term 'amoral familism' to connote the pathological condition he found in a small town in southern Italy, where people were only able to trust members of their immediate nuclear family and behaved opportunistically towards everyone else. The case described by Tocqueville was one of abundant social capital outside the family, which created the basis for successful democracy and economic development. Banfield's village, by contrast, was characterized by a dearth of social capital except within a narrow circle of kinship, a situation widely held responsible for the underdevelopment and political corruption characteristic of southern Italy.

More recent studies of social capital have shown that it is very important in understanding the flow of information in an economy. Social networks propa-

gate information on job opportunities, relative prices, and a host of other economic information, but they can also obstruct the flow as well. In the 1990s the World Bank has experimented with so-called 'microlending' projects that seek to use social networks to extend very small retail loans to poor customers in Africa and other regions. The success of microlending depends on adequate information about creditworthiness that is best captured through informal rather than formal information channels.

The concept of social capital has been criticized by both economists and sociologists for either being overly vague, or else being simply a repackaging of already-familiar concepts. One of the key weaknesses of the concept of social capital is lack of an agreed-upon method for measuring it, as exists for physical and human capital. Without a good metric, it is difficult to incorporate social capital into econometric models, and therefore to measure the impact of cultural factors relative to other types of variables.

5. *Directions for Future Research*

As the previous discussion indicated, the biggest challenge in studying culture and development is to find a way to incorporate cultural factors into theoretical and empirical models already in use by economists. Many cultural explanations of economic behavior tend to turn into detailed ethnographic studies, in which causal relationships become so complex that they are not generalizable beyond the particular group being studied. Economists, on the other hand, tend to favor abstract universal models of behavior that fail to take into account many of the complex contextual factors that often prove critical in the real world. It may be the case that these extremes cannot be reconciled, for example, because there is simply no reasonable empirical way to quantify cultural variables, or because causality is too multivariate and complex. On the other hand, the renewed interest in concepts like social capital may lead to the development of new data sources that will permit greater interaction between the ethnographic and model-building sides of the social sciences.

Culture and Emotion

In the history of emotion research in the modern social and behavioral sciences, the pendulum has swung repeatedly between universalist positions and social constructionist positions. This perhaps reflects the fundamental fact that emotions are both biologically grounded and culturally shaped. The debate continues, however, because theorists differ in their views on how large a role biology and culture play in the processes of emotion. For example, basic emotions theorists have suggested that culture modulates emotional expressions through culture-specific display rules, but that emotions themselves are innate and shielded from culture. In contrast, many social constructionists have argued that sociocultural processes participate directly in the formation of emotions themselves. However, with the advent of increasing cross-cultural data, a satisfactory integration of the divergent positions is very much needed. This integration should be consistent with the fact that the human is a species that has accomplished biological adaptation by inventing and elaborating cultural systems. Thus, there must be a cultural mode of biological adaptation, and emotion is no exception to this general principle (see *Culture in Development*).

1. *Cultural Perspective on Emotion*

1.1 *Culture, Biology, and Emotion: Definitions*

A cultural perspective on emotion assumes that humans are biologically prepared with a variety of physiological, neurological, and psychological components of emotion. A reasonable rule of thumb may be that humans are equipped with emotional competence and potential roughly comparable to those of

their immediate evolutionary kins such as primates and great apes (Tomasello 1999). Physiological drives of hunger, thirst, and sex, as well as attendant processes of homeostatic maintenance, will surely make this list. So will rudimentary responses of fight–flight and attachment. Further, basic brain processes of pleasure, pain, and arousal, as well as the corresponding psychological dimensions of valence and intensity of affect, are also part of the significant evolutionary heritage of human beings (see *Emotions, Evolution of*).

However, by themselves, these processes are not emotions. Emotions are higher-order mental organizations formed around certain core elements such as pleasure and pain, approach and avoidance, or fight and flight (Ortony and Turner 1990). Hence, many other processes and elements have to be combined and accorded their divergent functions and forms through social and cultural processes by which individuals try to accomplish, collectively and personally, a form of adaptation and adjustment to their own sociocultural environment (see *Cultural Landscape in Environmental Studies*; *Cultural Psychology*). It is important to note that as a human-made part of the environment, culture is fundamentally symbolic and meaning-ridden. In other words, culture includes a variety of tools, images, knowledge, conventions, and practices, which as a whole define the context of adaptation for each and every individual. The cultural perspective assumes that each individual becomes an agent who thinks, feels, and acts adaptively and functionally within a given sociocultural context both by incorporating cultural meaning systems into his or her individual memory and by coordinating his or her responses with the contingencies of external events that are defined and often taken for granted in the context. This applies to emotion as well. Thus, various innate components of emotion are likely to be configured differently, sometimes dramatically so, across different cultures and historical periods.

1.2 Emotions and Categories of Emotion

One significant contribution of the cultural perspective is to have raised a question on a commonsensical notion that emotions causally follow certain antecedent events (Lazarus 1995). In the emotion research of the past, it was often assumed that a cognitive appraisal of an attendant situation as, say, 'unfair' and 'demeaning,' leads causally to an emotion of 'anger.' Although the notion seems familiar, resembling closely our folk understanding of mental life, it is not at all obvious that the appraisal can be so neatly separated from, let alone causally placed prior to, the emotion itself. One may wonder what will really be left in, for example, anger if an appraisal of 'demeaning offense' is taken out. Perhaps, anger is made up of 'demeaning offense' and the actual social act that is readily interpreted as such. If this is the case, the appraisal and the attendant pattern of social interaction may more reasonably be seen as the integral components of emotional experience.

It is important to note that a large number of studies have documented cross-culturally stable associations between appraisals and emotions (Scherer 1997; see *Emotions, Psychological Structure of*). In these studies, subjects are asked to provide ratings on a variety of appraisal dimensions after having imagined an incident where they felt certain common categories of emotion such as joy, anger, and sadness. Although the degree of cross-cultural similarities observed in these studies is impressive, cautions are due for two reasons. First, there also exist small, but systematic cross-cultural differences in a predicted fashion (e.g., Fischer et al. 1999). Second, exactly what the documented cultural similarities might mean is far from clear. To the extent that appraisals are part of the meaning included in the emotion categories, the studies do show that people have cross-culturally and linguistically translatable folk categories of emotion. But do they equally experience the same set of emotions? Are these emotion categories embodied equally? That is, do they neatly correspond to the structure of online subjective experience, behavioral responses, and bodily reactions? The ability to understand each other's experience in terms of a common set of categories (i.e., translatability) surely points to a common human heritage of some sort. However, as some cultural anthropologists have suggested (e.g., Lutz 1988), the translatability is hardly equivalent to the universality of the emotion process (Parkinson 1995). In fact, with better methods, it has become possible to document considerable cross-cultural differences, as well as similarities, in emotional experience and process (Mesquita and Frijda 1992).

Evidence for the thesis that human emotions are biologically prepared, but socioculturally configured and conditioned is still sparse, limited largely to a few domains. Most notably, these domains include (a) culture and happiness; (b) culture of honor, insult, and violence; and (c) culture and facial expressions of emotion. This evidence is reviewed below.

2. Sociocultural Shaping of Emotion: Some Recent Findings

2.1 Culture and Happiness

Cultures vary considerably in terms of the conditions under which happiness is experienced. In North America and many European cultures, self-esteem is shown to be a major predictor of happiness and subjective well-being. Although the association between self-esteem and happiness can also be documented in many other cultures, it is considerably weaker outside of the European and American cul-

tures (Diener and Diener 1995; see *Well-being (Subjective), Psychology of*). In these cultures, appraisals of the self that is separate from other aspects of life carry an especially large weight in the judgment of the quality of life in general.

Cultures outside of Europe and North America tend to be more interpersonally and socially oriented. Instead of the ethos of independence (which is predominant in the West) the ethos of interdependence permeates various aspects of life in non-Western cultures (Markus and Kitayama 1991, Triandis 1989). So far, much has been learned about East Asian cultures (see *Cross-cultural Psychology*). Overall, in these cultures an assortment of interpersonal and social factors come out as more significant predictors of happiness.

For example, Kitayama et al. (2000) asked both Japanese and American undergraduates to report how frequently they experienced a variety of emotions. These emotions included three different types of positive emotions. Some positive emotions such as friendly feelings and respect are interpersonally engaging in that they subjectively result from a success in tasks of interdependence of the self with others in relationship. Some other positive emotions such as pride and feelings of superiority are perceived to have been caused by a success in tasks of independence and autonomy of the self. Finally, still other positive emotions such as happiness, relaxed feelings, and elation are more general in that other perceived antecedents are possible.

The results suggested that happiness is associated with very different experience in the two cultures. In the US, the reported frequency of experiencing the general positive emotions (e.g., happiness) was more closely associated with the reported frequency of experiencing the disengaging positive emotions (e.g., pride) than with the reported frequency of experiencing the engaging positive emotions (e.g., friendly feelings), thus conceptually replicating the earlier finding regarding the central significance of self-esteem in producing happiness among Americans. In contrast, in Japan the reported frequency for the general positive emotions (e.g., happiness) was much more closely associated with the reported frequency for the engaging positive emotions (e.g., friendly feelings) than with the reported frequency for the disengaging positive emotions (e.g., pride). In short, this and other related studies show that different types of people are likely to be happier in different cultures (Kwan et al. 1997). Thus, whereas in North America individuals with high self-esteem are most likely to be happy, in East Asia those with good social relations are most likely to be happy.

A similar point may apply to the question of when individuals are likely to be happy. In a recent study Mesquita and Karasawa (in press) used an experience sampling method to examine this issue. Both American and Japanese undergraduates were asked to record different aspects of their emotional experience four times a day for a period of several days. It was observed that whereas American subjects were likely to experience pleasant feelings when they thought that they had succeeded in tasks of independence, Japanese subjects were most likely to experience pleasant feelings when they thought that they had succeeded in tasks of interdependence. This social nature of happiness is likely to generalize to other Asian cultures. Thus, in an ethnographic work of Indian women, Menon and Shweder (1998) conclude that the well-being of these individuals is immersed in the notion of social harmony, cyclic continuity of the extended household and lineage, and associated duties and obligations.

The foregoing analysis has an important methodological implication. So far, this literature has been based on an assumption that happiness is a positive emotion that is attributed to the self. This assumption is required to justify the operational definition of happiness as an endorsement of a statement like 'I am happy.' However, cultures may vary in the degree to which emotions are defined and, hence, experienced to be shared in a social relationship or interpersonal space. The social sharedness of emotions may be especially pronounced in non-Western, collectivist, or interdependent cultures.

Finally, evidence indicates another curious cultural difference in the association between positive and negative emotions (such as happiness and unhappiness). Bagozzi et al. (1999) have proposed that Asian, especially Confucian, cultures hold a relatively holistic and dialectic construal about emotions. This construal, which asserts that positivity and negativity should coexist as yin and yang of the same process, may be contrasted with a more prototypically Western construal that assumes an opposition between positivity and negativity. These cultural assumptions seem to be related to the actual experience of emotions. Thus, there is considerable evidence in the West that positive and negative affect are statistically either independent or, otherwise, negatively correlated. Thus, feeling negative emotions does not influence or, otherwise, does decrease the likelihood of simultaneously feeling positive emotions. Recently, however, it has been shown that this is not the case in China (Bagozzi et al. 1999) and Japan (Kitayama et al. 2000). Consistent with the dialectic construal of positivity and negativity, in these Asian cultures the frequency or intensity of feeling negative emotions is often positively correlated with the frequency or intensity of feeling positive emotions.

2.2 *Culture of Honor, Insult, and Violence*

A remarkable degree of culture-dependence has also been demonstrated for another kind of emotion, namely, honor-related anger and aggression in the

American South. Nisbett and Cohen (1996) have suggested that there is a culture of honor in the American South and that this culture is responsible for a higher homicide rate in the South than in the North. A culture of honor is characterized by an ethos of individual power, masculinity, and self-protection (Pitt-Rivers 1965). That is to say, one reacts violently to even subtle cues of insult and attack. A resulting reputation of honor and proneness to violence is likely to preempt any actual insults or attacks on the person, hence serving the function of self-protection. Nisbett and Cohen hypothesize that the honor culture that is held in place in the contemporary American South has its origins in the herding and pastoral cultures of Celts who settled in the southern states of the US in the eighteenth century. They suggest that cultures of honor are likely to arise whenever no effective policing power is available for the protection of private properties. This surely applies to herding economies. Once established, however, a culture of honor often becomes self-perpetuating because many different aspects of the culture reinforce each other to form a sociopsychological system and, furthermore, some of those aspects are likely to be conventionalized (e.g., socialization practices) and institutionalized (e.g., laws that tolerate honor-related violence) (see *Emotions, Sociology of*).

Drawing on this general theoretical framework, Nisbett, Cohen, and colleagues have marshaled evidence from three different layers that constitute the cultural system of honor. This work is exemplary of a cultural approach to emotion. It uses multiple methods; it focuses on different interlocking aspects of a culture; and, as discussed above, it addresses historical origins of the psychocultural complex.

First, the researchers demonstrated attitudinal differences between the two regions of the US. Thus, as compared to Northern men, Southern men are more approving of violent responses when personal insults or other threats on one's properties such as houses and women are involved. Second, the authors have also shown that honor-related violence is sustained in part by social institutions. For example, personnel managers of many firms in the South show a much more tolerant attitude toward a potential employee who allegedly killed someone after having been insulted by him.

Will the honor-based system of culture and attendant attitudes and personal beliefs penetrate a much deeper layer of spontaneous emotional reactions? A third line of evidence, based on a series of ingenious experiments, addresses this issue. These experiments demonstrate that spontaneous emotional responses of Southern men are shaped in part through participating in the culture of honor. Specifically, in one condition of these experiments, when male subjects were arriving for the study, they had to pass another person (an experimental stooge) who was sorting files in an open file drawer. When the subject passed by, he inevitably interrupted the stooge because of the narrowness of the hallway. Further, because of the interruption, the stooge 'accidentally' dropped some files on the floor. Seemingly upset, the stooge audibly called the subject an asshole. There was no such insult manipulation in a control condition. Immediately afterward, a variety of measures were taken including levels of cortisol and testosterone (physiological measures of arousal and proneness to aggression). Half of the subjects were from the US South and the remaining half were from the Northeast or Midwest. The researchers found that the insult produced a visible increase of physiological arousal and behavioral readiness for aggression among Southerners. None of the effects were found among Northerners.

2.3 Culture and Facial Expressions of Emotion

How universal is people's ability to recognize emotions on the face? Earlier work had suggested that recognition of facial emotions is quite culture-specific (Bruner and Tagiuri 1954). In the 1960s, however, this conclusion was challenged by Ekman, Izard, and others, who proposed that several basic emotions (e.g., joy, anger, sadness, disgust, and fear) are innate and part of the built-in hardware of a human animal. The most impressive evidence was that posed faces of Americans corresponding to each of the basic emotions were correctly categorized even by New Guinea tribe men who had minimum contact with the West, and vice versa. The current hypothesis is that cultures vary in terms of intensity of perceiving the basic categories of emotion, but the emotion categories themselves are universal (Matsumoto et al. 1999). Although there is a kernel of truth in the universalist position that emotional expressions are biologically prepared, several reservations have been raised (see *Emotion and Expression*; *Facial Expressions*).

First, there are some methodological weaknesses in the cross-cultural studies by Ekman (1992), Izard (1994), and colleagues. Although minor by themselves, as a whole they may have led the researchers to overstate their case. In particular, Russell (1994) has argued that the available evidence is consistent with a much simpler assumption that people in all cultures categorize facial emotions in two dimensions of pleasantness and arousal. Thus, emotion categories such as joy, anger, and sadness may not be part of a universal hardware of emotion. Second, Wierzbicka (1986)—a linguist from Poland—has suggested that the categories of emotion that are claimed to be basic are relatively specific to the vocabulary of the modern English. Indeed, some cultures do not have any corresponding emotion categories for some of the emotions. The question she raises is apt: What would the list of basic emotions have looked like if it had been compiled by a psychologist who did not speak English? Third, as implied by the cultural perspective described

here, emotions may be much more social in both experience and origins.

Importantly, facial expressions of emotion appear to have different subjective consequences across cultures. Levenson et al. (1992) have shown that once the face is posed to mimic expressions of different emotions, there typically result (in North American subjects) both systematic changes in different aspects of autonomic activation, such as blood pressure, galvanic skin responses, and heart rate, and corresponding changes in subjective experiences of emotion. This suggests that the inner sensations caused by the contraction of facial musculature in, say, a grimace or smile, are often enough to generate an emotional state of anger and happiness. Yet, in a Sumatran village where the researchers conducted the same study, they failed to find comparable changes in the subjective experience of emotional states, although they replicated the physiological changes that were contingent on posed facial expressions. The researchers commented that in Asian cultural contexts interpersonal context serves as an important element of emotional experience, so much so that without the provision of an appropriate interpersonal context, the inner sensations are not sufficient to produce any distinct emotional experience.

3. Conclusions and Future Directions

Advances in culturally informed research on emotion towards the end of the twentieth century have highlighted the notion that emotions are both biological and cultural. Species-specific predisposition, potential, and competence are differentially configured and integrated into culture-dependent forms of communication and social life, which in turn are dependent on the historical, ecological, economic, and political conditions of different cultural groups and regions. Accordingly, all mental organizations, including emotional processes and structures, are likely to be significantly shaped and constituted by sociocultural processes. In turn, these mental organizations become integral parts of the sociocultural processes themselves. Much has been learned about the culture-dependence of emotional responses and processes. Yet, much more remains to be learned. It is especially important to develop better theories and methods that can be used to explore mutually constitutive interactions between sociocultural processes and mental organizations. In all likelihood, this will define one major agenda for research in the cultural psychology of emotion during the first decade of the twenty-first century.

Culture and the Self (Implications for Psychological Theory): Cultural Concerns

The self may be defined as the individual's understanding and experience of their own psychological functioning. As such, it is basic to human experience, while also being culturally constituted in fundamental ways. The present article examines the processes contributing to the cultural grounding of the self and considers implications for understanding variation in psychological processes and outcomes.

Discussion begins with a conceptual argument for recognizing the self as cultural. This is followed by a brief overview of research that highlights the existence of cultural differences in the self and considers implications of such variation for related areas of psychological functioning. Finally, attention turns to a consideration of challenges to be met in future work on culture and the self and to the potential contributions of this work to psychological inquiry.

1. *Theoretical Premises*

The recognition of the self as cultural is premised on core assumptions regarding the nature of psychological functioning and of culture. These assumptions include a conception of the person as self-reflexive and agentic, as well as a view of culture as forming a symbolic medium for human development.

A core assumption held about the self is that universally individuals maintain some awareness of their mental activity, of themselves as existing in time and space, and of their acting in the world. As Hallowell argues:

> it seems necessary to assume self-awareness as one of the prerequisite psychological conditions for the functioning of any human social order, no matter what linguistic and culture patterns prevail … the phenomena of self-awareness in our species is as integral a part of human sociocultural model of adaptation as it is a distinctive human level of psychological structuralization (Hallowell 1955, p. 75).

Along with this premise of self-awareness, the assumption is also made that individuals are agentic in actively contributing meanings to experience (Bruner 1990). From this perspective, that emerged with the cognitive revolution in psychology, individuals are understood to go beyond the information given in making sense of experience, rather than merely passively to absorb externally given information.

Also of critical importance to the view of self as culturally grounded has been the understanding of culture as a symbolic medium for human development, that encompasses shared meanings which are embodied in artifacts and practices (Geertz 1973, Shore 1996, Shweder and Levine 1984). Cultures are seen as encompassing knowledge of experience and rules for conduct as well as objects and events that are created, in part, by cultural definition. Importantly, this reality-creating role of culture is recognized to be broad, extending not only to the establishment of institutions (e.g., marriage), roles (e.g., bride), and artifacts (e.g., wedding ring), but also to the creation of psychological concepts and epistemological categories (e.g., commitment, time).

From the present perspective, it is understood that, whereas an involuntary response may proceed without cultural mediation, all higher order psychological processes depend, at least in part, on cultural input for their emergence. As Geertz asserts:

> We are … incomplete or unfinished animals who complete or finish ourselves though culture—and not through culture in general but through highly particular forms of it (Geertz 1973, p. 49).

Thus, for example, whereas involuntary physiological reactions may be elicited by situational events, whether they become interpreted and experienced in emotional terms depends, in part, on such input as culturally based theories regarding the nature, causes, and consequences of emotions, cultural routines for responding to emotions, natural language categories for defining emotions, as well as a range of other sociocultural processes. The present considerations lead to the expectation that qualitative differences in self-conceptions and in related modes of psychological functioning may be emphasized among individuals from cultural communities characterized by contrasting self-related sociocultural meanings and practices.

2. *Impact of Cultural Variation in the Self on Basic Psychological Processes*

The present section considers representative examples of empirical studies that embody this core insight regarding the cultural grounding of psychological

processes, an insight that is critical to the newly re-emerging theoretical perspective of cultural psychology (e.g., Cole 1990, 1996, Markus et al. 1996, Miller 1997, Shweder 1990, Shweder et al. 1998). Although the overview presented here is necessarily highly selective and incomplete, it serves to illustrate ways in which cultural research on the self is offering new process explanations of psychological phenomena as well as identifying fundamental variability in the forms that psychological phenomena assume.

2.1 Social Attribution and Cognition

In early groundbreaking research, Shweder and Bourne (1984) challenged the completeness of contemporary psychological theories of social attribution. It was documented that, as compared with European-Americans, Oriyan Indians place significantly greater emphasis in person description on actions as compared with abstract traits, with their person descriptions more frequently making reference to the context. Thus, for example, their research revealed that whereas European-Americans are more likely to describe a friend by saying 'she is friendly,' Oriyan Indians are more likely to describe them by saying 'she brings cakes to my family on festival days.' This type of cultural difference, it was observed, was not explicable in terms of the types of factors that had been emphasized in previous studies, such as variation in schooling, literacy, socioeconomic status, linguistic resources, or capacities for abstract thought. Rather, the trends were demonstrated to reflect the contrasting cultural conceptions of the person and related sociocultural practices emphasized in Hindu Indian as compared with European-American cultural communities. Subsequent cross-cultural developmental research on social attribution documented that cultural considerations impact as well on the direction of developmental change, with European-American children showing an age increase in their references to traits (e.g., 'she is aggressive'), and Hindu Indian children showing an age increase in their references to the social context (e.g., 'there are bad relations between our families') (Miller 1984). More recently, this type of work has been extended to understanding the development of individuals' conceptions of mind, with cultural work calling into question claims that theory of mind understandings develop spontaneously toward an endpoint of trait psychology and providing evidence that they proceed in directions that reflect the contrasting epistemological assumptions of local cultural communities (Lillard 1998).

In other lines of work on psychological implications of cultural variation in the self, research is calling into question the universality of various attributional and cognitive tendencies long assumed to be basic to all psychological functioning, such as motives to maintain self-consistency, or to emphasize dispositional over situational information. Thus, for example, it has been shown that Japanese college students tend to maintain weaker beliefs in attitude–behavior consistency than do Australian college students (Kashima et al. 1992), while being less prone than are Canadian college students to show cognitive dissonance biases, i.e., tendencies to distort cognitions to make them more congruent with behavior (Heine and Lehman 1997). Also, relative to European-Americans, various East Asian populations have been documented to display greater sensitivity to situational information in object perception and less vulnerability to the fundamental attribution error, a tendency to treat behaviors as correspondent with dispositions (Ji et al. 2000).

New lines of research in this area are also linking cultural views of the self and related cultural practices to variation in fundamental styles of cognitive processing, such as tendencies to privilege analytic as contrasted with dialectical epistemological stances. In one illustration of such a cultural difference, experimental research has demonstrated that American undergraduates tend to treat information in a polarized manner, as seen in their considering scientific evidence as more plausible when it is presented alone rather than in conjunction with contradictory information. In contrast, Chinese undergraduates tend to process information in ways that involve greater acceptance of opposing viewpoints, as seen in their considering scientific evidence as more plausible when it is presented in conjunction with contradictory information rather than alone (Peng and Nisbett 1999). These types of differences appear linked, at least in part, to contrasting cultural practices, such as the presence of traditions of debate in certain Western cultural settings as compared with their absence in certain East Asian cultural communities.

2.2 Self-esteem and Well-being

In the area of the self concept, cultural work is calling into question the widely held assumption that enhancement of one's self-image is fundamental to psychological functioning and necessarily yields adaptive advantage. It has been observed, for example, that whereas the open-ended self-descriptions of American adults emphasize positive attributes (Herzog et al. 1998), those of Japanese emphasize either weaknesses or the absence of negative self-characteristics (e.g., 'I'm somewhat selfish,' 'I'm not lazy'). It has also been observed that the scores of Japanese on measures of self-esteem tend to be at or slightly below the scale midpoint, an indication of a tendency to view the self as similar to others (Diener and Diener 1995). This contrasts with the tendency for those of Americans to be higher than the scale midpoints, an indication of a tendency for marked self-enhancement.

Challenging the cross-cultural relevance of the psychological construct of self-esteem, cultural research reveals that self-enhancement tendencies do not play as central a role in social functioning in various

Asian cultural populations as observed typically among European-Americans (Heine et al. 1999). For example, whereas self-esteem is found to correlate more strongly with life satisfaction in cultural settings that emphasize individualistic as compared with collectivist meanings and practices, a concern with relationship harmony shows the reverse pattern of correlations (Gabrenya and Hwang 1996).

Highlighting the role of sociocultural institutions and practices in creating and sustaining such self processes, it has been further documented that European-American behavioral practices tend to be viewed, by both Japanese and European-American populations, as leading to self-esteem enhancement, whereas Japanese behavioral practices tend to be viewed as giving rise to a more self-critical stance (Kitayama et al. 1997). Related types of differences in everyday cultural routines have been documented in research on child socialization. For example, ethnographic work reveals that the stories told by Chinese mothers to their children are more likely to focus on the child's transgressions whereas those told by European-American mothers are more likely to focus on the child's accomplishments (Miller et al. 1996). It has likewise been found that both Chinese as well as Japanese mothers tend to be more critical of their children's academic performance than are American mothers, despite the tendency for their children to show levels of academic achievement superior to those of Americans (Crystal and Stevenson 1991).

2.3 Emotion and Motivation

In regard to emotions, cultural work is providing insight into respects in which affective states, while biologically grounded, are nonetheless constituted, in part, by cultural meanings and practices. For example, somatic experiences that tend to be given a psychological interpretation as emotions by European-Americans are frequently understood and responded to primarily as somatic events within certain Hispanic as well as Asian cultural populations (Shweder et al. 1997). Such effects are closely linked to the tendencies within many Hispanic and Asian cultural communities to interpret social deviance and distress as disorders that originate in problems in interpersonal relationships and that require nonpsychological forms of intervention. In another illustration, research reveals that situationally based physiological arousal is not treated as a sufficient condition for experiencing emotions among men from the Minangabau, a matrilineal agrarian cultural group living on the island of Sumatra in western Indonesia (Levenson et al. 1992). Reflecting their culturally based views of self that treat social relations as integrally related to psychological states, Minangkabau men, unlike American men tend not to interpret their physiological arousal in a socially impoverished laboratory situation in emotional terms.

In turn, studies of culture and motivation are highlighting cultural variation in the experience of agency and challenge the widely held assumption that individuals experience most satisfaction when they are acting autonomously. Recent research has shown that, reflecting their culturally based views of self as inherently social, Hindu Indians report comparable satisfaction when acting to meet role-related interpersonal expectations as compared with when acting more spontaneously (Miller and Bersoff 1994). In striking behavioral findings, it has also been demonstrated that, whereas European-American children display highest levels of intrinsic motivation when they have chosen an activity on their own rather than are undertaking one that was chosen for them by their mothers, Asian-American children experience greater satisfaction when their mothers have chosen the activity (Iyengar and Lepper 1999).

3. Implications

3.1 Challenges

In future research, challenges exist in developing approaches to culture that have greater ethnographic validity and that are more dynamic. In this regard, it is important to go beyond dichotomous frameworks for understanding cultural differences, such as the global dimensions of individualism/collectivism, interdependent versus independent cultural views of self, or of Eastern versus Western approaches. While powerful in certain respects, these types of frameworks embody stereotypical generalities that fail to capture the complexity of individual cultural systems and that portray cultures in ways that are overly static, uniform, and isolated.

Equally, to fully appreciate the impact of cultural views of the self on psychological processes, greater effort must be made to enhance the cultural informativeness of the constructs brought to bear in psychological inquiry. This involves not merely being concerned with the extent to which methodological approaches are familiar and meaningful for different cultural populations. Rather, it requires as well working to insure the cultural inclusiveness of the theoretical constructs embodied in psychological research. In this regard, it must be recognized that many present psychological methods are informed by the cultural premises of the middle-class European-American populations that to date have been subject to most study by psychologists and remain insufficiently sensitive to the perspectives and concerns of other cultural populations.

Finally, there is a need for future research on culture and the self to become increasingly interdisciplinary, with investigators taking into account the conceptual and methodological insights of psychological, anthro-

pological, and sociolinguistic research traditions and avoiding the present insularity, which results either from ignoring or dismissing work from different disciplinary viewpoints. It must be recognized that ethnographic work and quantitative empirical modes of inquiry are interdependent and need to inform each other.

3.2 Contributions

In conclusion, work on culture and the self is succeeding in contributing not only to an understanding of diversity in psychological functioning but is highlighting the frequently implicit cultural dependence of many existing psychological constructs and theories. Work in this area is contributing new process explanations to psychological phenomena, through highlighting the dependence of many existing psychological theories on culturally specific views of the self and associated practices. It is also contributing to the broadening of existing psychological constructs and theories through its identification of alternative normative endpoints for human psychological functioning. Rather than leading to an extreme relativism that precludes comparison, work in this area holds the promise of leading to the formulation of models of human development that are increasingly culturally inclusive and theoretically insightful.

Culture as a Determinant of Mental Health

1. Introduction

Parallel to the revolution occurring with regard to the development of psychopharmacological therapies and biological theories of mental disorders, the health sciences and professions are undergoing a less visible change in theory and practice that promises to radically alter traditional notions about the nature of mental health (Kleinman 1988). The main underlying tenant of this occurrence is the belief that human behavior and its social determinants are critical variables for understanding the etiology, treatment, and prevention of many mental disorders previously attributed to biological causes. Known as cross-cultural psychology, it is defined as the study of behavior and experience as it occurs in different cultures, is influenced by culture, or results in changes in existing cultures. Cross-cultural psychology is not in itself a separate branch of psychology, but rather a method, a point of view, applicable in principle to all other areas of psychology (Dasen et al. 1988).

As a nation of immigrants, the USA has evolved into a multicultural society. The demographic changes that are occurring due to immigration and high fertility rates among the non-white population will continue to enhance the country's cultural diversity. Most researchers, however, address race and ethnicity as demographic characteristics rather than as distinct predisposing cultural and social environmental orientations. This approach has resulted in research and analyses that ignore the contributory role of sociocultural factors to mental health behaviors. Research is needed to understand how these factors contribute to individual and group coping and adaptive mechanisms, in alleviating the distinct socioeconomic and psychological disadvantages of categorical membership. Culture should be conceptualized as a potential individual and group resource, providing psychological, social, and personal identification and group connectedness for racial minorities in particular, and humans in general (Jackson et al. 1995).

In general, culture consists of those aspects of life that people construct and share within a specific reference group (e.g., race, ethnic, social class, age cohort, gender, nationality, and profession). The term 'culture' is so widely used and multidimensional in its applications (e.g., learned as opposed to instinctive behavior; tools humans create; and values and traditions) that its precise meaning varies from one situation to another (MacLachlan 1997). Culture can be seen as the collective heritage of a people handed down from generation to generation. It includes language, religious beliefs, customs, rules of etiquette, and ideas used by people to organize and interpret their lives and existence. Thus, culture refers to the way a people live, the rules of behavior, and conduct they set for themselves.

The interplay between culture and mental health is complex and multidimensional with respect to antecedents, perceptions, expressions, and treatments for numerous mental illnesses (Marsella and Dash-Scheuer 1988). Successful social adjustment, in effect, is the process of learning the habits, norms, and ways of thinking essential for fitting into one's society. This chapter investigates the cultural determinants of mental health, from the standpoint that culture provides a general design for living and a pattern for interpreting reality that impacts mental health. The emphasis here is on the pragmatic role of culture that is especially pertinent to mental health. The likelihood that different cultures encourage different worldviews that buffer or predispose its members to certain disorders is examined. In particular, the role of culture in psychotherapy is discussed in terms of preventing and treating 'non-dominant' cultural minority members within the USA: African Americans, Latinos, Asian Americans, and Native Americans. In sum, the specific focus is on how ideas, values, and assumptions about life guide both client and practitioner.

2. Coping and Prevention

Each culture transmits itself through the process of socialization. Throughout this process, what is conditioned are both general and specific behavioral patterns for promoting human survival and growth. What are learned are acceptable standards and idealized norms that reflect the hard-won wisdom of previous generations. Through culture, biological adaptive capacities are extended to deal with environmental demands. By understanding the ways that individuals from various cultural traditions cope, health researchers and practitioners can gain unique insights into the promotion of human health and prevention of human illness (Marsella and Dash-Scheuer 1988).

For non-dominant minority group members, the problems of living are not only the products of

biological dysfunctions, aberrant intrapsychic development, and familial dysfunctions, social forces also contribute to the onset and course of mental illness (Kleinman 1988). Political, social, economic, and historical and present day relationships (e.g., slavery, legal discrimination and segregation, immigration exclusion and restrictions, internment, poverty, and forced removal to reservations) with the dominant group in the USA, contributes to mental illness among minorities (Murray 1998). In effect, the larger society has played a major role in the developmental etiology of certain mental health disturbances (Wilson et al. 2000). How do the majority of people of color, in spite of ethnic and racial exploitation, cope, adapt, and succeed?

To answer this question, culturally defined strengths indicative of ethnic minority group life should be illuminated. While racial and ethnic groups of color vary widely in the content of cultural beliefs about time, harmony with nature, reciprocity, use of traditional medical substances, and community healers, certain common themes emerge (Jackson et al. 1995). These include deep and abiding community respect for elders, extended kin network, predominant family commitment, cultural aversion to institutional care, and a clear expectation for respect and dignity in the delivery of health care. Some researchers have specifically commented on the elaborate support networks, extended family relationships, and role flexibility of African Americans; the strong sense of communalism, generosity, and harmony characteristic of Native Americans; the socialization of children to respect the entire family system and put family needs over individual needs in Asian American communities; the socializing toward cooperativeness, and the comfort of their Catholicism in times of stress found in Latino communities (Wilson et al. 2000). These group characteristics facilitate coping and mental health, and lessen the nature and expression of disease and chronic conditions, and are necessary to consider for successful care and treatment.

While there are group commonalties, intragroup differences exist in life-course environmental conditions, degree of acculturation, and cultural traditions and beliefs. Thus, there is an indisputable need for mental health care providers to treat each client as an individual, while gathering information on the degree to which cultural coping strategies may facilitate mental health. It is imperative to conduct cross-cultural research on ethnic minorities within the US to identify the relationship between culture-specific coping skills and mental health outcomes.

3. *Cross-cultural Differences in the Perception of Mental Illness*

Although most, if not all cultures, have a notion of madness, ethnographic studies demonstrate that concepts of emotions, self and body, and illness categories differ so significantly cross-culturally that it can be said that each culture's beliefs about normal and abnormal behavior are distinctive (Kleinman 1988). The *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-IV*, APA 1994) recognizes the importance of cultural factors in diagnosing mental illness. Therapists who work with culturally different clients are instructed to take into account (a) the predominant characteristics of manifesting disorders (e.g., possessing spirits, nerves, fatalism), (b) perceived causes or explanatory models, and (c) preferences for professional and indigenous interventions (Sue and Sue 1999). The *DSM-IV* (APA 1994) describes culture-bound syndromes, which are patterns of abnormality only expressed in a particular group, including ghost sickness (a preoccupation with death and the deceased appearing among Native Americans), nervous (symptoms associated with distress and somatic disturbances, such as brain aches and tingling sensations reported by Latinos), and rootwork (illnesses attributed to hexes, spells, and voodoo by African Americans).

The prevalence and course of mental illness also varies cross-ethnically. Recent research comparing African Americans to Whites indicated no difference between the two groups with regard to panic disorders. However, African Americans exhibit a greater frequency of reported tingling in the extremities and a higher mean number of symptoms (Draguns 2000). A comparison of Mexican Americans and Whites, Mexican Americans presented higher rates of generalized anxiety disorder, agoraphobia, and simple phobia than Whites. While there is a dearth of research comparing Asian Americans to Whites, Lin and Endler (1993, cited in Al-Issa and Oudji 1998) reported that anxiety levels were higher among Chinese immigrants. Their findings were attributed to the stress of adapting to a new environment, which resulted in a sense of insecurity and inadequacy.

Another classical difference ignored by Western practitioners is the finding that bodily states and psychological experiences are monitored, perceived, assessed, and reported differently by members of different cultural groups. A consistent finding is that body complaints predominate over psychological complaints in depressive and anxiety disorders among members of non-Western societies, ethnic minorities in the US, and among less educated members of the lower socioeconomic classes (Kleinman 1988).

Culture may influence how depression is experienced and communicated. Some cultures perceive the physician as a healer of physical ailments rather than psychological ailments. The urgency surrounding physical as opposed to psychological ailments may vary across cultures, as may the degree to which psychological weakness is stigmatizing. The biology of depression and anxiety disorders underwrites the inner form of these disorders, but cultural beliefs and values shape the expression of the illness (Kleinman 1988).

4. Etiological Beliefs and Folk Approaches

All healing systems are shaped by the values, worldviews, and self-views of the cultures in which they develop and are utilized. Therefore, all healing systems are 'ethnomedical.' Rules and principles guiding the various ethnomedical models form discreet and different genre altogether, making cross-ethnic comparisons difficult. However, while distinction among the non-Western groups are difficult to delineate, very salient differences exist between various ethnomedical models and traditional Western methods in psychotherapy. For instance, Western psychotherapy is traditionally a one-on-one activity that encourages clients to discuss the most intimate aspects of their lives. In Latino culture, clients rarely describe their complaints as the main step in an intake process, expecting the healer to already know the client's complaints (Koss-Chioino 2000). Due to experience with oppression, African Americans are hesitant to self-disclose. This may serve a protective function against possible physical and psychological harm (Sue and Sue 1990), but individuals who do not self-disclose may be seen as resistant, defensive, or superficial by therapists. Many minorities who are reluctant to self-disclose are judged to be mentally unhealthy and, in the case of African Americans, are diagnosed as 'paranoid' (Murray 1998).

In spite of the differences in each group's healing practices, cultural commonalties do exist across the four ethnic groups described in this paper. Specifically, the commonalties consist of (a) a widespread belief that the causes of mental illness exist outside the person, (b) a group orientation to healing (i.e., family and/or community) as opposed to an individual orientation to treatment, (c) an emphasis on morality as a cause and condition for recovery (Koss-Chioino 2000), and (d) an emphasis on short range goals, as opposed to long range goals (Sue and Sue 1990). These similar healing practices among non-Western groups differ from Western therapeutic practices.

Latinos, Asians, Native Americans, and African Americans are all heterogeneous groups including many specific traditions that differ from each other in profound ways. Divination (i.e., beliefs in the supernatural and practices to connect with the spirit world) was originally part of each of these groups' healing practices. Unlike Western cultural groups who have discarded such practices, divination to some extent is still part of the healing practices of many, but not all of the subcultural groups within each of the broader categories. Among Native Americans, for example, traditional healing practices vary along tribal lines, and are largely shamanic (spiritual intervention to heal the sick). One of the major shamanic healing entities is the Native American Church, which is a pan-Indian religion based on a ritual that facilitates direct contact with the Great Spirit (also God) through peyote, pipe and cigarette smoking, drumming, and songs and prayer (Koss-Chioino 2000). African American healing practices differ in beliefs, practices, and types of healers based on locale (e.g., north vs. south, and places of special tradition such as the Sea Islands of South Carolina). Overall, the underlying belief system of African Americans is a blend of medical beliefs of an earlier day, African beliefs about voodoo, European folklore regarding the supernatural world, and fundamentalist Christianity. Etiological notions are divided into natural and unnatural categories, varying from unhealthy lifestyles and nonproductive worry to beliefs in evil influence or God taking punitive action. Physicians or herbalists can cure the first two causes, but the latter two causes demand intercession of a religious healer or a contract with God.

Among Latinos, divination may involve healer's use of shells or tarot cards as a guide to see into the spirit world to identify the cause of the client's problem. The healer describes the client's problems (somatic distress, bad feelings, and persistent interpersonal or social problems), and then the client confirms (most frequently) or denies. Very little epidemiological data are available on the utilization of ethnomedical treatments by Latinos in the USA. The existing data, however, indicate that the utilization of divination varies across Latino ethnic populations. Within the USA divination appears to be a flourishing mental health alternative in Miami, Florida, among the Cuban population. Estimates among Mexican Americans vary from 7 percent in San Diego to 54 percent in South Texas (see discussion in Koss-Chioino 2000). It is important to note that some studies separate the belief in traditional healing practices from reports of actual use, so discrepancies may not be so extreme.

Variations are especially salient among Asian Americans (e.g., Chinese, Japanese, Vietnamese, Koreans, and tribal people such as the Hmong or Lao). Among the Chinese, shamanic healing (e.g., divination) has not been reported in the USA. The Chinese-American ethno-healers emphasize a balanced and disciplined life to maintain physical and psychology health. In addition, physical/bodily manipulation, acupuncture, massage, and breathing exercises are common. In contrast, Southeast Asians in the USA see shamans (e.g., folk healers, witch doctors, etc.) when they are available (see discussion in Koss-Chioino 2000). This propensity to visit shamans is motivated by the belief that spirits are omnipresent throughout nature and can cause or heal illness. For example, there occurs among adult Southeast Asians, particularly male Hmong refugees living in the USA, a 'Sudden Death Syndrome.' Autopsies produce no identifiable cause of the death: A person in apparently good health went to sleep and died without awakening. Often, the victim displayed labored breathing, screams, and frantic movements just before death. Prior to their deaths, these men reported that they were experiencing spirit visitations, and that the spirits were unhappy and were punishing them. Clearly, these

deaths do not appear to have a primary biological basis, whereas the deaths do appear to involve psychological factors, including a belief in the imminence of death—either by a curse (e.g., voodoo suggestion) or some form of punishment (Sue and Sue 1999).

Western-trained therapists too often dismiss these belief systems and impose their own explanations and treatment upon culturally different clients. Without an understanding of the underlying cultural beliefs, there exists the tendency for the therapist to overestimate the degree of pathology. In the case of Southeast Asian men who report spirit attacks, a Western traditional therapist would most likely diagnose these persons as paranoid schizophrenic, suffering from delusions and hallucinations (Sue and Sue 1999). Such a diagnosis would most likely lead the therapist to prescribe a powerful antipsychotic drug and perhaps institutionalization. Studies indicate, however, that shaman techniques cure these symptoms (Sue and Sue 1999). The effectiveness of such treatment may lie in the client's belief in the power of the doctor (shaman) and the treatment (divination) received.

While the four groups presented here vary in their degree of homogeneity concerning beliefs in spiritual attacks, a sizeable number of each group does hold these beliefs. Western medicine does not embrace indigenous or alternative healing approaches and often rejects such approaches as unscientific. Using a culturally inappropriate approach may result in harm or even death (e.g., as in the case of Sudden Death Syndrome). In an attempt to insure cultural responsiveness, the mental health practitioner must either incorporate the legacy of ancient wisdom that may be contained in indigenous models of healing, or refer the culturally different client to a culturally appropriate healer.

5. *The Impact of Ignoring Culture in Therapy*

Culture (i.e., systems of symbolic meaning) impacts both mental health and therapeutic intervention. Specifically, culture influences our understanding of the major stages of the clinical process: patient and practitioner explanatory models of sickness; perception, labeling, and presentation of symptoms; health-seeking behavior; doctor–patient communication; curing and healing; and lay and health professional evaluations of therapeutic outcomes. Culture exerts its most fundamental and far-reaching influence through the categories we employ to understand and respond to sickness. As previously discussed, different societies and ethnic groups within one society often affix different sickness labels to the same syndrome (Kleinman 1988). When patient and practitioner explanatory modes reflect different cultural backgrounds, the clinical realities they define can be, and frequently are, quite disruptive to the treatment process. When those explanatory models are in conflict, the results may be client dropout, noncompliance and dissatisfaction, and/or practitioner missed diagnosis, inappropriate treatment, and poor quality of care. All of these reportedly exacerbate existing problems and even create new issues for the client (Sue and Sue 1990, Turner and Kramer 1995).

Although ethnic minorities are increasing in the USA, only superficial interest has been paid to training mental health professionals to deliver culturally sensitive services (Turner and Kramer 1995). Furthermore, the practice of substituting a model stereotype (i.e., the most frequent behaviors of middle class White males) for the real world, while disregarding cultural variations in a dogmatic adherence to some universal notion of truth culminates in a technique-oriented definition of the therapeutic process. The results are that a lack of culturally responsive forms of treatment is the single most important reason given for ethnic minorities being underserved, inappropriately served, and/or their significantly higher drop-out rate (Sue and Sue 1990).

Another significant aspect of cross-cultural awareness is the acknowledgment that disadvantaged people often experience oppression, discrimination, and racism. Instead, a lack of sensitivity on the part of mainstream therapists results in further abuse of the minority ethnic client (Murray 1998). On every index, minorities receive fewer and poorer quality services. Specifically, African Americans and Latinos, in contrast to Whites, holding symptoms constant, were less often given individualized psychotherapy, more often jailed instead of hospitalized, and more often treated with pharmacotherapy instead of talk-therapy (Lawson 1999). Many studies have demonstrated that clinicians given identical test protocols tend to make more negative prognostic statements and judgments of greater maladjustment when the individual was said to come from a lower rather than a middle-class background, or was an ethnic minority member (Lawson 1999).

When ethnic minority clients are met with insensitivity or outright racism on the part of the therapist, poorer outcomes are likely to result (Kurasaki et al. 2000). Thus, the need for changes in mental health delivery is real. For mental health professionals to effectively deliver services to members of a negatively stereotyped group, they must first become aware of their own culture and assumptions about human behavior, values, biases, preconceived notions, personal limitations and so forth. Secondly, they must actively attempt to understand the worldview of their culturally different clients in terms of the etiology, coping strategies, and course of mental disorders (Murray 1998). Cross-cultural sensitivity has been accomplished when the therapist has: (a) an understanding of his or her own culture and achieved self-awareness; (b) an understanding of the client's culture; (c) an understanding of the client's relationship to the sociopolitical system; (d) an understanding of the ways in which generic counseling and therapy may

limit the potential of the client; (e) an array of therapeutic techniques at his or her disposal; and (f) a willingness to exercise institutional intervention on behalf of the client when appropriate (Sue and Sue 1990).

6. Conclusions

In conclusion, culture plays a role in every aspect of mental health. Cultural influences vary greatly from individual to individual. Many mental health problems have culture-common, culture-specific, or both components. In the case of minority ethnic members, too often the larger society's role in the developmental etiology and maintenance of certain mental health disturbances is ignored. However, the literature does suggest that racial attitudes that poison our society and are internalized by mental health professionals can hamper the efforts of people of color to maintain or regain their mental health (Turner and Kramer 1995). In addition, despite the fact that coping is fundamental to our understanding of human health, mental health professionals often do not acknowledge characteristics of minority cultures that are adaptive and facilitate coping within a stressful environment. Every culture is a unique solution to the myriad forces imposed on its members. In fact, cross-cultural differences exist in perceptions of mental illness in terms of beliefs about the causes, the prevalence and course, and the experience of symptoms. Within the therapeutic environment, therapist/client communication, diagnosis, intervention strategies and techniques, client use of health facilities, and the course of mental disorders have all been impacted by culture. Therefore, mental health care providers must be trained to identify the role culture plays in mental illness. The culturally sensitive professional goes beyond the qualities of concern, empathy, and credibility. They have self-knowledge, and a willingness and ability to take the cultural background of clients into consideration. Without self-knowledge and cultural sensitivity on the part of the therapist, the mental health needs of ethnic minorities will remain underserved and inappropriately served at best, and at worst ethnic minorities will continue to be misdiagnosed and victimized under the guise of therapeutic intervention.

Culture as Explanation: Cultural Concerns

Culture is a shared interpretive scheme. The subject of this article is the process by which culture is created. Without being able to make comparisons, what can be said about culture? The theory to be described began as a method for comparing cultural bias (Douglas 1970). Twenty years later it had become a theory about political change (Thompson et al. 1990), with two explicit assumptions.

Assumption number one: people living together try to control one another. A culture develops in response to the need to persuade and to mobilize opinion; principles have to be argued, justifications advanced, and opposing opinions attacked. For sheer survival an organization depends on its members' efforts to keep it in being; it would dissolve if there were no will to maintain it. Members of a community put each other under continual pressure to show loyalty and give support. It follows from this that a culture protects and promotes a way of organizing, whether it be a family, a shop, or a kingdom.

Assumption number two: a culture is inherently adversarial (Thompson and Schwartz 1990). A culture grows stronger and more coherent by opposition. In one community there will normally be several cultures self-defined against the others; a progressive culture, a traditionalist culture, a culture of individualism, and no doubt always some members who are just not involved. The researcher needs to trace the alignments in any particular community, know what is at stake, and hear members justifying their own preferences and trying to delegitimate opponents. In any major public policy debate, contending parties tend to align themselves in opposed cultures. They invoke different theories of justice which fuel their conflict and keep the intercultural struggle alive (Davy 1997).

1. Four Types of Organization

The method provides an abstract model of organizational forms, a spreadsheet on which the biases of a group of human subjects can be located. The scheme is necessarily abstract, since it is intended to apply to any kind of social context or conflict. The intention is to show four incompatible social organizations. It represents a range of social constraints by which individuals are confronted. By choosing to align with one type, the person automatically invites opposition from the others.

Why four types? Because 500, or even 20, would be too difficult to manage. Another answer is that the two axes generate four types well known in Western social science writing, so the number fits well to the contemporary discourse. Another answer is that four is enough. That is, it is enough for demonstrating the thesis that culture provides a store of justifications which are used to protect or to attack the organization of social life. Another answer is that the four that are shown in Fig. 1 are clearly incompatible with each other. Anyone who uses the scaling possibilities can multiply the number of subtypes at will.

Why are they adversarial? The four cultural types in question are two groups, (complexly structured or unstructured groups), and two cultures of individuals; the culture of individualism, and the isolates. When the principles of their organization are examined, an inevitable rivalry between the four types appears.

Strong grid *Weak group boundary* Isolates	*Strong grid* *Strong group boundary* Hierarchy
Individualist culture *Weak grid* *Weak group boundary*	Egalitarian group *Weak grid* *Strong group boundary*

Figure 1
The four types of control

2. Hierarchy and Individualism

Different principles of organization make contrary demands on the use of time and space. For example, a hierarchy is organized in complementary-ranked compartments which subordinate the individual member to the whole. Its priorities will be reflected in the grandiose design of public spaces, such as a magnificent cathedral precinct, museum, and municipal park, sheer size contrasting with small individual dwellings stacked in tidy little groups; the pattern of the streets is confusing, new patterns built over the old ones without obliterating them, narrow winding lanes still known by their original names. In the individualist culture, old streets can be torn up to make room for wide, straight motorways, numbered for the sake of efficiency, an overall pattern of grand private mansions and tawdry public places, disorderly hovels. As to the use of time, a hierarchy is not in a hurry, it expects its institutions to last for ever, but the individualist culture puts pressure on the use of time as part of its commitment to efficiency. Such incompatible demands uphold the antagonism between these cultures.

To introduce Fig. 1, let us continue to contrast the idea of a hierarchy, quite fairly caricatured in accounts of bureaucracy, with the idea of an individualist culture. Hierarchy assigns status by birth, which gives age, gender, and place as further principles of identification. Hierarchy controls individual behavior and severely limits the scope of negotiations. In the individualist culture, merit, not heredity, determines status, the individualist has to negotiate everything. These are two kinds of organization, one organized by status, in which positions are assigned, the other organized by competition. To map these differences on a graph, start with the horizontal axis (called 'group' or 'group solidarity'). This indicates incorporation

into groups. Along that line the individual members of society have to be located according to how much their behavior is controlled by a group boundary. No group belongs at zero on the left corner, an environment favoring individualism, the strong group is towards the right. Some strong groups, such as sects or monasteries, strictly control their boundaries. Elsewhere, individuals can be members of several groups; a choir, a political club, or a sports club, the local neighborhood watch; none is exclusive, group control is weak, boundaries are weak. It is not difficult to find indices for these features.

3. *Four Types of Control*

These are shown in Fig. 1. The two axes combined provide a range of possible social environments. Strong measures for both grid and group correspond to the organization of hierarchy; weak grid and weak group correspond to the environment of an individualist culture.

There are other impersonal constraints that cut across group boundaries, which structure behavior and in this context are referred to as 'grid' or 'structure.' 'Grid' is an impersonal set of rules that prevents free communication and limits transactions, it imposes ceilings on endeavor and barriers to entry. A class system is a grid factor, immigrant status entails restrictions, so does the difference between wealth and its absence. Limitations on the rights of ethnic groups, prohibition on land owning, sumptuary laws, all these draw lines between how members of the same society can transact with each other. Restrictions on nonconformist religions in England used to prevent their access to universities. Such constraints are shown on the vertical axis. The restrictions cited are selective, but others fall on everybody in the community to the same degree; curfews in time of war, restrictions according to age for drinking alcohol, restrictions on road traffic, control of prices or quality of merchandise, health and safety regulations. At the bottom of that vertical line is a possibility of perfect freedom to wheel and deal, at the top, no options.

4. *Egalitarian Groups and Isolates*

Two corners of the diagram are still not described. One is the relatively rare social environment made by a group which encloses its members within strong boundaries but imposes no structure on them. The one constraint that matters is the external boundary; within it every transaction has to be negotiated. The founding principles of some sects lay down that all the members are free and equal, but in practice it takes a lot of regulation to create perfect equality (Rayner 1988). Where it differs from hierarchy is that this regulation controls all the members in the same way, like rules of the road; it does not create internal divisions.

Environmental or other activist groups as well as religious sects often observe egalitarian ideals. So long as the group is unstructured (a kibbutz, for example), they belong in what is often called (in contradistinction to hierarchy) the sectarian corner of the diagram. Of course, if a group were to maintain a hierarchical system, such as the Mormons or certain groups of environmentalists after having acquired political power, they should be placed along with other hierarchies on the diagram.

There are organizational reasons for why many protesting dissident groups (secular or religious) espouse a doctrine of equality. By withdrawing from the big, complex, mainstream society, the group has problems in maintaining itself. The leaders find they lack authority, they are afraid of being accused of free-riding, decision making becomes difficult. The doctrine of equality is often adopted as a solution, henceforth no-one will be superior to any other member, decisions will depend on consensus. But the solution entails other difficulties. It does not help decision making, or protect authority (Sivan 1995). The group expects to ensure its own survival, but it has no authority to stop its children from leaving. The danger of defection focuses attention on the boundary that defines the insiders. Inside/outside becomes the central cultural issue. Then the other cultural traits associated with sectarianism may come into play, a dichotomizing tendency in judgments, the world seen in black and white, outsiders as evil or ungodly, intransigence in negotiation.

The other is the environment of the isolates, dropout, noncommitted, unaligned individuals. They are by definition not involved when the members of the other three cultures argue strenuously about the right and the good. If they were, they would either have to join up with like-minded souls and be classed as members of a group, or they would have to speak as independents, joining the individualists on the diagram. The diagram shows up well the extreme types of organization, selected on the basis of their incompatibility with the rest. The human subjects have to be fitted into their slots according to agreed measures. Rayner and Gross (1985) have shown how to develop measures with a toy example of a conflict involving a group of environmentalists, town residents, an industrial corporation, and government officials. Theoretically, the four conflicting cultures are potentially available at any time, usually one dominant, each in competition with the others.

5. *Information*

Group boundaries make a hurdle that new information has to cross. The first test of reliability is the source; insiders are more to be trusted than outsiders,

but certain outsiders are privileged. If the group is divided into factions or into administrative compartments, each internal boundary constitutes another barrier.

Blocks to the flow of information abound in a hierarchy; each compartment has its own secrets. It would subvert the structure of the organization to make pressure to disclose records. Knowledge is dispensed according to 'the need to know.' Secrecy tends to be acceptable and normal, information is classified and stored systematically. As the organization has institutions for sifting and storing it, information from outside is not automatically unacceptable, but it is put under political scrutiny. Consequently, it travels slowly and often gets stuck.

An egalitarian commune is in worse case, since it lacks any formal structure for testing and classifying the news. Mistrust is the drawback when two strong group cultures try to negotiate with each other; they mishear what the other side is saying. Within an egalitarian group there may be so much mistrust that official envoys to a peace conference may not be fully informed.

Like the culture, information has to compete to be accepted. Individualism is not strong on protecting the commons against spoliation, it justifies its ways on grounds of individual human rights. Information can flow freely in the absence of boundaries, but public institutions for classifying or organizing it are weak. Instead of information there is uninterpreted noise; individuals may have to pay for special knowledge for serious decisions.

The isolates are in a similar pass. Their isolation means that they are not likely to be influential in councils, their news comes to them haphazardly, and they lack incentives to sort it out. They tend to have disconnected, idiosyncratic opinions. It does not matter because in that environment there is no-one else to argue with: they are isolates.

6. *Storage and Retrieval*

A hierarchy justifies itself by appeal to tradition, and by appeal to the well-being of the whole community. To strengthen its justifications it tends to take its origins back to the beginning of time. Since each subdivision uses the same kind of appeals and justifications as the center, hierarchy develops a characteristic sense of history, extending far into the past, and subdivided at every point that a separate subdivision came into existence. The calendar of feasts revives public memory as it celebrates each point of junction or division. The organization that is strong enough to protect its own security gives guarantees of stability to its members. Assuming the system will endure, they act to assure that it will. Partly because it has no advantage in looking for a sudden end to time, and partly because it is confident enough to allow loans to be repaid over a very long-term future (for example, leased property for 900 years), its sense of future time is also very long.

The individualist culture differs in all these respects. It does not justify itself by reference to history, nor does it regard any of its present ranks or subdivisions as unalterable, so that divisions in past time are not built into the organization. Its festivities are more apt to celebrate individual prowess than past events. Its sense of future time is short. An egalitarian group, by contrast, has no internal divisions whose annual celebrations endow their memories with structure. Their sense of time is millennial; the past will have started apocalyptically with the foundation of the group, the moment which is the point of reference for claims and justifications. Their attacks on outsiders and their justifications of their own record refer constantly to a coming catastrophe for the enemies of the group. The difficulties of organization invite covert competition for leadership; as there is a deficit of power, there are no grades for downgrading, no regular system of punishment, conflicts can only be solved by expulsion or by splitting the group. These structural weaknesses mean that though the movement may have its roots in a long-distant past, each community is relatively new: its history is short.

The fourth cultural type, the isolates, gives minimum opportunity for negotiation, either because of demographic sparsity (nobody to negotiate with), or because other people have restricted their freedom to negotiate, typically in the lower echelons of a big bureaucracy. The culture of isolates is politically apathetic, and limited to the short term. While the isolates themselves are not necessarily unhappy, their sense of a communal past is practically non-existent, and such individuals have little in the way of public benchmarks to help in remembering their private pasts.

In this perspective, only the hierarchy has the possibility of recalling a differentiated past with many twists and turnings, but it is certain that its history will be strongly biased in favor of itself.

7. *Decision Making*

Hierarchy's characteristic decision procedure is based on historical precedent and seniority. What is once decided can be made effective because the system protects authority. Individualist culture is also effective in decision making, because it reflects the balance of power at the time. By contrast, decision making in an egalitarian community is beset with difficulties; authority is weak and the group risks destruction from its own internal dissension. The isolates, knowing that they have no influence, realistically adopt a culture of fatalism, which militates against consistent decisions.

8. Conclusion

We could introduce the theory from almost any situation of conflict, but we have chosen to focus on selection of information, because, after all, it is about argument and disagreement on values. It can explain why information does not always travel, and how it sometimes gets blocked. Some cultures preserve information about a long historical past, some have a store of techniques for projecting the future, others live in the present and are not interested in the past or the future. The variation is due to the way that organizations act as filters and pointers (Douglas 1987). These examples illustrate how this type of analysis can trace different sources of failure to mobilize support for a given set of principles. It has been widely applied to disagreements about risk. In the late 1990s the scope has widened to include environmental politics of the great waterways, the Ganges and the Rhine (Gyawali 1998, Verweij 2000), traffic control in city planning (Hendriks 1999), conflict in recent British Labour party history (Bale 1999), kinds of control used in public administration (Hood 1998), and even to conflicting ideas about personal privacy (Perri 1998), and market research (Karmasin and Karmasin 1997).

Culture sets up the terms on which individual calculations of interest are based. Organization entails coordination, which entails classification and logic. As they responsibly calculate and negotiate, the rational beings are creating, changing, or sustaining their culture. The method is sometimes criticized for focusing on organizations and paying too little attention to the role of individuals in shaping culture, but far from neglecting the individual, the theory sets the individual person in a normal framework of interaction. At center stage, each rational person, assumed to be interested in the costs or benefits of subscribing to other people's opinions, is partaking in a process of collective choice.

Culture: Contemporary Views

1. Introduction: Kroeber's and Kluckholn's Prediction

' … few intellectuals will challenge the statement that the idea of culture, in the technical anthropological sense, is one of the key notions in contemporary American thought.' That prediction was made in 1952 by the American anthropologists A. L. Kroeber and Clyde Kluckholn in the introduction to their monumental book *Culture: A Critical Review of Concepts and Definitions* (1952). In the years immediately following World War 2 many scholars and intellectuals in the United States were quite confident and pleased that the concept of 'culture' was deeply entrenched in the human sciences. Kroeber and Kluckholn even began their famous treatise proclaiming the idea of culture comparable in explanatory importance to the idea of gravity in physics, disease in medicine, and evolution in biology. They ended by adducing a unified (albeit ponderous) definition that became the mantra for cultural anthropologists who

came of scholarly age in mid-century. 'Culture' they wrote, 'consists of patterns, explicit and implicit, of and for behavior acquired and transmitted by symbols, constituting the distinctive achievement of human groups, including their embodiments in artifacts; the essential core of culture consists of traditional (i.e., historically derived and selected) ideas and especially their attached values; culture systems may, on the one hand, be considered as products of action, on the other hand as conditioning elements of further action' (1952 p. 357).

Kroeber and Kluckholn were students of intellectual history and brilliant culture theorists but they were not prophets. Little did they know that during the 50 years following the publication of their book, the idea of 'culture,' in its mid-century anthropological sense, would be frequently debated, doubted, distrusted, and scorned, that the discipline of cultural anthropology itself would be 'rethought,' 'remade,' 'recaptured,' and 'reinvented' time and time again. They did not foretell the many types of humanists and social scientists (cognitive revolutionaries, structuralists, poststructuralists, sociobiologists, feminists, skeptical postmodernists, postcolonialists, subalterns, globalization theorists) who would associate the concept of 'culture' with a variety of supposed sins. Sins such as 'essentialism,' 'primordialism,' 'representationalism,' 'monumentalism,' 'reification,' 'idealism,' 'positivism,' 'functionalism,' 'relativism,' 'sexism,' 'racism,' 'colonialism,' 'Orientalism,' and just plain old-fashioned 'stereotyping' (see for example, Abu-Lughod 1991, Asad 1973, Clifford and Markus 1986, Denzin 1996, Fox 1991, Freeman 1983, Hymes 1972, Kuper 1999, Markus and Fisher 1986, Rabinow 1983, Reyna 1994, Rosaldo 1989, Said 1978, Sangren 1988, Scheper-Hughes 1995, Spiro 1986, Wikan 1996).

Nor did Kroeber and Kluckholn anticipate the ironic fate of the concept of 'culture' at the beginning of the twenty-first century. The irony is that today the idea of culture is once again a key concept in many of the social science disciplines, yet is viewed with great suspicion in some quarters of cultural anthropology. The irony is that after being reviled, pummeled, and rejected by one new wave intellectual movement after another an idea of 'culture' very much like the one recommended by Kroeber and Kluckholn in 1952 remains useful and defensible in social science research and public policy debates. The concept not only survives it thrives (see for example, Harrison and Huntington 2000, Huntington 1996, Landes 1998, Prentiss and Miller 1999, Kitayama and Markus 1994, Wierzbicka 1997). The contemporary discipline of anthropology continues to be a scene for various kinds of 'anticultural' or 'postcultural' critiques. Nevertheless, many anthropologists rehearse and recite some definition of culture, and make good use of it in their scholarship (see for example, D'Andrade 1995a, Dumont 1970, Geertz 1973, LeVine et al. 1994, Sahlins 1995, 1999, Shore 1996, Shweder 1991, Shweder and LeVine 1984). It remains to be seen whether and just how soon the concept regains its former popularity in anthropology. That discipline was historically identified with 'studies of culture.' Tripling the irony, in recent years some anthropologists have abandoned the idea of 'culture' and subjected it to intense critique under the banner of an intellectual movement known as 'cultural studies' (Denzin 1996).

2. *The 'Standard View' of Culture in North American Anthropology*

Kroeber's and Kluckholn's seminal definition of culture—which I shall refer to as the standard view from the perspective of North American cultural anthropology—was cumbersome, in part because it was so inclusive. It called on anthropologists to study not just other people's beliefs (their ideas of what the world is like) but also other people's normative standards (their ideas of what is good and what is right). It called on anthropologists to study not just the explicit 'ethnosciences' and doctrinal moral and religious codes of the members of a community but their tacit, implicit, or intuitive understandings as well. It sought a middle course between the *Scylla* of a purely behavioral definition of culture and the *Charybdis* of a purely ideational one. According to the standard view, 'culture' should be defined in such a way as to avoid the hazards of both behaviorism and idealism. On the one hand, Kroeber and Kluckholn suggest that culture is more than just social habits or 'patterns of behavior that are learned and passed on from generation to generation.' On the other hand, it is not just a system of categories, doctrines, propositions, or symbols *per se*. Thus in the 1952 definition, culture is defined as the ideational side of social action or social practice, and anthropologists are called upon to view cultural analysis as the interpretative study of behavior, although rather little is said about what particular theory of interpretation should guide the analysis.

Useful definitions deserve to be expressed in elegant terms, and Kroeber's and Kluckholn's definition of culture is cumbersome, to say the least. But it is not the only expression of the standard view. The most exquisite and straightforward formulation is Robert Redfield's definition: 'shared understandings made manifest in act and artifact.' Another variation, perhaps the most famous definition of culture since the 1950s, is the one proposed by Clifford Geertz (1973, p. 89). He puts it this way: '… the culture concept … denotes an historically transmitted pattern of meanings embodied in symbols, a system of inherited conceptions expressed in symbolic form by means of which men communicate, perpetuate, and develop their knowledge about and attitudes towards life.' In 1984 D'Andrade, writing very much within the North American anthropological tradition, defined 'culture' as 'learned systems of meanings, communicated by

means of natural language and other symbol systems, having representational, directive and affective functions, and capable of creating cultural entities and particular senses of reality' (D'Andrade 1984, p. 116).

The definitions proposed by Kroeber and Kluckholn, Redfield, Geertz, and D'Andrade call out for specification and clarification. Nevertheless, those definitions are a good reference point for understanding current debates about the values and dangers associated with the very idea of 'culture.' One can summarize the standard view by saying that 'culture' refers to community-specific ideas about what is true, good, beautiful, and efficient. To be 'cultural' those ideas about truth, goodness, beauty, and efficiency must be socially inherited and customary. To be 'cultural' those socially inherited and customary ideas must be embodied and/or enacted meanings; they must actually be constitutive of (and thereby revealed in) a way of life. Alternatively stated, the standard North American anthropological view of 'culture' refers to what the British philosopher Isaiah Berlin (1976) called 'goals, values and pictures of the world' that are made manifest in the speech, laws, and routine practices of some self-monitoring and self-perpetuating group. A cultural account spells out those 'goals, values, and pictures of the world.' A cultural account thus assists us in explaining why, the members of a particular cultural community say the things they say and do the things they do to each other with their words and other actions. These 'goals, values, and pictures of the world' or 'ideas about what is true, good, beautiful, and efficient' are sometimes referred to as 'cultural models' (D'Andrade 1995, Holland and Quinn 1987, Shore 1996).

3. *Fault Lines in Contemporary Anthropology*

The standard North American anthropological view of culture was synthesized and defined by Kroeber and Kluckholn before the discipline went through a series of revolutions and movements that fractured the field and divided it on the basis of somewhat different visions of its mission. Although it may be hazardous to propose a map of the current intellectual camps within cultural anthropology, such a map may also be helpful in understanding the various types of anticultural, postcultural, and procultural positions that have emerged within anthropology over the past 50 years.

I think it is fair to say that contemporary cultural anthropology is divided into at least these four conceptions of the field.

3.1 *Identity Politics*

The first is a conception of anthropology as a platform for moral activism in the battles against racism, sexism, homophobia, and neocolonialism and as a forum for identity politics in the fight against exploitation, discrimination, and oppression. Advocates of this conception of anthropology have several concerns about the idea of 'culture.' They argue that the idea of 'culture' is an excuse for the maintenance of authoritarian power structures and permits despots and patriarchs around the world to deflect criticism of their practices by saying 'that is our custom' or 'that is the way we do things in our culture' (see Abu-Lughod 1991, Said 1978, Scheper-Hughes 1995, Wikan 1996). The claim by liberal 'first world' feminists that 'multiculturalism is bad for women' (Okin 1999) is an expression of this view, which tends to associate 'culture' with the idea of patriarchal domination (Haynes and Prakash 1991, Reheja and Gold 1994). This conception of the mission of anthropology is closely allied with a global human rights movement that has a firm sense of what is objectively and universally right and wrong.

However, not all moral activists in anthropology want to dump the idea of 'culture' and some have found ways to put the idea of 'culture' to work in the service of their own political aims. Anthropologists who are active in the identity politics movement find the idea of 'culture' politically and strategically convenient in their egalitarian battles on behalf of 'oppressed peoples.' They find the idea useful as one of several ways to mitigate various types of invidious comparisons between groups (for example, comparisons in terms of wealth, occupational success, or school performance). There are generally three ways to mitigate invidious comparisons between groups: (a) deny that any real differences exist, (b) attribute all differences to a history of oppression or discrimination, or (c) celebrate the differences as 'cultural.' In the identity politics movement 'culture' is becoming a code word for 'race' and it may not be too long before the expression 'people of color' is replaced by a new shibboleth, 'people of culture.'

3.2 *Skeptical Postmodernism*

The second conception of the mission of anthropology is a conception of the field as a deconstructive discipline and as an arena for skeptical postmodern critiques of all ethnographic representations and so-called 'objective' knowledge (see, for example, Clifford and Markus 1986, Latour and Woolgar 1979, Rabinow 1983, also Culler 1982, Foucault 1973, Rosenau 1992). Advocates of this conception of anthropology call for a deeply skeptical reading of all anthropological representations of 'others,' especially of those accounts that make claims about some 'primordial' or essential or core cultural identity which members of some group are supposed to share. The skeptical postmodernists raise doubts about the reality and existence of groups. They are critical of all attempts to draw a portrait of 'others' that represents

them with any characteristic face. They are suspicious of the very idea of boundaries and borders and loyalties to ones 'tribe.' They view the idea of a 'culture' as a fiction, the goal of objective representation as misguided, and the products of ethnography as largely 'made up' or constructed in the service of domination.

One of the many ironies of contemporary anthropology is that for a while members of the first two camps of anthropology (the identity politics/moral activists and the skeptical postmodern/deconstructivists) thought they were allies. Indeed they had an imagined common enemy. In particular the hegemonic heterosexual 'first world' white males, such as Kroeber, Kluckholn, Redfield, and Geertz, who historically had defined the mission of cultural anthropology.

The alliance, however, was short-lived. Identity politics requires a robust notion of 'identity' and group membership. Moral activism requires a good deal of conviction that some things are 'objectively wrong.' Skeptical postmodernism is intellectually incapable of lending support to either of those metaphysical notions and is readily put to use deconstructing the 'woman' of 'Women's Studies,' the imagined common identity of the ethnic group, and all supposed objective moral foundations for any political cause. If 'groups' and collective identities are so easily dissolved so too are claims about group rights and affirmative action.

3.3 Neopositivism

A third conception of the mission of anthropology is a conception of the field as a pure 'positive' science (see for example, D'Andrade 1995a and 1995b, Sperber 1985, Romney et al. 1986). The positive scientists view anthropology as a value-neutral and nonmoralizing discipline. Their preferred aims for the discipline are to reliably and validly represent the law-like patterns in the world and to develop universal explanatory theories and test specific hypotheses about objectively observable regularities in social and mental life. Advocates of this conception want to protect anthropology from identity politics and skeptical postmodern critique by accurately recording rather than judging and condemning other peoples practices, and by developing objective or scientific standards for evaluating the truth of ethnographic evidence. This is a laudable aim, although one that has been contested by skeptical postmodernists, and there has been much useful work in neopositivist fields such as 'cognitive anthropology' representing the content, structure, and degree of sharing of 'cultural models' (see for example, D'Andrade 1995a, Holland and Quinn 1987, Romney et al. 1986). Nevertheless, the positive scientists in anthropology thereby tend to beg a critical question close to the heart of all great social theorists. Is this or that social order really a moral order? Is this or that social order a way of living that might appeal to a rational and morally decent person, and if not how can we make it become so? When it comes to evaluating what is truly desirable or really 'good' in social life the neopositivists are very much like the skeptical postmodernists—both turn radically subjective or relativistic and believe there is no scientific or objective foundation for value judgments.

3.4 Romantic Pluralism

A fourth conception of the mission of anthropology is a conception of the field as a romantic discipline designed to test the limits of pluralism. Pluralism is the idea that things can be different but equal, and that diversity can be good. It is a measure of some of the tensions within contemporary anthropology that while the 'ethnography of difference' is viewed with suspicion by some of the anticulturalists, it is universally embraced by romantic pluralists. Anticulturalists worry that any description of cultural difference merely sows the seeds of invidious comparison and ethnic conflict, and thus should be disavowed. For the romantic pluralists, however, the recognition and appreciation of cultural differences is one of the major aims of ethnography in particular and cultural anthropology in general.

The intellectual inheritance of the 'romantic' tradition most relevant to this camp of anthropology is a conception of culture as an extension of the creative imagination, which is said to be a distinctive intellectual capacity of human beings (see Geertz 1973, Sapir 1963, Sahlins 1995, Shweder and LeVine 1984, Shweder 1991). According to romantic pluralists, a 'genuine' culture is a reality-binding product of the human mind that is not dictated by either logic or direct (meaning-free) experience. There is thus plenty of room within the limits of logic and experience for cultural variety, and for the historical creation of different lived conceptions of what it means to be a rational and morally decent human being. According to this view social and cultural realities are neither logically deduced nor simply found in direct experience but are rather constructed by, and for, more or less rational agents. The human creative imagination has the capacity to fill in, and give definition to, a vast discretionary space that stretches in between the necessary truths of formal logic and the uninterpreted evidence of the senses. Advocates of this conception of anthropology are dedicated not only to the project of accurate ethnographic representation, but also to the cognitive and moral defense of different ways of life, frames of reference, and points of view. They write books or articles about Azande Witchcraft (Evans-Prichard 1937) or Balinese conceptions of the 'person' (Geertz 1973) or Oriya Hindu family life and gender relations (Menon and Shweder 1998) which portray

the ideas and practices of others as different but equal to our own, in the sense that such ideas and practices are represented as meaningful and imaginative yet supportable within the broad limits of scientific, practical, and moral reason.

4. *A Fifth Camp Within Anthropology? The Return of Cultural Developmentalism and the 'First World's' Burden*

Increasingly these days, as the world 'globalizes,' the concept of 'culture' gets used to explain differences in the economic, social, political, educational, and moral accomplishments of nations, groups, or peoples. An 'evolutionary' or 'developmental' view of culture has returned to the intellectual scene. Along with it comes the claim that some groups have the wrong models, the wrong values, the wrong patterns of behavior, and that is the reason that their economies are poor, their governments corrupt, and their people unhealthy, unhappy, and oppressed. The cultural developmental view of cultural differences was quite popular at the very beginning of the twentieth century, and is associated with the 'civilizing project' or the 'white man's burden' to uplift those who are ignorant, superstitious, primitive, savage, and poor. Quite remarkably the cultural developmental view is increasingly popular at the beginning of the twenty-first century as well, especially outside of anthropology, for example, in economics and political science (Harrison and Huntington 2000, Landes 1998). In development economics (for example, at the World Bank), the view that 'culture counts' or that 'culture matters' is now popular in part because it is a discrete way of telling 'underdeveloped' nations (either rightly or wrongly) that the 'Westernization' of their cultures is a necessary condition for economic growth. Cultural developmentalists want to convert others to some preferred superior way of living. Their aim is to eliminate or at least minimize the differences between peoples rather than tolerate or appreciate them as products of the creative imagination. This viewpoint has returned, at least implicitly, in anthropology as well, especially among moral activists.

Relatively few anthropologists would actually describe themselves as cultural developmentalists. Nevertheless, that stance is far more common in anthropology than many admit, especially when the topic concerns gender relations and family life practices, for example, polygamy, purdah, arranged marriage, bride-price, female circumcision, and the association of femininity with domesticity and the production of children. So along with the international human rights movement and other agents and agencies promoting Western-style globalization, there are anthropologists these days who now take an interest in other cultures mainly as objects of moral scorn. The up-from-barbarism theme of (certain versions of) Western liberalism has once again become fashionable on the anthropological scene, at least among those anthropologists who are the most 'politically correct.'

5. *Culture Theory: Some Classic Problems*

A detailed description of the core assumptions of each of the 'camps' within cultural anthropology is not possible here. Nevertheless, any review of this topic should include at least brief reference to some classic questions that are always addressed (although answered somewhat differently) by the scholars in each of the camps.

5.1 *The Problem of 'Difference': A.K.A, the Problem of the 'Other'*

One tension inherent in all anthropological interpretation is the problem of 'difference,' what to make of it and what to do about it. This is also called the problem of the 'other,' although the term 'other' is used variously in the anthropological literature. It is sometimes used to connote difference *per se* without any initial judgment of relative worth. It is sometimes used to connote unbridgeable differences. It is sometimes used to connote a solipsistic gap between self-knowledge and a mysterious or 'spectral other' whose identity can never be truly inscribed. It is sometimes used to connote the representation of 'others' as so different as to be less than or other than human, or as different in ways that condemn them to inferior status and/or justify their domination. Here I use the term to connote difference *per se*.

The problem of 'difference' inherent in anthropological interpretation is not just a problem for anthropology. It arises whenever members of different groups (for example, Jesuit missionaries and Native North American Indians; British traders and Hindu Brahmans; Western feminist human rights activists and Islamic fundamentalist women) or members of different social categories (for example, gay men and heterosexual men) encounter each other. Someone finds the encounter disturbing, puzzling, strange, or astonishing because of some apparent difference between self and 'other,' and wants to know what to make of it and (if they have the power) what (if anything) to do about it.

In the history of anthropology the apparent differences mostly concerned differences in the ideas and practices of members of different groups. What should one make of and what should one do (if anything) about such ideas as 'witchcraft,' 'ancestral spirit attack,' 'reincarnation,' or 'menstrual pollution' and practices such as 'polygamy,' 'animal sacrifice,' 'infanticide,' 'purdah,' 'child betrothal,' 'suttee,' or 'adolescent circumcision'? Such encounters are obviously hazardous and fraught with dangers of many kinds, intellectual, ethical, and political. Who is that 'some-

one' who finds 'difference' problematic and wants to know what to make of it and what if anything to do about it? Who is doing the representing of the 'other' and to which audience and to what end? Who has 'voice' and authority in such encounters? Who ought to have 'voice'?

Confronted with apparent differences between other people's ideas and practices and one's own, anthropologists have historically reacted in one or the other of three ways, which are instructive to keep in mind when surveying the fault lines in cultural anthropology today. Some, the universalists, have sought ways to minimize or erase the appearance of difference or to deny that any significant differences exist, and to treat 'otherness' as an illusion. Some, the developmentalists, have perceived in the encounter between cultures a story about a 'civilizing process.' They have argued that the more evolved and progressive cultures (those that are enlightened, scientific, ethical, educated, and rational) bear the ('white man's) burden of lifting 'others' up out of ignorance and superstition. They have argued that 'developed' cultures have an obligation to intervene if necessary to bring a halt to the monstrous or barbaric practices of other lands. Still other anthropologists, the pluralists, have argued that cultures can be different but equal, and have cautioned against cultural imperialism, suggesting that one must beware of (ethnocentrically) confusing ones own local cultural evaluations with universal scientific, practical, or moral reason.

5.2 Globalization

The narrowest definition of 'globalization' refers to the linking of the world's economies (e.g., free trade across borders) with the aim of promoting aggregate wealth and economic growth. Yet it readily expands to also include the free flow of capital and labor. A new cosmopolitan economic order gets imagined, which consists entirely of global economic organizations (the IMF, the World Bank), multinational corporations, and multicultural states with open borders. According to this rather utopian vision of a 'borderless capitalism,' goods, capital, and labor ought to be freely marketed on a worldwide scale for the sake of global prosperity. For those who adopt such a perspective any desire for an ancestral homeland or for a national identity based on religion, ethnicity, 'race,' or 'tribe' with associated restrictions on residence, affiliation, and trade is viewed as 'illiberal' and disparaged as a form of retrograde or irrational 'apartheid' or 'ethnonationalism.'

Fully expanded, however, the idea of 'globalization' actually becomes a hypothesis about human nature and an imperial call for 'enlightened' moral interventions into other ways of life in order to free them of their supposed 'barbarisms,' 'superstitions,' and 'irrationalities.' This expansive 'globalization hypothesis' makes three related claims: (a) that Western-like aspirations, tastes, and ideas are objectively the best aspirations, tastes, and ideas in the world; (b) that Western-like aspirations, tastes, and ideas will be fired up or freed up by economic globalization; and (c) that the world will/already has and/or ought to become 'Westernized.' Western-like aspirations include the desire for liberal democracy, free enterprise, private property, autonomy, individualism, equality, and the protection of 'natural' or universal 'rights' (the contemporary human rights movement is in many ways an extension of an expansive 'globalization' movement). They include the modernist notion that all social distinctions based on collective identities (ethnicity, religion, gender) are invidious. They include as well the notion that 'individuals' should transcend their 'tradition-bound' commitments and experience the quality of their lives solely in secular and ecumenical terms, for example, as measured by wealth, health, or years of life.

The true connection between 'globalization' narrowly conceived ('free trade') and 'globalization' expansively conceived (Western values, culture, and institutions taking over the world) has yet to be firmly established. Nevertheless, the picture of a cosmopolitan world of individuals without groups, in which meanings are detached or abstracted from communities and traded on a free market of ideas, has influenced the thinking of some postcultural theorists. Whether that picture is realistic remains to be seen. It is quite possible that other cultures and civilizations do not need to become just like the United States to materially benefit from participation in an emergent global economy. Modern technologies (e.g., television, cell phones, computers, weapons) and economic institutions (e.g., private property) seem to have effectively served many interests, including the interests of communitarians and religious fundamentalists all over the world. It is quite possible that a genuinely successful global political economy will not emerge, or will fail to sustain itself, or that efforts to globalize values and culture will be effectively resisted (in some cases for very good reasons), or that the world will go to war. That is how the last big push to globalize the world came to an end, with World War 1. Nevertheless, the idea that the rich nations of North America and Northern Europe have an obligation to use their economic and military power to civilize and develop the world is no less popular today than it was 100 years ago when the empire was British rather than American.

6. 'Culture': Popular Objections and Common Misattributions

Within anthropology there have been many critiques of the idea of culture. Some are associated with a fear of 'the ethnography of difference.' Some with doubts about the grounds and authority of 'ethnographic

representation.' Some with a renewed interest in, or fear of, a universal civilizing project. Some with claims about the emergence of a cosmopolitan capitalist economy. Many reasons have been advanced for doubting the usefulness of the culture concept. But are they persuasive or decisive reasons? Those who continue to embrace some variety of the Kroeber and Kluckholn definition of 'culture' tend to believe that their idea of culture does not carry most of the implications that are the supposed grounds for various anticultural critiques.

For example, the Kroeber and Kluckholn definition of 'culture' does not really imply that 'whatever is, is okay.' It is important to recognize that valid social criticism and questions of moral justification are not ruled out by the 'standard view' of 'culture.' Nothing in the Kroeber and Kluckhohn formulation suggests that the things that other peoples desire are in fact truly desirable or that the things that other peoples think are of value are actually of value. Consensus does not add up to moral truth. In other words, a definition of culture *per se* is not a theory of the 'good.' From a moral point of view, one need not throw out the idea of culture just because some tyrant puts the word 'culture' to some misuse, or because at times some ethnic groups enter into geopolitical conflict.

The idea of culture also does not imply passive acceptance of received practice or that human beings lack 'agency,' a common claim among anticulture theorists. Indeed, many proculture theorists find it astonishing to see the idea of 'agency' or 'intentionality' used as synonyms for 'resistance to culture' in the discourse of 'anticulture' theorists. Even fully rational, fully empowered, fully 'agentic' human beings discover that membership in some particular tradition of meanings and values is an essential condition for personal identity and individual happiness. Human beings who are 'liberationists' are no more agentic than 'fundamentalists,' and neither stands outside some tradition of meaning and value.

The idea of culture also does not imply the absence of debate, contestation, or dispute among members of a group. Nor does it necessarily imply the existence of within group homogeneity in knowledge, belief, or practice. Every cultural system has experts and novices; one does not stop being a member of a common culture just because cultural knowledge is distributed and someone knows much more than you do about (e.g.) how to conduct a funeral or apply for a mortgage. One does not stop being a member of a common culture just because there are factions in the community. The claim that there are between group cultural differences has never implied the absence of within group differentiation or that there is no variation around the mean. The idea of 'culture' does not imply that every item of culture is in the possession or consciousness of every member of that culture. The idea of culture merely directs our attention to those ideas about what is true, good, beautiful, and efficient that are acquired by virtue of membership in some group. Not everything has to be shared for a 'culture' to exist. Members of a cultural community do not always agree about this or that, but they do take an interest in each other's ideas about what is true, good, beautiful, and efficient because those ideas (and related practices) have a bearing on the perpetuation of their way of life, and what they share is that collective inheritance. Since the standard view does not assume that a culture is a well-bounded, fixed, and homogeneous block, the critique of the concept of 'culture' that starts with the observation of internal variation and ends 'therefore there is no cultural system' should have been a nonstarter.

The idea of culture also does not imply that other kinds of peoples are 'other,' in the sense of being less than human or possessing qualities that entitle us to intervene in their way of life. We live in a multicultural world consisting (as Joseph Raz has put it) 'of groups and communities with diverse practices and beliefs, including groups whose beliefs are inconsistent with one another.' The aspirations (a) not to lose your cultural identity, (b) not to assimilate to mainstream pressures, (c) not to be scattered throughout the city, country or world, (d) not to glorify the Diaspora, and (e) not to join the highly individualistic and migratory multinational, multiracial but (in many ways) monocultural cosmopolitan elite are real and legitimate aspirations, and those aspirations cannot be properly understood by treating them as illusions. They are certainly not the only legitimate aspirations in a multicultural world; there is much that can be said in favor of a liberal cosmopolitan life. But they are legitimate aspirations. Even in a 'global' world, cultural communities and ethnic groups are not going to disappear. We cannot avoid the question, what form does and should multiculturalism take in our emerging postmodern society (see Daedalus 2000)? Perhaps that is one reason that so many social scientists and public policy analysts look to anthropology for a useful concept of 'culture,' not for no concept of culture at all.

Culture in Development

At present, the term 'culture' generally is used to refer to the entire body of socially inherited past human accomplishments that serves as the resources for the current life of a social group ordinarily thought of as the inhabitants of a country or region (D'Andrade 1996). Although there is evidence of the rudiments of culture in nonhuman species (Tomasello 1999), human beings are unique in their dependence upon the medium of culture and the forms of organism–environment interactions that culture supports to sustain and reproduce themselves.

1. *Defining Culture*

For purposes of thinking about culture as it relates to development, it is useful to begin by tracing the concept of culture as it has evolved since entering the English language from Latin many centuries ago (see *Culture: Contemporary Views*). Modern conceptions of culture originate in terms that refer to the process of helping things to grow: 'Culture, in all of its early uses, was a noun of process: the tending of something, basically crops or animals' (Williams 1973, p. 87). From earliest times, this notion of culture included a general theory for how to promote growth: Create an artificial environment in which young organisms could be provided optimal conditions to develop. Such tending required tools, both material (hoes) and mental (the knowledge that one does not plant until winter is over). These tools are perfected over generations and designed for the special tasks to which they were put.

2. *Culture in Development*

Combining the historical notion of culture as a process of growing things with the modern conception of culture as social inheritance of prior generations' accomplishments, the study of culture in development can be seen to focus on the way in which biologically immature human beings are incorporated into the cultural 'designs for living' that are their social heritage by more mature humans who have already been enculturated. Although the role of culture begins even before conception (for example, by beliefs and customs that restrict who the parents are likely to mate with), it is sufficient for our purposes to begin with the period of prenatal development and provide examples of culture's role in development through infancy, childhood, and the transition to adulthood referred to in many societies as 'adolescence.'

2.1 *Prenatal Development*

The cultural environment influences the growing fetus both indirectly and directly. In the category of indirect influences, mediated by the mother's physiology, are dietary laws in some societies that limit pregnant women's access to nutrients deemed important to later development (Mead and Newton 1967). In others, the use of substances such as cigarettes and alcohol, or the presence of industrial pollutants, can materially damage the fetus, depending upon such factors as timing and degree of exposure (Cunningham et al. 1997).

An important example of a direct influence of the cultural environment comes from evidence that during the last trimester, despite distortion introduced by filtering through the mother's body, fetuses are capable of hearing the language spoken in the mother's immediate environment (Lecanuet and Schaal 1996). Moreover, when they are born they show a preference for their native language, the sound stream of which is specific to the culture in which it is used (Moon et al. 1993). This universal sensitivity to language and culture-specific preference for one's own language provides the starting point for the crucial process of learning to extract meaning from the sound stream.

2.2 *Birth*

When babies emerge from the birth canal and the umbilical cord is cut, their automatic supply of oxygen and nutrients comes to an abrupt halt. Following birth, even essential biological processes occur *indirectly*—they are mediated by culture and other human beings. In order to survive in an environment mediated by culture, the baby must act on the nurturing environment in a qualitatively different way than was true before birth. While the effects of fetal activity *in utero* are minimal, once the baby is born it begins to make urgent, vocal demands upon its caregivers. Babies become social actors who re-order the social relationship among the people around them.

At the same time, babies become cultural objects for the older members of their community; their biological characteristics are interpreted in terms of the community's beliefs to a significant degree. For example, studies which present young infants wearing pink or blue diapers to adults to interact with (pink and blue being the symbolic representations of female and male gender in the society in question) show that the adults interact with them and interpret their behavior in terms of their *symbolic* gender, not their *biological* sex. Regardless of their biological sex, babies dressed in pink diapers are treated in a gentle manner and interpreted as physically pretty and sweet tempered, while babies dressed in blue diapers are bounced vigorously and have 'manly' attributes attributed to them (Rubin et al. 1974).

These forms of adult behavior illustrate a universal feature of the way in which culture mediates adult behaviors toward children: children are behaved toward in the present in terms of culturally prescribed theories that bear no necessary relationship to the

biological child with whom adults are interacting at the time.

2.3 Infancy

The role of culture in development manifests itself in a wide variety of ways during infancy. Perhaps the most direct, and certainly universal, influence of culture is in the way it shapes the development of the system of coordination between infant and caretakers known as 'getting on a schedule.' For example, rural Kenyan (Kipsigis) infants sleep with their mothers and are allowed to nurse on demand. During the day they are strapped to their mothers backs, where they often nap as their mothers go their daily work rounds. By contrast, the children of urban, middle-class North American parents generally sleep separately from their mothers and must adjust to a parental schedule which is governed by the clock (Super and Harkness 1997). As a consequence, within a few weeks of birth, North American children have begun to bunch their sleeping spells in longer and longer night episodes that approximate the adult pattern. Kipsigis children, by contrast, show comparatively slow development of long sleep spells, and remain more flexible in their sleeping habits even as adults.

Whereas the example of getting on a schedule highlights the role of contemporaneous constraints in shaping infant development, studies of mother–child interactions that incorporate objects indicate the way that cultural beliefs concerning future 'proper' behaviors influence current maternal behaviors. One such study of mothers and their 5-month old infants in Tokyo and New York found that the Japanese mothers were more responsive when their infants responded to them, while US mothers were more responsive when their infants oriented to the objects. At this early age, there was no difference in the infants' behavior at all. But at a later age, the Japanese and US children begin to differ in a manner that matches the differential parental behaviors observed at 5 months, although their language and play skills are judged to be of equivalent developmental level (Bornstein et al. 1991).

An area of development which has received special attention with respect to the role of cultural factors is the development of emotional attachments between babies and their parents (Crittenden and Clausen 2000). In a wide range of societies it has been observed that between 6 and 9 months of age children begin to display wariness of strangers, a heightened degree of distress when they are separated from their primary caretakers, and a marked tendency to cling to their parents in unfamiliar situations. The frequency and intensity of these behaviors increase for several months and then begin to wane as children approach the end of infancy at $2\frac{1}{2}$–3 years of age. This universal trend is accompanied by apparent cultural variations in the patterns of distress that children display, a result which is often interpreted as a reflection of cultural differences in the development of attachment relationships (see *Attachment Theory: Psychological*; *Cultural Psychology*; *Cross-cultural Psychology*).

For several decades, a major means of assessing qualitative differences in attachment behaviors has been to confront infants and young children with a standardized set of experiences referred to as the 'Strange Situation.' In this procedure, infants are first left in a room with their primary caretaker, who then leaves the child with a stranger and eventually returns (see Ainsworth 1967 for a more precise delineation of procedures). Children's responses to this sequence of events are coded into three major categories: *Anxious–avoidant* children turn away or run away when their caretaker returns instead of seeking closeness and comfort. *Securely attached* children go to their caregivers, calm down quickly after their early upset, and soon resume playing. *Anxious–resistant* children are often upset even when their caretaker is with them just as a result of being in the strange environment; they become excessively upset when their caretaker leaves and both reject and seek comfort when the caregiver returns.

The Strange Situation has been widely used in cross-cultural research. In middle-class US families that dominant pattern is one of secure attachment; anxious–avoidant behaviors are second most frequent. In Germany, an Anxious–avoidant pattern has been found to be dominant, while in Japan and Israel, the level of secure attachment approximates that of the US but there are high percentages of Anxious–resistant children. Psychologists are divided on the significance of these findings. Some believe that they mirror basic cultural differences (for example, reflecting a German emphasis on early independence). Others believe that the findings reflect more about the relative strangeness of the Strange Situation itself, and reject it as a measure of socioemotional development (see Cole 1999 for a summary of the issues).

Patterns of language socialization have provided a rich source of evidence on cultural universals and similarities. In societies throughout the world, caregivers speak differently with children than with adults, but there are wide variations in the specific forms of interaction. In a great many, if not all societies, adults use a special speech register (something akin to a 'baby-talk' mode with its high pitch, isolation of simplified words, and simplified grammar) when speaking to young babies. In many cultures, adults deliberately seek to teach vocabulary, style of address, and other linguistic features. The Kaluli of Papua New Guinea, for example, hold their young infants facing away from them and caregivers speak for them (Schieffelin and Ochs 1986). There is no evidence that any one of these practices enhances the rate of language acquisition in general although it certainly produces differences in the speech forms that children come to master.

Following infancy, there are wide cultural variations in the forms of experience that adults begin to arrange for their children. In rural, agrarian societies, even children as young as 3–4 years of age will be given work tasks to carry out and their older brothers and sisters will be assigned to watch over them. This form of socialization of children by children produces a distinctive pattern of interpersonal characteristics that mix nurturance and authoritarianism. By contrast, in societies where young children live in nuclear families and spend time in adult-supervised settings, interpersonal behavior is marked more by patterns of attention seeking and playful sociability (Whiting and Whiting 1975).

Even in societies where preschools are the dominant out-of-family settings for young children, the form of that experience can differ dramatically. For example, US preschool teachers are shocked and disapproving when they observe Japanese preschool classrooms with 30 children for each teacher. But Japanese teachers equally are shocked and disapproving when they observe American classrooms with one-third the number of children per adult. Tobin et al. (1989) found that these differences in both classroom organization and evaluation reflect different cultural conceptions of the optimal environment for creating a productive (Japanese or American) adult. The Japanese teachers believed that the children's development is most fully realized in their ability to feel a part of, and to coordinate with, their social group. The US teachers sought to foster independent initiative in the children reflecting the dominant norm in North American cultures. As in several previous examples, the *anticipated future* of the children, based on cultural norms and ideals, played a significant role in how adults structure the environments of children.

2.4 *Middle Childhood*

One of the most pervasive changes in the cultural organization of children's lives is the new social arrangements that societies institute when their children reach the age of 6–7 years (Sameroff and Haith 1996). Even in societies in which there is no schooling, marked changes in children's activities are likely to occur. For example, among the Ngoni of Malawi in Central Africa in the middle of the twentieth century (Read 1960), the boys, who had been living and socializing with other children of both sexes and their mothers, left the protection of the women, stopped playing childish games, and moved into dormitories where they submitted to male authority and began to engage in at least rudimentary forms of adult work. The girls lived among the women and participated in their work practices.

When we contrast the experiences of children who spend several hours a day, five days a week, attending formal schools with comparable children who remain at home helping their parents, several prominent characteristics of the classroom experience stand out (Serpell and Hatano 1997) (see *Academic Achievement: Cultural and Social Influences*; *Cross-cultural Study of Education*).

(a) The settings in which schooling occurs are removed from contexts of practical activity.

(b) There is a distinctive social structure to formal schooling, in which a single adult interacts with many (often as many as 40 or 50, sometimes as many as 400) students at a time. Unlike most other settings for socialization, this adult is unlikely to have any familial ties to the learner.

(c) There is a peculiar value system associated with schooling that sets educated people above their peers and that, in secular education, values change, and discontinuity over tradition and community.

(d) There is a special mediational skill—writing—that is essential to the activity of schooling. Writing is used to represent both language and nonverbal systems (e.g., mathematics).

(e) Language is used in quite distinctive ways in formal schools (Mehan 1978).

A wide variety of evidence indicates that extensive exposure to schooling brings about changes in the intellectual skills, values, and uses of language which it promotes. The degree to which these experiences engender general changes in development remains unclear. At present, it appears that the intellectual changes associated with schooling are rather narrowly tied to particular contents and interactional formats and do not infuse thinking in everyday life. However, changes in values and cultural norms appear to generalize well beyond the school to influence the cultural organization of the community in which the school is located. This is seen, for example, in the way that the experience of formal schooling increases the use of complex language and problem-solving strategies when mothers interact with their children (Le Vine et al. 1996).

2.5 *Adolescence: Stage or Transition?*

By and large, the various periods of development we have used to organize this discussion take for granted the reality of the periods named, reflecting broad agreement across cultures in the basic age periodization of development. When we arrive at the transition from childhood to adulthood, the situation changes (see *Youth to Adulthood across Cultures*, *Transition from*).

An interesting fact about adolescence is that in many societies, there is no word corresponding to this presumed universal stage of life. This linguistic fact raises an interesting psychological question: there may be a universal transition from childhood to adulthood, but is there a distinctive stage of adolescence independent of cultural or historical circumstances?

What is indisputable is that some time around the end of a decade of life (the exact onset time depends

greatly on nutritional and other factors), a cascade of biochemical events begins that will alter the size, the shape, and the functioning of the human body. The most revolutionary of the changes that will occur is the development of the entirely new potential for individuals to engage in biological reproduction (Katchadourian 1989). These biological changes have profound social implications for the simple reason that reproduction cannot be accomplished by a single human being. As their reproductive organs reach maturity, boys and girls begin to engage in new forms of social behavior because they begin to find other individuals sexually attractive. According to many psychologists, some combination of biological changes in the brain and changed social circumstances give rise to new cognitive capacities. Consistent with this line of reasoning, some scholars argue that adolescence is indeed a universal and necessary stage of development, with its own special characteristics (Schlegel and Barry 1991)

However, the universality of adolescence as a unified stage is by no means clearly established on the basis of these data. The evidence from other cultures may support the idea that the transition to adult status is universally fraught with anxiety and uncertainty, but it provides equally strong evidence that adolescence, as the term is used in modern industrialized societies, exists only under particular cultural circumstances (Whiting et al. 1986).

Among the Inuit Eskimos of the Canadian Arctic at the turn of the nineteenth century, for example, special terms were used to refer to boys and girls when they entered puberty, but these terms did not coincide with Western notions of adolescence (Condon 1987). Young women were considered fully grown (adult) at menarche, a change in status marked by the fact that they were likely to be married by this time and ready to start bearing children within a few years. Young men were not considered fully grown until they were able to build a snowhouse and hunt large game unassisted. This feat might occur shortly after the onset of puberty, but it was more likely for boys to achieve adult status somewhat later because they had to prove first that they could support themselves and their families. In view of the different life circumstances of these people, it is not surprising that they developed no special concept corresponding to adolescence that applied to boys and girls alike; such a concept did not correspond to their reality.

When we consider the actual organization of life in terms of the role of culture in development, we are reminded that the process of biological reproduction by itself is insufficient for the continuation of our species. It must be complemented by the process of cultural reproduction (education, broadly conceived), which ensures that the designs for living evolved by the group will be transmitted to the next generation. According to this view, adolescence will exist as a distinctive period of life only when there is a gap of several years between the biological changes that mark the onset of sexual maturity and the sociocultural changes that confer adult status (such as the right to marry without parental consent or to run for elective office).

Matters can be expected to be different in those societies in which there is little or no gap between the beginning of sexual maturity and the beginning of adulthood (Whiting et al. 1986). These are often societies in which the level of technology is relatively low and in which biological maturity occurs relatively late by our standards. By the time biological reproduction becomes possible, which is about the age of 15 in many nonindustrial societies, young people already know how to farm, weave cloth, prepare food, and care for children. Although they still have a good deal to learn (a fact that their elders impress on them, often with considerable force), they are capable of the basics of cultural reproduction. In such societies, there may be no commonly acknowledged stage of development equivalent to adolescence.

2.6 Development during Adulthood

So long as development is thought of essentially in biological terms, adolescence marks the 'high-water mark' of development; the species, imperative to reproduce is achieved and psychological processes remain more or less unchanged for a decade or so until they begin to deteriorate as a consequence of biological aging. However, for those who accord an essential role to culture in development, developmental change is a lifelong process. In fact, owing to the fact that cultural experience continues to accumulate, at the same time that biological capacities wane, serves to highlight a lifelong dynamic of bio-cultural change which is somewhat obscured so long as both biological and cultural capacities are increasing in tandem with each other (Labouvie-Vief 1981, Smith and Baltes 1999).

When the interplay of biological, cultural, and social factors which interweave to produce development are examined during adulthood and later life, one can see complex and shifting mosaics in which gradual change and predictable experiences are mixed with sudden, unexpected events—new insights, conceptual reintegration, and developmental triumphs occur side-by-side with loss of power and decline in a process which Baltes (1997) has referred to as the 'gain–loss' dynamic.

The precise contour of this dynamic depends importantly on the sociohistorical circumstances of development. In modern, industrial societies characterized by rapid change and rigidly enforced bureaucratic rules which remove adults from productive labor and the social supports such labor provides, the ensuing isolation and loss of status can combine with biological decline to hasten the decline or power and block further development. In nonindustrialized

societies where there is no social institution comparable to what we refer to as retirement, and technological change is less rapid, old people are likely to continue to play active and valued roles: among the Ashanti of West Africa in the middle of the nineteenth century, for example,

> The grandparents … on both sides are the most honored of one's kinfolk. Their position and status are of very great importance to the social system. In Ashanti it is the grandparents who are the prototypes of person and institutions commanding reverence and submission to norms of tradition (Fortes 1950, p. 276).

As early in life, the course of development during adulthood and old age depends crucially on the cultural organization of people's experience. If elderly people are placed in settings where they are confronted with new and unfamiliar events over which they have little control, they may simply give up on life (Rodin 1986). However, if special care is taken to provide experiences that increase social connectivity and are enabling and satisfying, healthy development remains a lifelong potential.

3. *Future Directions*

There is urgent need for increased research on the role of culture in development. At the same time, cross-cultural research is hampered by difficult methodological problems such as those encountered in the study of attachment. Future progress will depend upon the development of more adequate methods to ensure the validity of researchers' conclusions.

Culture in Nonhuman Organisms

Whether or not nonhuman animals can be said to have 'culture' is a contentious issue that hangs on definitions of culture and the complexities of animal social behavior. However, it is well established that numerous animals have the ability to acquire from others skills, calls, and information concerning predators, mates, or resources. In some instances this information transmission is sufficient to propagate the diffusion of novel behavior patterns through animal populations, and to maintain distinct behavioral traditions between different populations of the same species. Such traditions are sometimes regarded as analogous to human culture in many respects, and have been described as 'proto-culture.' However, the use of this term indicates little more than that the behavior concerned has been learned socially, and does not necessarily imply that the animals concerned are unusually intelligent, or that they have exceptional linguistic or cognitive capabilities.

1. Social Learning in Animals

Underlying culture in nonhuman animals is a capacity for 'social learning.' The term social learning refers to learning that is influenced by observation of, or interaction with, another animal (typically of the same species) or its products. Social learning is frequently contrasted with individual or asocial learning, in which animals learn exclusively on the basis of their own personal experience, without recourse to social cues or guidance. In any instantiation of social learning, the learner or receiver of information is generally described as the 'observer,' while the transmitter of information is called the 'demonstrator.' Social learning occurs when the communication of information between two animals results in the observer learning from the demonstrator. Frequently the observer learns through social interaction to perform the same behavior as that exhibited by the demonstrator and, if repeated amongst other animals, this process can result in the spread of a particular behavior pattern and behavioral conformity in a population. Less frequently, animals may learn by observation to perform a different behavior from that exhibited by the demonstrator.

Social learning among animals has been of interest to scientists from a number of different disciplines. Psychologists traditionally have been interested in animal learning. Contemporary animal learning theory describes much learning in animals as resulting from associations formed between two external stimuli (stimulus-stimulus, or classical conditioning), or between the behavior of an animal and an external stimulus (response-reinforcer, or operant conditioning). Arguments abound as to whether there will be anything different or special about social, compared with asocial learning, and whether social learning can be adequately explained in conditioning terms. Many psychologists have suggested those more complex forms of social learning might be indicative of the animal concerned possessing unusual or sophisticated psychological capabilities (Heyes 1994). For instance, it has been suggested that for an animal to imitate the motor patterns of another animal it must be conscious, must be capable of taking the other animal's perspective, must be unusually intelligent, or must be capable of intentional action. All such claims are hotly disputed.

At the same time, social learning has been of interest to ethologists and behavioral ecologists because it seems to allow animals to learn about their environments rapidly and efficiently, without having to engage in potentially costly or hazardous learning trials, or expend considerable time and energy exploring the environment. Animals can learn which foods to eat, acquire food processing skills, learn to identify predators, learn which members of the opposite sex to mate with, or develop songs and calls, by exploiting the knowledge base of more experienced conspecifics (Heyes and Galef 1996, Zentall and Galef 1988). Social learning can be regarded as a short cut to learning about the environment, but may incur a cost if the acquired knowledge is inappropriate or outdated.

Evolutionary biologists, biological anthropologists, and archeologists have also studied animal social learning because it is accorded a prominent role in the evolution of human culture. Although definitions of human culture vary, one central feature is the transmission of acquired information between individuals through social learning processes. Many researchers believe that an understanding of the ways in which social learning operates in animal populations will generate insights into the evolutionary roots of human culture. Social learning is regarded as pivotal to a number of social intelligence hypotheses, which maintain that the evolution of high intelligence or large brains was driven by a capacity for social learning and for proto-culture (Byrne and Whiten 1988).

2. History of Research into Animal Social Learning

The study of social learning in animals dates back to Darwin, and flourished as a result of attempts to demonstrate mental continuity between humans and animals in order to prove that humans had evolved. For many Victorian scientists, demonstrations of imitative learning in animals was seen as providing evidence of an evolutionary origin of the higher mental faculties of humans. Imitation was regarded as intermediate in psychological complexity between animal instinct and human reasoning (Boakes 1984). The verb 'to ape' and the phrase 'monkey see monkey do' are manifestations of the then commonly held view that simian primates are frequent imitators of each other's behavior.

While numerous observations of imitative behavior in primates and other animals were reported in the late nineteenth century, attempts to demonstrate imitation proved problematic. It became apparent that there are many processes that can result in two animals expressing similar behavior. Researchers began to realize that anecdotal stories concerning animals in uncontrolled environments would not provide satisfactory evidence to address this issue. In the first decades of the twentieth century, Edward Thorndike, a leading psychologist, attempted to introduce some scientific rigor into investigations by carrying out controlled experiments exploring imitation in cats, dogs and monkeys (Galef 1988). Thorndike's experiments led him to the controversial conclusion that there was no evidence that animals could 'from an act witnessed learn to do an act.' Out of the controversy there emerged two distinct research traditions in the study of social learning: a laboratory experimental tradition, dominated by experimental psychology, and a second tradition that carried out observations of natural populations of animals, dominated by ethologists and primatologists. The laboratory approach has focused on investigating the psychological mechanisms underlying social learning. In contrast, field studies have reported behavior patterns spreading through animal populations, or cultural traditions. Recent years have seen the development of experimental approaches to the study of the spread of learned information through animal populations, including transmission chain and diffusion studies (Laland et al. 1993). In addition, mathematical approaches have explored the conditions under which social learning is expected to evolve, and the evolutionary consequences of social learning. (See Galef 1988 for more on the history of research into animal social learning.)

3. Laboratory Studies of Animal Social Learning

Modern laboratory experiments investigating social learning in animals commonly train animals (called demonstrators) to perform a target behavior (e.g., to push a lever to get a food reward), pair these demonstrators with untrained experimental subjects (called observers) that watch the demonstrator perform the behavior, and then test the observers alone to establish whether they have learned to perform the target behavior (Galef 1988). Frequently, the rate at which the subjects learn to perform the behavior is compared with control subjects, which have received different forms of observational experience. Such experiments have established that there are a number of ways that animals can learn socially, the variants reflecting the nature of the observer's learning and the type of information transmitted from demonstrator to observer. For instance, in the lever-pressing example, the observers might learn at an accelerated rate relative to controls, (a) because they learned of the presence or significance of the lever, (b) because they learned of the presence of food, (c) because their observational experience allowed them to form an association between the depressed lever and the appearance of food, or (d) because they formed an association between the action of pressing and the appearance of food. In addition, there are other nonsocial-learning processes that could result in an elevation in the observers' performance, for example, if observation changes its motivational state.

Such experiments have engendered a fissioning of imitative phenomena, resulting in a multitude of terms to describe the different processes that can result in social learning and spawning a host of classificatory schemes. At present there is little consensus as to the use of terms, and little agreement as to which classification is superior. Whiten and Ham (1992) distinguish four classes of social learning. 'Stimulus enhancement' occurs when the observer learns from the demonstrator to which object or location its behavior should be oriented. For instance, British birds learned to peck open milk bottles and drink the cream by having their attention drawn to milk bottles by other feeding birds (Hinde and Fisher 1951). (The term 'local enhancement' is sometimes used to describe similar phenomena). 'Observational conditioning' occurs when the observer learns to what circumstances a behavior should be a response. For example, infant rhesus monkeys learned to respond to the presence of a snake with fear and flight behavior through observations of the screams and avoidance behavior of adults. 'Imitation' occurs when the observer learns from the demonstrator to perform a specific motor pattern in a particular context. For instance, orang-utans have been reported to go through the motions of washing clothes in the presence of human caretakers that were doing the laundry. Finally, 'goal emulation' refers to instances where the observer learns from the demonstrator the goal to pursue or the result that can be achieved. For example, juvenile chimpanzees that observed a stick being used to rake in out-of-reach food appeared to learn that the food could be gained using the stick but developed their own means of doing

so. Earlier Galef (1988) identified seven processes that could result in social learning. Other researchers (e.g., Heyes 1994) have argued that social learning can be best described by using the same conceptual tools as are employed by psychologists to describe asocial learning. In general, there remain considerable doubts as to whether any of the current classification schemes are comprehensive, or whether each of a given classification's categories is mutually exclusive. The plethora of competing terms and usage reflect an ignorance of the biological basis of social learning. At present there is little understanding of the genetic, neural or physiological processes that underlie the processing of sensory information, the associationist or transformational organization of this information, and the production of motor patterns, during social learning. Nonetheless, there is little doubt that the laboratory experimental approach has greatly enhanced understanding of the processes that can result in social learning, and developed the methodologies and conceptual tools to further that understanding.

4. *Field Transmission Chain and Diffusion Studies*

In a population of Japanese monkeys, a young female began washing sweet potatoes provisioned on a beach before eating them. This previously unobserved behavior was subsequently recorded to increase in frequency in the troop, with 90 percent of individuals eventually adopting the potato-washing behavior, presumably by learning from each other. There are hundreds, perhaps thousands, of such reports of the spread of novel behavior patterns in populations of animals. Well-known examples include the transmission of dietary preferences by rats attending to cues on each other's breath, the transmission of predator recognition in birds, mammals, and fish, the learning of vocal dialects in song birds, feeding on pine cones among black rats, and tool-using traditions in primates (see Bonner (1980) for a readable overview). Probably all vertebrates and many invertebrates will eventually be found to exhibit some form of social learning. In the main, these reports are observations of acquired behavior patterns spreading through single populations. In other cases, distinct cultural variations may characterize the behavioral repertoires of different populations of the same species. For instance, much birdsong is thought to be learned from older males, and frequently regional song dialects characterize neighboring populations. Undoubtedly the most impressive case of local cultural traditions is provided by the different tool-using repertoires of populations of common chimpanzees. For instance, termiting (using a stalk to fish for termites) is reported in some but not all chimpanzee populations and is thought to be maintained within populations through social learning processes. A recent study documented 39 different behavior patterns, including tool usage, grooming, and courtship behaviors, that were habitual in some chimpanzee communities and absent in others, where ecological explanations had been discounted (Whiten et al. 1999).

These field reports are of value in documenting the breadth of animal cultures and throwing light on the contexts in which social learning occurs. However, it is difficult in the field to establish reliably whether or not a behavior genuinely is socially learned (as opposed to learned independently by each animal), to determine whether local traditions reflect different cultural repertoires or varying ecological resources, or to investigate the psychological and social processes underlying the diffusion.

More recently there have been attempts to investigate animal cultural traditions experimentally, under controlled conditions. 'Diffusion studies' are characterized by the introduction of a trained demonstrators into captive populations, and a careful monitoring of the increase in the target behavior over time (Lefebvre and Palameta 1988). 'Transmission chain studies' involve the gradual replacement of a founder population of trained demonstrators with untrained animals, and explore whether the target behavior remains in the population when the founders have been removed (Laland et al. 1993). These methods have been valuable in determining how processes of social interaction impede, or propitiate, the diffusion of information. It has become apparent that the structure of animal populations (dominance relations, spatial positioning, sex, age, and size differences) strongly influences the pathways by which learned information spreads, a phenomenon known as 'directed social learning' (Coussi-Korbel and Fragaszy 1995). For instance, novel skills often spread at different rates among juveniles and adults, among the two sexes, or within and between family groups.

Typically the new behavior pattern found in an animal culture will have been invented by a single individual. There has been comparatively little investigation of the process of innovation. It is not clear whether innovation should be characterized as a personality trait (associated with clever, creative, or nonconformist individuals), a state-dependent variable (e.g., hunger may drive foraging innovation), or resulting from environmental changes (such as a drought). Preliminary studies suggest that the adage 'necessity is the mother of invention' may be appropriate, with innovation appearing at elevated frequencies in hungry, low status, and small individuals. Across primate species, incidence of innovation co-varies with incidence of social learning (also with tool use and deception), suggesting that innovation and social learning may be manifestations of a general capacity for behavioral plasticity. However, within a given species it is not known whether innovative individuals tend to be good, average, or poor social learners.

5. *The Adaptive Value of Animal Social Learning*

Theoretical analyses have explored the circumstances under which natural selection will favor reliance on social learning, as opposed to asocial learning or evolved nonlearned behavior (see Laland et al. 1996, for an overview of this literature). A consensus has been reached that the issue hangs, in part, on patterns of variability in the environment. In an environment that is changing comparatively slowly, or that exhibits relatively little spatial heterogeneity in resources, populations are able to evolve appropriate behavior patterns through natural selection, and learning is of little adaptive value. In contrast, in rapidly changing or highly variable environments asocial learning pays. Here natural selection cannot track environmental fluctuations quickly enough, while social learning is unreliable because it may lead individuals to acquire outdated or locally inappropriate behaviors. It is intermediate rates of change and patterns of spatial heterogeneity that favor social learning, and within this window vertical transmission of information (social learning of offspring from parents) is thought to be an adaptation to slower rates of change than horizontal transmission (social learning among unrelated individuals of the same cohort). Although these findings are theoretically robust, a number of questions remain. For instance, do contemporary populations of animals capable of social learning switch between social and asocial learning depending on the pattern of environmental variability they experience in pertinent resources? Which other factors affect reliance on social learning? For instance, is social learning more likely when individuals are confronted with an unfamiliar problem, or a threatening environment?

6. *Social Learning and Social Intelligence*

Social learning has been central to a number of social intelligence hypotheses, which suggest that complex social behavior drove brain evolution and intelligence. Allan Wilson's (1985) concept of 'behavioral drive' is the hypothesis that most explicitly emphasises social learning. Wilson noted a positive relationship between relative brain size and rate of evolution in vertebrates. He explained this by arguing that big-brained species exhibit greater behavioral plasticity, are more innovative, and are more capable of social learning than small-brained species. Cultural traditions, he argued, allow populations of animals to open up new niches, and exploit novel resources, thereby exposing themselves to new selection pressures, and accelerating the rate of fixation of mutations. Wilson's hypothesis is supported by recent evidence that there is a significant correlation between relative brain size and incidence of both innovation and social learning in primates.

Culture, Production of

The production of culture perspective focuses on the ways in which the content of symbolic elements of culture are significantly shaped by the systems within

which they are created, distributed, evaluated, taught, and preserved. Practitioners of this perspective are most likely to focus on the fabrication of expressive-symbol elements of culture such as art works, scientific research reports, religious celebrations, legal judgments, television programming, and newsmaking which, in turn, embody, modify, and give concrete expression to the 'norm,' 'value,' and 'belief' elements of culture. The perspective has also been successfully applied to a range of quite different situations where the manipulation of symbols is a by-product rather than the goal of the collective activity (Crane 1992, Peterson 1994).

Two early studies show the promise of what later came to be called the production perspective. First, in their study of the emergence of impressionist art in nineteenth-century France, Harrison and Cynthia White (1965) found inadequate the then prevalent theories that said changes in art are associated with revolutionary changes in society or with the emergence of persons of genius. Instead they found that the older Royal academic art production system survived the economic turmoil and ideological changes of the French Revolution but collapsed a generation later because of the emerging art market created by Parisian art dealers and critics who fostered unconventional artists such as the Impressionists.

Second, noting the set of nineteenth century American novels that traced the battles of lone individuals against nature, novels ranging from the frontiersman stories of James Fenimore Cooper to Herman Melville's saga of the titanic struggle of a man against a white whale, Moby Dick. Literary critics and Americanists had long asserted that these works evidenced America's distinctive culture of individualism and entrepreneurship. They contrasted such works with the novel of manners produced by English authors which were held to represent English culture. In her careful analysis, Griswold (1981) put this facile generalization in doubt. She found that the English novels of manners sold better in the United States, as well as in England, than the man-against-nature novels. Significantly, before 1909 American publishers preferred works by English authors because they could be sold in the US without paying author's copyright fees, while American authors had to be compensated. To sell their work, American authors turned to several specialty topics, including the man-against-nature theme. With the changed copyright law of 1909, American and English authors were put on the same footing, and a rapidly increasing number of American authors successfully published 'English' style novels of manners. This fact, that was once read as evidence of 'the closing of the frontier,' Griswold sees as an important result of changes in copyright law and its ramifying influences on the literary production process.

Research in the production perspective draws freely on theories, methods, and concepts developed in other branches of sociology. It is, however, distinctive in focusing on the consequences of social activities for culture. Thus, for example, the 'newsmaking' studies of the 1970s exemplify the production perspective because their authors were not satisfied to simply deconstruct the content of news or to trace the organizational and occupational dynamics of news organizations. In addition they highlight the consequences of these for the formation and transformation of 'news' (cf. Molotch and Lester 1974, Tuchman 1978, Gans 1979).

1. *Establishing the Production Perspective*

The production perspective emerged in the 1970s largely in response to the failure of the earlier dominant idea that culture and social structure mirror each other. This 'mirror' or 'reflection' view had been developed by anthropologists who studied small preliterate groups, where it seemed credible that a self-consistent set of social institutions would be reflected in a cognate coherent set of cultural symbols. The idea that there is a symbiotic relationship between a singular functioning social system and its coherent overarching culture was freely embraced by most theorists of contemporary society as well, including in the 1950s and 1960s most Marxists and functionalists such as Talcott Parsons. The former asserted that those who controlled the means of producing wealth could shape culture to fit their own class interests. The latter believed that a set of monolithic abstract values were more long-lasting and determined the shape of social structure.

The reflection view proved to be of limited use, however, in understanding the relationship between social structure and culture in industrial societies and was also being widely questioned by anthropologists studying preliterate societies. Breaking with the older mirror view, the production perspective—like most of the other contemporary perspectives in cultural sociology—views both culture and social structure as an emergent patchwork and the relationship between them as problematic (Peterson 1979).

Publication in 1976 and 1978 of anthologies entitled *The Production of Culture*, edited by Peterson and Coser, respectively, signaled the emergence of the production perspective as a coherent and self-conscious approach in culture studies, claiming to be applicable across a wide range of specific fields and genres. Many of the early researchers in the perspective had been trained in the sociology of organizations, industry, and occupations and brought their skills in the analysis of material production to the fields of symbol production. Others came to the perspective with a love of or commitment to a particular form of cultural expression such as opera, rock, dance, television, or literature. A number of developments since the 1970s show the progressive establishment in

sociology of the production of culture perspective. Two textbooks and an anthology have appeared with the title *The Production of Culture* (Crane 1992, Ryan and Wentworth 1998, Gay 1997), and the perspective receives full chapters in recent texts in the sociology of art (Zolberg 1990) and in the sociology of culture (Hall and Neitz 1993).

From the outset, the perspective promised not only a way to better understand the shape and form of any particular cultural expression but also to facilitate three kinds of comparisons: (a) comparisons across broad cultural production realms including art, popular culture, religion, science and law; (b) comparisons across the division between 'elite' and 'common' that tends to emerge in each realm; and (c) comparisons across societal, institutional, or organizational, and microlevels of analysis (Peterson 1976). Progress toward achieving these goals has been uneven (Ryan and Wentworth 1998).

We will review progress and problems in working toward these three goals and point to several emerging lines of inquiry that link the production perspective to other approaches in cultural studies, citing studies that exemplify the perspective, even when the authors have not formulated their work in production terms. We begin by showing the utility of the perspective by reviewing a few specific lines of research. This review will also briefly note, as appropriate, cognate work in other realms.

2. *The Production System in the Cultural Diamond*

Griswold (1994) has argued that to be complete, the study of any cultural phenomenon, be they books, paintings, legal systems, religious precepts, or news stories, must take into account four classes of phenomena. In addition to a close analysis of the cultural works themselves, they also focus on the situation in which people create works, the nature of the audience, and the relevant aspects of the society at large. She sees these as four points on a diamond with society at the top, the cultural work at the bottom, the creators on the left point, and the audience on the right. With this model in mind, the production system can be seen as a square overlaying the diamond, the square being large enough so that its corners intersect each of the sides of the diamond. This addition makes clear that elements of the production system intervene between each of the four facets of the diamond, so that the influence of each on the others is mediated by the production system.

To illustrate the workings of the production system in shaping culture, Peterson's (1990) analysis of why rock music became the dominant form of popular music will be used. In the early 1950s, the music industry was blind to the large and growing unsatiated demand for greater variety in music and was deaf to the efforts of musicians who might have satisfied that demand. The music industry was financially as well as aesthetically committed to the big band-crooner style of popular music of the time, and, because of its oligopolistic control of the production, distribution, and marketing of new music, was able to thwart the marketing of alternative styles. Yet in the mid-1950s the power of the music industry oligarchy was broken and the rock of Chuck Berry, Elvis Presley, Bill Haley, and Little Richard became the defining force of music in the United States and much of the world. In the middle of the quiescent Eisenhower years, no major political or economic upheaval could account for such change.

Six production factors working together are identified as making possible the rapid cultural change. These include law and regulation, technology, industrial structure, organizational structure, occupational careers, and the consumer market. In brief, with the transfer of network radio programming to the emerging new medium, television, radio turned to playing records as the cheapest effective form of programming. The granting of many new radio station licenses, the arrival of cheap transistor radios, and the development of the top 40 radio-as-jukebox format meant that the listening audience was exposed to a much larger number and far wider range of music. Using the new durable 45 rpm records, and taking advantage of the developing network of independent record distributors, numerous independent record companies experimented with a wide range of new sounds in an effort to tap the unsatiated market demand. In a matter of 24 months between late 1954 and early 1957, rock was forged in this caldron of entrepreneurial creativity (Peterson 1990, Ennis 1992). In the decades since, the large media conglomerates have gradually reconstituted their oligopolistic control of the industry, and the market has been divided into an ever larger number of increasingly homogeneous market segments (Lopes 1992, Negus 1999).

Using the same six variables employed in the analysis of the emergence of rock music, the production perspective can bring some order to a welter of different trends taking place in commercial music at the turn of the millennium. On the one hand, a few artists are accounting for an ever larger proportion of diminishing aggregate record sales, and at the same time there is an explosion in the number and diversity of artists who are making and independently distributing CD recordings. To increase their popularity with the masses of sometime music buyers, megastars such as Michael Jackson, Garth Brooks, Celine Dion, the Spice Girls, and Shania Twain make their work ever more safe and predictable. This aesthetic shift is encouraged by the marketing needs of their record companies who are aggregating into ever larger multinational media conglomerates, dependent for promotion on radio stations whose ownership is rapidly consolidating as well. These large firms can

work efficiently only if they sell millions of units of a few recordings. The majors have been able to control the market by effectively controlling the channels of marketing and distribution.

The hegemony of this star-marketing system is being challenged by a new system of promotion and distribution that is coming into being. Since the late 1980s the technology has been available to make possible the digital recording of music and, therefore, the storage, reproduction, and transmission of sound without any decay in quality. Given the increasing power of Internet technology, its maintenance as a free highway of information, and the availability of inexpensive software, making it easy for any musician to create a 'home page' and transmit sound. In this emerging field independent music producers can make, market, and distribute their work independent of the major media conglomerates.

If this system develops successfully, it can increase the power of artists, reduce the power and profitability of the large firms, foster an explosion in the number of artists and firms able to reach wide audiences, and significantly increase the levels of experimentation in popular music, creating new markets for an explosion in the range of music regularly on offer. It is as likely that, through the elaboration of copyright and censorship law, together with control of the patents for the technology necessary for the new system, the major firms will keep control of developments in popular music.

3. *The Promise of Comparative Analysis*

One of the features of the production perspective is that it facilitates comparative analysis of three sorts: comparisons across symbol-producing realms, comparisons between elite and popular forms within each realm, and comparisons across societal, institutional, and microlevels of analysis. To date, most studies in the production perspective have focused on particular fields, and progress toward fulfilling the promised benefits of comparison has been uneven, as we will show.

3.1 *Comparisons Across Symbol-producing Realms*

Mid-twentieth century functionalists argued that cross-realm comparisons are fruitless because each has its own unique core value. Essentially Parsons (1961) argued that science deals in experimentally established fact, law deals in reason, art deals in aesthetics, and religion concerns faith in the supernatural. The nominalist stance of the production perspective, however, problematizes these differences, making the assertion of uniqueness a residual to be asserted when no similarities can be established.

The expectation that the same range of processes are present in all realms of culture production, be they religion, art, science, law, etc. does not mean that new discoveries in physics are produced in the same way as is new religious doctrine. Rather it means that the differences can be explained, in large part, by the conditions of production in each of the realms (Crane 1976). For example, knowledge in physics today is largely controlled by a single subsidized and self-perpetuating worldwide 'priesthood' that works to allocate resources and rewards in ways that perpetuate its views; at the same time, religious doctrine varies greatly from country to country, and, particularly in the United States, a wide range of religious specialists mu compete with each other in an open market for the lay consumer's attention and for resources, loyalties, and rewards.

These differences, however, are not inherent in the nature of the subject matter of these two realms, as can be seen by reference to earlier times when the production systems of science and religion were very nearly reversed. In the eighteenth century, English scientists supported themselves and their work by periodic shows of spectacular findings that induced laymen to give them further support, and in the seventeenth century religious scholars worked with the support and protection of an Established Church orthodoxy and defied it only in mortal peril of their lives. Likewise, eighteenth-century French painters worked with the protection of an all-powerful Academy, while today they work in conditions of near perfect competition. In each of these instances, the movement from one sort of production system toward the other has had profound consequences for every aspect of the art world, including even what is considered to be art (White and White 1965, Becker 1982).

As recent research on the roles of women in each of the symbol producing realms has shown, much less dramatic changes in the nature of the production process may have major consequences for a particular class of producers. Systematic comparison across realms will highlight the structural and symbolic underpinnings of such institutional discrimination.

3.2 *Distinctions Between High and Low*

An invidious distinction between artifacts, practices, and practitioners considered reverentially and those who are considered to be profane is found in each of the culture-producing realms, and this fact furnishes a great opportunity for comparisons both within and across production realms. To date, however, the distinction has done more to inhibit such comparisons because the truth value vested in high (art, science, religion, law) symbols and the honor status accorded to those in the fields where they are produced is often

seen to render these fields incomparable with each other and also with the low counterparts in their own realms (Gans 1974).

Working from the nominalist stance of the production perspective, one can cut through these problems by asserting that any of the invidious high–low distinctions are not inherent in the cultural objects, but rather they involve a social, or better, a cultural construction of reality. At issue are the questions: who gets to make the designations, on what basis are they made, and within what range are they accepted. There are a number of excellent case studies touching on these issues, but there has been very little thinking about the conditions supporting one system of evaluation or another across all the realms of cultural production. The most systematic efforts in this direction can be found in the works of Pierre Bourdieu and his colleagues. In the paragraphs that follow, two issues are considered: the mobility between high–low categories, and the differentiation and de-differentiation of high and low.

3.3 Cultural Mobility

In the arts, particular works and artists, and even entire genres, experience aesthetic mobility over time (Becker 1982, Griswold 1986). DeVeaux (1997) details the sociopolitical and music industry conditions that caused the aesthetic mobility of jazz from folk to popular to fine art music. In the religious realm in the United States, there has historically been a cycle in which the established church organization becomes increasingly rigid and out of touch with people's felt needs, and a number of reformist charismatic groups form to serve the demand. As the established churches loose power the surviving reform groups become ever more established and church-like.

3.4 Changing Criteria of Prestige

The distinction between popular culture and high art that was such a fixture of American society by the middle of the twentieth century (Gans 1974) only began to be clearly articulated in the later decades of the nineteenth century. The differentiation of high–low was driven by the class interests of rising status groups, and the criteria for claiming prestige has changed in recent decades (Crane 1992). There is evidence that the highbrow exclusiveness that was at the core of cultural capital at mid-century has been replaced by a cultural capital based on cosmopolitan, even omnivorous, tastes. Volume 25, numbers 2 and 3 of *Poetics* are devoted to describing this changing representation of status through taste displays.

4. Micro, Institutional, and Societal Levels of Analysis

The production of a culture model has been formulated at the level of personal interaction, relations among organizations, and the workings of entire societies. Ideally, work at each of these levels complements work at the other two, and while this may happen in the best individual studies, the theoretical questions and research techniques employed at the three levels are different enough that research has tended to develop separately, and practitioners working at different levels of analysis do not learn all they might from each other.

The great strength of studies that explicitly take into account societal level conditions is their view of the culture industry as an expression and reinforcer of the sociopolitical system of the larger society and the attendant systems of domination and subordination, including social class, ethnicity, religion, and gender. Excellent studies can be cited. The danger in looking from the societal level is that the workings of the production process may be seen to follow automatically from the society-level constraints. This need not be the case, as exemplified in a number of empirical works which show the way in which societal values and beliefs are mediated by the culture industries.

Production studies that focus primarily on the organizational or institutional level take advantage of the decades of studies of particular organizations, occupations, industries, and the theoretical developments in these research specialties. Because researchers want to remain value-neutral, they tend to bracket their own aesthetic and political views and use uncritically the aesthetic judgments and ideological stances implicit in the symbolic field being studied. Thus the work of these researchers helps to perpetuate the established categories of the systems they study. At the same time, their reports expose for public review the workings of the systems which create and perpetuate self-serving classifications of a given field (cf. Lamont and Fournier 1992).

Production studies that focus primarily on the microlevel of interaction between persons draw from the rich tradition of research in symbolic interactionism, as well as from the social-psychological elements of the sociologies of occupations and organizations. The most wide-ranging and influential work in this tradition is Howard S. Becker's *Art Worlds* (1982). He shows that by bracketing societal and institutional levels of analysis, one can illustrate how groups of symbol producers create and are shaped by the conventions of aesthetic judgment and collaboration in culture production. In effect such microlevel studies focus less on the production of culture and more on the culture of production (Fine 1992).

Some microlevel studies can be criticized for unreflexively assuming the perspective of the group or occupational category under review, and thus obtain-

ing an incomplete and misleading reading of the field. This 'going native' as it were is cognate to the problem of becoming an unwitting apologist for the institution under study, and the research strategy of comparison across subfields is one of the best ways of guarding against unreflexively adopting the perspective of just one of the groups in a production system.

5. *The Production Perspective in Cognate Areas*

The production perspective has proved a useful model for organizing ideas and research in a number of areas where the production of culture is itself not the conscious aim of the activity.

5.1 *Reception and the Autoproduction of Culture*

Reception by the reader, listener, viewer, or purchaser has always been a central concern in cultural studies. The term 'reception' suggests the end of a communication process. However, reception is an active process of selection, interpretation, and recombination of elements that can be seen as the production of a symbolic world which is meaningful for 'consumers.' A prime question here is how people go about selecting cultural elements, and in turn, the meanings that they attach to them. This production of a lifestyle for oneself and one's group is best referred to by the Latin word for self—'auto' thus the autoproduction of culture. The autoproductions of marginalized groups such as youth, ethnics, eccentrics, and the like have received much scholarly attention, but all individuals and collectivities create lifestyles that display their patterning of cultural choices (Peterson 1983). A growing number of studies focus on how people of different sorts produce meaning out of mass-mediated symbols.

In the 1940s a 'mass culture' was seen as the unreflexive response to the seductions of the mass media (Rosenberg 1957), dissolving the social class-based hierarchy of class cultures by which wage worker, tradesperson, business person, and farmer could readily be distinguished. While the extreme elitist alarm over massification has fewer proponents now (Gans 1974), much of the debate since has focused on the question of the degree of fit between social class, defined in relationship to production, and culture class defined in relationship to consumption. Gans (1974) and Bourdieu (1984) assert that the fit between social class and culture class (groupings of people sharing patterns of consumption) is quite close. However, their perceptive analyses of the United States and France respectively reveal numerous autoproducing status groups that cannot easily be fit into a linear hierarchy.

More recent studies of autoproduction of culture suggest that most people of high status (in the United States at least) are now little concerned with the old class markers of cultural capital that centered on the appreciation of the fine arts. They no longer shun as inferior all forms of popular or mass culture (Goffman 1951). In their study of the musical tastes of the full range of occupational status groups, Peterson and Kern (1996) suggest that the cultural symbols of class position are undergoing a profound transformation. While the top strata were earlier characterized by an elitist and exclusive interest in the fine arts and avoidance of other cultural expressions, now persons and groups show their high status as cultural omnivores, consuming not only the fine arts but also showing a knowledgable appreciation of many, if not all, forms of cultural expression. Near the bottom of the status hierarchy, in sharp contrast to the old conception of the undiscriminating couch potato of the mass audience, they find groups who are univores, that is, people involved with a single form of cultural expression.

The systematic study of the autoproduction of culture is going forward rapidly along several fronts: (a) ethnographic studies of distinctive groups tease out the processes by which group members appropriate and incorporate cultural symbols for their own purposes; (b) other studies show the re-appropriation of the mass media-disseminated pop culture by youth and other specific taste groups; and (c) population surveys with increasingly sophisticated culture questions are becoming available, making possible a much richer understanding of patterns of cultural choice.

5.2 *Tradition, Collective Memory, and Boundary Formation*

Early anthropologists, folklorists, and sociologists developed the idea of 'tradition' as the repository of all that is ancient and virtually unchanging. This fitted the needs of both romantics seeking the 'noble savage' and imperialists needing a rationale for ethnic and racial exploitation. In recent decades this view has been attacked on all sides as factually incorrect and self-serving. For example, Hobsbawm (1983) in a study showing that much of the British monarchial tradition was in fact purposefully created in the middle of the nineteenth century, has coined the felicitous term 'invented tradition' to describe this kind of production of culture.

The term 'collective memory' is now often substituted for 'tradition' in recognition that the past is continually reinterpreted to fit the changing needs of the present. Some studies point to specific individuals or groups of memory 'doctors' and 'cultural entrepreneurs.' One of the most exciting applications of the idea of the mutability of collective memory has been in the study of the manipulation of memory in the service of making status distinctions along the lines of gender,

race, class, etc. Gusfield (1963), in one of the earliest works of this sort, studied the role of status politics in the efforts of the (old-family Protestant) Women's Self-Temperance League to stigmatize the alcohol-use norms of immigrant Catholics. A wide array of applications of this sort of culture-production study can be found in Lamont and Fournier's (1992) anthology, *Cultivating Differences*.

6. Prospects

Research perspectives tend to come and go over the years, so what are the prospects for the production perspective? The numerous emerging developments described above show that the production perspective continues to gain utility for significant research and theory development. The perspective has proved an essential part of any full analysis of cultural phenomena, although some practitioners in cultural studies still do not take into account the influence of production factors. The globalization of production and the high rate of technological development as well as changes in censorship law and intellectual property rights make it all the more imperative in the twenty-first century to take into account the changing influence of production factors. Whether under the distinctive designation 'production of culture' or not, future scholars will find it rewarding to ferret out the many ways in which the system of culture production influences what culture is and what it can become.

Culture-rooted Expertise: Psychological and Educational Aspects

Introduction

The gaining of expertise is usually characterized cognitively, as a process of enhancing one's competence in a target domain by accumulating experience

of problem solving, understanding, and task performance in that domain. However, expertise is almost always rooted in culture in the following three respects:

(a) Many forms of expertise occur through participation in practice, in other words, under sociocultural constraints.

(b) Some forms of expertise are culturally valued; thus, practice for them is culturally organized.

(c) Consequences of expertise are sociocultural as well as cognitive: experts share particular evaluative criteria for assessing performances in their domain of expertise; their acquired knowledge and skills have a sociocultural origin; and an increase in cognitive competence is often accompanied by a fuller participation in the community of practitioners.

These culture-rooted aspects of expertise will follow and be elaborated on, and their implications for schooling and instruction will be discussed.

1. *The Acquisition of Expertise Occurs through Culturally Organized Practices or under Sociocultural Constraints*

In many domains of expertise, knowledge and skills are acquired through participating in culturally organized practices that are interesting and/or significant to the participants (Goodnow et al. 1995). Such cultural practices can be characterized as a set of sociocultural constraints that help participants produce culturally valued products and performances. There are a number of built-in factors and conditions that serve to control and direct a participant's attention or that serve to eliminate in advance a large number of logically possible procedures and interpretations. Although such constraints are to support participants' performance, rather than to contribute to their acquisition of expertise, repeated participation enhances the skills and knowledge needed to perform well in these practices.

External sociocultural constraints include (a) other people with considerable prior experience and (b) physical, symbolic, and social tools. When interacting with other people, human cognition and learning are constrained in that what they observe is not randomly selected out of almost infinite pieces of information, but is directed by joint attention to specific items. What they try to do is not a randomly chosen chain of responses from their repertory, but is often triggered by imitation, and how they interpret a set of observations is influenced by guided comprehension activity. Thus, people tend to be more competent when they collaborate than when they work alone. Therefore, when the mastery of skills requires a lot of experience, the opportunity to gain such experience is often provided through apprenticeship. Novices or newcomers are able to participate in practices as apprentices, with little or no pretraining, because they are initially assigned to relatively simple and peripheral parts of the practice, and come to fulfill gradually increasingly difficult and central roles as they gain better skills and an understanding of the total practice. For example, Lave (1988) reported that apprentice tailors in Liberia are given such jobs as fixing buttons, which are simple and repairable tasks, but constitute authentic and essential parts of dressmaking. To generalize, when the master can manage to maintain a balance between the goals of increasing productivity and (the apprentice's) learning, and when the apprentices are committed to enhancing their skills, this learning arrangement can be effective and enjoyable.

Tools or shared artifacts also serve to direct the user's attention and narrow the range of procedures and interpretations they consider. For example, a pedometer draws the user's attention to how far they have walked. A vending machine helps the user find how to convey their request for an item and pay for it, because the machine does not respond to operations performed out of their proper sequence. A set of tools can function as enabling constraints to help participants to perform a task successfully, and also to acquire knowledge and skills. For example, it is often much easier to actually perform steps in cooking than to state the steps verbally or to comprehend them, because human actions are highly restricted by the shared artifacts that are available (e.g., utensils and appliances).

That novices become experts by incorporating culture may be a misleading phrase, because what really occurs is the individual (re)construction of knowledge and skills under sociocultural constraints, with the resultant cognitive products being analogous to the knowledge and skills found in the culture. The emphasis on culture is compatible with the notion of the human construction of knowledge and the internal (cognitive) constraints imposed on it.

2. *Some Kinds of Expertise are Culturally Valued*

Most domains for expertise are apparently optional in technologically advanced societies; that is, individuals are allowed to choose the domains in which they pursue expertise. However, this does not mean that all domains are equally respected and valued in each culture. On the contrary, each culture contains a wide variety of 'cognitive values' (Goodnow 1990), which differentiate domains of expertise in terms of their significance. Some areas of knowledge, for example, are described as 'basic' while others are described as 'extra.' For the former type, people growing up in the culture have almost no choice than to seek mastery in them. National sports constitute a good example of such, almost obligatory, domains of expertise. Many Fijian children are interested in playing rugby, pri-

marily because their culture denotes, though implicitly, that being good at rugby is more significant than expertise in other sports.

Cultures organize practices, the products of which are valued in a particular culture, so that a large number of people can acquire the knowledge and skills needed. The process of cultural imposition need not take a compulsory form. More often than not, developing individuals tend to choose those domains of expertise that are valued by their culture, because the culture provides them with many opportunities to participate in relevant practices, and because people close to them tacitly encourage them to do so.

Similarly, each sub-culture of a given domain or each community of practitioners has its particular set of values. For example, abacus operators are socialized in terms of the values they hold regarding the importance of abacus skills and their status in general education, as well as a respect for the speed of calculation (Hatano 1997). In fact, the community of abacus educators and skilled operators constitutes a strong pressure group in the world of education in Japan. Skilled abacus operators calculate speedily, but they are motivated to perform their operations even faster.

What kinds of experience or participation encourage the development of particular values or forms of privilege? Experts' values are undoubtedly forms of culture in the mind, acquired through internalization. They serve as the source of motivation for experts to excel at the target domain. Although knowing little about the way in which these values emerge, it can be assumed that they are gradually internalized in the course of gaining expertise, through conversing with other practitioners, acquiring sophisticated evaluative criteria, and spending time and effort in and for the domain.

3. *Consequences of Expertise are Sociocultural as well as Cognitive*

Gaining expertise is far from purely cognitive. It is a social process (Lave and Wenger 1991); more specifically, a process in which beginners become fully qualified members of the community of practitioners. The case of gaining expertise in abacus operation exemplifies this sociocultural nature of expertise (Hatano 1997). Abacus school pupils are usually first enrolled by their parents while in elementary school. The parents may believe that the exercise there will foster children's diligence and punctiliousness as well as enhance their ability to calculate and to make numerical estimations. Pupils are first motivated to learn abacus skills to receive parental praise, especially by passing the qualification exam. Like many other out-of-school domains of learning in Japan, abacus learning has an elaborate qualification system and frequent qualification exams. However, the pupils' motivation changes when they join an abacus club at school or become a representative of the abacus school. At this point, they compete in matches and tournaments, like tennis or chess players. Also like these players, abacus club members not only engage in deliberate practice (Ericsson et al. 1993) at least a few hours every day, but also think about how to improve their skills. Their learning is strongly supported by the immediate social context of the club and the larger one of the community of abacus operators. Formal and informal relationships with an instructor, oldtimers, and peer newcomers organize their ways of life, and sanctions from other players regulate their daily activities. Moreover, they may participate in the community of abacus operators by taking an administrative role in players' organizations or by serving as an examiner or judge at matches and tournaments. They begin to increase their participation, by increasing their significant responsibilities within the community.

Consequences of expertise are sociocultural in another sense. The knowledge and skills acquired in the course of gaining expertise have a sociocultural origin, in that they are shared by mature members of the community, before being incorporated by individuals who are gaining expertise. In other words, such knowledge and skills constitute built-in constraints in the relevant practices. Even novices have learned, to a considerable extent, the methods and concepts used in practice that are needed to perform accurately. They have also learned, though to a lesser degree than experts or intermediates, to use the methods and concepts readily and skillfully. Most, if not all, of the knowledge and skills of experts have a sociocultural origin, although the experts may have added something new to their domains. Experts' performance is often more standardized than novices.' For example, wine experts are different from non-experts in their ability to readily classify a set of different kinds of wine almost uniformly in terms of the type of grape and region of production (Solomon 1997). Moreover, they have acquired a complex set of evaluative criteria by which they can aptly judge the quality of innovative as well as conventional products or performances in the domain (Oura and Hatano 1989).

4. *Educational Implications*

What educational implications can be derived from the aforementioned culture-rooted aspects of expertise? To the extent that the acquisition of subject-matter knowledge in educational practices is considered analogous to the process of gaining expertise, the above discussion is relevant. Educators might organize classroom activities, so that students are

supported by sociocultural constraints, at least in the initial phase of learning. They might try to establish a local community within the school in which the target subject-matter knowledge is highly valued. Also, educators might invite students to be involved in designing learning activities and evaluation of their products. In fact, these principles have been incorporated into the 'community of learners' approach to school reform (e.g., Brown 1994).

Culture Shock

Anyone who has spent time in a culture significantly different from his or her own has more than likely experienced a sense of disorientation and perplexity at life in the new culture. After an initial period of excitement about the novelty of the new culture and perhaps pleasure in the absence of some of the constraints of one's own society, the traveler may be plunged into a period of anxiety and frustration at the difficulty of understanding and making himself or herself understood. The visitor may feel confused by differences in expectations and in interpersonal relationships, abhorrence at some cultural practices or perceived dispositions of the people, followed by intense homesickness, depression, and perhaps regression to unaccustomed bouts of annoyance and labile feelings. Frequent manifestations include food concerns—yearning for familiar foods or anxiety about the safety of the drinking water.

Such reactions on encounter with a new culture have been referred to in anthropology as 'culture shock,' a term which has been in currency since 1950, when Kalervo Oberg gave a talk of that title to the women's club of Rio de Janeiro—a group of wives of American businessmen and diplomats. Bronislaw Malinowski, although he did not use the term, gave one of the classic descriptions of culture shock in 1922, in the introduction to *Argonauts of the Western Pacific*:

> I well remember the long visits I paid to the villages during the first weeks; the feeling of hopelessness and despair after many obstinate but futile attempts had entirely failed to bring me into real touch with the natives, or supply me with any material. I had periods of despondency, when I buried myself in the reading of novels, as a man might take to drink in a fit of tropical depression and boredom.

Culture shock has been noted frequently in anthropological fieldwork. It has become a regular part of anthropological thinking about culture, especially in the USA. Yet discussion of its manifestations has been comparatively rare in anthropology, only one major book being devoted to it. Some more specialized spinoff concepts, such as Toffler's 'future shock,' have been more extensively written on. Culture shock has been best described, perhaps, in some fictional works by anthropologists and others—Laura Bohannan's *Return to Laughter* (see Bowen 1954); E M Forster's *A Passage to India*—or in briefer introspective works by anthropologists such as Mary Catherine Bateson (1968) and Jean Briggs (1970). George Devereux's *From Anxiety to Method in the Behavioral Sciences* (1968) still remains one of the best theoretical explorations of its significance.

The earliest writings on culture shock treated it as a kind of pathology, an obstacle to smooth operation in the culture one is entering and to communicating with its people. Kalervo Oberg listed a number of 'symptoms' of this 'transitory disorder,' including: compulsive handwashing, emotional lability and excessive preoccupation with cleanliness. The psychoanalyst Gertrude Ticho, in a 1971 article, expands this list to include

> increased rigidity, fatigue, withdrawal anxiety, depression and elation, distressed obsessive neurotic-like symptoms such as over concern with the cleanliness of food and water, and hysterical reactions.

She goes on to add that

> at times, after a period of enchantment with and enthusiasm for the new culture, a hostile reaction to the people of the foreign culture ensues. This reaction becomes endowed with more global prejudices, such as 'they are lazy and un-

trustworthy, rigid, treacherous and sabotage progress.' The previously open-minded, outgoing 'foreigner' avoids contact with the people of the host country and withdraws to 'his own people,' if possible, thus creating an enclave within the foreign country.

'If this pattern is not reversed,' she concludes, 'the gap between the different cultures may be widened and result in a vicious circle' (Ticho 1971, pp. 324–5).

More recently, culture shock has been seen as an essential part of adapting to an unfamiliar culture, of coming to understand ways of living and of seeing the world that are different from one's own. Recent anthropological writers have viewed the process in different ways:

(a) as a loss of one's own culture, with a resulting process of grieving or mourning the loss;

(b) as a 'rite of passage,' a kind of 'initiation' marking the transition from membership in one culture to at least being conversant with another;

(c) as a 'resocialization' into another culture; and

(d) as a process like therapy or psychoanalysis for reorganizing one's personality, resolving old conflicts along new lines (see Kracke 1987).

The first of these, 'mourning the loss of one's own culture,' along with the old view of culture shock as a 'transitory psychological crisis,' may be grouped together as a 'negative' view of the phenomenon, emphasizing the crisis of moving *out of* one's previous 'culture of orientation.' The last three—'rite of passage,' 'resocialization' and the analogy with change in psychotherapy—are 'positive' viewpoints, emphasizing the transition *into* the new culture, the learning of new ways of thinking and reacting.

1. *Phases of Culture Shock*

While everyone's experience of cultural transition is unique, depending on one's own personality and past experiences, and on the cultures involved—the entry into another culture tends to develop in common stages. Unless the entry into the culture is under duress (capture, exile, or fleeing from a natural or political disaster at home), one's first experience tends to be one of enchantment or delight. One may also experience shock at aspects of the new culture like poverty, dirt (or antiseptic cleanliness), or noise and confusion (for a rural person arriving for the first time in the city); but at first, one is likely to feel curiosity about exploring the new culture. For a while, one may take pleasure in the absence of some of the constraints of one's home culture, at the warmth of emotions people express (if you come from a reserved culture), or the willingness of people to help you. After a time, frustrations begin to mount as one realizes, for example, that the directions people give may be more based on desire to be helpful than on a real knowledge of the information asked for, or that invitations are not to be taken at face value. One becomes aware of not knowing the cues for judging situations or people's intent, and finds oneself in awkward situations, or making gaffes. After a certain period, which varies from a few days to a few months, one begins to feel a certain 'culture fatigue' (as George Guthrie has termed it (Szanton 1966)—an irritation at the accumulating aggravations which may mount to an exasperation with the culture itself.

At this point, if one does not give in to the inclination to leave, one begins the process of learning the new culture: what William Caudill (1961) calls 'resocialization.' The phases of distress and learning are reiterated in cycles as one is more and more deeply socialized into the culture, gradually approaching a phase of being more at home in it. The process is to some extent that of reconstructing one's identity, or constructing an alternate identity for one's sojourn in the culture. Over years of living in a new culture, the process may culminate in the formation of a new identity, as Garza-Guerrero (1974) suggests, combining patterns and values from one's culture of origin with patterns and values of the new one.

2. *You Can't Go Home Again*

An unexpected feature of culture shock is the disorientation one experiences on *returning* to one's culture of origin—a phenomenon which has been designated 'reverse culture shock' (Hertz 1977). Many people feel even more difficulty in readjusting to their *own* culture after returning from abroad than they did adjusting to the foreign culture or cultures they have lived in. Why is this? In part, it is the phenomenon which the novelist Thomas Wolfe identified in *You Can't go Home Again*: You have been changed by your encounter with another culture, and you no longer 'fit' in the same place you did before going. You have an experience you do not share with your compatriots who remained at home. It is perhaps exacerbated by the very unexpectedness of it: you have had dreams of coming back home where everything will at last be unproblematic, and suddenly it is not.

Reverse culture shock reveals something about the nature of the culture shock experience itself: it measures the depth that one is changed by the encounter with another culture. We come back a different person from what we were; we have taken something of the other culture into ourselves, and can never again be fully at home in any one culture.

3. *Aspects of Culture Shock: The Epistemology of Knowing Other Cultures*

Culture shock may be an important, if not essential, part of the process of learning another culture, the central task of social or cultural anthropology. In a brilliant article, Mary Catherine Bateson (1968) discusses her own experience of culture shock in a very personal way. Culture shock, she suggests, is, among other things, a useful tool for recognizing where the

new culture differs from one's own. Where something about the new culture annoys or angers you, disgusts you, or arouses anxiety or a sense of disorientation, that is a point where one must look for fundamental differences in assumptions about life or in conceptualizing the world. In our western culture, for example, we view death and mourning as something highly private, and avoid talking with the bereaved person about the loss for fear of intruding on their privacy. Filipino culture, which regards bereavement as something that must be worked through with others, so that friends talk openly with the bereaved about the loss, helping the bereaved person to re-experience the loss and the grief in a context of concerned support. Initially, she was shocked at the direct way in which Filipinos ask the bereaved person about the loss, often provoking tears; by the time she came to experience a deep loss of her own in the Philippines, she was prepared to find 'deeply healing' the opportunity to articulate and vent her feelings of loss.

Another view of the nature of cultures leads George Devereux (1968) to formulate a deeper view of the source of culture shock. In a psychoanalytic viewpoint, he suggests that different cultures have different 'distribution of repressions': some feelings and fantasies are acceptable and may be talked about and accepted in oneself, others are repugnant and should not be acknowledged. The latter, in general, will be repressed, or at least disavowed, by most people in that culture. If something that is regarded as deeply disturbing and repugnant in one's own culture is considered acceptable and openly talked about in the culture you are entering into contact with, that may lead to considerable anxiety on your part. On the other hand, if something you consider normal and not anything to be ashamed of is regarded as repugnant in the culture you are going into, that may lead you to do or say things that will cause great distress to others in that culture; you may inadvertently arouse anxiety and distress, without at first understanding why.

4. Culture Shock and Mental Illness

Culture shock has received more attention in psychiatric and psychoanalytic literature, where the propensity of cultural estrangement to precipitate emotional problems or mental illness has been widely recognized. A number of articles have been written by psychiatrists and psychotherapists on the need for psychotherapeutic treatment for people whose culture shock has led them to emotional crisis. The Nigerian psychiatrist T. Adeoye Lambo has discussed certain psychiatric problems of African students abroad. Prakash Desai and George Coelho have written about the adaptation problems of Indian immigrants in the USA. Juana Antokoletz and many others have written on problems of Mexican and other Latin American immigrants in the USA. One of the most thorough discussions of culture shock was published by the expatriate Cuban psychoanalyst Garza-Guerrero (1974). Recently, the anthropologist George Spindler has developed a 'cultural therapy' to deal with problems of culture shock and intercultural communication.

Why is the encounter with another culture so unsettling? Perhaps it is because each encounter with a different way of life puts in question our own beliefs and values, confronted as we are with alternative ways of looking at reality or at social relationships, with different rules to guide our conduct. Each culture we come into contact with raises these issues anew, challenging new aspects of our world view and ethical standards. The depth to which these experiences disturb us is an indicator of how deeply the cultural framework we grow up in shapes our view of the world and of relations with others. It may be that this experience, the discomfort we feel in encountering another culture, is what most moves our curiosity about other cultures: the stimulus to anthropological study.

Culture, Sociology of

The word 'culture' has completely different meanings in the social sciences and in current language. In the latter, the meaning of the term has for long been mainly influenced by the humanistic conception of culture, which derives from the Roman *cultura animi*—a term that Cicero seems to have invented in order to translate the Greek concept of *paideia*. This is the classical sense of the word, based upon high productions of mind and art. Referring to the intellectual, esthetic, and ethical aspects of human beings (for which the German language uses the term *Bildung*), culture thus involves the legitimacy of value judgments and of the idea of a hierarchy between societies as much as inside them.

In the social sciences, on the contrary, the term has generally a widely inclusive meaning, which is actually aimed against the humanistic normative conception of culture, since almost anything may be considered as 'culture.' This conception, which opens an almost unlimited field to the term 'culture,' has been the basis of the ensemble of theories which may be termed 'culturalist trend.' It is characterized by a systematical relativism, strongly backed up by the fact that the overall conception of 'culture' is in itself a powerful relativistic tool. The popularization of the relativistic use of the term 'culture' in postmodern societies since the late 1900s poses a serious danger for culture.

1. *The Term 'Culture' in the Social Sciences*

This term has received, first in anthropology and afterwards in sociology, a very specific meaning, that prevailed despite the reluctance of very important authors, such as Morgan, Durkheim, and Radcliffe-Brown to use it in this way.

1.1 *The Tylorian 'Everything is Culture' Conception*

At the basis of the concept of culture as it is mostly used in the social sciences stands the well-known founding definition of the English ethnologist Edward Barrett Tylor (1832–1917), in his book *Primitive Culture* (1871). He borrowed much of the sense he gave to the term from Bismarckian Germany, whose conception of *Kultur* included any kind of expression of the national character. According to the German usage, Tylor takes culture to be *synonymous with civilization*, and therefore gives to that word what he calls 'a wide ethnographic sense.' For him, culture is 'that complex whole' produced by people's historical experience, of which he gives several examples: 'knowledge, belief, art, morals, law, custom.' But this enumeration is not a closed one. Tylorian culture also 'includes … any other capabilities and habits acquired by man as a member of society.' This definition is characterized by the huge breadth of its application.

Derived from the German term *Kultur*, the idea of a broad ethnographic sense of the word 'culture' perfectly suited Anglo-Saxon ethnologists from German or Austrian origin. The German-born US anthropologist Franz Boas (1858–1942) and the British anthropologist Bronislaw Malinowski (1884–1942), who was born in Poland as an Austrian subject, both took an outstanding part in the victorious settlement of the term 'culture' in the very core of the social sciences.

Although since Tylor many other definitions of culture have been formulated, his 'everything is culture' conception remained a basic creed for nearly all anthropologists during the twentieth century, and it still prevails. In its anthropological sense, culture includes religion, law, art, and literature, as well as all of everyday life in its often prosaic and even trivial aspects, such as cooking, sexual habits, or sanitary practices.

In the early 1900s, Emile Durkheim, Marcel Mauss and other French sociologists were reluctant to use the term 'culture' in its Tylorian sense, and preferred to go on using the word 'civilization.' Yet, the anthropologists' broad use of the term 'culture' has progressively spread to sociology. Nevertheless, during the 1950s, many American intellectuals, like Hannah Arendt, did resist the idea of mass culture, which they deemed to be no culture at all, but a deadly threat to it. In the early 1960s, American sociologists still regarded mass culture as a subject of debate, and the mass media as a most important field for sociological studies. Meanwhile, it was a French sociologist, Edgar Morin (1962) who took mass culture as an essential sociological field of study.

1.2 *Radcliffe-Brown's Attempt to Resist Tylorian Culture*

The founder of social anthropology, the British anthropologist Alfred Reginald Radcliffe-Brown (1881–1955) based his theory upon the study of 'social structures,' along the lines of Durkheim's sociological concept of function. In order to keep social anthropology completely separated from cultural anthropology, for some 20 years Radcliffe-Brown and his followers avoided using the word 'culture' as much as possible. Then, in 1952, he defined culture as 'the

process by which a person acquires, from contact with other persons or from such things as books or works of art, knowledge, skill, ideas, beliefs, tastes, sentiments.' So culture is for him the process of intellectual, esthetic, and ethical human development. Culture is the process by which one becomes a cultured person.

Though an anthropologist, and although his functionalist theory is as much relativistic and holistic as culturalism is, Radcliffe-Brown has a classical and humanistic conception of culture. This is because the term has no part in his system, not being his own relativistic tool. He states (1952) that 'the total social structure of a society together with the totality of social usages in which that structure appears and on which it depends for its continued existence' are constituent of a social system, whereas most anthropologists would have regarded all that as culture. Since he had decided to take as basic the social structure instead of the 'culture patterns' of cultural anthropology, Radcliffe-Brown had no need of the Tylorian sense of culture. In fact he had even every reason to refuse that use of the word, which was the basis of a powerful rival theory. Hence his humanistic formulation. Furthermore, Radcliffe-Brown's functionalism derived from Morgan, Durkheim and the whole French sociological school. As they had not admitted the Tylorian use of the term 'culture,' Radcliffe-Brown was naturally induced to follow their example.

However, Malinowski, the other great name of anthropological functionalism, regarded a broad conception of culture as natural. Posthumously published in 1944, his most important book is entitled: *A Scientific Theory of Culture and Other Essays*. Thus, in the 1930s and 1940s, anthropological functionalism was divided into two rival schools: 'social structure' against 'culture,' Radcliffe-Brown's school versus Malinowski's school, one of their motives of disagreement being opposing ideas about the concept of culture. In the UK, this quarrel was considered as opposing social anthropology to cultural anthropology. But, at the same time, nearly all US anthropologists were adherents of cultural anthropology since studying 'cultures.'

As a result of that, in the USA, since the end of the 1940s, the functionalist theory has been taken over, in an somewhat attenuated way, by sociologists, chiefly Robert King Merton and Talcott Parsons, who adhered to the social anthropologists' point of view. Accordingly, they stressed society and not 'culture' as the subject of their research. US sociologists thus stood opposed to US cultural anthropologists. So that the past rivalry of the functionalists schools of Malinowski and Radcliffe-Brown had become a professional quarrel opposing US anthropologists and sociologists, since the former claimed to deal solely with 'culture,' and the latter with 'society.'

Yet, in the early 1950s, some of Radcliffe-Brown's followers began to use the term 'culture' with a very broad meaning: for Raymond W. Firth, it included both the way of life and the content of social relations (1951), and for Meyer Fortes, both social structure and organization (1953). Afterwards, in 1958, American anthropologists and sociologists made an end to their quarrel by means of a peace treaty signed by A. L. Kroeber and Parsons, who mutually acknowledged the validity of one another's field of study: society as well as culture. The 'everything is culture' conception had won.

2. *The Culturalist Trend*

The Tylorian 'omnibus conception of culture' (Singer 1968) has been the basis of the set of theories known as 'culturalism,' and it remains the basis of the culturalist way of thought which still reigns over anthropology and a large part of sociology.

In the first half of the twentieth century, US cultural anthropology has been principally influenced by Tylor, Boas, and through him by the German diffusionists, like Fritz Graebner, who had introduced the idea of *Kulturkreis* (culture area). In the 1930s, US cultural anthropologists began to develop the idea that each 'culture' was an individual unity, well-organized and functioning as a system. This *holistic* and *systemic* conception was clearly formulated by Malinowski in the article on 'culture' that he wrote for the *Encyclopædia of the Social Sciences* (1931). A few years after, Margaret Mead (1935), Ralph Linton (1936) and Abram Kardiner (1939) emphasized the idea of a 'culture' being an integrated totality. The aim of ethnologists and anthropologists became to show the *inner coherence* of each 'culture' functioning as an organized whole, in which any component element is linked to all the others.

For the ethnology and cultural anthropology of the 1930s–1950s, the organization of culture systems consisted of a complex architecture of 'patterns of culture,' which Ruth Benedict had endeavored to describe and classify (*Patterns of Culture*,1934). Hence the definition formulated in 1952 by Alfred L. Kroeber and Clyde Kluckhohn:

> 'Culture consists of patterns, explicit and implicit, of and for behavior, acquired and transmitted by symbols, constituting the distinctive achievement of human groups … '

Each society is regarded as a distinctive cultural whole, characterized by its peculiar system of values. The beliefs existing in a given society are thought to be a product of 'culture.' Following Linton, several culturalist authors even affirmed that the personality structure of the individuals in a particular group was determined by the group's 'culture.' The most extreme advocate of this opinion was Kardiner, with his idea that each sociocultural system shaped a basic personality, the 'I' just being a 'cultural precipitate.' Therefore, culturalists deem socialization, the social process through which the main values of a society are

transmitted from one generation to the next, to be of the utmost importance, and they believe it to be a very deterministic process (see *Action, Theories of Social*; *Socialization, Sociology of*). On the whole, those theories led to an extremely mechanic conception, which attributes to 'culture' the production of beliefs, and to inculcation and conditioning the power to put them into people's minds and to determine their behaviors. So the US anthropologist Leslie A. White, the leader of the culturalist school called 'culturology,' went so far as writing (1968) that 'man is, and remains, a puppet of his culture.'

Culturalism has rightly been reproached for its belief in the ability of social systems to work in such a mechanical way that people so much believe what they have to believe that they feel the need to do what they have to do. It has also been established that the culturalists' holistic conception of a system of values common to a whole society was generally untrue, except perhaps in the very simplest ones. Hence the notion of 'subculture' used by culturalists for their study of complex modern societies (see *Subculture, Sociology of*). As for the culturalist principle of an inner coherence of culture systems, which comes from a counterhistorical method, it maybe partly exist in the most simple societies, but certainly not in complex ones. Against this assumed idea of a whole inside linkage of each 'culture', the French sociologists Raymond Boudon and François Bourricaud also observed (1982) that the 'everything is culture' conception was based upon an erroneous obviousness, so that it would be more adequate to use the term 'culture' only when speaking of artifacts and mental products.

A few anthropologists have dared to criticize the mechanical conditioning model of culturalism. It is chiefly the English anthropologist Robin Horton (1973) and the American anthropologist Melford E. Spiro (1987) who disputed the creed according to which belief and behavior did not result from reasons but were just the product of cultural conditioning. Nevertheless, since Boas the culturalist point of view does represent the mainstream in anthropology. And it has also influenced a great deal of sociology, and even philosophy. For instance, Richard Rorty asserts in a perfectly culturalist way that the idea prevailing in democracies of totalitarianism being evil is just the result of cultural conditioning (1989). The culturalist trend always works for the benefit of relativism, and the mere use of the term 'culture' in an 'everything is culture' sense does just the same.

3. *The Comprehensive Sense of 'Culture' : A Relativistic Tool*

As an evolutionist, Tylor naturally regarded nineteeth-century England as the pinnacle of civilization. But since he intended 'to treat mankind as homogeneous in nature,' he felt the need of a concept synonymous with 'civilization,' but more applicable to everybody and every society, past as well as present. Hence his widely inclusive definition of culture, which permitted him to find evidences of 'culture' among all societies and human groups, 'though placed in different grades of civilization.' Since everything was asserted to be culture, it became possible to find 'culture' everywhere. The Tylor revolution granted a 'culture' even to the most primitive peoples.

Yet, the most famous ethnologist in the 1870s and 1880s, the American evolutionist Lewis H. Morgan (1818–81), did not adopt the Tylorian meaning of the term 'culture.' In his book *Ancient Society* (1877), he went on using the notion of 'society'. Instead of Tylor's stages of 'culture', he prefered to delineate 'ethnical periods,' which he considered to be developmental stages leading, through barbarism, from savagery to civilization. But Morgan died and Tylor prevailed, and in the USA, at the end of the 1800s, Boas, being of German origin, naturally used the Tylorian sense of culture.

It was also Boas who threw out of anthropology the very idea of grades of civilization determining a hierarchy of societies and human groups. Rejecting the evolutionist theory, he declared the total relativity of 'cultures.' The 'Boas revolution' closely followed the Tylorian one. However, through Boas, *cultural relativism* actually proceeded from Nietzsche, who had brought all traditional values to trial, and announced that they were now delusive, since deprived of basis by the decline of dogmatic creeds. As it is well known, Nietzsche sought to destroy the very idea of objective reality, so that he is the father of modern relativism. The influence of Nietzschean ideas accounts for Boas's basic postulate of the relativity of values in the different 'cultures' and his complete rejection of the value judgments of nineteenth-century evolutionism.

In the 1940s, cultural relativism received, through the American anthropologist Melville J. Herskovits's *Cultural Anthropology* (1948), the support of Ernest Cassirer's German historical idealism (1942). According to Herskovits, exactly following Cassirer, human beings are living in a symbolic universe built by them: the universe of 'culture,' and so know no reality but the symbolic, that is, cultural. Herskovits asserts that all human experience of the physical world as well as of society are determined by enculturation, and accordingly culturally mediated. In this theory, all perceptions, evaluations, and judgments are a function of the cultural system to which one belongs, and are relative to it. Since Herskovits as well as Cassirer consider that all 'reality' is perceived through the screen of 'culture,' this one is deemed to be the measure of all things.

The Tylorian sense of 'culture' has been very useful for cultural relativists, as it permitted them to dispense with the word 'civilization' in order to avoid the

closely related ideas of hierarchy and comparative judgment. Being based upon the determinist assumption that values are a function or product of each 'culture,' cultural relativism does infer that all value judgments are necessarily culturally conditioned or determined. Therefore they are deemed to have no validity outside the cultural context from which they proceed. Value judgments concerning alien 'cultures' are therefore strictly forbiden by cultural relativism, which reproaches those judgments with being the product of a preference for one's own 'culture' and a prejudice against the other ones: namely ethnocentrism, which twentieth-century relativistic anthropology has regarded as the supreme offense, as much as evolutionism itself. Since the relativistic postulate of comparative judgment having no validity is asserted to be accurate, the corollary cannot but be the principle of an equivalent validity of all value systems. So that the American anthropologist David Bidney could observe (1968):

> 'Reverence for cultural values, rather than reverence for life, becomes the absolute virtue advocated by the cultural relativist.'

The term 'culture' used in a comprehensive sense has been the main vector of the *egalitarianist assumption* ensuing from cultural relativism, according to which all value systems must be considered to be equally legitimate units. If the meaning of the word 'culture' is taken to include ways of life as well as social relations, there is 'culture' everywhere. Whereas the humanistic idea of culture stands opposite to the absence of culture, or even the barbarity, of certain individuals, groups, or societies, the very fact of absence of culture or barbarity is denied by using the term 'culture' about these individuals, groups, or societies. Since everybody belongs to a social structure and a value system, everybody is regarded as belonging to a 'culture' or a 'subculture.' Sociologists as well as anthropologists consider each society and each social group to have its 'culture,' and they usually strictly obey the relativistic prohibition of comparative evaluations of values, which would lead to classifications showing the factual existence of various grades of civilization. The widely inclusive conception of 'culture' of the social sciences is used with the purpose of eliminating the very idea of uncultured groups. It allows indeed the social scientist to report the presence of 'culture' in the working class or in a primitive tribe as well as in the most learned circles. The 'everything is culture' use of the word 'culture' works just like an optical illusion. It brings about that fallacious value of equality of all societies and groups which is imperatively ordered by cultural relativism. The term 'culture' taken in a comprehensive sense is a necessity of cultural relativism, of which it is the most indispensable tool as well as the very basis.

The theory according to which all reality is symbolic is in no way cogent. As has been noticed by Raymond Boudon and François Bourricaud (1982), if that means that all human experience is mediated by a symbolic system like articulate speech or science, it is merely a commonplace statement. And if symbolic is taken as synonymous with ficticious, it is an erroneous idea. Likewise, the rejection of value judgments actually lacks logical validity. As a matter of fact, the assumption of an equivalent value of all 'cultures' is itself nothing but a value judgment, hidden behind the virtuous looking façade of cultural relativism. The prohibition of value judgments thus results from a value judgment. As emphasized by Allan Bloom (1987), the assertion of values and 'cultures' being relative is by no means proved: it is just a philosophical postulate, which stems from a political intention. And when cultural relativism disclaims freedom of judgment and rational analysis in order to prevent the development of any prejudice against alterity, it is just a way to avoid subjecting our own prejudices to logical criticism. Hence, the social sciences have the utmost need, as David Bidney (1968) had already stressed, 'to transcend the limitations of both cultural relativism and ethnocentrism through the pursuit of scientific truths concerning facts and values.'

However, the relativistic trend prevails, particularly in anthropology. Since nearly all twentieth-century anthropologists have repudiated evolutionism, Leslie A. White (1968) and his school being the main exception, anthropology has been, through the twentieth century and at the present time, essentially relativistic. Despite the endeavors of some authors like Melford E. Spiro (1987) and Robin Horton (1973), or like the British anthropologist Robin Fox (1989) who has turned to sociobiology (see *Biology's Influence on Sociology: Human Sociobiology*), anthropology and cultural relativism may almost be taken as synonyms. The US social anthropologist Clifford Geertz did affirm (1984) that cultural relativism was justified by the factual obviousness that value systems are of course disparate. According to Geertz (1984), relativism has such an obvious validity that it is impossible to resist it. Yet, what is most obvious is that relativism is the core and basis of culturalism, and that twentieth-century anthropology works as a *relativistic machine*. Accordingly, the relativists' fancy for anthropology is in no way surprising. They have often stated anthropology to be the queen of sciences. The cognitive relativist Feyerabend even asserted (1975) that it was the sole genuine science.

The use of a broad sense of the word 'culture' as a relativistic tool is also present in the other social sciences, especially in sociology. Such is the case in the neomarxist functionalist theory of the French sociologist Pierre Bourdieu (1979). In the 1960s and 1970s, Bourdieu emphasized the statement that culture (in the classical and humanistic sense of the term) was nothing but a 'culture' expressing the beliefs and behavior of the 'dominant class.' According to him, this 'culture' is just a 'culture' amongst many others,

but it is imposed as the only legitimate one by school, universities, and other cultural institutions, in order to bring about what he terms 'social reproduction.' Since they have been brought up in other 'cultures,' working-class children are considered by Bourdieu to be handicapped when facing at school a 'culture' which is not their own one, while children from the dominant class have all the means to be successful with it. So, stresses Bourdieu, the domination of the same upper class can be reproduced from generation to generation. Bourdieu deems culture to have in itself no real superiority, but just to be useful for the members of the dominant class in order to distinguish themselves from the rest of the society. He regards artistic or literary value, which he believes to have no actual existence in itself, as merely resulting from the preferences of the dominant class, and hence as being an illusion. Therefore, the combination of Bourdieu's Marxist ideology with his perfect relativism leads to an absolute *cultural nihilism*.

In sociology, the culturalist holistic idea of values being the product of closed wholes has probably been taken in the most absolute way by ethnomethodologists. According to them, 'cultures', subcultures, and any other groups are so much closed units that their values have solely an inside meaning. And they even assert that observers can understand nothing of the cultural products of a group in which they are not immersed. So ethnomethodologists deny the validity of outside observers' studies, affirming that their supposed understanding would be distorted by the fallacy of sociocentrism. Although ethnomethodologists do not consider, as most culturalists do, social actors to be 'puppets of their culture,' ethnomethodology is certainly an extremely relativistic sociological theory, based upon an 'everything is culture' conception.

Several streams of sociology explain beliefs and behavior by the mechanical model of inculcation and conditioning, just as does cultural anthropology. So does the neomarxist functionalism of Bourdieu (1979), with the theory or *habitus* thought as a class-conditioned behavior. But the idea of inculcation and conditioning by means of socialization is also present in the whole Durkheimian trend, and even to a certain extent in Parsons 'functionalism', since it particularly stresses social integration. And, of course, behaviourists following B. F. Skinner's positivistic line regard moral instincts as a product of social conditioning.

As they have to study the diversity of 'cultures,' and as this term has long been linked to the idea of relativism, anthropologists have a professional slant to take cultural relativism as granted. But the prevailing of relativism in the social sciences is very much strengthened by the general *relativistic atmosphere* which characterizes postmodern societies. Relativism has invaded literary criticism, with the deconstructionistic theory of the French Heideggerians Roland Barthes and Jacques Derrida, and the French Heideggerian Michel Foucault has initiated a relativistic interpretation of history. As Allan Bloom (1987) and Raymond Boudon (1990) have pointed out, all those theories mainly derive from the Nietzschean assertion that there are no facts, but only interpretations: a famous phrase that Barthes, Derrida, Foucault and their followers wrongly separated from its context, so that they unduly took it literally. These same authors' theories have been used as a justification by the relativistic movement known as *political correctness*, which since the 1980s has dominated US universities. Relativism has even been epistemologicaly theorized (see *Relativism: Cognitive*), chiefly by Thomas S. Kuhn (1962) and Paul K. Feyerabend (1975). Feyerabend's anarchist cognitive theory, which does not differentiate science from archaic myths or from magic, is clearly a counter-epistemology. With Feyerabend's well-known saying, 'anything goes,' relativism leads to nihilism.

The lack of validity of these theories has been pointed out by Raymond Boudon (1990, 1995), who demonstrated that cognitive relativism was based upon an epistemological archaism. He also observed, about the assertion of an obvious legitimacy of relativim, that since Geertz (1984) considered all conceptions of the world to emanate from 'cultures,' relativism itself was one of these conception. Therefore, in a culturalist perspective, relativism in no way can be a methodological rule that is above suspicion, but just a plain 'cultural product' of postmodern societies. In fact, it is because relativism does fit in with them that it is at the present time so fashionable. Here lies its strength, which is extremely dangerous for culture.

4. *Cultures versus Culture*

The 'everything is culture' conception is no longer confined to anthropological and sociological books and journals, but has spread beyond, so that the broad sense of 'culture' now belongs to everyday language. It is daily used by the media, and has become popularized.

There is even in several countries a ministerial department entrusted with 'culture'—an idea proceeding from the USSR. Such a department was created in France as early as 1958, and departments were established in the 1980s and 1990s in some other Western democracies, such as Belgium, Spain, Italy, and Germany. The French Culture Ministry has adopted since the 1970s, and still more since 1981, a comprehensive sense of 'culture.' In the sociological research ordered by this department, the different ways of filling spare time, and all kinds of fun and entertainment, are called 'cultural habits.' In a political purpose, the 'wide ethnographic sense' of culture is officially acknowledged by the French government.

The term 'culture' as it is used in postmodern societies, particularly in the media, has mostly nothing to do with genuine culture, but is more frequently used in order to refer to beliefs, behaviors, ways of life, customs, habits, and even the whole of society: 'culture' is now often used instead of the term 'identity.'

Having a relativistic effect, a broad use of the term 'culture' puts everything on the same level, so that fun and entertainment are regarded as equal to genuine culture. As pointed out by Allan Bloom (1987), the failure of culture becomes a 'culture.' Though the present democratic societies formally worship 'culture', the popularization of the relativistic use of the term actually destroys in the whole society the very idea of the eminent value of culture. Here is indeed the main danger for culture.

Raymond Boudon (1999), following Tocqueville, has shown that relativism is the very theory congruent with democratic societies, as it conciliates their egalitarian passion (see *Egalitarianism, Sociology of*) with the variety of the opinions. Hence, through the popularized relativistic use of the term 'culture', it is democratic egalitarianism that stands as an adversary of culture.

Curiosity, Psychology of

Curiosity is an important motivator of animal and human behavior. It is a critical motive underlying educational achievement, entrepreneurship, and scientific discovery. Less positively, curiosity has been found to play a key role in such nonsanctioned behaviors as early sexual experimentation, voyeurism, and illicit drug use.

Positioned at the crossroads of cognition and emotion/motivation, curiosity is not only of practical importance but of theoretical interest. As Malone (1981, p. 363) notes, curiosity 'is evoked by the prospect of modifying higher level cognitive structures … [and] … can be thought of as a desire to bring better "form" to one's knowledge structures.' Hebb (1955) and Nissen (1954) both argued that curiosity is a manifestation of the brain's natural tendency toward cognitive processing. According to Nissen (1954, p. 300), 'the requirements of all tissues is that they perform their normal functions … It is positively painful to deny any organ the exercise of its usual function … It is the function of the brain to perceive and to know.'

Research on curiosity has been stymied by divergent interpretations of the concept. Perhaps the most important demarcation lies between 'specific' and 'diversive' curiosity (Berlyne 1960). Specific curiosity refers to the desire for specific information, as exemplified by one's desire to know the perpetrator in the Jon Benet Ramsey case. Diversive curiosity refers to

unfocused exploratory behavior as exemplified by a rat's initial exploration of a new cage. In addition to the different types of curiosity, researchers have examined curiosity-like motives without clearly specifying their relationship to curiosity. For example, the 'need for cognition' (Cohen et al. 1955) is defined as 'a need to … to understand and make reasonable the experiential world.' Likewise, research on 'interest' seeks to understand what particular topics people find interesting and why.

1. Two Waves of Curiosity Research

Curiosity research has unfolded in two waves. The first peaked around 1960 and addressed the question of curiosity's underlying cause. The second, which peaked in the late 1970s but continues into the early twenty-first century, has focused on the problem of measuring curiosity.

1.1 The Underlying Cause of Curiosity

One early account of curiosity, articulated by William James, then extended by McDougall, viewed curiosity as closely related to fear, in the sense that both are produced by similar stimuli. To illustrate the close connection between curiosity and fear, James cited the behavior of an alligator he had observed swimming toward a man seated on the beach, 'gradually drawing near as long as he kept still, [but] frantically careering back as soon as he made a movement' (James 1950. An alternative perspective proposed by Freud characteristically viewed curiosity as derivative of the sex drive (Aronoff 1962, Voss and Keller 1983). Somewhat later, Bühler and colleagues (Bühler et al. 1928) proposed that curiosity could be interpreted as a manifestation of the 'investigatory reflex'—the label that Pavlov (1927) gave to the tendency of his canine subjects to orient themselves toward novel stimuli.

The first well-researched and coherent account of curiosity was offered by Berlyne (1960). Struck by similarities between curiosity and drives such as hunger, Berlyne viewed curiosity as a type of drive. In support of this view, he argued that curiosity exhibits drive-like qualities: it has strong motivational force, intensifies over some interval, and produces arousal if not 'satisfied' (see Loewenstein 1994, p. 81).

In contrast to Berlyne's drive theory, White (1959) argued that curiosity results from the motivation to master one's environment. Reinterpreting the phenomena that Berlyne had cited in support of his perspective, White argued that curiosity has none of the characteristics usually associated with physiological drives such as hunger. When one becomes satiated from eating one type of food, for example, almost all food decreases in appeal. In contrast, satisfying one's curiosity in one area has a negligible impact on curiosity in other areas (see Fowler 1965). White's analysis was extended by Deci, who proposed to subsume curiosity under 'the more general realm of all intrinsically motivated behaviors' (Deci 1975, p. 53).

Yet a third theoretical interpretation of curiosity was proposed by Hunt (1963), who saw curiosity as a response to violated expectations or perceived environmental incongruity, both of which signal an incomplete understanding of the environment. Hunt's theory of curiosity drew on the writings of Hebb and Piaget, and others, which had emphasized the importance of violated expectations as interrupters or motivators of behavior. Hunt's incongruity account of curiosity was refined by Kagan (1972) in a classic paper on motivation that postulated four basic human motives: the motive to resolve uncertainty, sensory motives, anger, and hostility, and the motive for mastery. The first he saw as synonymous with curiosity. Kagen extended Hunt's analysis in part by pointing to sources of uncertainty not discussed by Hunt: incompatibility between ideas, incompatibility between ideas and behavior (both based on Festinger's cognitive dissonance theory), and the inability to predict the future.

Most recently, Loewenstein (1994) proposed an 'information gap' account of curiosity that integrates insights from incongruity theories, Gestalt psychology, and behavioral decision theory. According to this theory, curiosity arises from the perception of a gap between what one knows and what one wants to know. The theory attempts to make sense of three characteristics of curiosity: its intensity (particularly as compared to the often-subdued pleasure one derives from the satisfaction of curiosity), its transience, and its association with impulsive behavior.

1.2 Measurement of Curiosity

A variety of paper-and-pencil scales have been developed to measure an individual's state or trait curiosity (e.g., Day 1971, Naylor 1981, Spielberger 1975). Other attempts to measure curiosity have relied on teacher evaluations, peer evaluations, and self-evaluations (Maw and Maw 1972), as well as the tendency to explore curiosity-evoking items (Coie 1974).

Research on the measurement of trait and state curiosity has produced a number of interesting findings. For example, positively worded items that measure curiosity typically load on a separate, and largely uncorrelated, dimension from negatively worded items. These results have been interpreted as indicating that curiosity (measured by positively worded items) and boredom (measured by negatively worded items) do not lie on a unidimensional continuum, but rather reflect different underlying phenomena.

The use of curiosity scales to measure individual levels of curiosity or to study group differences is, however, inherently problematic. Inevitably, to measure a person's curiosity, one has to measure their curiosity about something, but different people are curious about different things. Thus, if older people register as highly curious on a particular scale, it may be because that scale includes items that evoke curiosity in the elderly. The near intractability of this problem may help to explain why studies of group differences in curiosity have yielded contradictory relationships between curiosity and age, gender, and other demographic factors.

2. *Two Gaps in the Curiosity Literature*

With the current focus on individual and group differences, two aspects of curiosity have received inadequate attention. First, little research has examined curiosity's situational determinants. Second, few investigations have studied curiosity's neural underpinnings.

The lack of attention to situational determinants is unfortunate because insights in this area could have much greater practical ramifications than measures of individual or group differences. Most people are curious some of the time—often intensely so—but at other times completely lacking in curiosity. Knowledge of the situational determinants of curiosity could aid in the development of educational interventions to stimulate curiosity or interventions to reduce youthful curiosity about harmful drugs.

Educational psychologists have made the greatest progress on situational determinants in their attempts to stimulate curiosity in the classroom. For example, Lowry and Johnson (1981) found that group interactions which promoted epistemic conflict stimulated students' curiosity. In another investigation of situational determinants, Loewenstein (1994) tested and confirmed the main prediction of his information gap account of curiosity—that curiosity to learn a specific piece of information increases with the accumulation of background information.

The second major void in the curiosity literature is investigation of its neural underpinnings. In one of the few discussions of this topic, Panksepp (1998) argues that the mesolimbic dopamine system, an area where local application of electrical stimulation evokes exploratory and search behavior, plays a critical role in curiosity. Studies that have measured the response of neurons in this system find that they are activated by novel stimuli that elicit orienting reactions, but that for most stimuli this activation only lasts for a few presentations (Schulz et al. 1997). One study also found that electrical stimulation of a subregion of this area produced a subjective response in one human subject that was reminiscent of curiosity (Heath 1963). Writing of an electrical stimulus repeatedly chosen by this subject, Heath noted that it

> did not, however, induce the most pleasurable response; in fact, it induced irritability. The subject reported that he was almost able to recall a memory during this stimulation, but he could not quite grasp it. The frequent self-stimulations were an endeavor to bring this elusive memory into clear focus.

It is also worthy of note that the same region plays a central role in Berridge's account of 'wanting' and 'liking' (see Berridge 1999). Traditional accounts of motivation assume that people want to engage in actions because they expect to like the consequences of those actions. However, Berridge and co-authors have found that wanting and liking often diverge, and they attribute such divergences to the separation of the two systems in the brain. Analogous to Panksepp's view that the mesolimbic dopamine system is the seat of 'seeking' behavior, Berridge argues that it plays a central role in 'wanting.' The idea that curiosity may be centered in the wanting, but not in the liking system, is of interest given Loewenstein's (1994) argument that one of curiosity's salient features is that the intensity of the motivation to possess information—the wanting—is often vastly out of proportion to the pleasure—i.e., liking—that one experiences upon obtaining the information.

Positioned at the junction of motivation and cognition, the investigation of curiosity has the potential to bridge the historical gulf between the two paradigms. The two most promising avenues for future research are the situational determinants and neural underpinnings of curiosity. An enhanced understanding of situational determinants could produce significant practical benefits and could also provide evidence supporting or challenging some of the alternative theories that have been proposed (which differ in terms of the situational determinants they identify). A better understanding of the neural underpinnings of curiosity could help to clarify issues such as whether exploratory behavior and specific curiosity are closely related phenomena in the sense of sharing underlying neural mechanisms.

G. Loewenstein

Curriculum as a Field of Educational Study

The word 'curriculum' appears to be quite straightforward in meaning. Most people would identify with the definitions in *Webster's Third New International Dictionary*: 'The whole body of courses offered by an educational institution; all planned school activities including besides courses of study organized play, athletics, dramatics, clubs, and home-room program.' Laymen might well assume that specialists making of curriculum a field of study would devote their attention primarily or exclusively to describing, analyzing, and evaluating the nature and effectiveness of such institutional programs.

A cursory review of the vast body of literature produced by these specialists reveals considerable attention to institutional programs in place but as much or more to a larger domain implied by definitions such as 'all the activity and experience that life unaided would not provide' (see Tanner and Tanner 1995, Chap. 5 for a comprehensive array of definitions). Specialists point out that there are distinctively different genres of curriculum: the courses of study mandated by nations, states, and school districts; the course offerings listed in the schedules and catalogs of educational institutions; the activities actually arranged and conducted by teachers; and what students experience. The scope of the field becomes virtually that of education itself: anthropological, economic, existential, historical, linguistic, philosophical, political, psychological, sociological (see Vandenburg 1990). The present paper seeks to sort out from this wide domain what appear to be three dominant sectors of curriculum inquiry, two of which acquired their legitimacy in the second half of the twentieth century.

1. *From Clear to Unclear Borders*

Curriculum praxis—that is, the development and conduct of schedules of study, work, and other human activity—appears to be an old endeavor. It has ranged from tribal rites of passage to programs for a nation's schools. Curriculum praxeology—the study of practice—is a relatively new endeavor. The book identified as probably the first in the West addressed to curriculum as a field of study was published in 1695 (Schubert 1980). Chapters in contemporary books that address 'early beginnings' rarely include references prior to the nineteenth century. Presumably there were, centuries ago, narratives of debate over what to teach the young, for example, that today would be considered part of the epistemology of curriculum as a field of study. Surely the twelfth-century Chinese philosopher Chu Hsi would be seen currently as a curriculum theorist for his neo-Confucian views on education as a moral imperative and the school curriculum as a vehicle for its implementation (see deBary and Chaffee 1989).

From the beginnings of formal schooling in Europe during the sixteenth and seventeenth centuries, the dominant curricular issue has been whether the needs and interests of children or the 'essentials' of subject matter should be of first priority. Few contemporary

treatises addressing the tension between so-called child-centered and subject-centered curricula omit the contribution to twentieth-century thought of seventeenth- and eighteenth-century reformers and thinkers such as Jean Jacques Rousseau (on children following their own interests as depicted in the volume *Émile*), Johann Heinrich Pestalozzi (on teaching directed to the natural powers of the individual), and Herbert Spencer (on the nature of knowledge, with particular attention to his essay, 'What knowledge is of most worth?').

It is reasonable to conclude that the roots of curriculum as a field of study, with all the usual accompaniments of inquiry, professional organizations, conferences, and publications, are to be found in the subject vs. child debate. At first embraced primarily in psychological and philosophical discourse, the issue broke out of the boundaries of these disciplines to constitute the very core of a field now virtually incapable of defining its own borders. The program of the 1999 conference of the American Educational Research Association (AERA, enjoying a large international membership) lists more than 60 sessions, each with four or five papers presented, for Division B entitled 'Curriculum Studies.' The following selection of session titles suggests the incredible scope of what those in the field consider to be legitimately within it: social, political, and cultural contexts of curriculum renewal in Europe; interpretive research paradigms: ethnography, community and transformation; unpacking in public: exploring social/racial identities in an urban university; gender, education, and citizenship: an international feminist dialogue; masculinities at school: gender relations and representatives of boys, men, and masculinity; pedagogy and remembrances of historical trauma; issues in mathematics and science curriculum; ideology and curriculum revisited: alienation, privilege, and dispossession in the college classroom; the future of the research university and the professoriate; education reform in historical perspective. There are some titles here that might have appeared decades ago, when members of the AERA were primarily white males. The newer themes appear to require long, double titles, separated by colons, to establish their legitimacy.

2. *A Focus on Practice*

Had there been a comparable gathering in 1900, most of the above titles would have been missing. The gathering would have focused primarily on the school subjects, with accompanying argument regarding priorities with respect to topics within them. There probably would have been presentations and discussions regarding the general education of all children in elementary schools and of the priority subjects for the few going on to secondary schools. The most controversial paper would have been on the issues of whether the subject oriented curriculum of the past had any relevance for the increasing numbers of children coming to school and staying there longer, and whether the mismatch was having a negative psychological impact on the young.

World War I stimulated attention to the world beyond national borders. To the old question of how much the curriculum should be child or subject oriented was added that of the extent to which it should be society oriented. This broadening of interest in sources of curriculum development focused much more on technical matters of construction than on bringing into the classroom social issues such as the then budding feminist movement (Rugg 1926).

The central stream of curriculum inquiry throughout the first half of the twentieth century was on what Joseph Schwab (1970) referred to as commonplaces: aims, purposes, and objectives; subjects and the balance of attention to them; scope and sequence of subjects and the curriculum as a whole; and measurement of student progress. The 'pure' study of curriculum was of these. But two domains of inquiry in their own right increasingly come into curriculum discourse.

One of these pertained to the impact of the public context on institutional curricula, attracting the scholarly attention of economists, historians, philosophers, and political scientists, many of whom eschewed identification with the curriculum field but influenced it, nonetheless. The other spilled over quite naturally out of psychological inquiry into learning and the scientific ordering of what was to be learned. Major contributors identified with their disciplines, but their names are embedded in the scientific tradition of the curriculum field: Pavlov, Thorndike, Watson, Piaget, Skinner, Bruner, and more.

The name most commonly identified as contributing significantly to all three streams of inquiry is John Dewey. Arguably, a wider impact on curriculum making was made by Edward L. Thorndike, whose focus on the hierarchical ordering and measuring of subject matter profoundly influenced the structure of school textbooks. During the concluding decades of the twentieth century, one would as likely find—in curriculum conferences and journals at least—as many papers on the social context and the scientific processes of curriculum making and measurement as on the description and analysis of curricular commonplaces in practice.

3. *Theory*

A peculiar aspect of the focus on the ends and means of curricular practice was the general absence of studies from which principles to guide and predict action and its consequences might be deduced—in other words, the absence of theory building. The conference held at the University of Chicago in 1950, designed to explore what the foundations of such theory building might be, appears to be the first of its

kind and one of few to date (see Herrick and Tyler 1950). It received little attention then and has been little cited since.

Arguments for curricular relevance, on the one hand, and for efficiency, on the other, stimulated advocacy rather than inquiry. Proposals for curriculum practice, even when argued from principles such as of child development, rarely were accompanied by studies of implementation and effects. Marketing rhetoric triumphed over empirical evidence. A kind of meta-theorizing about alternative advocacies came to characterize inquiry labeled curriculum theory from the 1950s to the 1970s.

The field of study that centered on practice during the first half of the twentieth century shifted in the second half to discourse about proposals for practice. It became increasingly divisive, noncumulative, and unclear in the criteria for claiming scholarly membership. Two consequences followed: the interest and attention of the constituency in curriculum practice declined; and streams of thought not previously identified with the traditional mainstream declared themselves curricular. What occurred was more a takeover than a joining. Much of what had been the curriculum field was pushed aside and declared by some to be moribund.

4. *Three Streams in Search of a River*

A better fate for an unprecedented study conducted in the 1930s might have altered somewhat the post-World War II development described above. The great depression that engulfed much of the world from 1929 into the war years accelerated decline in the value of children to the workplace, particularly in the most industrialized countries, increasing both the growth of secondary schools and their custodial function. The issue of the suitability of a narrow academic curriculum for all became critical. The seeds for innovation were planted, inviting both advocacy and the study of advocacy in institutional settings. But the state of scientific inquiry in curriculum was primitive.

The study generated during the 1930s in the USA, responding to a provocative question, was groundbreaking. Should not the ends and means of the secondary school reflect the democratic ideals of the nation? Arguably the first of its kind, the Eight-Year Study was born: a comparison during their college years of graduates from 30 schools left free to reconstruct in their own ways, and graduates of control schools not similarly engaged. Uniquely, the inquiry required documentation of ongoing changes in the experimental schools and the development of measures for assessing a wide range of student behaviors in both groups.

By the time five books reporting the work were published in 1942 and 1943, the country was deeply into war. The small number of volumes published, purchased primarily by libraries, virtually ensured that lessons learned were lodged in the minds of few other than the participants (see Thomas 1990, Aiken 1942). There were in the study the makings of a disciplined field of inquiry focused on the commonplaces of practice that, in turn, it is reasonable to assume, constitute the source of a legitimate mainstream of curriculum inquiry.

In his role in the Eight-Year Study, Ralph Tyler had brought into educational measurement the concept of evaluation: determining the values embedded in the educational ends sought, developing techniques for determining the presence of these values in the conditions established and in the outcomes obtained, and then constructing hypotheses and explanations regarding cause and effect. Tyler's conception forced attention not just to outcomes but to the whole of curricular ends and means. During the second half of the 1940s, at the University of Chicago, Tyler developed a graduate course on curriculum making entitled *Basic Principles of Curriculum and Instruction* (Tyler 1949). Never intended to be more than a syllabus free of scholarly references, never revised, and reprinted over and over into the present, this little monograph earned him a firm place in curriculum as a field of study.

Given Tyler's role in the research methodology of the Eight-Year Study, it is puzzling that he turned the research questions of the soon-forgotten study into a procedural tool for curriculum development: what educational purposes should the school seek to attain? What educational experiences can be provided that are likely to attain these purposes? How can these educational experiences be effectively organized?

How can we determine whether these purposes are being attained? A slight rewording changes each of these into a research question, as with the first: what educational purposes *is* the school seeking to attain? Had Tyler constructed the syllabus around his four questions phrased to guide research on practice, using the Study as illustrative, those who took his course, the many more who read his monograph, and curriculum as a field of curriculum inquiry, might have proceeded differently in the postwar years. Instead, the Tyler Rationale (as it came to be known) took on a life of its own in the meta-theorizing that accompanied advocacy. The study of practice languished.

From the 1960s to the 1970s, the dominant stream of curricular thought, part historical and part philosophical, focused on whose interests were being served by the schools, challenging the conventional wisdom that established practices nourished democratic principles. Meanwhile, evaluation (influenced by Tyler, sometimes referred to in the literature as the father of evaluation) was establishing itself as a stream of curriculum thought and practice in its own right. Some scholars engaged in critical inquiry into the values embedded in curriculum policy viewed those in evaluation as mere technicians; some evaluators per-

ceived the reconceptualists, as they came to be called, as inventing the truth divested of evidence. The two groups invigorated and frequently dominated dialogue at curriculum conferences, but there were those in the traditional domain of studying the commonplaces of practice who viewed both as house guests overstaying their welcome.

5. *The River Curriculum*

What Tyler accomplished in a short space was the identification and alignment of the essential components of curriculum construction—the commonplaces. For many critics, the synthesis was too tidy, too linear, or too little attentive to their specialties. Indeed, the Tyler Rationale lent itself to conversion into a sloppy algebraic formula: P (purposes) + L (learning experiences) + O (organization) + E (evaluation) = C (curriculum). Nonetheless, for decades many specialists found it necessary to take a stand with respect to Tyler's work in advancing their own positions. What Tyler contributed was a systematic arrangement of a language of curriculum—a lexicon.

This became clear at the International Seminar for Advanced Training in Curriculum Development and Innovation, supported by UNESCO and the International Association for the Evaluation of Educational Achievement (IAEEA) and directed by Benjamin Bloom, in Gränna, Sweden, during the summer of 1971 (Bloom 1971). Teams of four to six persons from 23 countries of South America, Africa, Asia, and Europe attended lectures by Tyler most mornings and read his monograph. There were fears in the subgroups, each comprised of one member from each of the teams, that cultural differences would deny conversation around common issues. They soon discovered, however, that the lexicon of ordered curriculum commonplaces of the Tyler Rationale provided common ground.

Schooling, especially at the elementary and secondary levels, is a highly political endeavor that connects only loosely and sporadically with scholarly inquiry. The support and use of studies of existing curricula are rare. The seminal studies of Torsten Husén and his colleagues decades ago that influenced practice in Sweden appear to have suffered the fate of the Eight-Year Study; there is no mention of them in the massive *Handbook of Research on Curriculum* (Jackson 1992). The several rather comprehensive inquiries into practice in the USA conducted in the 1980s were supported by private philanthropy and their recommendations obliterated by publicly supported nonresearch reports of state and federal commissions. Had Benjamin Bloom and his associates been successful in securing financial support for creating the International Curriculum Organization of national centers such as those represented at the Gränna conference, an organization conceived as a companion of the IAEEA, the international perspective and exchange thus gained might have served to offset the bureaucratic monitoring role most specialists and centers have been required to perform.

With the macro-issues of curriculum practice dominated by political machinations, today's students of curriculum are limited largely to fine-grained micromatters. Given the current state of scientific inquiry in curriculum, this is society's loss. A robust future for curriculum as a field of study devoted to educational renewal depends on it being recognized and supported for its potential benefit to humankind.

Curriculum Evaluation

The term 'curriculum evaluation' has historically been used to refer to several different but inter-related concepts that have not been well delineated in the research literature. Some writers have used 'curriculum evaluation' to refer to curriculum product evaluation; others employ the term in reference to curriculum program evaluation. Curriculum products such as textbooks or natural curricula are evaluated prior to large-scale implementation. These evaluations are conducted using prespecified external criteria, outcome data from field trials, or both. Curriculum programs refer to the instruction that takes place within specific field contexts.

1. *Curriculum Product Evaluation*

Curriculum product evaluation centers on the evaluation of curriculum products by their developers or by those who make election or adoption decisions. Curriculum product evaluation is conducted in a variety of settings. Tamir (1985) categorized these as: (a) part school-based curriculum development; (b) national curriculum study organizations; (c) within the framework of national curriculum development centers; and (d) development, by university teams. Curriculum product evaluation is also conducted by local, state, or national textbook selection committees, which also consider other instructional materials.

1.1 *Evaluation Based on External Criteria*

One type of curriculum product evaluation employs specified external criteria intended to describe appropriateness. The work of Tyler and Klein (1976) offers an excellent early example of curriculum product evaluation employing prespecified criteria. Their evaluation procedure uses characteristics such as: specification of instructional objectives on which the material is based; appropriateness of the materials given the skills, background knowledge, age, ethnicity, and socioeconomic background of the intended students; and adequacy of the teachers' manual for classroom application and for providing an explanation of the content selection, sequence, and presentation. Later, Gall (1981) presented a listing and elaboration of 39 criteria for analyzing curriculum materials.

These evaluation procedures, particularly Tyler and Klein's, reflect a behaviorist orientation to evaluating curriculum products. Brophy and Alleman's work (1991), derived more heavily from research on teaching, provided a constructivist framework for the evaluation of instructional activities. The principles they proposed for evaluation include goal relevance, appropriate level of difficulty, feasibility, cost effectiveness, multiple goals, motivational value, topic currency, whole-task completion, higher order thinking, and adaptability. This constructivist view led to the formation of new curriculum evaluation standards in California and many other states.

Standards typically originate when a policy-making body invites colleges, universities, professional organizations, school districts, and other agencies to nominate distinguished professionals with expertise in a given field to serve on a panel. The standards do not require all products or programs to be alike except in their quality, which assumes different forms in different environments. Judgments as to whether standards are fulfilled are made by professionals who have been trained in their interpretations.

The use of standards for product evaluation is particularly relevant for the evaluation of textbooks. Procedures for textbook evaluation have been most thoroughly systematized in the larger states that practice state-based textbook adoption. California and other large adoption states in the United States are fine tuning selection procedures and standards for each subject area in order to obtain a more tailored product from textbook publishers. In these procedures, criteria are provided for evaluating textbooks to be considered for adoption. The criteria are well specified, further elaborated, and weighted in a separate rating document. A minimum total score cut-off creates the possibility that none of the textbooks will be deemed acceptable at the first review.

1.2 *Evaluation Based on Outcome Data from Field Trials*

A second type of curriculum product evaluation relies on field data for judging the adequacy of curriculum products, specifically the product's actual impact on students. In this sense curriculum evaluation is an examination, or validation, of the impact of a newly developed product.

Curriculum product evaluation based on field data may be performed both formatively (to shape or modify the curriculum under development) or sum-

matively (to validate the curriculum prior to its release). The type of products included are usually more limited than for curriculum product evaluation using external criteria. However, the two procedures are sometimes used concurrently (e.g., when a state evaluation proposed textbook is asked to provide descriptions of the product development process, including field testing data).

2. Curriculum Program Evaluation

The term 'curriculum program evaluation' refers to a complex set of interactions between a given curriculum/instructional program and its setting. Curriculum evaluation activities in this broader context examine particular curricula, instructional programs, courses of study, or national programs within their situational context. Theorists whose work is relevant to curriculum evaluation are mainly those who are known for their work in evaluation of educational or social programs.

Alkin and Ellett (1985) have noted that models of evaluation are 'prescriptive' rather than 'descriptive.' A descriptive model is a 'theory' consisting of empirically derived statements containing generalizations that might describe, predict, or explain evaluation activities. The models in evaluation instead prescribe which evaluation activities are good or bad, right or wrong, adequate or inadequate, rational or irrational, just or unjust. These models claim that evaluation should be conducted in prescribed ways, indicate evaluator's obligations and responsibilities and provide advice, recommendations, and pitfalls in conducting an evaluation.

Three features define the unique characteristics of different evaluation models: (a) the collection and analysis of data (methodology); (b) the ways in which data are valued or judgments made (values); and (c) the purposes for providing evaluation information (uses). All evaluations involve some kind of methodology for description and explanation, all necessitate the valuing of data acquired within the particular context, and all evaluations are conducted with some intended use in mind. Thus, the distinction between evaluation models based on these three dimensions is not exclusionary; for example, it is not claimed that one model only represents the necessity of employing a methodology and others do not. Rather the classification system for evaluation models presented here is based on the relative emphasis within the various models. In essence, the issue is: when evaluators must make concessions, what do they most easily give up and what do they most tenaciously defend?

The methodology-oriented models may be viewed in three subsets: the measurement outcome-oriented models, the research and/or quantitative methodology-oriented models, and models that focus on naturalistic methods. The values-oriented models presented here are expertise-oriented valuing, process-oriented valuing, and valuing based on principles of social justice. 'Uses' will be examined in two categories directed toward decision-makers and primary users.

2.1 Measurement Outcome-oriented Evaluation

The Tylerian evaluation model has been most closely associated with the term 'curriculum evaluation' (see Tyler 1942). This model is one of the earliest oriented toward measurement outcomes as a governing basis for the conduct of evaluation; its ultimate purpose is to determine whether a given program (or curriculum) achieved its intended purposes. For those using this model, or more recent variations of it, the important questions ask how the objectives are to be determined, behaviorally defined, and measured. Other important considerations are short- and long-term objectives, and the use of traditional and nontraditional forms of measurement. The important evaluative focus is on discrepancies between measured outcomes and intended objectives.

2.2 Research and/or Quantitative Methodology-oriented Evaluation

Other methodology-oriented evaluators perceive evaluation as nearly synonymous with experimental research methods. Thus, an emphasis on the experiment or quasi-experiment as the appropriate methodology for social science research/evaluation was lauded by Campbell and Stanley (1963) and embraced by a generation of evaluation researchers. The evaluation text by Rossi et al. (1999) most closely reflects this viewpoint.

Postpositivism represents an extension of this evaluation model category. Greene and McClintock (1991 p. 14) noted that postpositivists retain 'a preference for the quantitative methodology of experimental science. This preference includes a continued emphasis on causal explanation.' However, they are more willing to allow the use of multiple instruments for a given phenomenon, multiple analysis procedures, and critiques from alternative value frameworks.

2.3 Naturalistic Evaluation Methods

A number of theorists have developed their views partly in reaction to what they viewed as a dominance of measurement and other quantitatively oriented evaluation procedures. These evaluation writers have acquired 'naturalistic' evaluation points of view, which emphasize the richness that qualitative and descriptive data can bring to the evaluation process. Naturalistic

evaluation methods typically rely on data from several sources, respect the variety of perspectives, allow understanding to emerge from the process, and portray multiple realities.

Most influential of the group of theorists associated with this category is (see McLaughlin 1991). His early writing provided a framework for viewing the evaluation process more broadly. His later emphasis on the case study as an appropriate method for conducting evaluations served to expand professional perspectives at that time.

2.4 Expertise-oriented Valuing

Values-oriented evaluation theorists have 'values' as their primary concern but differ on their positions concerning who should make the value judgments about programs, and how such judgments should be reached. Some values-oriented theorists maintain that the evaluator should be responsible for making value judgments based primarily on his or her own personal background, knowledge, and experience. This point of view we label 'expertise -oriented valuing.'

Educational connoisseurship and criticism are the cornerstones of Eisner's (1993) approach. He maintained that, like the art connoisseur, the educational connoisseur is capable of deep appreciation, combining an understanding of formal qualities, socio-historical-cultural contexts, and influences. Not unlike wine connoisseurs, educational connoisseurs have attained refined perceptual capabilities acquired in part through previous relevant experience. While connoisseurship is the art of appreciation, criticism concerns itself with the art of disclosure.

Another view of expertise-oriented valuing is presented in Scriven's writings. The expertise of Scriven's evaluator is founded on several bases: (a) the objectivity for unbiased valuing provided by the use of the goal-free technique, the evaluator being 'blind' to the program's goals (Scriven 1973); (b) the broad education of the evaluator (e.g., formal education, human development, academic disciplines) providing the basis for recognizing and defining objective values; and (c) the empirical, statistical, and logical skills, and a sense of perspective, provided by training as a philosopher of science. To these, he adds 'a little toughening of the moral fiber' as the final justification for his evaluator as the person having the expertise to value data.

2.5 Process-oriented Valuing

Other approaches that focus on the valuing of evaluation data do not rely primarily on the expertise of the evaluator but instead depend on a well-defined process for performing the valuation task. One such process-oriented approach involves the employment of standards. Standards may be used for conducting evaluation of programs as well as for evaluation products. In this process, review teams visit and examine a program in terms of a set of process criteria consisting of attributes of programs presumed to be indicators of quality. That is, there is a presumption that these processes will lead to quality outcomes. Most typical of such procedures are the various types of program accreditation involving self-appraisal and site visit teams guided by defined process standards.

The constructivist-hermeneutic model—what Guba and Lincoln (1989) called 'fourth generation evaluation'—emphasizes another approach that focuses on negotiation as the key dynamic of evaluation. Here, the construction of meaning and the valuing of that meaning are the evaluation's principal foci, and a central purpose of the evaluation is to create outcomes that appropriately reflect all participants' values. A principal assumption underlying this approach is that 'realities are not "out there" simply to be discovered,' but are created through human interactions and that there are many possible coexisting realities created out of those interactions.

According to Guba and Lincoln, the evaluation process is necessarily value-laden, as all participants bring with them not only expectations as to what the purpose of the evaluation might be, but personal values that are the products of each individual's social, psychological, and physical context. The evaluation is designed to allow for the participation of competing value-systems, and is organized to produce, through the processes of negotiation, a consensus that takes into account all perspectives.

2.6 Valuing Based on Principles of Social Justice

Sometimes valuing occurs through the application of commonly accepted external principles. Ernest House the theorist has been guided by a concern for democratizing public decision-making (House 1999). In addressing this purpose, he has recognized that evaluation, as a political tool, becomes a means for determining 'who gets what' (distributive justice) in a societal program. He noted that many people's well-being depends on evaluations that provide a 'fair/just' distribution of benefits and responsibilities. Thus, the most important role of the evaluator is applying explicit theories of justice in valuing data. A key aspect is the development of a 'fair evaluation agreement' in which all participants are guaranteed to have their 'real interests' identified and addressed. In rendering judgements on programs, the social justice evaluator must be guided by the following principles: moral equality, moral autonomy, impartiality, reciprocity, and utility.

2.7 Decision Maker-oriented Evaluation

Unlike the previous evaluation models which have a more general audience (e.g., the research community, stakeholders generally, consumers, government),

models oriented toward decision-makers focus on specific individuals and thus emphasize use. The first of the decision-maker models, the CIPP model (developed in the early 1960s and presented in revised form in Stufflebeam 1983) focused on evaluation as a systematic procedure designed to provide information that would 'enlighten' decision-making. Thus, the focus of these evaluation efforts were decision-makers—usually interpreted to mean program administrators, and most typically those who contracted for the evaluation. Stufflebeam described the attributes of four different evaluation types (Context, Input, Process, and Product) each designed to 'serve,' that is, provide information for a different kind of management decision.

2.8 User-oriented Evaluation

Patton (1997) extended the concern for information provision beyond specified decision-makers and presented a model in which evaluators are obligated to identify likely 'primary users.' Thus, the evaluator must seek out those specific stakeholders for whom the evaluation is most likely to be of value in actually effecting change. Patton noted that this means finding strategically located people who are committed and competent and who are able and willing to use information. Patton also recognized a dynamic relationship existing between evaluators and users, a relationship in which prespecified decision concerns have been replaced by interactions, thus illuminating the more incremental nature of decision-making as it applies to educational programs. Alkin's writing also reflects a user-oriented approach to evaluation (see McLaughlin 1991).

3. Other Models: 'Collaborative'

Recently, various kinds of 'collaborative' evaluations have received substantial prominence. These include illuminatory evaluation (Partlett and Hamilton 1976), participatory evaluation (Cousins and Earl 1992), empowerment evaluation (Fetterman et al. 1995), and emancipatory and critical action research (Carr and Kemmis 1988). Some have programmatic interests, philosophic interests, or political interests. These collaborative evaluation approaches are not categorized separately. Indeed they would be placed into existing categories based on the intent and purpose of each evaluation type.

For example, participatory evaluation is generally concerned with participation as a means to increase the utilization of evaluation and would be included in category 2.8 above. Likewise, emancipatory and critical action research is more directly concerned with achieving 'emancipation' from the dictates of injustice, alienation, and unfulfillment, clearly falling into category 2.6 above, as would empowerment evaluation.

4. Current Issues in Curriculum Evaluation

We will briefly comment on several current issues in curriculum evaluation. These relate to the nature of appropriate measures for design considerations and the use of discourse analysis.

4.1 Measurement

One current issue relates to the reliance on standardized tests as the instrument for assessing the impact of curriculum. Although information from such tests is relatively inexpensive to collect, easy to aggregate, and somewhat reliable, standardized tests seldom match national and state goals. These tests are an inadequate measure of what is learned (they fail to sample content adequately) and are limited in assessing the depth of student understanding (no allowance for multiple forms of representation of student's knowledge). Black (1998) has drawn attention to the difficulty of finding tests that meet requirements of validity (determining that the inferences based on the test results are justified) and reliability (showing that the results are reproducible on different occasions and with different questions).

Hence, curriculum evaluation must be based on more than standardized test scores and includes assessing long-term consequences, a wide range of source reports/interviews, classroom observation, work samples, inventories, portfolios, records, exhibits, and the like. Information from such sources is also necessary for determining how the curriculum is implemented, the processes of student learning, and identifying factors that facilitate or restrain implementation.

A related issue concerns the interactions that take place between curriculum evaluation at different levels. Political leaders and central administrators favor standardized testing for the quantifiable data that will guide education policy and control and monitor schools and classrooms. Professional educators and those engaged in classroom instruction and the guidance of individual students favor consumer-oriented evaluation that integrates assessment with learning, such as continuous assessment of student's regular work and self-assessment, using the results formatively as feedback and diagnostically for guidance to reinforce learning and to encourage learners to take responsibility for their own learning as well as to suggest more appropriate curriculum. The challenge

for the next decade is to overcome the polarization between those who put standards and testing to the forefront in the interest of accountability (control) and those who see evaluation as a tool for the promotion of learning.

4.2 Critical Discourse Analysis

Finally, critical discourse analysis is emerging as a powerful tool for showing how curriculum works, how it operates politically, how it constructs and regulates social relations, and how it positions students, teachers, and others. Allan Luke (1995) has used critical discourse analysis to show how the curriculum of the home and preschool orients children toward family, property, social practices, and ownership; how the language of the primary school teacher constructs identities of children and guides them for participation in different content areas; and how textbooks influence students to reproduce, naturalize, and accept particular forms of cultural logic and social identity under the guise of transmitting neutral skills. Similarly, Shirley Grundy (1994) has deepened understanding of the contrasting public curriculum policies in Australia and Canada using this analytic tool.

Essentially, evaluators using discourse analysis study and interpret the language and language patterns as found in both written and oral contexts. The analysis reveals how the curriculum: (a) relates to the students' life trajectories—the kinds of futures portended (field); (b) instills a view of authority and degree of individual freedom, teaching students where authority lies, when and how one can speak, what can be said, and constructing social relations (tenor); and (c) defines a given subject matter—its purposes and functions, modeling what it means to learn the subject, what counts as knowledge in the field, and defining what the students' relations to the subject should be (mode).

Curriculum Theory

The curriculum is defined as programs of teaching and learning which take place in formal settings. Examples of formal settings are schools, colleges and universities. A curriculum may refer to a system, as in a national

curriculum, an institution, as in the school curriculum, or even to an individual school, as in the school geography curriculum. The four dimensions of curriculum theory are aims or objectives, content or subject matter, methods or procedures, and evaluation or assessment. The first dimension refers to the reasons for including specific items in the curriculum and excluding others. The second dimension is content or subject matter and this refers to the knowledge, skills, or dispositions which are implicit in the choice of items, and the way in which they are arranged. Objectives may be understood as broad general justifications for including particular items and particular pedagogical processes in the curriculum, or as clearly defined and closely delineated outcomes or behaviors, or as a set of appropriate procedures or experiences. The third dimension is methods or procedures and this refers to pedagogy and is determined by choices made about the first two dimensions. The fourth dimension is assessment or evaluation and this refers to the means for determining whether the curriculum has been successfully implemented.

1. Aims or Objectives

Any curriculum is always a selection. Sets of justifications for curricular inclusion may be divided broadly into four types: logical delineations between domains of knowledge, distinctive mental or cognitive operations, cross-cultural social distinctions, and deliberative activity about the ideal society.

An example of logical delineations is Hirst's (1974) forms of knowledge and experience: logico-mathematical, empirical, interpersonal, moral, esthetic, religious, and philosophical. Each of these forms has distinctive kinds of concepts and distinctive ways of determining truth from falsehood. Hirst claimed, therefore, that each has a separate logical form. An example of the second type of justification is Gardner's (1983) seven forms of intelligence: language or linguistic intelligence, logical–mathematical analysis, spatial representation, musical analysis, bodily kinesthetic thinking, interpersonal knowledge, and intrapersonal knowledge. His justification for inclusion of these forms of intelligence is psychological: individual learners have cognitive or mental modules which are separate and act separately from other mental modules. Individuals have been shown to differ in their capacity to perform these different types of operations. A third set of justifications moves us out of the mind and focuses on the culture we inhabit. Lawton (1989) argues that all societies have cultural subsystems: sociopolitical, economic, communication, rationality, technology, morality, belief, esthetic, and maturation. Because these are universal and cross-cultural, Lawton concludes that curriculum developers should seek to represent the forms of knowledge which underpin them. A fourth set of justifications focuses on the arrangements made by particular societies, both currently and in the future. The normative needs of society are given precedence over logical, cultural, or psychological justifications. This is best exemplified in relation to the debate about the respective merits of academic and vocational curricula.

2. Content or Subject Matter

2.1 Relations Between Items

A further concern of curriculum theorists is the relations between these different items of knowledge. The two most important types of relations are the degree of integration between different knowledge domains and progression within the domain itself. The first of these is the degree of integration. A curriculum may be understood as strongly or weakly classified and as strongly or weakly framed. A strongly classified curriculum is defined by Bernstein (1990) as clearly delineated domains of knowledge with strong boundaries between them; conversely, a weakly classified curriculum is understood as having weak boundaries between the different knowledge domains. A strongly framed curriculum, on the other hand, is defined as a program of study in which teacher and student have limited control over the selection of items and the way it is organized in respect of the pedagogical relationship. A weakly framed curriculum is characterized by greater control by teacher and student over the selection of content, the way it is organized and its pacing. Bernstein, in relation to the first of these principles, classification, identifies two types of curricula: 'collection codes' where strong boundaries between domains are present, and 'integrated codes' where weak boundaries are in evidence. Fogarty (1991) has identified 10 models of curriculum integration and these range from strongly classified and strongly framed curricula, as in the traditional approach, to weakly classified and weakly framed networked approaches to curriculum planning. Between the two extremes, traditional and networked approaches, she identifies eight other points on the continuum: connected, nested, sequenced, shared, webbed, threaded, integrated, and immersed.

The second dimension is progression within the domain, or, with integrated curricula, domains. Underpinning the notion of progression is a rationale for teaching some aspects of the knowledge domain before others and a belief that a subject can in fact be arranged in a reliable hierarchy. Adey (1997) argues that it is possible to do this and develops a three-dimensional model comprising conceptual complexity, breadth, and extent. Using only the last of these two dimensions leads to a naive view of learning. For Adey, a measure of conceptual complexity is also

needed to provide a fully developed model of curriculum progression. Examples of these frameworks are Piaget's (1971) schema comprising progression from concrete operational to formal operational thinking and Kohlberg's (1976) stages of moral thought, where the subject progresses from premoral and conventional rule conformity levels to the acceptance of general rights and standards, and even to adopting individual principles of conduct. These hierarchies are based on empirical investigation. The other way of establishing knowledge hierarchies is through some form of logical ordering, where complexity comprises both a progressive development of more items of knowledge and the making of more complicated connections between these items of knowledge.

2.2 Modeling Objectives

However, curriculum theorists have also focused on the way in which those aims and objectives are expressed. Three models have been developed: curriculum as product, curriculum as process, and curriculum as content. The first model specifies the development of behavioral objectives, and this approach has been discussed in a number of classical commentaries on curriculum (Tyler 1949). Curriculum-making is understood as a linear process which starts with the development of clear objectives or goals, proceeds through to the selection of content which is specified in behavioral terms—that is, its acquisition must be an observable or testable process—and finishes with the evaluation of that process to see if those objectives have been met. This behavioral objectives model has been criticized (Elliott 1998) for the following reasons: first, complex and important learning outcomes of any educational program may be neglected at the expense of the more trivial and less important, because it is easier to describe them in behavioral objective terms. Second, the prespecification of behavioral goals may encourage an inflexibility of approach within the classroom, and learning outcomes which may incidentally flow from classroom interaction will be deliberately underexploited. Third, there is a danger of assuming that if something cannot be measured, then it cannot be assessed and therefore it should not be a part of the learning process. Fourth, lists of intended behaviors do not adequately represent the way individuals learn: this is because logical order cannot be conflated with pedagogic process.

In opposition to behavioral objectives, it has been suggested that curriculum theorists should designate appropriate processes which learners need to go through—the second model. This avoids the problems inherent in the designation of prespecified behavioral objectives noted above and builds into the curriculum itself a more active and influential role for the teacher.

The third model, curriculum as content, comprises the transmission of a body of knowledge from the teacher to the learner and is underpinned by a symbol-processing view of cognition (see below) and a positivist/empiricist view of knowledge. The principles which underpin this view of knowledge are a belief in realism, a belief that there is a correct way of describing reality, a belief that scientific theories are superior to commonsense understandings of the world, a belief in the cumulative and progressive nature of scientific knowledge, a belief that it is possible to make a distinction between observation and theory, and that as a result it is possible to collect facts about the world, a belief that language is a transparent medium, that is, words have fixed meanings and concepts can be defined unambiguously, and finally, a belief that the methods which are appropriate to the natural sciences are equally appropriate to the social sciences. These assertions have been challenged in the twentieth century by interpretivists, critical theorists, and postmodernists. New knowledge constructions have implications for, and are reflected in, new ways of understanding learning and therefore new forms of pedagogy.

3. Methods or Procedures

Pedagogy is defined as the mode of delivery of the curriculum. A number of approaches have been developed. The first of these is imitation. The learner seeks to copy the actions of the teacher and in the process incorporate into their behaviors the observed characteristics of the teacher. Much learning of an informal nature, especially in childhood, takes this form. Didacticism, on the other hand, comprises instruction where the teacher inculcates the learner into either a knowledge, skill or affective domain by informing them about what they should do and how they should behave. This view of pedagogy has been disputed by constructivists and situationists who understand learning as contextualized, and thus as incapable of being understood without reference to the environment in which it takes place. In its place they would want to substitute a notion of intersubjective interchange in which the learner constructs knowledge in the light of the experiences they have in the classroom, and in the process creates meanings for themselves and others. The fourth pedagogic approach is apprenticeship, in which learners are supported in their attempts to gain access to the culture of the society in which they are being educated.

The two most important learning theories, symbol-processing and situated approaches, allocate distinctive roles to learning styles, assessment, and meta-cognition. Symbol-processing approaches understand the learner and the environment as separate; learning takes place within the human mind as the individuals process information they receive through

their senses, assimilate that information and create new ways of understanding. This theory understands the individual as a passive recipient of environmental influences. It separates out mind from body, language from reality, and the individual from society. Situated cognition or environmentally embedded learning understands the relationship between the individual and the environment in a different way. Situated learning approaches view the person and the environment as mutually constructed and as mutually constructing. Bredo (1999) suggests that this relationship should be viewed actively and as involving dynamic modification rather than static matching. The learners act with and on the environment, shaping or modifying themselves and at the same time shaping or modifying the environment. Situated cognitive approaches stress active, transformative, and relational dimensions to learning; indeed, situated cognitionists understand learning as contextualized. This new approach to learning has implications for the last of the four dimensions of curriculum, evaluation, or assessment.

4. *Assessment or Evaluation*

Assessment usually refers to the judgments made by individuals about their learning or by others about that learning. Evaluation refers to judgments about systems, institutions, or curricula, and the same tensions which can be found in formal assessments are present here. Notions of reliability and validity which have informed most of the traditional theories about assessment are now being reformulated in response to a number of criticisms (Gipps 1994). The first criticism is that formal assessments focus on the performance of the individual at a set point in time and in controlled conditions, and not to the levels of competence reached by the learner. The second criticism focuses on the social dimension of formal assessment. Formal assessments are designed to produce accurate representations of what learners can do and what they know. Situated cognitivists, on the other hand, argue that the information collected about an individual is always context- and culture-bound. Items in a formal test are chosen by examiners and this process of choosing reflects their own understanding of the world and the set of constructs they possess to order it. This set of constructs may not be shared by the individual taking the test or being assessed. The third problem with formal assessments is that they do not, and cannot, act formatively.

Learning, whether formal or informal, is closely related to assessment. Learners want and need to know what they have learnt in order to make a judgment about what and how they need to learn next. Learning is therefore always self-reflective and indeed self-reflexive, in that learning transforms the individual's sense of how they understand themselves and the world. This is why the word 'formative' is used to describe assessments which are useful to the formation of the individual through learning. The relationship between learning and assessment of that learning is complicated and depends in part on the way summative and comparative assessments—that is, imposed descriptions by other people on the individual concerned—impact on the learning situation. If these are given priority, then the process of formative assessment, indeed the process of learning itself, is impoverished.

Customer Satisfaction

Simply stated, customer satisfaction is a customer's evaluation of their purchase and consumption experience with a product, service, brand, or company. Policy researchers have long debated the value of

using satisfaction as a subjective measure of just how well a market system is able to meet customer needs (Ölander 1977). More recent interest in satisfaction stems from its role in affecting customers' repeat purchase decisions and subsequent company profits (Johnson and Gustafsson 2000). As the link to profitability has become clear, customer satisfaction is now a prominent business performance metric. As a result, satisfaction research has become an important component of an organization's stakeholder management, social accounting, and reporting. This article provides a broad overview of customer satisfaction, its meanings, the streams of research that have emerged in recent years, and key methodological issues that surround it. The article is not meant to be a review of what has become a vast literature (see Yi 1991). The first part of the article describes two distinct yet complementary streams of customer satisfaction research. After a brief overview of methodological issues surrounding customer satisfaction modeling, future research directions are discussed.

1. *Two Views of Satisfaction*

Customer satisfaction research has developed around two different types of evaluations: transaction-specific satisfaction and cumulative satisfaction. Transaction-specific satisfaction is a customer's evaluation of their experience with and reactions to a particular product transaction, episode, or service encounter. Early transaction-specific satisfaction research explored the cognitive-psychological antecedents of satisfaction, while more recent research has focused on the effects of positive and negative emotions on satisfaction (Oliver 1997).

Since the early 1990s, satisfaction research has grown to include an emphasis on cumulative satisfaction, defined as a customer's overall experience with a product or service provider to date. This definition is more consistent with those in economic psychology and welfare economics, where customer satisfaction is synonymous with the concept of consumption utility. It is cumulative satisfaction upon which the prominent national satisfaction, indices, such as the American Customer Satisfaction Index (ACSI; Fornell et al. 1996), are built.

These two streams of satisfaction research are complementary rather than competing. Transaction-specific research focuses on satisfaction with a product or service on a given occasion or transaction, or over a limited period of time. In cumulative satisfaction studies, the period of evaluation is left open. In the ACSI survey, for example, customers consider all of their experiences to date when evaluating their satisfaction with a product or service. The distinction is important as it affects how one views and models the evaluations. Whereas transaction-specific models provide a rich understanding of the dynamics of product and service encounters or episodes, cumulative satisfaction provides a stable basis for determining the drivers of satisfaction and its consequences (customer retention and subsequent economic performance).

1.1 *Transaction-specific Customer Satisfaction*

Oliver's extensive contributions to satisfaction research over the past 20-plus years illustrate how transaction-specific research has evolved over time (see Oliver 1997). Oliver posited that customers form preconsumption expectations, observe product performance, compare this performance with expectations, and then combine this information with expectation levels to judge satisfaction. When performance exceeds expectations (positive disconfirmation), satisfaction increases. When performance falls below expectations (negative disconfirmation), satisfaction decreases. The disconfirmation of expectations model has dominated the literature for years; a simple version of it is presented in Fig. 1. The direct effect of expectations on satisfaction is the result of a framing or assimilation effect; the expectations establish a baseline or anchor that directly influences the resulting satisfaction judgments. Thus attribute performance, expectations of performance, and disconfirmation of expectations may all have direct effects on evaluations of satisfaction.

The disconfirmation model has been augmented over the years to include the effects of equity, attribution, and emotions on satisfaction evaluations. The concept of reciprocity, and more specifically customer perceptions of equity and fairness, lies at the heart of marketing as an exchange process. Thus customers should be more satisfied when they are treated more fairly or equitably in a transaction, especially when there is a prospect for future transactions with the same party. Oliver and Swan (1989) posited and showed that equity is an important driver of satisfaction. Attribution theory has also been used to explain transaction-specific satisfaction from a cognitive perspective. The attribution of favorable outcomes to oneself and unfavorable outcomes to others systematically affects perceptions of performance and satisfaction (Folkes 1990).

However, Westbrook, Oliver, and others have recognized that these more cognitive perspectives on transaction-specific satisfaction do not completely capture the more affective basis of satisfaction (Oliver 1997, Westbrook and Oliver 1991). Customers form both positive and negative affective states that systematically influence satisfaction. For example, on the positive side there is joy and interest, and on the negative side is anger, disgust, and contempt, which affect satisfaction as expected.

1.2 *Cumulative Customer Satisfaction*

Cumulative satisfaction gained momentum with the advent of national customer satisfaction indices.

Figure 1
The disconfirmation of expectations model

Figure 2
The American Customer Satisfaction Index (ACSI) model

Johnson and Fornell (1991) speak specifically to the problem of constructing broad-based satisfaction measures. They argue that cumulative satisfaction, as an overall evaluation of the consumption experience, should be viewed as a theoretical or latent variable (similar to an attitude). As a latent variable, satisfaction can be empirically measured and meaningfully compared as a weighted-average or index of satisfaction indicators.

The ACSI model exemplifies the measurement and modeling of cumulative customer satisfaction. The model is presented in Fig. 2 (see Fornell et al. 1996). There are three main drivers of satisfaction in the model: quality, value, and customer expectations. Satisfaction, in turn, should reduce the incidence of complaints and increase customer loyalty. Most of the survey questions are rated on 1 to 10-point scales and the measurement variables are specified as reflective indicators of the latent or abstract constructs (circles) in the model.

Of particular interest is the overall satisfaction index, which is a weighted average of three survey ratings: (a) an overall rating of satisfaction, (b) the degree to which performance falls short of or exceeds expectations, and (c) a rating of overall performance relative to the customer's ideal good or service in the category. The three measures provide a highly reliable and stable index of satisfaction. Notice that factors that may be conceptually and empirically distinct drivers of satisfaction in a transaction-specific sat-

isfaction model become multiple measures of a more overall evaluation in a cumulative satisfaction model. Consider the differential role that disconfirmation plays in transaction-specific vs. cumulative satisfaction research. From transaction to transaction or episode to episode, one would expect some variation between performance and expectations. Service providers have a particularly difficult job of conforming to specifications on any given occasion. When these transactions or episodes are accumulated and evaluated over time, they become easier to predict. Thus significant disconfirmation, when it occurs, is more likely when studying a particular transaction or episode than when studying consumption experience to date. Because cumulative satisfaction is a more overall or molar-level evaluation, disconfirmation of expectations is one of several valuable proxies by which customers evaluate their overall experience.

Cumulative satisfaction is systematically related to various financial and business performance measures. Research using the national indices demonstrates the positive impact that cumulative satisfaction has on both market value and accounting returns (Fornell et al. 1996). It is no wonder that customer satisfaction has become an important part of companies' overall accounting, stakeholder management, and business performance measures. Cumulative satisfaction research has also explored the nature of customer expectations and how satisfaction varies across industries. For example, whereas price expectations tend to be more rational, performance expectations are more adaptive; they do not adjust as quickly to changes in performance. Fornell et al. (1996) report that satisfaction is highest among goods industries, lower among services, and lower still among public and government agencies.

2. *Methodological Issues*

In customer satisfaction modeling, satisfaction plays a key role in linking customer perceptions of a product's price and quality with customers' behavioral intentions and subsequent behaviors. Companies use two essential outputs of a satisfaction model to set priorities for improvement. First, how well do products and services perform on their attributes, the benefits they provide, and the customer satisfaction and loyalty that results? Second, what impacts do the attributes and benefits have on satisfaction and subsequent loyalty? That is, how important are the attributes and benefits to customers? This performance and importance information is combined to set priorities for improvement. From a cost–benefit standpoint, the essential benefits to improve are those where importance or impact is relatively high and performance is relatively low.

As latent variables, performance levels on abstract benefits (such as the 'cleanliness' or 'convenience' of a retail store) and overall satisfaction can be constructed using weighted averages or indices of more concrete attributes or proxies. There is a debate, however, as to how to determine attribute and benefit importance measures. Many satisfaction measurement systems rely heavily on customers' direct ratings of importance. The primary advantage of direct importance ratings is that they are easy to collect and analyze. Yet direct measures assume that customers understand what is meant by 'important,' just what attributes are important to them and that they are willing to tell you. As a result, direct importance measures often result in socially acceptable or status quo answers and poor discrimination. More objective estimates of importance or impact can be obtained using statistical estimation. This statistical estimation must accommodate the fact that a satisfaction model is a network of cause and effect relationships (which predicts a pattern of relationships) that contains latent (abstract) variables. Partial least squares (PLS) and principal-components regression (PCR) are particularly well suited to estimating a satisfaction model and deriving importance measures (see Johnson and Gustafsson 2000).

3. *Future Research*

Transaction-specific satisfaction research recognizes that customers may have very complex psychological reactions to a product's performance on a given occasion or over a given time period. Cumulative satisfaction recognizes that, when forming intentions or making decisions regarding their behavior, customers rely on their entire experience to date with a product or service provider. Yet there has been little in the way of an integration of these two perspectives. Going forward, it will be important to better understand just how satisfaction-related constructs and their relationships change when customers move from transaction to cumulative-based evaluations. There is also a need to better understand the psychological and behavioral consequences of satisfaction, specifically customer loyalty (an intention) and retention (a behavior).

Company or brand image (reputation) and relationship commitment (involvement or strength), when combined with overall satisfaction, should explain much greater variation in loyalty and retention than does satisfaction alone. Finally, research in the quality improvement and product development areas must strive to 'bridge the gap' between internal (organizational) quality measures and processes and external (customer) perceptions of quality and satisfaction. It is not sufficient to simply understand what attributes and benefits drive satisfaction. Companies must understand how to break customer satisfaction down into its means of accomplishment within an organization.

Cyborg

In its first definition, a cyborg—literally a contraction of 'cybernetic organism'—was a machine/human hybrid with skills and survival abilities not available to human beings alone. This definition remains widespread both in science and technology studies, and in science fiction. More recently, the hybrid character of the cyborg has been emphasized in additional ways. In particular, it has been defined as an active mixture of fact and fiction, intended as a political tool to transform desirable fictions into facts.

1. *Scientific, Technical, and Military Origins*

The word 'cyborg' was coined by Manfred Clynes and Nathan Kline (1960) in a paper presented to a symposium on the *Psychophysiological Aspects of Space Flight* sponsored by the US Air Force School of Aviation Medicine.

In the context of the challenges posed to human survival in space, and reflecting on the unsatisfactory temporizing needed to provide air and other support systems, Clynes and Kline wrote: 'For the exogenously extended organizational complex functioning as an integrated homeostatic system unconsciously, we propose the term "Cyborg."' They went on to write: 'The purpose of the Cyborg … is to provide an organizational system in which … robot-like problems are taken care of automatically and unconsciously, leaving man free to explore, to create, to think, and to feel.' They listed a series of possible enhancements including both available techniques and imaginative possibilities for enhancing wakefulness, radiation resistance, reduced metabolic demands, oxygen transport, fluid balance, and cardiovascular control.

The 'cyborg' reflects the development of the discipline of cybernetics in the USA in the Cold War. The central concepts of the discipline were developed in an influential series of annual conferences between 1943 and 1954 funded by the MACY Foundation. The major theme of the early MACY conferences was the primacy of information over the material. The aim was to develop a theory of communication and control applicable to humans, animals, and machines alike. The crucial move was to treat organisms and the new machines, computers, as self-controlled and self-regulating information-processing systems. Key figures in this work were Norbert Wiener, John von Neumann, Warren McCulloch, and Claude Shannon.

During the 1950s and 1960s, cybernetics was closely related to work on defense and space exploration. Cybernetically informed research and conferences on bionics, human augmentation, teleoperators, and biotelemetry were funded by the US military and NASA (1963). The concern was with the close coupling of man and machine in weapons systems, the control of human behavior in extreme situations, and augmenting human sensing, intelligence, and decision making under conditions such as combat flying and space travel. This context led to the development of the cyborg as an analytic concept and as a possible socio-techno-scientific assemblage.

2. *Cultural Contexts*

Cyborg-like creatures also proliferated in popular culture where they were used to explore the visionary potential of human–nonhuman hybrids and the mixture of science fact and fiction.

Much 1950s and 1960s science fiction and film was modernist, being either utopian or dystopian. Often it either celebrated or problematized modernity and multinational capitalism, with their futuristic and/or threatening visions of space exploration, nuclear energy, and genetic engineering. It also explored the social, personal, and political threats of invasion by machinelike, coldly rational, and alien others. At the

same time, more 'postmodern' themes were also visible. Boundary disputes around the human body were explored, together with issues of otherness and difference in human/nonhuman encounters. Since 1970, and especially in film, difference has become less threatening, sometimes coming close to dissolution. Aliens and cyborgs have often been pictured more like friendly relatives than hostile invaders. Sometimes, as in Ridley Scott's 1992 *Blade Runner*, they appear more human or humane and less alienated than humans.

At the same time, formerly exotic technologies (cyberspace, virtual life, artificial intelligence, genetic engineering, organ transplants, and xenobiology) have been commodified and domesticated. This is also reflected in cyberpunk, the science fiction sub-genre or genre that grew up in the 1980s (see William Gibson's *Neuromancer* 1984). The cyberpunk literature, often cast in a melancholy mood, wavers between euphoria and nostalgia. It explores the dissolution of human/nonhuman distinctions through electronic technologies, genetic engineering, and the consumer culture controlled by multinational business. Overall, this hugely popular branch of contemporary science fiction has circulated science facts and fictions to such a degree that the cyborg characters of its novels, films, and television series are familiar to an almost global audience.

At the same time, the traffic between science and science fiction is two-way. An early example of the fantasies inhabiting science is found in *The World, the Flesh, and the Devil* (1929), a novel by radical British scientist J. D. Bernal. Since Bernal, science fiction has fuelled developments and informed research and development priorities. Science fiction influences can also be found in contemporary techno-science work on cyborgs: in immersive virtual life applications such as 'cybersuits'; in the bio-robots of artificial life labs; in the development of the bionic chip; and in the diagnostic DNA technology, the 'GeneChip.'

3. *Appreciation*

In *The Communist Manifesto* Karl Marx and Friedrich Engels notoriously observed that 'all that is solid melts into air.' This observation of the erosive character of nineteenth century capitalism prefigures a trope and movement that accelerated during the twentieth century. This is a tendency towards what might be described as 'ontological softening,' the erosion of distinctions between categories and realities that were previously taken to be stable and discrete. Systems thinking, cybernetics, the growth of models of reality as codes of information, and the increasing use of prostheses all tend to problematize previously more stable distinctions. At the same time, they treat future versions of those distinctions as temporarily stabilized expressions of larger, system-based, relations. In both popular culture and techno-science, the cyborg has participated in this process of ontological softening. It has blurred and rendered problematic the distinctions between people and machines, fact and fiction, mind and body, and real and virtual.

At the same time, in the more recent literatures of both social science and science fiction, it has also reflected postmodern skepticism about the limits of organization, the coherence of systems, and the centered, rational, and disembodied picture of human subjectivity implicit in the earlier work of authors such as Clynes and Kline. Instead, reasoning, consciousness, and conscience are seen as more or less unstable or incoherent effects reflecting the mobile and sometimes multiple identities of high modernity. The cyborg has thus become a vehicle for political critique. Nowhere is this more obvious than in the writing of feminist techno-science author Donna J. Haraway, although it is also to be found by others writing within women's studies/feminist theory, postcolonial/cultural studies, science studies, and cyborg anthropology.

Haraway (1985) offers a radical political analysis of the dystopic, gendered, and military character of the 1960s cyborg and the individualist and frontier oriented society from which it emerged. This critique is linked to a vision of the social world as simultaneously non-coherent and exploitative. The cyborg becomes a liberatory set of partial connections between human and nonhuman on the one hand, and a political reality and politically liberatory myth on the other. Seen as a creature located in and produced by partial incoherences, it becomes an ironic figure which participates in and interferes with the current 'state of disorder' to enact better alternative futures. This feminist cyborg thus both extends and rejects earlier work. On the one hand, it continues to soften ontology, but on the other hand, it no longer locates this within a single control-related cybernetic logic. Partially coherent and situated, cyborgs (see *Situated Knowledge: Feminist and Science and Technology Studies Perspectives*) are radical political images that seek to take us beyond system on the one hand and individualism on the other.

4. *Conclusion*

The cyborg concept is a creature of the dissolving character of modernity as it yields space to postmodernity. In this, the human is no longer necessarily central and is replaced by a set of heterogeneous functions. The particular way this dissolution has taken place reflects its circumstances, and in particular US military concerns (command, control, centralization, self-regulation) and US individualism (anarchism, frontier imagery, the lone, self-reliant (usually male) person against both the system and anarchy). These

two circumstances are in tension, as is visible in the differences between cybernetics and cyberpunk. But they are also in tension with a further vision of the cyborg as a form of post-individualist political interference. This resonates with a particularly US version of radical politics which attempts to avoid both holism and individualism in an area of ontological softening and mobile identities.

Cycles: Social

The concept of cycles in the social sciences is multifaceted. Economic cycles, cycles of problem solving in organizations or small groups, or cycles of societal value change are but a few of its forms. Moreover, cycles as a concept are—often simultaneously—used as philosophical heuristics, theoretical explanation as well as analytical technique.

1. Cycle as a Philosophical Concept

Since ancient times the cycle has been believed to be an ideal concept (Weininger 1920). It signifies completeness; all points on a cycle re equal. The wheel of time, eternally going round, is one of the powerful symbols of this kind of thought. Cycles seem to reflect nature quite elegantly: the cycle of life (in modern sociological terms 'life cycles'), the cycle of four seasons (in moderate climates), and the cyclical movements of the sun and stars around the earth (in a Ptolemean view). It is thus not surprising that it took quite a long time for evidence-based science to overrule cyclical concepts so tightly connected to esthetics like Ptolemean worldview.

Christianity marks a counter-philosophy to a strict eternally cyclical worldview: Christ is a singularity, after him nothing will be as it was before. The spell of the eternal wheel of time hence is broken. Christian rebirth is, in contrast to other religions, not a cycle; it is but one step up to an end state. Some philosophers thus believe Christian noncyclical thinking to be among the elements of social and individual progress (Guardini 1946). However, Christian thinking does not exclude cyclical concepts. Christ could be thought of as being a singularity, separating one big cycle from the next.

Another strong symbol of societal and human dynamics is the straight, often directed, line. Linear, noncyclical dynamics of societal developments is one of the basic concepts of modernity and progress. Finally, a sequence of stages is also among the influential philosophical concepts, e.g., Kohlberg's or Piaget's stages in the ethical development of children, adapted by Habermas for societal development (Habermas 1989, Kohlberg 1981, Piaget 1970).

All three ideal concepts, cycle, linear trend, and stage, represent directed dynamics in contrast to stochastically, nondirected fluctuations. Thus they can be used to explain a given societal situation as being embedded in a specific movement towards an end or with a 'known' outcome (next phase going up, going down, coming back). They allow the sequence of historical events to be given an inherent and consistent meaning. Linear dynamics is inherent in socialist and capitalist ideologies, but not necessarily part of social realities (cf. Häder and Mohler 1995 on cyclical worldviews in the GDR). Modern cyclical philosophies, like those based on Friedrich Nietzsche or Oswald Spengler, hence can be understood as counter-attacks on modernism and its Christian roots by conservative intellectuals (A. Mohler 1972 Wendorff 1980).

2. Cycles in Sociological Theory

Sociology is, by definition, a modern science. Ideal societal cycles are seemingly concepts of premodern thinking. Thus it would be hard to find any modern sociologist who explicitly subscribes to cyclical movements. The term is almost absent in modern textbooks. However, reading through influential books on modernizing organizations and companies one finds quite often fourfold sequences of development, i.e., organizational dynamics (Senge et al. 1994). Whatever the labels used are, these fourfold tables resemble quite strongly Bales' concept of problem-solving sequences in social groups (Bales 1953, Bales and Strodtbeck 1953) which in turn relates to Schumpeter's classification of business cycles (1939). Based on empirical observation, Bales proposed a four-stage dynamic for small group problem solving: expressive, adaptive, instrumental, and integrative. Parsons adapted this scheme and transformed it into his famous AGIL scheme (Adaptive, Goal Attainment, Instrumental, Latency; Parsons 1971). Thus one of the most influential modern sociological theories takes advantage of a cyclical model in explaining societal developments. However, other than Bales for small groups, Parsons did not present strong empirical evidence for his assumption of similar dynamics on the societal level. While the AGIL scheme has been taught to many thousands of students during the latter half of the twentieth century, its assumed cyclical societal dynamics has had little influence on actual social research.

3. Cycles in Economic Theory

By contrast, in economics, cyclical dynamics has a long pedigree and was widely discussed (Forrester 1977, Gordon 1952, Gulap 1989, Kleinknecht et al. 1992, Metz 1984, Wallerstein 1980). However, one should differentiate between 'cyclical movements' and 'cycles.' The former refers to fluctuations but not to ideal, recurring cycles. It is this rather ambiguous concept which is mostly used in the literature and the media.

Among the most prominent economic cycles, in the sense of an ideal concept, are Kondratieff's long waves in economic life (1926). These were understood by the Soviet government as a counterattack on the Marxian linear progress concept. Consequently they sent Kondratieff to the Gulag. Schumpeter (1939) in turn developed a complex system of interlaced and superpositioned cycles with Kitchin cycles as the shortest (average three years), followed by Juglar cycles of seven to 11 years, and Kondratieff cycles with 49 to 60 years wavelength.

Today ideal cycles in the Kondratieff and Schumpeter tradition are discussed in relatively small economic circles. Sources for information on cyclical socioeconomic thinking are: Long-Wave Theories of Development (http://faculty.washington.edu/krumme/207/development/longwaves.htm) and the Longwave and Social Cycles Resource Centre (http://www.1-888.com/longwave/lwintro.html).

However, the relative success of cyclical concepts in economics compared to sociology reflects observed ups and downs in economic development coupled with long empirical observations of macroeconomic characteristics like price indices, average growth rates, interest rates, etc. It is also arguable that the prevalence of cyclical thinking in economics is itself cyclical. In a phase of economic growth, linear concepts are prevalent (accepting few setbacks) without seriously investigating the next turning point. As soon as the economy slides into recession cyclical concepts are 're-invented' by predicting the next turning point into an upward development.

4. Critical Issues in Identifying Cycles

Ideal concepts like cycles require sophisticated theoretical arguments to convince skeptics, and special techniques to extract cycles from the usual mass of data. Critical issues in defining cycles thus are: identifying periods with homogeneous dynamics (i.e., no singularity disrupting a cyclical movement), interlacing and/or superposition of cycles of different wavelength, combination of cycles and linear trends, identification of wavelengths and their respective measurement.

Identifying periods of identical wavelength is crucial for cyclical theories. Otherwise there would be eternal cycles, which are counter-evident even to everyday observations (cf. the change in the generational sequence due to higher life expectancy in the last century). Whether a certain historical event is a singularity or just a very prominent event within an otherwise homogeneous cycle is an important issue considering long social cycles. For instance, did the end of WWI and the beginning of WWII represent singularities separating distinct cycles? If so, there would be no time for a full Kondratieff cycle of at least 48 years length between the two events. How does one interpret the interlacing or superposition of different cycles? Are the cycles really a fine-tuned system of small and big cycles, as Schumpeter assumed? What happens if big cycles (long waves) are not multiples of small cycles? If uneven movements due to nonsynchronous multiple cycles in organizations, cohorts, institutions, business, the arts, education, science, welfare, etc. are at work, can one in the end identify the grand cycle? Or, will it be that due to the individual cyclical dynamics the overall outcome will result in unique cyclical superposition at each and every point in time (cf. the discussion between P. Ph. Mohler 1987, 1989, and Namenwirth and Weber 1989). Finally, as is the case with a straight line plotted through a cloud of

data points, a cycle is an analytical construct. Stochastic fluctuations are filtered and smoothed to get as close as possible to the ideal concept of a pure sine wave (i.e., cycle, Namenwirth and Weber 1987, Allen 1997, Drucker and Wesche 1999). Because of the strong underlying, non-modern theoretical assumptions, models using cycles as a heuristic are much more controversial than the linear models used in everyday statistics.

5. *An Example of Empirical Analyses of Cycles in Societal Development*

Instead of the numerous and often less theoretically anchored economic analyses, a strict sociological approach is presented here as an example of identifying cyclical dynamics. Namenwirth and Weber showed in their seminal work on *Dynamics of Culture*, how to use sophisticated methods parsimoniously to establish an empirical model of the real world (1987).

It is obvious that a direct translation of small group dynamics into societal dynamics must fail due to the different time scales at work (Luhmann 1973, Wendorff 1980). Moreover, Bales' work is based on laboratory experiments only. Such experimental settings make the standardizing of situations and filtering of noise much easier than is the case in observing real situations. Thus any empirical investigation into the validity of Parson's assumption that the dynamics of society as a whole is similar to that of the small group has to overcome serious technical and methodological obstacles.

Any observation of a cycle requires at least a full cycle; better, a series of cycles. If societal dynamics works on a time schedule similar to that observed for economic cycles, then to observe one full long Kondratieff cycle requires time series of about 60 years. Considering that systematic sampling-based interviews only came into existence in the 1920s and assuming that enough comparable data is available, early twenty-first century sociologists have barely enough data to analyze one full Kondratieff cycle. However, Namenwirth and Weber found even longer cycles in their data (about 120 years), thus it will be the middle of the twenty-first century before their results can be verified with robust survey data. Moreover, for such long time series, the society observed should keep its basic identity over the period of observation, i.e., the time series should not be interrupted by a singularity.

As Namenwirth showed as early as 1973, there are indeed both time series and societies at hand, which allow for an empirical test of Parson's assumption. However, as we will show, all observed dynamics are a superposition of both linear tends (modernism) and cyclical dynamics. Namenwirth's solution to the data problem was to take textual indicators measured on a group level instead of individualistic interviews. In doing so, he freed long-term sociological investigation from the regression to interviews as its only source of information. He also avoided the individualistic fallacy of inferring from individual level data to societal level dynamics. As a data source he used party platforms of the two leading American parties since 1844. He found two cycles, one of about 152 years (actually longer than the observed period of 120 years), and one of about 48 years (Namenwirth and Weber 1987). Weber refined Namenwirth's technique by separating linear trends and cyclical dynamics in his analysis of 'speeches from the throne 1689–1972' (statements of the government read by the monarch).

In additional to cycles similar to those found by Namenwirth in the United States, his data indicated a break/singularity in the dynamics at about 1795—note the coincidence with the French Revolution. Thus he found two periods with different cyclical dynamics which he named 'mercantilist' and 'capitalist.' However, studies using equivalent measures and similar approaches did not reveal cyclical dynamics (Eisner 1991 for Switzerland, and P. Ph. Mohler 1987 for Germany). Finally in a reanalysis of Sorokin's famous data on cultural changes, Klingemann et al. (1982) found strong evidence for long-term trends plus long waves of philosophical dominant thinking. In accordance with the above observation of the general absence of cyclical theories in the social sciences, the data showed an extremely strong (linear) trend for empirical philosophical theories since 1720, i.e., since then the predominant development in philosophical thinking has been the linear increase of a specific of philosophy over a long period of time.

The techniques developed by Namenwirth and Weber for identifying cyclical dynamics are non-standard in time series analysis. Other than the rather complex mathematical models used there, they use two straightforward strategies: first, they check for a linear trend in the time series of a single variable; second, they test for a short cyclical dynamic in the residuals of the de-trended data; and third, they search for a long trend in the residuals of the residuals of the de-trended data. Because the target is the wavelength, they do not attempt to estimate the magnitude of the cyclical dynamics; thus the amplitude is always set to '1'.

In essence, this approach is a special form of residual analysis. Translated into theoretical concepts: first, a linear dynamic is assumed, which is, second, underpinned by one or two cyclical dynamics. These cycles can be interpreted within an AGIL-like pattern. Moreover, Weber's observation of a break between mercantilist and capitalistic dynamics may be taken as an indicator of a singularity in a society (nothing will ever be like it was), which allows differentiation between epochs like Bales might differentiate between different social groups.

In doing so, this approach re-specifies non-directional theories (like Parsons,) into directed ones.

It also bridges the gap between linear modernism and cyclical conservatism. Modernity is the linear (but not infinite) dynamic in societies, while the cyclical elements of the moving process point to basic laws of problem solving (assuming that problems have to be solved, if at all, in a finite period of time). Singularities, like the one between mercantilism and capitalism in 1795, make us aware that there is no infinite continuous movement in societies.

6. Conclusion

Cycles and straight lines are two idealizations of directed movement (dynamics). Linear trends, be they directed upwards or downwards, have predominated in sociological thinking to the end of the twentieth century. Cyclical theories seem to be absent in the grand social theories, but they are not. They are ever present in schemata like the famous Parsonian AGIL scheme. Cycles are, often without mentioning the concept, inherent in almost all contemporary approaches dealing with organizational and group changes. This indicates the robustness and validity of Bales' early findings. Survey data will not be available for a long time as a base for analyzing societal dynamics, be they linear, curved, or even cycles. Thus one must rely on other data to model the dynamics of a given society.

In economics, long waves are a dated concept. The concept of business cycles, however, is widely used to identity regularities within the fluctuations of economic indictors.

Dance, Anthropology of

Dance has been studied in anthropology for over a century, also in classical works, but mostly in passing as an element in ritual and ceremony. This neglect is likely to have come about because of the elusive nature of dance, in combination with the fact that dance has the potential of releasing emotional and erotic forces that are kept at bay most of the time in everyday life. There are many examples of political and religious control of dance, not least in colonial contexts. This has often produced resistance, expressed through the creation or revitalization of ethnic and national dances.

In an article about the beer dance among the Azande, E. E. Evans-Pritchard (1928) was among the first anthropologists to show that the study of dance had a wider analytical potential and that dance needed to be addressed from a contextual perspective. But it was not until the 1960s and 1970s that the anthropology of dance emerged as a subdiscipline, evoking discussions about the origins and definition of dance that became complicated by the cross-cultural perspective. As Adrienne Kaeppler (1985, p. 93) has remarked, the concept 'dance' is a Western category which often fails to distinguish among different cultural activities. This concern is also paralleled, however, in the anthropology of music and the arts. Drawing on her research in Tonga where movement around ceremonial pig presentations, *kava* mixing, and choreographed group speeches revealed hierarchy and social solidarity, Kaeppler suggested 'structured movement systems' as an alternative concept to that of dance. Another anthropological strategy has been to identify dance events as units of study, rather than to look for particular dances in isolation. On the whole, dance anthropologists seem to converge on a consideration of bounded rhythmical movements that are performed during some kind of altered state of consciousness, an elevation or even trance.

The pioneering dance anthropologists had to deal with the ethnocentric assumptions prevalent among the then mostly autodidact dance historians, about dance as a universal language and 'primitive dance' (often constructed in terms of a generalized 'African dance'), as an early phase in a Western scheme of dance evolution entailing a hierarchicalization where ballet was regarded as a superior dance form. This prompted Joann Kealiinohomoku (1983) to write an article where she argued for a view of ballet as an ethnic dance, as one dance form among others. This is a crucial anthropological contribution to dance scholarship, but Kealiinohomoku's idea that ballet reflects Western cultural traditions is perhaps a bit exaggerated, especially in the long run. Admittedly Western, ballet speaks to a limited historically dominant segment of the West, by contrast with the shifting multicultural landscape of contemporary Europe and North America. To state that ballet is a form of ethnic dance also disregards the traditional difference between ethnic dance as a participatory ritual practice and ballet as a stage art performance separated from the audience, although ethnic and folk dance are now frequently moved from secular and sacred ritual to the realm of art in stage dance. The genres are further blurred by contemporary stage dance experiments with the audience taking part in the performance—even being invited to go on stage.

The central quest and *raison d'être* for the anthropology of dance has been to find out what dance says about its society, informing about social or cultural circumstances that cannot be sufficiently expressed in any other way. This does not only come about through direct reflection, but also through social commentary and critique in the form of parody like (gender) role reversal or suggestions about alternative social scenarios and even predictions of political events. Dance has increasingly been recognized as having an impact on social change (Hanna 1988, Royce 1977). But there is also the cathartic view of dance as a safety valve, a structural outlet, which will keep the social order and its inequalities intact. Dance is moreover often a feature of socialization. One of the functional aspects of dance is that of transformation: the classical examples are rites of passage when people are moved from one stage in the life cycle to the next one, such as initiation rites, wedding celebrations, and funerals.

Like all subdisciplines, the anthropology of dance has followed main theoretical currents in its parent discipline. Dance has thus been analyzed through structuralism, symbolic anthropology, semiotics, and linguistic theory, generating studies of the deep structures of dance and dance as nonverbal communication. Taking these theoretical approaches as points of departure, some of the first dance anthropologists worked out their own elaborate models and classificatory schemes for movement analysis. Drid Williams' (1976) theory of semasiology, the meaning of human movements as action signs, for instance, has

been developed further by Brenda Farnell (1995) in a study of Plains Indian sign language.

There are basically three kinds of anthropological studies of dance. One kind has dealt with meaning, function, and the cultural context of dance, another kind has concentrated on the choreographic form. The majority of anthropological studies of dance, however, have combined these approaches by taking both meaning, function, and context *and* choreographic form into account, as well as including textual descriptions of the movements and/or illustrations such as photographs or simple movement transcriptions consisting of circles and arrows that indicate directions and patterns of dance.

In the United States, research on dance in its cultural context has dominated, just as in the United Kingdom where John Blacking was a key figure in the emerging interest in the anthropology of dance. In continental Europe, dance ethnologists, also called choreologists, who came out of a long nationalist folklore tradition, documented folk dances in their own societies, for preservation and revival, stressing formal characteristics along the lines of music research there. During the Communist era in Eastern Europe, dance (and other folklore) researchers found themselves in ideological conflict over state manipulations of their objects of study and control of their investigations (Giurchescu and Torp 1991).

In the 1980s a new generation of dance anthropologists joined the growing interdisciplinary area of dance and movement studies. Engaging with feminist and gender critiques, notions of the body, identity politics, and literary and cultural studies, scholars of dance and movement studies became more visible in the academic world, also because there was an increasing number of them. Dance historians have moved towards ethnography and social and cultural theory redefining their field as critical dance studies, while dance anthropologists have added Western stage dance and culture, as well as European folk dance, to their previous focus on non-Western dance and movement. Most dance scholars, including dance anthropologists, have been trained as modern and/or classical dancers. The anthropological study of dance usually requires participation in the dancing, at least some kind of bodily knowledge of the steps that are investigated. The fact that dance anthropologists learn sequences of steps and movement that are completely different from their earlier movement experiences is something they often report on in a humble spirit, while it actually deserves recognition not least as an important methodological strategy. Some dance anthropologists have thought of their own dancing in the field as a part of the recent reflexive turn in anthropology, which has also had an impact on the anthropology of dance. The presence of the ethnographer in the field seems to have been more of a problem for neighboring dance scholars, however, who have worried that this would entail undue subjective influence, than for those who have been trained in anthropology.

1. *Moving Bodies, Gender, and Sexuality*

In the upsurge of studies in the human and social sciences on the body as culturally constructed, the *moving* body has nevertheless continued to be marginal (Reed 1998), except in recent dance scholarship including dance anthropology where it has been prominent often in tandem with issues of gender and sexuality. Such issues, also including gay dancers, were early identified by Hanna (1988) in a cross-cultural review. Since then a few monographs that combine attention to moving bodies, gender, and sexuality have appeared. Jane Cowan's (1990) work on the body politics of gender in a town in Northern Greece focuses on dance events, including for example lively wedding dances which unite a contradictory ideology of inequality and visions of closeness in the dancing bodies. For the women, dance is an ambivalent pleasure since they have to balance their sexual expression carefully between release and control; unlike that of the men, women's dancing demeanor always runs the risk of being interpreted as indecent.

This is also a problem for the professional female entertainers, singers, and belly dancers in Cairo that Karin van Nieuwkerk (1995) writes about, who see their job as 'a trade like any other.' Performing at celebrations such as births, engagements, and weddings, these Egyptian entertainers create much happiness and are in fact crucial for the success and prestige of these occasions. Nevertheless, they are regarded as dishonorable in the context of Islam and class in Egyptian society because they make a living out of disclosing their bodies in public, thereby tantalizing men. In Cynthia Novack's (1990) ethnography of contact improvisation, the American communal art-sport that emerged in the 1960s, gender relations are quite differently featured in line with the prevailing ideology of egalitarianism. Although the body is constructed as nongendered in contact improvisation, the performers' touching and supporting of each other's weight while moving together, usually in duets, sometimes produce sexual and sensual feelings both among them and the observers.

Novack's study spans more than two decades, showing that the movements of contact improvisation, and thus the construction of these moving bodies, and the arts organizations around them, followed changes in American culture so that this dance form gradually diminished together with the egalitarian agenda of the 1960s and 1970s. Body and space are in focus in Sally Ann Ness's (1992) interpretation of the sinulog danced in Cebu City in the Philippines. Ness connects dance movements and space to everyday movements like walking and the urban landscape of Cebu City. A Philippine ballet, *Igorot*, which Ness (1997) discusses, produces neoethnic bodies in a structure of post-

colonialism and transnationalism. J. Lowell Lewis (1992) also links everyday movement and dance movement in Brazilian *capoeira*, the martial art and dance with roots in Brazilian slavery and, further back, in Africa. Lewis analyzes *capoeira* as a cultural style through the metaphor of play: bodily, musical, and verbal.

2. *Ethnicity, Nationalism, and Transnationality*

Ethnicity and nationalism are often negotiated through dance, but in different ways depending on historical and political circumstances. J. Clyde Mitchell's (1956) small classic monograph on the Kalela dance in colonial Northern Rhodesia is an early instance of ethnic dance. The Kalela dance was performed every Sunday by labor migrants who had moved from the countryside to the town of Luanshya. While describing colonial society, the dance was also a marker of a 'tribal' group identity called for in contrast with other groups in the town. The European folk dances which European dance ethnologists have long been documenting can be categorized as ethnic dances. Yet it was the growth in studies of nationalism in the social sciences generally that inspired dance anthropologists to investigate ethnic and national dance, for example, by relating Irish traditional dancing and Javanese court dance to the wider escalating concern with questions of representation, authenticity, and appropriation. In a study of the *devadasis,* female temple dancers in South India, Joan L. Erdmann (1996) points out that it is time to rewrite the history of Indian dance without orientalism such as the Western label 'oriental dance,' in order to make room for indigenous categories. This is a completely different situation than that in post-revolutionary Cuba which Yvonne Daniel (1995) discusses in her study of how the government replaced ballet with rumba as the Cuban national dance. Rumba was associated with the working class and the African heritage, which suited the socialist state ideology. Although most dance anthropologists seem to agree that all dance forms are more or less mixed, with increasing global contacts, ethnic and national dance forms are becoming even more mixed than before. *Igorot*, the Philippine ballet which is a mixture of classical ballet and traditional Philippine dance, has been described as an instance of cultural hybridity (Ness 1997). Helena Wulff (1998) discusses homogeneity and diversity in the transnational world of ballet, drawing on Howard Becker's (1982) notion of art worlds.

3. *Transcription, Technology, and Property Rights*

To convey movement through the text is an obvious ambition for dance anthropologists. In her little book on tango and the multidimensional national Argentine identity, accurately entitled *Paper Tangos*, Julie Taylor (1998) has inserted small black-and-white photographs in the margin on every page. A quick flipping through the pages thus creates an image of live movement, of a film as it were, of couples dancing the tango.

In addition to simple figures illustrating the text, some dance anthropologists have learnt advanced standardized notation systems for transcription of movements, such as Labanotation, which is the most widely used, or Benesh or Eskhol–Wachmann notation systems. As it takes about two years to master any of these systems completely, it is like learning another language. In the Western dance world, trained notators, or choreologists, document ballet and dance productions through these systems, and they have also been important in the medical rehabilitation of disabled people. There is, however, a degree of interpretation involved in the notating process, which means that different notators may describe the same movement somewhat differently. There has also been a discussion in dance anthropology about the applicability of these Western notation systems to non-Western dance and movement forms, although there seems to be an agreement that they can be used for such purposes as well. Certain conventions have developed to deal with cultural translation problems, so that the particular use of Labanotation, for example, may be explained in a 'key' for readers.

Photography and film are other, often complementary techniques, for conveying dance and movement. There is, however, an element of cultural selectivity in their use, as in video recording which has increased substantially during recent years. Video has also become a significant aid in the mechanical work with drawing the symbols for the scores of Labanotation and the Benesh notation system. The expanded use of technology in dance research has accentuated questions of copyright and ownership which are further complicated in a transnational context. The area of dance and technology (also including television, CD-ROM, and choreography software computer programs) is generating a growing amount of new research.

Future research in the anthropology of dance is likely to include more systematic reception and audience research. The anthropological inquiry into dance is already being extended to popular dance genres such as rave, dance shows and dance in musical videos, and to world dance, both in Western and non-Western contexts. Unlike ethnomusicology which attracts mostly men, the majority of dance anthropologists have been women. This may have played a role in the relatively modest position of the subdiscipline. Another circumstance that works against an accumulation of knowledge that would produce major growth in the anthropology of dance is that anthropologists often write one book on dance and then move on to other research interests.

Still, the anthropology of dance contributes to central debates in the human and social sciences, especially to an understanding of culture in terms of process and diversity. Importantly, dance and movement are not only shaped by society—dance and movement also shape society. This occurs in increasingly complex ways as the genres of dance and movement in society shift and grow, inviting more studies of the anthropology of dance.

Darwin, Charles Robert (1809–82)

1. Darwin's Life

Charles Robert Darwin was born in Shrewsbury, England, on February 12, 1809. His Father, Robert Waring Darwin (1766–1848) was a prosperous physician. His mother, Susannah Wedgwood (1765–1817), was the daughter of the industrialist Joshiah Wedgwood II (1769–1843). She died on July 7, 1817. This early bereavement is often invoked as having affected Darwin's health, both physically and mentally.

Although he developed an extracurricular interest in the natural sciences, the young Darwin was considered a mediocre student. At the age of 16 he was sent to Edinburgh to study medicine. He interacted with scientists there and furthered his interests in natural history, but he had no desire to become a physician and realized he would not need to earn a living. His father however insisted upon his having a respectable profession, and it was decided that he would prepare to become a clergyman. He therefore enrolled at Cambridge University on October 15, 1827, and remained there until 1831. His academic performance was respectable, though not outstanding. But his scientific interests were encouraged by the faculty, especially the botanist John Stevens Henslow (1796–1871).

Darwin was preparing for some scientific travel when he was invited to join a naval surveying expedition on HMS Beagle as unofficial naturalist and gentlemanly companion to the captain. The Beagle departed on December 27, 1831, circumnavigated the globe, and returned on October 2, 1836. This long period of field research laid the foundation for Darwin's later career. Working in isolation no doubt forced him to think for himself, and he had much opportunity for reflecting on the many books he had with him, especially the *Principles of Geology* (1830–2) by Charles Lyell (1797–1875). Darwin became one of Lyell's major supporters. While in South America he developed a theory of coral reefs which he verified later on during the voyage. It was his geological work that first made him famous. However he also studied

zoology and botany and assembled a superb collection of specimens.

Darwin did not become an evolutionist until after his return to England, though he began to take the idea seriously toward the end of the voyage. Back in England he began to sort out his specimens and put them in the hands of specialists. Expert opinion, especially on the birds of the Galapagos Archipelago, convinced him (ca. early March, 1837) that evolution was a viable idea, and he set out to develop a theory. That included a search for a mechanism. His notebooks indicate a vast amount of reading and thinking about many topics, including psychology.

Darwin's discovery of natural selection occurred around September 28, 1838, when he read the *Essay on the Principle of Population* (Malthus 1826). Its author, who went by the name of Thomas Robert Malthus (1766–1834), was the first professor of economics. Darwin had already changed his conception of the natural economy to a competitive one but he had not made the crucial connection. The insight came from understanding what happens to human reproduction as resources get harder to come by with an increasing number of mouths to feed. It then became evident that some individuals would reproduce more than others. How much economics Darwin actually knew is questionable, but the general notion of individualistic competition was clearly available from the economics of his day. When, in the 1850s, Darwin developed his ideas about biodiversity he was to some extent helped by his reading of the French zoologist Henri Milne-Edwards (1800–85), who applied the idea of the division of labor to physiology and anatomy. Darwin realized that specialization would make for more efficient use of resources. Evolving populations would seize upon different places in the economy of nature (Eltonian niches, as they are now called).

Darwin married his cousin Emma Wedgwood on January 29, 1839; their first child was born on December 27 of that year. They set up house in London, but his health began to deteriorate and he suffered from mysterious ailments for the rest of his life. In 1842, the family relocated to a country residence near Down, south of London. Nonetheless Darwin was highly productive. A book on his voyage (Darwin 1839) was a popular as well as a scientific success. He edited the zoology of the voyage and, in addition to minor papers, published three volumes on his geological research: (Darwin 1842, 1844, 1846). Development of his ideas on evolution continued, and he wrote a sketch of a book on it in 1842, and a draft in 1844.

In 1846, Darwin began some research on barnacles which led him to spend eight years revising the group and writing a vast taxonomic monograph (Darwin 1851, 1854) which in effect was his first book on evolution. He then proceeded to work up his materials on evolution. A large book entitled *Natural Selection* was in the process of composition when, on June 18, 1858, a manuscript from Alfred Russel Wallace (1823–1913) arrived in which the same basic mechanism was proposed. A joint paper was read before the Linnean Society on July 1, and on July 20, Darwin began to write an 'abstract' that ultimately became the *Origin of Species* (Darwin 1859). The first of six editions was published on November 24, 1859.

Darwin brought out a series of books that dealt with a broad range of evolutionary topics. These books all included results of his ongoing empirical research, much of it on the sexuality, physiology, and behavior of plants. A book on orchids (Darwin 1862) was followed by one on climbing plants that first appeared as a journal article (Darwin 1865). What had been a section of *Natural Selection* became *The Variation of Animals and Plants Under Domestication* (Darwin 1868). It was the second of what are considered Darwin's 'major' evolutionary works. The third was *The Descent of Man, and Selection in Relation to Sex* (Darwin 1871). *The Expression of the Emotions in Man and Animals* (Darwin 1872) was followed by a series of botanical works (Darwin 1875, 1876, 1877a, 1877b, 1880). The last of his books dealt with earthworms, especially their behavior (Darwin 1881). Darwin died at his home at Down on April 19, 1882. He was buried at Westminster Abbey on April 26.

2. *Darwin's Scientific Contribution*

Darwin brought about the most important revolution in the history of the human intellect. For that very reason it has taken a long time for his ideas to become assimilated and the process is far from complete. Although he was able to convince the scientific community that evolution had in fact taken place, he was far less persuasive with respect to natural selection, which only became the majority view towards the middle of the twentieth century. Furthermore, evolution as Darwin and his successors have come to understand it was something quite different from the 'evolution' of his predecessors and many of his contemporaries. This is true of both evolution and its mechanisms.

Darwin's early geological research was crucial to his intellectual development. It gave him experience in thinking historically, dealing with real events that happened to concrete particular things. The fossil record, however, was still very poorly understood, and one of Darwin's major contributions was showing how incomplete it was. It was biogeography, not paleontology, that convinced Darwin that evolution had occurred and provided his most compelling arguments for it. But that required thinking about groups of organisms not merely changing but also having common ancestors. Darwin's predecessor Lamarck (1744–1829) had published a branching diagram, but his basic conception was that of multiple

origins of simple organisms by spontaneous generation, and their descendants becoming increasingly complex as independent lineages. It was a more historical version of the traditional idea of a *scala naturae*, with organisms ranked as higher or lower according to how closely they resembled human beings.

When Darwin's predecessors attempted to explain the transformation of species they invoked the kinds of causation that they were familiar with in other areas of experience. Supernatural influences played a diversity of roles in such thinking, often important ones. Change in lineages was largely thought of in terms of analogies with the development of embryos. A kind of 'evolutionism' was possible in which simple organisms had been created followed by a long succession of generations before the result that had been foreseen from the beginning—Man—was realized. Alternatively, the Creator had ordained laws of nature, such that matter would organize itself into increasingly complicated forms with Man, again, the preordained result. These unknown laws of nature were often conceptualized as similar to those that govern the formation of crystals.

In Darwin's theory evolution was subject to the laws of nature, but there was no law or other cause that drove things in any particular direction. Organisms evolved the properties that they did because of historical contingencies, and Darwin's critics often equated such contingency with 'chance.' Attempting to find explanations for evolution in terms of 'law' rather than 'chance' has been a recurrent theme in efforts to find alternatives to Darwinism.

The term 'orthogenesis' is often applied to notions of evolution occurring along predetermined lines, especially when there is some sort of analogy with the formation of an embryo. Such quasi-evolutionary ideas began to receive attention from social scientists before the publication of the *Origin of Species* (Darwin 1859). The stage theory of Auguste Comte (1798–1857), with its theological, metaphysical, and positivistic levels, is one important example. Closer to what we moderns think of as evolution was the philosophy of Herbert Spencer (1820–1903). Spencer analogized both biological and socio–economic evolution with the embryology of Karl Ernst von Baer (1791–1876). In Spencer's 'synthetic philosophy,' the increasing specialization of the parts in developing organisms was analogized with the specialization and diversification that occurs in society.

The 'super-organism' view of social and biological evolution has been firmly rejected by Darwin's followers. However, a more limited form of 'holism' that affirms the reality and importance of supra-organismal groups has become increasingly popular in the philosophy of systematics. Ontologically, species and other taxonomic groups are now considered not to be classes but individuals in the broadest sense: particular, concrete things that have a definite position in space and time. Like individuals in the familiar sense of organisms, they can change indefinitely, they have no definitions, and there are no laws of nature for any one of them.

Species are now understood to be supra-organismal wholes that are held together by sex. Darwin however never had a satisfactory species concept. But he did emphasize the interaction between organisms and the reproductive competition among them as the fundamental cause of change. As he saw it, the competition for such resources as food is important only insofar as it affects reproductive success. The crucial role of sexual reproduction is underscored in Darwin's theory of sexual selection, a major topic in *The Descent of Man* (Darwin 1871). The 'secondary' sexual characters, such as gaudy plumage in birds and the antlers of stags, were interpreted by Darwin as the result of purely reproductive competition, based upon monopolizing mates, and unrelated to survival or procreation pure and simple.

Misunderstandings about competition have always been a major impediment to the assimilation of Darwin's theory. In economics, competition is thought of as a market condition that is antithetical to monopoly. The lay person, however, tends to confuse competition with other phenomena, such as physical combat, and to treat it as if it were the opposite of cooperation. For many, even teachers who grade on a curve, it is something antisocial, if not downright immoral. Of course political considerations have added to the confusion but it also reflects a deeper, metaphysical problem. The pre-Darwinian mentality has generally tended to assume that the world was created by God and that, in the words of Alexander Pope, 'Whatever is, is right.' Short of rejecting the basic premise, there are two popular alternatives. One is to endorse the conditions that exist. The other is to deny their existence. Various forms of Social Darwinism have opted for the former. More tender-minded social thinkers, from Prince Kropotkin to Stephen Jay Gould, have opted for the latter, portraying the natural economy as one in which competition is unimportant. Darwin of course rejected the basic premise. That perhaps bothered his contemporaries more than any other aspect of his theory. It allowed the phenomena of life to be explained in purely natural-science terms, without recourse to teleology in any but a trivial sense. Everything came into existence as a matter of historical contingency in the course of a vast sex contest.

Partly because of his experience with barnacles Darwin became increasingly aware of the importance and pervasiveness of sex. The barnacles, although generally hermaphroditic, turned out to crossfertilize. Turning his attention to plants, Darwin found out that they cross far more often than anybody had realized. Indeed, there were widespread adaptations furthering outcrossing. He undertook extensive empirical investigations, with striking results that revolutionized floral

biology. His first book after the *Origin of Species* (Darwin 1862) dealt with the pollination biology of orchids. It documented in great detail the often complex adaptations that enabled the orchids to have insects transfer pollen from one flower to another. These adaptations were often quite bizarre and the book can at least be read as a sort of satire on traditional natural theology. It also counteracted the morphological tradition that had tended to dismiss function. The book evoked a debate between Darwin and his supporter the Harvard botanist Asa Gray (1810–88). Darwin firmly resisted Gray's efforts to find God superintending the overall trend of evolution. In the orchid book and other botanical publications, Darwin showed that inbreeding could be highly deleterious and that plants have both anatomical and physiological adaptations that further outcrossing.

In *The Descent of Man, and Selection in Relation to Sex* (Darwin 1871), Darwin laid the foundation for a great deal of work on the comparative biology of reproduction. His theory of sexual selection followed from his basic idea that evolution results from reproductive competition between individuals. Such features as the antlers of stags and gaudy plumage in male birds he interpreted as adaptations used in monopolizing mates, and not as contributing to survival or otherwise giving an advantage in competing with organisms of other species.

Individualistic competition also has a great deal to do with another important topic in that book: the evolution of morals. Darwin was quite clear on the point that organisms generally act in their own interest. He even suggested that an adaptation in one species that existed solely for the good of another species could not be explained in terms of his theory. He likewise ruled out adaptations that would benefit a species as such. There was as he saw it no good evidence that such adaptations exist. However, he still had to account for the existence of self-sacrifice upon the part of social organisms, including apparently altruistic acts by human beings. His discussions of such topics include basically everything that was considered by late twentieth-century sociobiologists but without the genetics. He seems to have understood kin selection, insofar as he pointed out that in artificial selection traits could be favored by what Darwin called 'breeding from the same stock.' A relative of an animal with a trait such as flavorful meat could be selected for breeding instead of that particular animal. He seems not to have considered kin selection very important, however. Neither did he emphasize reciprocity, though he recognized its existence. Rather, he stressed familial selection, which was important in his treatment of the neuter casts of social insects such as ants and termites. He treated families as individuals, with the relevant competition going on between nests of ants or hives of bees. In dealing with human morality Darwin invoked selection at the level of the tribe or nation. His reasons for invoking such group selection, rather than, say, reciprocity, are not explicitly stated in his writings.

To what extent did Darwin go along with the 'social Darwinism' of his times? This term is by no means monolithic and merely saying that he endorsed some of it hardly answers the question. Social Darwinism was basically a political doctrine and it generally had a basis that was if not religious, at least teleological. Interfering with the struggle for existence would tend to prevent the desirable end result from happening. It would be like interfering with the growth and maturation of an organism. Darwin did not endorse such claims. However, he did maintain that free competition favored both biological and economic progress, the two being interrelated insofar as the human intellect is a source of innovation. Lessening the struggle would, he thought, tend to be dysgenic.

There was also a psychological aspect to Darwin's thinking about morals, one that often focused upon the 'moral sentiments,' as Adam Smith had called them. He tried to derive those sentiments from a feeling of sympathy. He considered morality highly serviceable in the struggle for existence, but the selective context was crucial. He suggested that in bees, in which the drones are killed by the workers, it would be appropriate for such fratricide to be a matter of conscience. Some of his readers were scandalized. Selection favoring instinctive behavior was important here, and it contrasts with much of the thinking of his contemporaries. Herbert Spencer had attributed moral sentiments to a more Lamarckian mechanism. There was a kind of racial memory of the sufferings of our ancestors. The British empiricist tradition had sought to explain ethics in terms of personal experience. Spencer made it racial experience. Darwin replaced experience with reproductive success.

The Descent of Man, and Selection in Relation to Sex (Darwin 1871) was followed by its sequel, *The Expression of the Emotions in Man and Animals* (Darwin 1872), which further elaborated upon Darwin's evolutionary psychology. Darwin rejected mind–body dualism and thought that the functioning of the nervous system and the rest of the body were very tightly linked. He used facial expression and other body movements as a means of gaining access to the inner workings of the nervous system. It also provided examples of evolutionary continuity. As he saw it, emotional expressions might come to function in communication, but in keeping with his general anti-teleological position they did not originate that way. Rather, they could be traced back to historical antecedents having a different functional significance. Darwin's interest in psychology can be traced back to his undergraduate years and was a major topic for his empirical research. Two features of this work need to be stressed at the outset. First, although he owed much to the extensive literature on such topics, with which he was quite familiar, much of his contribution came from rejecting the assumptions that had often been

made. For example, he rejected the (teleological) notion of Charles Bell that there are anatomical adaptations for expressing emotions. Second, his work in that area rested upon a solid basis in experience, including laboratory experiments as well as natural history observations, with much attention paid to the underlying physiological mechanisms. This at a time when psychology was just beginning to disassociate itself from philosophy and become a laboratory science.

Much of Darwin's behavioral research was done on plants. One naturally hesitates to call such work 'ethology' or 'physiological psychology,' but the lack of muscles and nerves in plants does not prevent them from moving and responding to stimuli. Bridging the gap between plants and animals was part of Darwin's effort to overturn traditional metaphysics. The book on insectivorous plants does more than just allude to that point. In his work on climbing plants Darwin found a morphological continuity between the organs used in climbing and less modified precursors. Tendrils were the modified petioles of leaves, for example. He also found that he could trace the circling movements with which the plants located objects upon which they climbed to a circling movement that had no such function. That led him to investigate the manner in which plants respond to directional stimuli. His research on that topic was first-rate plant physiology and gave rise to a vast literature. His follower George John Romanes (1848–94) extended that sort of reasoning to simple marine animals and thereby founded an important tradition in the study of animal behavior.

Darwin also concerned himself with the ontogeny of behavior, especially that of human beings. He kept detailed notes on the behavioral maturation of his own children. Some of this material was incorporated in *The Expression of the Emotions in Man and Animals* (Darwin 1872). A paper containing excerpts from the notes (Darwin 1877a) is considered one of the classics of child psychology. Darwin had several reasons for studying behavioral ontogeny. Not the least is the light it may cast on the role of inheritance vs. learning. If there has been no opportunity for learning, and behavior appears spontaneously in the course of maturation, then a strong case can be made for inheritance.

Another reason for studying the ontogeny of behavior was Darwin's basic position on the relation between development and evolution in general. For him, the modification of ontogeny was a fundamental evolutionary process, and he routinely approached evolutionary problems from the point of view of embryology. Darwin believed that the processes responsible for the development of a a fertilized egg into an adult are something that themselves evolve. This was in itself an important innovation. Perhaps more importantly he showed how natural selection could modify the structure and function of organisms by affecting the various stages of development. By implication, the history of life could be approached by asking how the underlying developmental processes had been modified. His great follower Fritz Müller (1821–97) developed Darwin's approach by suggesting that the history of certain crustaceans could be interpreted as the result of stages being added at the end of the life cycle. As a consequence, the most modified animals would repeat, during their life cycles, the series of adult ancestors. Another of Darwin's followers, Ernst Haeckel (1834–1919), took Müller's special case and treated it as the general rule, and enunciated what he called the fundamental biogenetic law, according to which ontogeny recapitulates phylogeny.

Darwin's views on the relationship between development and evolution are discussed at length in *The Variation of Animals and Plants under Domestication* (Darwin 1868). The variations that play an indispensable role in natural selection are here shown to occur in a more or less orderly fashion, evidently as a result of the modification of existing developmental mechanisms. Variation was thus physiologically constrained, and evolution by natural selection was by no means affected only by external conditions as is so often maintained in caricatures of Darwinism. Because this book contains toward its end an effort to explain heredity as well as development, the work is often misinterpreted as mainly about genetics. Darwin attempted to explain the inheritance of acquired characteristics (and much else as well) in terms of particles that control development. These particles could be affected in the somatic tissues, not just the germ. The particles interested some of Darwin's followers and, with considerable modification in the hands of Hugo De Vries and others, they evolved into the 'genes' of later authors.

3. *Darwin's Relevance for Today*

Darwin was a remarkably creative thinker, as attested by the surprise with which his discoveries were so often met. One reason for this was the sort of wide-ranging curiosity and erudition that has become increasingly difficult to emulate as knowledge becomes ever more specialized. He was a very good observer, but insisted (at least in private) that this was because his observations were guided by theory. On the other hand, he was also an empiricist, and did not sympathize with the 'deductive' approach as he called it of such authors as Herbert Spencer. He confronted his theories with a mass of evidence and modified them in the course of investigation.

Darwin was not constrained by academic fashion or pedantry in seeking material that could be put to scientific use. He unearthed a wealth of information in the writings of plant and animal breeders and appealed

to gardeners and others to provide additional materials. He also carried out extensive series of observations and experiments, often opening up new areas for investigation. We should mention his studies of competition between plants as pioneering contributions to experimental ecology. Darwin's experimental work is very highly regarded by plant physiologists and students of animal behavior. However, his originality so far as methodology is concerned has more to do with comparison than with experiment. In Darwin's hands, comparative biology became linked to the revolution in systematics, a discipline which was now based upon genealogical relationships and therefore fundamentally historical. Hypotheses could be developed and tested by such procedures as plotting data onto a phylogenetic tree. Phylogeny was especially important with respect to adaptation, which was now conceived of as the outcome of an historical process.

The shift to historical narrative is an aspect of the rejection of traditional, teleological modes of thinking in which states of adaptation had implied purposefulness, even conscious design. Although structures might give many of the appearances of having been constructed by an intelligent being, it was no longer legitimate to treat ours as the best of all possible worlds. By taking an historical approach and understanding the actual processes and events that have brought about the present properties of organisms we can avoid the teleology. Instead of asking what an organ is 'for' we ask what has brought it into being. It then becomes apparent that the world abounds in maladaptations and historical vestiges.

Contrary to what has sometimes been maintained, natural selection is not capable of explaining just about any conceivable property of organisms. Indeed the mechanism places strong restrictions upon the actual course of evolutionary change. For that very reason, it provides a powerful tool for evaluating hypotheses, especially where adaptation is involved. There is nothing that might reasonably be considered analogous to foresight when evolution occurs by natural selection. Any 'preparation' for future conditions of existence has to be the result of coincidence, and populations remain adjusted to present circumstances, and organisms repeat that which furthered their ancestors' reproductive success.

Because natural selection depends upon individualistic competition, there are strong constraints upon the kind of adaptation that can occur above the level of the organism. As already mentioned, Darwin clearly recognized that the individuals that reproduce differentially can be families as well as organisms, and on that basis he was able to explain the evolution of neuter castes in social insects. How readily that can happen has been a serious topic of controversy ever since. Darwin did not believe that differential reproduction of species could produce adaptations that exist 'for the good of the species,' though the possibility has subsequently been taken seriously by some authors. 'Group selection' was widely invoked in the early twentieth century. A critical attitude toward it did not become common until the latter half of that century, when in fact there would seem to have been something of an over-reaction. From the point of view of Darwin's contribution, however, what matters is not the ultimate answers that may emerge, but rather the manner of framing the question. One needs to ask precisely how the world is structured and how the components might interact, formulate explicit hypotheses and then test them.

Such issues of course are particularly important in the study of social behavior. The modern discussion of what sociobiologists call 'altruism' is a continuation of Darwin's pioneering work in that area. It is important, however, to recognize that 'altruism' in this sense is a technical term without ethical connotations and means self-sacrifice pure and simple. But people habitually slip back into older ways of thinking and tend to attach value judgments to statements of fact on the assumption that what is 'natural' is therefore good. Even where the teleology is repudiated explicitly it may persist in the form of implicit assumptions. It is clearly an over-reaction, however, to reject the study of adaptation in favor of so-called proximate causes. 'Teleology' in the limited sense of homing behavior and the capacity for foresight and understanding on the part of human beings and some other animals is by no means inconsistent with the expectations of selection theory.

Darwin recognized that natural selection is capable of accounting for the phenomena of progress. He reasoned that in a competitive economy innovations that are effective in dealing with the environment would tend to accumulate. On the other hand, he rejected the views of many of his predecessors and contemporaries whose conceptions of progress remained teleological. Notions about evolution, whether social, economic, or biological, based upon analogies with the growth of crystals or the development of embryos implied a kind of inevitability that was out of line with Darwin's theory. But they appealed to those who were looking for some kind of long-term goal to it all. Darwin witnessed a great deal of technological progress in his day, and like the overwhelming majority of scientists then and now, he obviously believed in scientific progress as well. Although the idea of progress has recently come under attack by philosophers and social scientists, this may just be another episode in the ongoing process of coming to grips with Darwin's contribution.

Darwinism

'Darwinism' can properly be dated from 1859, the year in which English biologist Charles Robert Darwin (1809–1882) published his magisterial evolutionary work: *On The Origin of Species by Means of Natural Selection*. In order to understand the magnitude of what Darwin achieved in that work, and the nature of the movement to which he gave his name, it is perhaps best to recognize that there are three different kinds of issue at stake here (Ayala 1985). First, there is what one might speak of as the very fact of evolution itself: the claim that all organisms, living and dead are the result of a developmental process governed by natural law. Then second, one has the question of paths of evolution, or as these are known technically, of phylogenies. Here one is concerned about the routes along which evolution proceeded. Third, there is the question of causes or mechanisms. The work of the early nineteenth century French biologist, Jean Baptiste de Lamarck (1809), who argued that organisms change thanks to the inheritance of acquired characteristics, speaks to this particular issue. Here one is concerned with the driving forces behind the evolutionary process.

Although Charles Darwin was not the first evolutionist—in the eighteenth century, at length in rhyming couplets, his own grandfather Erasmus Darwin had celebrated the joys of organic change—it was in the *Origin* that Darwin established once and for all the fact of evolution. He did this through making appeal to a unificatory argument or what he would have thought of as a 'consilience' (Ruse 1979). Darwin argued simply that if evolution were true, then one could explain facts in a wide range of areas. For instance, one can show why it is that the fossil record is roughly progressive. Likewise, one can show why it is that organisms are distributed as they are around the world. One can explain the facts of embryology, why it is that organisms are very different forms when adult (like the man and the dog) but have embryos which are almost identical. Why it is that the facts of anatomy are as they are? Why do we find skeletal isomorphisms (known technically as 'homologies') between the forelimbs of organisms, despite these limbs having different functions? The bat uses its forelimb for flying, the mole for digging, the whale for swimming, the man for grasping, and yet the bones are very similar. One can explain this, argued Darwin, through the fact of evolution. All of these phenomena, and many more, can be explained by evolution. Conversely, they point backwards up to the truth of the fact of evolution.

In the *Origin*, Darwin had relatively little to say about the paths of evolution, although it was he who tied evolution firmly to the metaphor of the tree of life. Unlike some early evolutionists, Darwin always stressed the extent to which all life is related and descends 'from one or a few forms,' branching as time unfurls to the vast diversity which exists today. But, paradoxi-

cally in the nineteenth century it was the non-evolutionists—particularly Lamarck's contemporary and fellow countryman Georges Cuvier, who was both the father of comparative anatomy and an accomplished paleontologist—who first started to work out the actual course of life's history (Ruse 1996). In such labors, Cuvier was backed by German-style biologists—particularly the Swiss-American ichthyologist Louis Agassiz—who saw analogies between life's history and the development of individuals. Darwin himself relied on both the fossil evidence and on embryology and its supposed analogies when around 1850 he performed a massive taxonomic study of barnacles. It is clear that although he did not draw explicit inferences about evolutionary paths, he had some strong convictions and suspicions (Richmond 1988). But none of these found their ways into the *Origin*, and later in the century it was Darwin's young supporters like Thomas Henry Huxley who were most interested in particular paths. In the USA there was much activity in this direction, thanks particularly to the magnificent fossil findings, especially those of the horse and of dinosaurs (Bowler 1996).

1. Natural Selection

It was when it came to causes or mechanisms that Darwin himself felt that he really was able to make significant scientific advances. He proposed his well-known mechanism of evolution through natural selection brought on by a struggle for existence, starting from the claims made by the English clergyman Thomas Robert Malthus (1826), that population numbers will always outstrip food supplies and space availability. Generalizing this to the animal and plant world, Darwin suggested that there will always be, at the same time, naturally occurring variation within populations: his studies of barnacles convinced him strongly that this was true. Darwin therefore concluded that in the struggle, success would be at least in part a function of the differences occurring naturally within organisms. There will thus be a natural form of selection, corresponding to the artificial selection practiced so successfully by animal and plant breeders in the first part of the nineteenth century in the UK.

But more than just this. Darwin believed that natural selection would lead to change of a particular kind, namely towards adaptive advantage. Darwin had read and been much impressed by the teleological arguments expressed by Archdeacon William Paley (1802), a work which Darwin had to read as an undergraduate. Paley argued that the eye is very much like a telescope, and that just as a telescope has a telescope maker, so the eye has an eye maker. That is to say the Great Optician in the Sky. Darwin rejected Paley's conclusions, but he completely accepted Paley's premises about the design-like, teleological nature of the organic world. It was Darwin's belief that natural selection speaks to this aspect of organic life, providing a naturalistic—that is to say law-bound—mechanism of explanation.

2. Huxley's Program

After the *Origin* was published, evolution as fact was never again seriously challenged as a matter of science. But the mechanism of which Darwin was so proud got relatively little attention. Darwin's great supporters, Huxley particularly, had other ends for evolution than a functioning professional science with selection at its core (which had surely been Charles Darwin's own aim). Huxley and his fellows were busy creating a secular society in Victorian times: one which would have open education for all without religious qualifications; one which would have a professionally trained civil service; not to mention other things like a military which did not simply depend on one's social status and personal wealth. With some good reason, the Huxleyites saw the established church as being very much part and parcel of the powers that they wished to overthrow. Hence, they were eager to find some alternative secular substitute (Ruse 1996).

Evolution fitted this need entirely. It was not so much that evolution was being pushed as something in direct violation of Genesis or anything like that. Rather, evolution could function as a kind of secular religion or ideology, on which one could hang all sorts of hopes of progress and ethical change, and the like. It is no surprise to find that, as the nineteenth century drew to an end, the evolutionist *par excellence* was less Charles Darwin, and more his fellow countryman Herbert Spencer (Richards 1987). The latter, in his massively written 'Synthetic Philosophy,' was providing a world picture, which would be all encompassing, right up to and including, our own species. Naturally, as a prospective religion, evolution was used to promote moral and social causes. Notoriously, Spencer and his supporters—prominent in this respect were the American businessmen John D. Rockefeller the First and Andrew Carnegie—endorsed a kind of *laissez faire*, arguing that as with the struggle for existence and survival and selection in nature, so also should there be such a struggle and selection in society. It is paradoxical that this movement became known as social Darwinism, for although there are certainly hints of such ideas in Darwin's own writings (especially in his work on our species, *The Descent of Man*, 1871), primarily this was a movement to which he contributed little and which altogether took evolutionism in directions he rather regretted.

3. The Synthetic Theory

Darwin's ideas as science only provided part of the picture. The whole question of mechanisms hung fire

rather until the twentieth century. Then came the development of an adequate theory of heredity explaining how and why it is that organic characteristics are transmitted from one generation to another, and why new variations appear occasionally, spontaneously as it were. When first this was done, many thought that the new theory of heredity, genetics, was in opposition to any kind of selection mechanism. But by the 1930s, a number of mathematically gifted biologists—notably R. A. Fisher (1930) and J. B. S. Haldane (1932) in the UK and Sewall Wright (1931, 1932) in the USA—showed that one can put together Darwinian selection with Mendelian genetics in a smooth synthesis (Provine 1971). Finally, an adequate mechanism for the evolutionary process was developed and accepted. However, much more work needed to be done. It fell to the next generation of evolutionists, notably people like Julian Huxley (1942) (the grandson of Thomas Henry Huxley) in the UK, and Theodosius Dobzhansky (1937), the Russian-born American geneticist and his associates to put the empirical flesh on the mathematical skeletons of the 'population geneticists.' Thus, around 1950, one had a full theory, which came to be known as the 'synthetic theory of evolution' or 'Neo-Darwinism': Darwin's theory of natural selection spliced in with Mendelian genetics, offering the way forward for a full and satisfying causal picture of evolutionary change.

4. *Sociobiology*

The years since around 1950 have been amongst the most exciting in evolution's history. Although no one now wants to challenge the ultimate picture, there have been both extensions and challenges. Most notably the former has involved the pushing of a Darwinian selective approach into the realm of social behavior. Darwin himself always thought that such behavior was part and parcel of the evolutionary picture, but he recognized that it was extremely difficult to study. However, by the 1960s evolutionists felt sufficiently confident to extend their work to such organisms as the Hymenoptera (the ants, the bees, and the wasps), as well as to mammals and even up to and including our own species. This development of the evolution of social behavior from a Darwinian perspective—so-called 'sociobiology'—has been highly controversial. The leaders in the field, people like William Hamilton (1964) and John Maynard Smith (1982) in the UK, and Edward O. Wilson (1975) in the USA, not to mention the great popularizer Richard Dawkins, author of *The Selfish Gene* (1976), have been subject to a great deal of critical attention. But now I think it is generally realized that one can profitably take a Darwinian selection-based approach into the social realm, dissecting and showing in great detail how the behavior of organisms is just as much a function of their evolutionary past as is their physical nature.

Still highly controversial has been some of the work by human sociobiologists, trying to take a selection-based approach to human nature and behavior. By way of example, one might mention the Canadian researchers Martin Daly and Margo Wilson (1988). They show that, in many respects, family patterns are tightly controlled by evolutionary considerations. Why it is for instance that violence in families almost always comes from the hands of men: usually not by biological fathers, but by stepfathers. Remarkably, Daly and Wilson show that stepfathers are 100 times more likely to murder their children than are biological fathers. This they relate to straightforward Darwinian principles, namely that from a biological point of view, survival and reproduction may be improved if one can clear the way (as it were) for one's own offspring, but that damaging or harming one's own biological offspring is to go completely against the whole Darwinian evolutionary process.

5. *Critics of Adaptation*

On the other side, there are the critics of adaptationism, most notably the American paleontologist Stephen Jay Gould. Like Richard Dawkins, a very popular writer, Gould has put forward his theory of so-called 'punctuated equilibria,' arguing that if we look at evolution over long time scales, we see that selection as a force for constant, unbroken change falls away dramatically (Eldredge and Gould 1972, Gould 1982). Rather, what we get are long periods of inactivity (so-called 'stasis') broken or punctuated by very rapid changes from one form or blueprint (Gould likes the German term *Bauplan*) to another. Gould argues that although selection certainly perfects organic characteristics, tuning them up as it were, by and large the basic patterns of organisms are part of a general morphologically constrained non-selective picture. A vertebrate having four limbs, for instance, rather than six like many invertebrates, has nothing whatsoever to do with natural selection.

There are many other developments going on, particularly those involving molecular biology. For instance, it is suggested that perhaps at the molecular level, beneath the level at which selection operates, one gets a whole different dimension to evolution: perhaps a dimension where random factors are very significant. (This is the theory of 'molecular drift,' Kimura 1983.) Perhaps also in other spheres there are major factors yet to be discovered: possibly viruses carry units of heredity ('genes') from one organism to another of a very different kind. Also, there is much work going on at the moment of related questions such as the origin of life. Certainly, no one has a firm solution in this direction, although once again major advances have been made and we know a great deal more than we did in the 1980s or 1990s.

6. *The Meanings of 'Darwinism'*

So, in conclusion, trying to tie together strands from history and from the present, how then are we to define and characterize 'Darwinism,' or a 'Darwinian' meaning someone who accepts the doctrine? Darwinism certainly commits one unambiguously to the fact of evolution. The only people today who challenge this seriously are those driven by religious commitments namely the extreme Christian evangelicals known as 'fundamentalists,' finding that evolution clashes with their prior commitments to the Bible (especially Genesis) taken literally (Johnson 1991). There are some Darwinians who think that their position also demands of you, belief in some kind of philosophical materialism, claiming that any kind of supernatural belief is false or impossible (Dennett 1995). However, this is surely not a universal view, and there are many (and not all believers) who think that although evolution holds exclusively in the scientific realm, there may be more to life—certainly there may be more to the after-life—than strict science allows (Ruse 2001).

As far as evolution as a path is concerned, although it is true that one does not have to be a Darwinian to believe in a tree of life, it is still surely true that Darwinism itself commits one to some kind of tree of life. But Darwinism does not specify the details as such. The much-debated question, for instance, as to whether the birds are descended from the dinosaurs or whether from reptiles that were not dinosaurs has no bearing on Darwinism as such. What about the above-mentioned speculations that life's history may have involved such things as the moving of genes from one group to another very different through the agency of viruses and the like? Hence the tree of life might be a bit more net-like than one would have suspected. Certainly this is something which was not envisioned by Darwin himself or indeed by many successors who would have called themselves Darwinians. But I doubt that there would be much concern or felt need to repudiate Darwinism. After all, things like this are more extensions than major denials of the traditional picture.

Evolution as cause is as always the crucial issue. Darwinism has and continues to make natural selection absolutely central. If one does not accept that natural selection is the major cause of evolutionary change and that adaptation is the defining characteristic of organisms, then one is no Darwinian. This applies to humans as well. Interestingly, the very first speculations we have of Darwin about natural selection was a discussion about human evolution and how selection leads to bigger brains and greater intelligence. As far as other points are concerned, then perhaps as with paths there is more flexibility. Darwin himself always stressed that selection works for the benefit of the individual over the group. This is very much the stance of sociobiologists in the twenty-first century, and is indeed the basis of Dawkins's metaphor of the 'selfish gene.' But there have always been those who have yearnings towards a group based form of selection—one of the first indeed was the co-discoverer of natural selection, Alfred Russel Wallace. Perhaps therefore with something like this there is room for difference within the fold (Sober and Wilson 1997).

It was never the claim of Darwin or of any subsequent Darwinian that natural selection is the only mechanism of evolutionary change. Darwin himself accepted Lamarckism. This mechanism is today totally discredited, but there are other putative causes of change, and one can certainly allow them some force and still be a Darwinian. There are many debates about how much of an allowance one can give and still is subscribing to Darwinism. To a certain extent it all depends on how far one is modifying traditional views and how far one is standing outside of, or beyond them. Controversial is the question of 'genetic drift,' the claim by Sewall Wright that evolution can go by chance, even when selection is operating (Coyne et al. 1997). Really strict ultra-Darwinians like Fisher would have very little tolerance for something like drift, thinking it unimportant at best. Others (including most of the American founders of the synthetic theory) found some drift to be quite compatible with their Darwinism. Kimura himself felt (perhaps with good reason) that he was a good Darwinian because he did not propose drift at the physical level but at the molecular level. Darwin himself had said nothing about molecules and so in proposing molecular drift there was no reason to think that one was being non-Darwinian.

7. *Social Darwinism*

Finally, what about social Darwinism? Few want to use that label given its unfortunate connotations with such things as the ruthless business practices of the last century. But still there is a thriving industry among those who want to derive more from evolutionism than mere science (Ruse 1999). Julian Huxley (1927) was one person in this century who wanted his evolution to be the basis of a 'religion without revelation' and more recently Edward O. Wilson (1998) is another. In one of his prize-winning books, *On Human Nature* (1978), Wilson is explicit in his seeing evolution as more than mere science, as a 'myth,' which will absorb or push aside conventional religion:

> 'Make no mistake about the power of scientific materialism. It presents the human mind with an alternative mythology that until now has always, point for point in zones of conflict, defeated traditional religion. Its narrative form is the epic: the evolution of the universe from the big bang of 15 billion years ago through the origin of the elements and celestial bodies to the beginnings of life on earth.'

And so on and so forth up to humans. Little wonder that:

> 'Theology is not likely to survive as an independent intellectual discipline.'

Wilson even finds place for an evolution-based morality—not the *laissez faire* of yesterday but a call to biodiversity and species preservation, else we humans decline and fall in a word impoverished of living nature.

It is certainly not necessary for a scientific Darwinian to be a social or philosophical Darwinian, but a remarkably large number are. The important conclusion is that however defined, Darwinism has a rich tradition, and although it has never been without its critics it continues in the twenty-first century as an important and ever developing testament to human reason and creativity.

Darwinism: Social

The term 'social Darwinism' was coined in Europe in the 1880s and rapidly spread through the UK and the USA. It negatively refers to the theories and doctrines which turn the social laws into the aftermath of the laws of nature.

1. The Term 'Social Darwinism'

The first persons ever to use the term—among others, Emile Gautier in France and Achille Loria in Italy—criticized more the Spencerian philosophy of the 'struggle for life' and the 'survival of the fittest' than Darwin's theory of natural selection. Emile Gautier explains that the selection law does not apply to human societies. He describes this extrapolation as 'social Darwinism' and contrasts it with the true social Darwinism which implies reforming society. All this initial confusion has still not been entirely clarified, as is evident with eugenics, a notion mingled with social

Darwinism while being distinct from it. Coined by Francis Galton, Charles Darwin's cousin, and derived from the Greek words *eu* meaning good and *genos* meaning stock or race, the term refers to

> 'the science of improving stock, which is by no means confined to questions of judicious mating but which, especially in the case of man, takes cognisance of all influences that tend in however remote a degree to give to the more suitable races or strains of blood a better chance of prevailing speedily over the less suitable than they otherwise would have had (Galton 1883, 1951, p. 17)

The starting point of eugenics is that natural selection no longer plays its role in modern society, thus leading to the degeneracy of the human species. Therefore an artificial selection, fully recognized, must be substituted for the failing natural selection. The means that are advocated either refer to 'negative' eugenics or 'positive' eugenics. 'Negative' eugenics aims at preventing people with hereditary diseases and serious deformities from getting married while restoring to means ranging from segregation to sterilization. 'Positive' eugenics aims at encouraging 'gifted' or 'strong' individuals, that is to say the carriers of favorable physical and intellectual characteristics, to reproduce themselves as much as possible.

2. *Was Darwin a Social Darwinist?*

While social Darwinists use the term 'struggle' in the literal sense and make of the survival of the fittest its legitimate sanction, Darwin points out that he used the term 'struggle for life' as a metaphor including different levels of opposition and dependency. The word 'struggle,' borrowed from the geologist Lyell, means making efforts in difficult conditions and at the same time facing an opponent. In Darwin the 'struggle for life' is not defined as a direct clash involving individuals but as a set of solidarity mechanisms and clashes precariously balanced, and taking into account the milieu in which individuals and species live and fight. Darwin only used the term 'survival of the fittest' as late as the fifth edition of *The Origin of Species* in order to refer to the process of natural selection and not the struggle for life. Then in *The Descent of Man* (1871), he derived the emergence of morality in humans from animal social instincts. But at the same time, ambiguously enough, Darwin agrees with Galton's eugenic ideas and claims that the development of social instincts should not eradicate competition and the struggle for existence.

3. *Unity and Diversity of Social Darwinism*

Social Darwinism can be defined as an ideology, a philosophy of history or a sociology which not only postulates an analogy between the laws of nature and the laws of society but also affirms that the laws of nature are the 'survival of the fittest,' the 'struggle for life,' and the laws of heredity and that there should be no opposition to this for the welfare of society. At the risk of reducing the great diversity of its forms, historians agree to distinguish two major types of 'social Darwinism':

(a) a liberal and individualistic social Darwinism which makes the struggle between individuals the fundamental law of society;

(b) a selectionist and interventionist social Darwinism which can be defined as a sociology of struggle and emphasizes the struggle between races.

3.1 *Liberal Social Darwinism*

The first social Darwinism, that of Herbert Spencer (1820–1903) appeared before *The Origin of Species* and *The Descent of Man*. It can be defined as an evolutionarist philosophy without any connection to biology. Spencer's concept of the 'survival of the fittest' combines natural selection and economic competition between individuals. It does not deal with struggles between groups and races.

Whereas Spencer, who was not a Darwinist, referred to the population laws, he did not draw the same conclusions as Malthus: the survivors are those who are endowed with a capacity of self-preservation superior to those who could not participate in life's banquet. Economic competition is thus part of the laws of nature and nothing should hamper them because the survival of the fittest is the only process capable of ensuring human progress.

The population's growth not only stimulated competition but also is the driving force behind civilization:

> 'This constant increase of people beyond the means of subsistence, causes, then, a never-ceasing requirement for skill, intelligence and self-control—involves, therefore, a constant exercise of these and gradual growth of them' (Spencer 1865–7, pp. 498–99)

The demographic pressure is meant to come to an end when its task has been carried out, bringing the process of civilization to its end. That was not the case in the last third of the nineteenth century.

Even if the changes in English society and increasing state intervention did not correspond to his expectation, Spencer wrote again about the notion of the survival of the fittest in the *Principles of Sociology*, published from 1876 to 1880. from then he distinguished between two types of modern societies—military societies characterized by an increasing part played by the state, the growing number of civil servants, and faith in authority, and those he thought to be superior forms of society—so-called industrial societies—characterized by the decline of the state and the blooming of personal freedom through the play of competition between individuals. Liberal and indi-

vidualistic social Darwinism mainly spread through the Anglo-Saxon countries. In the USA the economist William Graham Sumner, the major theoretician of this type of social Darwinism explained that the differences between individuals merely reflect natural inequalities: people are not equal in the state of nature, and this should be taken in account.

Sumner was opposed to any type of state intervention, protectionism, and socialism whose goal is to save the individuals of any society from the difficulties or hardships of the struggle for life and vital competition through state intervention.

This type of social Darwinism, which was very popular at the time when liberal ideas gained support in the Anglo-Saxon countries, proved less successful on the European continent. Opponents did not fail to underline the contradictions and weakness of liberal social Darwinism. In the 1890s sociologist Lester Ward explained that economic competition did not result in individual advancement but in big new corporations whose power might need to be controlled and he criticized the social Darwinists' 'fundamental error' that 'the favors of the world are distributed entirely according to merit.' This first type of social Darwinism should be distinguished from that of the end of the nineteenth century which is based on a sociology of struggle between groups, collectivities, and races in order to call for state intervention and the control of human procreation.

3.2 *Selectionist Social Darwinism and Eugenics*

At the end of the nineteenth century this form of social Darwinism, especially in the UK and in the USA has been understood as a eulogy of colonization and imperialism inasmuch as the strongest nations were supposed to be the fittest ones.

Ludwig Gumplowicz developed the concept of race struggle: 'Under the term race struggle we shall designate the struggles of the most varied and heterogeneous ethnic and social units, groups and communities. They are the essence of the historical process' (Gumplowicz 1893, p. 193). The social Darwinism is also mixed up with eugenics because of similarities and converging views between the two ideas where the postulate that races and individuals are unequal or the role of heredity are concerned.

In the preface to the first translation into French of *On the Origin of Species* Clémence Royer justified the natural inequalities between people and was opposed to any restriction to competition: 'Men are unequal by nature: this is where we should start from …' (Royer 1862). Georges Vacher de Lapouge, the theoretician who first introduced eugenics in France, underlined the hereditary character of inequity:

> There are superior peoples and inferior peoples, and among these peoples there are elements more perfect and more imperfect than others. Unequal the classes, unequal the families. Inequality is everywhere and so is differentiation. Individuals are not only unequal but their inequality is hereditary, classes and nations and races are not only unequal but each of them cannot undergo absolute improvement (Vacher de Lapouge 1888).

Vacher de Lapouge explained that in modern societies natural selection no longer played its role and was replaced by what he called *social selections* leading to the eradication of the fittest and which he qualified as military, political, religious, moral, economical, professional, and urban selection. Consequently an artificial selection must be substituted for it so as to prevent society and civilization from being weighed down by the degenerate and inferior people. He therefore advocated *selectionism* as the only remedy for 'senile democracy' and combined it with socialism.

The German Otto Ammon, a theoretician of anthroposociology like Vacher de Lapouge, developed a less pessimistic vision of the evolution of society inasmuch as the prevailing social order expressed and reproduced the natural inequalities between people. If, due to 'defects associated with an exclusively intellectual culture and a sedentary life,' the superior classes are threatened with eradication for the benefit of the inferior classes, the latter can better themselves through education and food, thus contributing to the renewal of the superior classes: The existence of social classes promotes the working of natural selection, restricts also 'panmixia', i.e., the pairing of individuals without previous selection, and favors a much more frequent production of highly endowed individuals (Ammon 1895).

Karl Pearson was the major advocate for selectionist social Darwinism in the UK. Though he was a socialist, he was opposed to revolution and he was in favor of gradual reforms allowing society to strengthen and face international competition. In his eyes, eugenics and socialism could be separated—natural selection must give way to artificial selection in order to prevent the unfit from replacing the fit ones. But all these similarities cannot make one forget that many eugenicists were not Darwinist but rather neo-Lamarckians.

4. *Social Darwinism Today*

The decline of social Darwinism, which was already felt after World War I, has on the one hand been ascribed to the use that has been made of it, especially to justify imperialism, and on the other hand to the atrocities committed by the Nazis in the name of eugenics (mass extermination, euthanasia).

Even if nowadays social Darwinism is not explicitly referred to any more, it is still part of the intellectual scene as the rise of sociobiology shows. The latter is a scientific discipline founded by the zoologist Edward O. Wilson and gave rise to serious ideological controversies in the late 1970s and early 1980s. Wilson

(1975, p. 4) defined it as 'the systematic study of the biological basis of all social behavior.'

The biological basis is provided by the modern theory of evolution as it has developed from Darwin's work and contemporary genetics. Social behavior is the result of evolution—it has been selected and is therefore determined. In a sense sociobiology is a form of biological determinism without being a form of reductionism at the same time since Wilson contends that humans are the product of the joint influences of heredity and environment. To Wilson *biological* only meant that there are genetic predispositions contributing to the shaping of social behavior. To his opponents *biological* meant that social behavior was *biologically determined*. In the wake of the question of animal social instincts dealt with by Darwin in *The Descent of Man*, sociobiology strove to shed new light on the problem of altruism.

While natural selection is a selfish process which endows certain individuals with a superior capacity of reproduction, how can one explain the kind of altruism which is noticed among social insects and how can natural selection favor deeds harmful to those who do them? The answer given by sociobiology is that altruistic deeds toward relatives could favor the survival and the dissemination of the altruists' genes which the parents have in common with them. In the same way, the mother instinct and the care given to the child are explained by social biologists as being the best possible way of arranging gene transmission from one generation to the other.

Data Archives: International

Data archives are professional institutions for the acquisition, preparation, preservation, and dissemination of social and behavioral data. These data commonly are stored as electronic records. Evolving in the 1950s with the growth of an ethic of data sharing among social scientists, they have enabled thousands of researchers to undertake a wide variety of analyses of data for which they were not the primary data collectors. This leverages by many times, the original investments in data collection. Many archives also provide training and data services, including statistical analysis and consultation.

1. The Contents of Data Archives

Most data archives offer numerically coded data, but those data are not necessarily quantitative. Numbers may represent either quantitative measurements, such as dollars or years of school completed, or merely serve to label categories, such as sex and occupation. Textual, sound, visual, geographic information systems (GIS) data, and physiological data are also now found in some archives. Two main kinds of data are offered.

Microdata are measurements taken on many distinct units of observation, such as persons, families, companies, governmental units, transactions, events,

conflicts, and dyadic and group relationships. Each unit of observation, for example, a particular person, generates one or more 'records,' each of which contains measurements on a body of variables pertaining to that person, such as occupation or income. It is common for data records to contain hundreds of variables, some measured directly by observation and some derived from other measurements (such as the prestige score of the respondent's occupation). Microdata are based typically upon censuses and sample surveys (see *Statistical Systems: Censuses of Population*), although direct observation, administrative records, news articles, regulatory instruments, and experiments also are used and occasionally are combined with survey data. Microdata generally are rendered anonymous by removing both direct identifiers (names and addresses) and indirect identifiers that might permit sound guesses as to the identity of a respondent, whether a person or an organization.

Macrodata are aggregated microdata measurements in the form of matrices, tables, and charts. They are the result of statistical operations, such as a count of the persons of a certain ethnic heritage in a geographical area or the sum of an entire industry's revenue. This form of data presentation is used widely for the reporting of official data at fine levels of geographic identification, as it permits concealing the identities of individual respondents. However, because it is not possible to disaggregate macrodata and perform a different analysis on the underlying microdata, macrodata provides considerably less analytical power to the researcher. Macrodata may be merged with microdata to facilitate contextual analyses.

The archives also contain the documentation that is required to use these data accurately. Most important are 'codebooks,' documents that give conceptual meaning to numerical codes and describe the process of measurement in detail. Increasingly, electronic codebooks are linkable by software to statistical analysis programs such as SPSS, SAS, and STATA, relieving the user of programming tasks that are intellectually arid but fraught with potential error.

Archives make their greatest investments in the preparation of data and its documentation in order that analyses can be undertaken later, even much later, without personal consultations with the original data collector. This preparation involves identifying and resolving undocumented codes, correcting technical errors in data entry, adding substantive information about measurement processes and response categories, and preparing full sampling descriptions, all in consultation with the original data collector. Major changes in format may be made for the convenience of data users.

As the size of archival collections grew, it became essential to create finding aids of various kinds (e.g., catalogs and indices), now on the World Wide Web for interactive access. In recent years, the catalogs of some of the data archives worldwide have been made interoperable, enabling an interactive search of the holdings of several data archives in one operation. Some archives' collections also include ancillary materials, such as detailed records of fieldwork, basic frequency distributions, statistical analyses of the data, methodological notes, and publications based on the data.

As data archives developed, a specialized profession of data librarian/archivist emerged, blending knowledge and skills from information technology, librarianship, statistics, and the social sciences. These professionals staff most national and many campus data archives. The International Association for Social Science Information Service and Technology (IASSIST) is their central professional organization. Among the organization's goals are the promotion of archiving and the development of standards for the preservation of data.

2. *The Establishment of Data Archives*

The intellectual leaders of what came to be known as the 'data archives movement' came from both the academy and the private sector. From the academy came the founder of modern comparative politics, Stein Rokkan (Norway); two of the pioneers of the empirical study of political behavior (see *Databases, Core: Political Science and Political Behavior*), Philip E. Converse and Warren E. Miller (United States); and a leader of comparative research on social structure (see *Human–Environment Relationship: Comparative Case Studies*), Erwin K. Scheuch (West Germany). Converse and Miller sought to share with their colleagues the election data they were collecting and also to use the new model of the National Election Studies to foster the collection of data on the re-emerging European democracies. Rokkan and Scheuch sought to describe and understand the movement toward a united Europe. All recognized the great potential of data archives to facilitate comparative and time-series (see *Time Series: General*) research as well as to aid the social and behavioral sciences to become more transparent and self-correcting.

The private sector saw its polling data as integral to the functioning of modern democracies and held that understanding public opinion was crucial for a free society. One of the founders of modern polling (see *Polling*), Elmo B. Roper, organized the first of the social science data archives before the 1950s when he decided to share with social scientists and others the data from his polls. These collections of survey data were under development by 1947 at Williams College (Massachusetts), based upon holdings that Roper had been accumulating for 10 years. Williams College formally established the Roper Center for Public Opinion Research in 1957. Roper was joined in

contributions by two other leaders of public opinion polling in the US, George H. Gallup and Archibald Crossley, and by many of the other leading survey firms.

A succession of archives followed. The Central Archive for Empirical Social Research (ZA), based at the University of Cologne in the former West Germany, was next in 1960, followed in 1962 by the Steinmetz Archive in Amsterdam, the Netherlands, and the Inter-university Consortium for Political Research (ICPR), at the University of Michigan, Ann Arbor. By the beginning of the 1970s several more European countries had data archives. By 1964 the International Social Science Council (ISSC) had sponsored a second conference on Social Science Data Archives and had a standing Committee on Social Science Data, both of which stimulated the data archives movement. By the beginning of the twenty-first century, most developed countries and some developing countries had organized formal and well-functioning national data archives. In addition, college and university campuses often have 'data libraries' that make data available to their faculty, staff, and students; most of these bear minimal archival responsibility, relying for that function on a national institution.

Data archives usually are administratively housed in research universities or in government science or information agencies. Funding for these operations varies widely in scale and stability. The financially largest of the data archives, the Inter-university Consortium for Political and Social Research (formerly ICPR), had in 2000 an annual budget of almost $7 million that was about equally divided between (a) income from grants and contracts and (b) income from tuition and annual dues paid by more than 350 institutions. Many archives have both long-term governmental support and income from user fees; others subsist on small annual grants or support from individual universities. Since 1977 the archives have been organized loosely under the International Federation of Data Organizations (IFDO), which is an associate member of the ISSC. IFDO provides for cooperation among the archives and has been of material assistance in assisting nascent archives, particularly by providing technical and organizational assistance to new archivists in developing countries. European archives are organized more closely under the Council of European Social Science Data Archives (CESSDA), which has provided a basis for cooperative planning and execution of projects, technical assistance, and training. There is no comparable North American organization, although in the 1960s there was the Council of Social Science Data Archives. The archives are largely national in funding, organization, and substantive scope; there is no single international archive of social science data to which all social and behavioral scientists can turn, nor is there as yet a complete 'union catalog.' There was discussion in the late 1950s of organizing central data archives for all of Europe, but the present nationally based system emerged in its stead.

Because archives' holdings have now accumulated to encompass decades of observation in some societies, it may be anticipated that future historians will be among the heaviest users of data archives. So also will sociologists and political scientists involved in comparative and time-series research. Urban anthropologists and humanists are finding in data archives information about values, knowledge, and mass culture that was previously unavailable to them. There is also a substantial level of usage by journalists, policy analysts, and citizens. Usage can be expected to increase substantially as broader categories of researchers realize the value of archived resources and as technological progress eases access to data.

3. *The Ethic of Data Sharing and its Benefits to Science*

Both natural and social scientists have long recognized the value of sharing data with their contemporaries and of preserving data for their successors. Records of astronomical observations have been kept for several thousand years. During the 1957 International Geophysical Year, the natural sciences established a system of World Data Centers that still exists today. Historical parish, census, and tax records, although not originally designed as scientific data collections, were nevertheless a foundation for the development of actuarial science and demography in the eighteenth century. From the nineteenth century onwards, cultural anthropologists carefully documented and preserved their observations, some of which were incorporated into the Human Relations Area Files (see *Databases, Core: Anthropology and Human Relations Area Files (HRAF)*.

Data archives have made much possible: using their resources social scientists ask diverse research questions that go well beyond those posed by the original data collectors, address new questions to old data, apply newly developed statistical techniques to data gathered long before the methods were developed, construct time series and repeated cross-sections, and perform meta-analyses. Investigators have used data archives in replication research to correct errors and omissions in the published literature and even to ferret out fraud. Archived data have been the foundation for thousands of monographs, research articles, theses, dissertations, and reports. The agencies that support research have benefited because the archives have enabled researchers to avoid needless duplication of data collection. As social surveys are relatively expensive by the modest standards of the social sciences, many social scientists have been enabled to do research

that would otherwise have been impossible. Without the archives, education at the graduate level would be seriously deficient, for it is rare that a graduate student can afford to undertake primary data collection on a large scale; for at least 40 years, analytical theses and dissertations have been based upon archived data. Undergraduate training in the social sciences has increasingly come to resemble the laboratory-oriented training of the natural sciences, with archived data serving in place of biological specimens and chemicals.

Underlying this system of data archives is the ethic of data sharing: scholars should share with other scholars a crucial part of their intellectual property, the data that they have collected. Increasingly, this ethic is codified in formal rules, such as the requirement at the US National Science Foundation that publicly funded data be made available in a public archive in due time after the end of data collection. Journals in economics, political science, and sociology often require that the data supporting an article be made publicly available. The ISSC has stated 'Full and open sharing of the full suite of datasets for all social scientists is a fundamental goal.' The International Council for Science (ICSU) recommends '… as a general policy the fundamental principle of full and open exchange of data and information for scientific and educational purposes.'

One of the several reasons for such norms is the high value that science puts upon the ability to perform independent replications of published analyses. In 1901 Sir Francis Galton (quoted in Stigler 2000, p. 657) observed:

> I have begun to think that no one ought to publish biometric results, without lodging a well arranged and well bound manuscript copy of all his data, in some place where it should be accessible, under reasonable restrictions, to those who desire to verify his work

Today much of the social and behavioral science community shares Galton's view. Indeed, when the raw data are not available, there can arise a cloud of suspicion (or worse) about a researcher's published work. Had Cyril Burt's raw data from his study of the inheritance of intelligence among separated twins not been burned by his secretary upon his death, Burt's reputation might have survived, or at least he might have escaped the most serious charge, that he knowingly fabricated his data.

4. *Concerns for Privacy and Confidentiality*

Data archives have been governed historically by a high professional standard for the protection of the privacy and confidentiality of the individual subjects of research. Today, they are also governed by both laws and restrictions imposed by data collectors. The laws arise from societal concern, over protecting the privacy and confidentiality of individuals and organizations. The restrictions arise from researchers' legitimate concerns with protecting their intellectual property.

Most data archives require a prior commitment by the user of the data to use the data solely for statistical purposes and never to seek to use the data for purposes of identifying a person or an organization. Such pledges could be electronically signed on the Internet, permitting instant access to the data. However, this easy procedure is not the practice worldwide and is unlikely to be the practice in the near future. There are indications that access to data may become more, not less, difficult, primarily because of privacy concerns that arise with particular force now that technology permits extremely rapid and broad dissemination of data. In addition, there is concern about the growing ability to combine information about individuals from several sources of information. Governments differ greatly in data protection practices and laws. The US system provides open access to microdata that has been properly made anonymous, but this is the exception rather than the rule. Some governments consider demographic, microeconomic, and macroeconomic data to be matters of national security or heritage. Public opinion polls and data collected under academic auspices are more often made available for data sharing than are official microdata. Stringent data protections, sometimes involving criminal penalties, exist in many countries. In 2000 there was an ongoing dispute between the European Union and the United States over the protection of personal data collected from European citizens over the Internet.

The most common restriction arising from intellectual property concerns is the provision of a reasonable length of time for the original data collector to have exclusive access for the data, often one year. Other restrictions can effectively block access. Some archives will not accept data deposited with onerous restrictions, while others are forced by law or custom to do so. Several kinds of restrictions may be imposed: (a) the original investigator will permit the data to be used for scientific research and teaching, but not for publication until a 'special release' is personally obtained from the original investigator; (b) the depositor will decide whether to grant permission for specific scientific research and teaching uses of the data on the basis of requests; and (c) the depositor may require prior review (and perhaps censorship) of any publications. Such conditions run counter to the underlying ethic favoring the sharing of data and work against the ready conduct of research. Further inter-archival cooperation in addressing such issues is warranted. Moreover, the archives must strive to ensure that privacy concerns are not inappropriately permitted to limit the kinds of questions that researchers ask.

5. *New Ways of Protecting Privacy and Confidentiality*

Concern over the protection of individual privacy and confidentiality, particularly of official data, has led to the emergence of secure data enclaves. In such enclaves the researcher does not deal directly with the data but instead has highly controlled access to the results of analyses. The raw data never leaves the enclave or passes through the researcher's hands. One of the oldest of these arrangements is that of the Luxembourg Income Study (LIS), which supports comparative research on the economic status of the populations of more than twenty countries. The stringent data protection laws of the Grand Duchy of Luxembourg presume that all personal data, privately or publicly collected, are sensitive. The law further requires the licensing of computer systems that will be used to process personal data. Under these circumstances many governments have agreed to provide access through LIS to data that they would never archive for public dissemination.

The US National Institute on Aging and National Science Foundation are now providing support to data enclaves in the United States, permitting a level of access to detailed Census and other data that was previously unknown. Controls are physical as well as technical and involve searching the contents of materials entering and leaving highly secure data facilities, screening of computer analyses for intentional or inadvertent disclosure of individual information, and limits on the detail of information that may be extracted from the data files. It is unclear what role data archives will play in constructing and operating secure data enclaves, as their aim has always been to allow researchers considerable flexibility in their data analyses. Nevertheless, there may be economic efficiencies to be obtained from embedding secure data enclaves in data archives.

6. *Technological Changes in Data Archives*

The information technology (see *Information Technology*) infrastructure of data archives has undergone the same remarkable transformation as was experienced recently in the worlds of business and government. When data archives began, the principal data storage medium was the punched card, also known as the Hollerith card from its development by Herman Hollerith for use in processing the 1890 US Census. This technology persisted basically unchanged for 60 years. Magnetic media (such as low-density tapes) were introduced into data processing in 1951, when the US Census Bureau installed 'the world's first electronic general purpose data processing computer,' the UNIVAC I. Tapes were in extensive use by data archives by 1965, and their ever-increasing capacity (due to higher recording density) made them practical for storing and copying large-scale data collections that punched cards could never have accommodated. By the mid-1980s the desktop computer was beginning to have the capability of running complex statistical software, with high-speed central processing units, large random access memory, and hard disks capable of handling such large files as those from the International Social Survey Program and the General Social Survey. Risking obsolescence, most archives took many years to adjust fully to the new computing environment. However, major archives now provide services directly to desktop computers through client-server computing environments. In doing so, they are often creating service relationships with individual data users that previously existed only with campus-wide data libraries. The growth of cheap computing has encouraged some data archives to provide new exploratory analytical services from their own servers, as well as the ability to extract variables or units of observation. One of the most advanced of the new efforts is the Networked Social Science Tools and Resources (NESSTAR) project, a collaboration of the United Kingdom Data Archive, the Norwegian Social Science Data Service, and the Danish Data Archive. It enables users to tabulate and visualize the data on-line and to obtain the data over the Internet, as well as to access detailed information. Perhaps equally importantly, NESSTAR can locate multiple data sources across archives and national boundaries, creating what could become a virtual global data archive. Related software developments are underway at the Center for Survey Methods, University of California, Berkeley; the Integrated Library and Survey-data Extraction Service (a project of several Dutch, German, French, and Irish institutes and the ZA); and the Virtual Data Center of Harvard University and the Massachusetts Institute of Technology. Archives' clientele has shifted from being almost exclusively experts in data analysis to including less trained users, and this kind of service is particularly beneficial to these new users.

Archives also had to respond to a second great technological revolution: the telecommunications (see cross-reference) revolution of 1990 onwards. In the era of punched cards, transmittal of data sets to users was exceedingly cumbersome and slow. Magnetic tapes relaxed those problems to a degree, but even as late as 1995, the delivery of one copy of the Public Use Microdata Samples from the US Census involved dozens of high-density tapes. The telecommunications revolution saw the virtually complete elimination of tapes as dissemination media, although they remain valuable as archival media. Internet access, coupled with CD-ROM physical media, took their place. It will soon be possible to assume that high-speed telecommunications are available in much of the world. Fiber optic and wireless technologies have ample capacity to transmit the entire contents of the Library of Congress in only a few seconds; social science data will be trivial

passengers. Thus, Converse's vision of 1964 can be realized:

> … the day when an investigator at one of the far-flung California campuses can, in an afternoon's work at a satellite of his local computer facility, learn just what data exist in the total network bearing on the hypothesis he wishes to check out, order by telecommunication either a statistical analysis of those data from an East Coast repository (or the raw data themselves if he has more extended use in mind), and have his output in time for dinner, all at minimal immediate cost (Converse 1964, p. 280).

This was the idea of the virtual archive: a number of data archives that are 'coordinated' so as to offer an investigator the ability 'to know both that they (data) exist and where they exist.' Archives still require coordination of their finding aids, which in Helen Crossley's vision of 1958 (Riley 1958) would have involved a 'common system of indexing' so that users could find resources across archives. The archives may be nearing that goal with an international project known as the Data Documentation Initiative, an effort to formulate an interarchival standard for describing data.

7. *Conclusion*

In 1944, President Franklin D. Roosevelt asked Vannevar Bush a set of questions about science after the conclusion of the war. Among those was 'With particular reference to the war of science against disease, what can be done now to organize a program for continuing, in the future, the work which has been done in medicine and related sciences?' In the response, *Science—The Endless Frontier*, Bush observed 'The striking advances in medicine during the war have been possible only because we had a large backlog of scientific data accumulated through basic research in many scientific fields in the years before the war.' Perhaps some future scientist will observe that the striking advances in the social and behavioral sciences of the first decades of the twenty-first century were similarly due to the 'large backlog of scientific data' preserved by the data archives. These relatively young sciences have yet to accumulate the centuries of observations of most natural sciences, but the archives are prepared to facilitate that accumulation. Progressively sounder sciences may be built upon this accumulation of observations.

Data Collection: Interviewing

The social science interview is a situated social interaction the purpose of which is to transfer information from one person to another. Information or data are obtained from one person, the respondent or subject, as they answer questions posed by another, the interviewer or researcher. The interview in its myriad forms is a primary data-gathering tool of social scientists, and, therefore, it is important to understand the interview process since this will affect the nature and quality of the data gathered or generated.

1. *Situating the Interview*

Interviews may be conducted in a variety of ways and in a variety of situations. Inevitably they are socially and methodologically embedded in larger contexts. Relatively little research has been done either on the impact of different social situations and settings on the conduct of interviews, or the impact of varying situations on the reliability and validity of interview results. The social setting may range from the privacy of the home to the office to the public 'person on the street,' and the social context may range from a highly private, anonymous, or confidential one-on-one interview to one involving the presence of strangers, or intimate family and friends as co-respondents. Research has shown that in contrast to the one-on-one interviewer/respondent situation, the presence of others tends to produce more socially normative responses (Lever 1981). Much more research is needed on the impact of these varying social contexts.

We must also situate interviews in the different methodologies or styles of research used by social scientists. For heuristic purposes we can identify four

major styles of research—experimental, survey, fieldwork, and nonreactive research. The interview, though found in all four methods, is particularly important in survey and field research and these may be thought of generally as representing quantitatively oriented vs. qualitatively oriented interview styles, respectively. The quantitative/qualitative distinction itself encompasses a variety of comparisons that may range from more philosophical and epistemological issues such as objective vs. subjective knowledge, to more grounded and specific issues of questionnaire construction and closed vs. open answer formats. A central distinction running throughout these comparisons is the question of the nature of control over the interview format and content.

2. *A Note on Control Over the Interview—Form and Content*

Different interview formats may be arrayed on a number of different continua but of particular significance is the question of varying degrees of control. At one extreme the interviewer exerts full control over the situation and at the other the interviewer seemingly minimizes control, relinquishing more control over the situation to the respondent. There is a zero-sum quality of control in the relationship between interviewer and respondent. The case of maximal interviewer control is exemplified by the 'forced choice' survey interview where not only the format of the question is standardized (stimulus) but the possible answers of the respondent are standardized as well (response). The interviewer ensures a constancy of routinized control in order to generate highly reliable data. Concerns over such control are often associated with surveys where the interview is used as a tool to generate standardized data from a sample of numerous units for the purposes of aggregate analysis that may be generalized to some larger population.

The other extreme, where the interviewer exercises minimal control, is seen for example in the Rogerian psychoanalytic interview. Here the respondent is 'in control' as to the content of the interview and the interviewer is trained to be 'nonreactive.' It should be noted, however, that even here the interviewer is exercising control over the format or form of the interview, and that both the forced choice survey interview and the nonreactive interview (Rogers 1945) are interaction situations far removed from the 'natural' form and content of everyday personal interaction. The field interview of participant observation is, by contrast, a situation often closer to the give and take of everyday 'normal conversation' (Seidman 1998). The respondent exercises a degree of control over both the content and the form, but the interviewer, through judicious use of probes, can often guide the interview into topic areas of interest to the researcher. This is the case of the 'focused' or 'topical' interview (Merton 1956). From these considerations one may construct a typology of control which the researcher exercises in the interview situation:

Typology of interviewer control in different styles of research interviews

	Control over content: Hi	Control over content: Low
Hi	survey questionnaire	nondirective psychoanalytic
Low	semifocused in-depth	conversational fieldwork

These different interview formats are often associated with survey vs. fieldwork but extend to a variety of methods. A multimethod strategy which emphasizes different strengths and weaknesses of different methods or styles of research nonetheless values the interview as a central data collection tool that can simultaneously provide quantitative and qualitative data, and even be used in multimethod experimental strategies. For example Schuman et al. (1985) incorporated an experimental design into a survey by having interviewers systematically vary the format of questions asked of different respondents.

3. *The Theory of the Spring*

Some have suggested that all measurement involves interaction (Babbie 1998)—interaction with the external world in some form or another in order that information about that external world may be transferred to an observer. Theories of measurement take into account a detailed exposition of the measurement process itself as constitutive of the data generated. In the prosaic act of weighing a bunch of bananas in the produce section of a grocery store, for example, one is operating on an assumption about how the spring in the scale responds to varying masses of bananas subjected to the law of gravity in moving the dial in a consistent and credible way. One operates on the assumption that some scientist or engineer has worked out in detail the physical elasticity of the steel spring at the heart of the scale's measurement process. In the interview this interaction is particularly noteworthy since it is *social* interaction—usually between two people—and the corresponding theories of measurement most applicable are theories of social interaction itself. In this section we will briefly apply four distinct theories of social interaction to the interview to see the varying perspectives they provide on this all-important data-gathering tool. The four theories of social interaction are: (a) role theory, (b) exchange theory, (c) conflict theory, and (d) symbolic interaction.

4. *Role Theory*

Role theory begins with a set of normative expectations that are presumed to define particular positions or statuses in social structure and their corresponding

roles or behaviors in interaction with others. The roles or statuses most clearly central here are those of 'interviewer' and 'respondent' themselves. How well one knows these roles, that is, knows the normative expectations for behavior associated with the respective roles, is a function of one's prior experience and knowledge gained either first hand or through vicarious observations—in the media, through cartoons, conversations, or the classroom. To be 'trained' as an interviewer is to learn a set of normative expectations about how one should interact with a respondent. The simplest norms are of ten those that are 'taken for granted' such as who asks the questions and who gives the answers. Sometimes there are widely accepted norms defining the ideal interviewer role such as—one should not reveal personal information that might thereby bias the respondent's responses (Gordon 1975). However, even these commonplace widely shared norms may come into question as there may be conflict among the different goals for the interview. For example, one goal may be to get as much revelatory information as possible vs. another goal which is to not bias the respondent's answers. The different goals of the interview (unbiased data vs. more fully revelatory data) may come into conflict and suggest different contradictory norms, for example, about how much personal information the interviewer should reveal to the respondent in the interview situation.

Role theory asserts that the norms governing interaction are there for the purpose of realizing specified goals out of the interaction. In short, normative behavior is goal oriented. The norms governing the interviewer are likewise oriented to maximizing certain qualities (or values) of the data—for example, norms that call for a common stimulus to achieve validity across respondents, or other norms that emphasize supportive interaction to produce full and complete responses.

A common application of role theory to the interview situation is a concern with bias introduced by other social statuses in a person's status set—the most obvious and frequently researched being the ascribed and highly visible social statuses of race, gender, and age. These statuses are often considered to be especially important when questions in the interview touch on topics closely related to them. Much research has been conducted on the effects of these statuses on interview outcomes precisely because they are considered to be master ascribed statuses that are both readily observed and ubiquitous in all interactions. They are often attributed even in telephone interviewing and not just in face-to-face situations.

One of the earliest findings of interviewer effects by race, dating to World War II, was that answers to questions about race relations were strongly impacted by the races of the interviewer and respondent (Hyman et al. 1954). African-Americans reported lower levels of satisfaction with race relations to African-American interviewers than to Caucasian interviewers. Caucasian respondents reported lower levels of acceptance of African-Americans to Caucasian interviewers than to African-American interviewers. These results have been demonstrated repeatedly since then in studies by Schuman et al. (1985) and Anderson et al. (1988). The latter study found that blacks interviewed by whites were much more likely to express warmth and closeness toward whites than blacks interviewed by blacks. It is important to note that more limited effects of race of interviewer and respondent have been observed on studies of other topics, unrelated to race.

Another interviewer status examined in some detail has been gender. Earlier research has generally shown that the gender of the interviewer has no effect on responses to survey questions except when the content of the questions relate to sexual behavior or gender related issues (Clark 1952, Hyman et al. 1954). Research by Kane and Macaulay (1993) found that both male and female respondents express more egalitarian gender related attitudes or greater criticism of existing gender inequalities to female interviewers. Furthermore, male respondents offer significantly different responses to male and females interviewers on questions dealing with gender inequality.

Age, as the third of the most visible ascribed status characteristics, has also been found to have only limited interviewer effects. School age subjects have shown different responses to older vs. younger interviewers for questions about peer influences (Ehrlich and Riesman 1961). Younger interviewers obtained slightly more peer-oriented and less adult-oriented answers than older interviewers. With respect to age of respondents, research has shown that telephone surveys tend to under-represent older respondents, but response distributions do not vary by telephone vs. face-to-face interviews across age categories (Herzog et al. 1983). As with race and gender, age appears to have little effect on interview responses except when the topic being covered is directly related to the status itself.

5. *Exchange Theory*

The central assumption of exchange theory is that all interaction is based on ego's attempt to realize a 'social profit' by minimizing the cost of one's own actions and maximizing the benefits from alter's actions. The operating principle is that for interaction to continue, the norm of reciprocity must be followed such that the ratio of two parties' costs to benefits should be equal. If we view the interview as an exchange, it is relatively easy to define the benefits to the researcher; they are the data provided by the respondent which are his or her costs in time and effort in answering the questions. It is often more nebulous to define what the benefits to the respondent are, that is, the costs incurred by the interviewer that directly benefit the respondent. Of

course when respondents are being directly paid by the interviewer for their time, the benefits are clear and unambiguous. Market researchers, for example, sometimes establish panels of randomly selected respondents who are paid for their time in a variety of repeated surveys. In short, they are 'professional respondents' for whom the exchange is a pure labor market transaction. Exchanges in kind may also be provided such as a lunch or dinner, a free gift, or a chance at a drawing. More often than not, however, the benefits are assumed to be some nebulous internal psychic reward that can include everything from the opportunity to vent one's opinions on a particular topic, that is, make use of a willing listener, to an increased sense of self-worth engendered by volunteering to help someone out, especially when the interviewer may have already appealed to one's 'specialness' by indicating that they have been 'selected' to participate. Altruistic appeals also redound to one's sense of self-worth as when one is solicited as a respondent to provide data that may be useful in developing new policies and programs or evaluating existing ones even if one is not seen to be a direct beneficiary of them. Even the most abstract altruistic appeal—that by responding one is 'contributing to knowledge'—may at times work as a sufficient psychic reward.

What the exchange perspective highlights is that 'time spent' by the respondent is a very real but variable cost that may influence their willingness to be interviewed in the first place, and their loquaciousness even if an interview is granted. The preciousness of 'time spent' doing an interview is differentially valued from one potential respondent to another (for example, the working mom vs. the elderly retired nursing-home resident). Such calculations are highly likely to influence differential response rates in a selective or biased way. Not only are these calculations likely to vary from one set of statuses to another, but they will likely vary even for the same individual under different circumstances and in different situations, such as time of day or day of week or season of the year, or at home, shopping, or workPol 1992).

The cost of an interview is not simply one-sided, for the interviewer's time is also a very tangible cost, and one that must be taken into consideration often in a direct monetary way as when one is hiring interviewers or relying on a survey supplier. Such costs may have direct bearing on the nature and quality of the data gathered, for they can affect the length of the interview forcing real choices in research design as to sample frame and size, or number of topics explored and questions asked.

In short, from an exchange perspective the interview is a cost/benefit transaction. The calculus of these varying costs to the interviewer/researcher must be weighed against the value of the data to be generated. In the design of surveys, for example, a distinction is often made between open-ended vs. closed-ended questions, and the former generally prove to be more difficult and more expensive to code and analyze than those from closed-ended questions. However, Geer (1991) found in an experiment that the open-ended comments are very effective in measuring the important concerns or 'salient' issues of respondents. In short, it appears to be cost considerations as much as validity issues that have led to the dominance of forced choice questions in survey research.

Costs and benefits of the interview also form a part of the calculus of the ethical considerations involving human subjects. Costs to the respondent slide over into a variety of 'risks' that may result from the disclosure of certain data and the loss of privacy. Anonymity or confidentiality may be required to forestall those costs. The idea behind 'informed' consent is that this calculus should be made by the subject/respondent based on a full disclosure of risks and benefits. Research in which there are substantial risks can only be justified by substantial benefits that outweigh these costs, and above all it is up to the respondent to make this determination.

We should be aware that the utilities (value) of a respondent's cost/benefits may differ from those of the researcher and one is confronted with incomensurability which may work to the advantage of the researcher. For example, an elderly retired single respondent may have a surplus of free time which is of low cost to give in answering a lengthy questionnaire, while to the highly trained interviewer this time is a valuable costly commodity in the research budget. Such incommensurability may at times work to the detriment of the interviewer when the inability to reach a common understanding of the relative value of information or time leads to an unwillingness to participate in what is considered to be a 'worthless' activity. (We note that this is one of the points of the symbolic interactionist perspective outlined below which involves negotiating not only a common value but a common understanding of the meaning as well as the value of various social goods.)

6. *Power Theory*

The power or conflict perspective directly addresses the insight that much social interaction—and also the interview—involves differences in power among the parties. To be sure, power or conflict theory may be closely linked to either role theory (as when, for example, one talks about the differences in power that are present between the status of a male and a female in interaction) and also to exchange theory (as when the costs to participating in the interview are different between the interviewer and the respondent, or the benefits that one can provide to the other are different and one or the other party uses those differences in resources to extract what they want from the other). What the power or conflict perspective stresses is the

reality that interviewer and respondent often have different degrees of power relative to one another and these may influence the nature and quality of the data generated in the interview.

Let us first address situations in which the interviewer has more power. We will use power in its broadest meaning to encompass the most subtle uses of prestige to the blatant uses of physical coercion. The latter is rare if ever present but the former is quite ubiquitous. The imprimatur of an individual's title 'Doctor' or 'Professor,' or an institution's stature 'X University,' or 'Y Agency' are often used to impress potential respondents as to the importance of the research and the desirability of their participating. In the actual conduct of the interview itself power may be reflected in who makes the effort to initiate the contact or who travels to whom to conduct the interview. Being on one's home turf would seem to imply more power and control over the situation. A notable exception is the case in which elites may avoid being interviewed in certain situations (coming to their homes) in order to maintain a heightened degree of privacy. Researchers have sometimes strategically relied on the interviewer shifting out of the role of interviewer to becoming an observer and recording the presence or absence of such things as a piano, types of pictures and paintings hung on walls, and the use of curtains or drapes (Laumann and House 1970). This is an example of combining methods in a multimethod strategy (Brewer and Hunter 1990) to provide validity checks surrounding lifestyle and status and class variables.

At times respondents may sense a threat from the interview situation that reflects a potential power differential between them and their interviewers. Potential threats may apply to divulging information concerning content areas that include socially undesirable and even illegal behaviors and could lead to not reporting or under-reporting various forms of deviance and even criminal behavior ranging from drug use to official 'cheating' (Bradburn et al. 1979). Implicit threat could also lead to over-reporting socially desirable behavior such as voting or charitable giving. There is some limited evidence that interviewer characteristics are related to threat. Respondents are willing to report socially undesirable behavior such as drug use to interviewers who are perceived to be more like themselves (Johnson et al. 2000).

The most widely used procedure to reduce threat is to eliminate the interviewer entirely or as far as possible from the data gathering process. In some cases this means group administration of the interview in a public or quasipubic setting but where responses are private, such as a school classroom setting. Even if the interviewer is present, it is possible that the threatening questions may be self-administered. Maximum privacy is obtained when the threatening questions are on a computer and the respondent reads questions from a screen. The respondent enters the answers directly into the computer and the interviewer is completely unaware of what answers are given (Tourangeau and Smith 1996). It must be recognized that the use of self-administered methods reduces but does not eliminate respondent misreporting due to the power differentials in the interview situation and the potential threat of disclosure. It is precisely why the use and assurance of anonymity or confidentiality are not only ethical considerations but themselves may have a direct and positive impact on the validity of data generated through the interview.

Power is implicit in the very asymmetry of who asks questions and who answers them. The benefit is seen to be asymmetrical as the powerful ask questions of, glean information from, and acquire data about the less powerful. Much more rarely does information flow in the reverse direction—from the powerful to the powerless. Knowledge is power and its differential distribution is a means of obtaining and maintaining that power (Hunter 1993).

Interviewing of elites is a situation in which the respondent often has more power than the interviewer. Such control may be reflected first in limiting the ability to gain access to begin with and continue through the interview situation with control over the content, format, recording, and even the use of interview data (Thomas 1993). Although interviewers in their comportment should, of course, show respect to all respondents, an added degree of deference might be shown to those having more power or higher status than the interviewer. This deference could easily affect the likelihood of the interviewer's continuing to probe in finer and finer detail into the lives of the respondents, thereby limiting the quality and depth of the data.

The power differential enters as well into ethical considerations of the interview, and this is why interviews must be voluntary, since the counter case involving any form of coercion, no matter how mild, may be deemed unethical. For example, if a welfare recipient is being interviewed for research purposes, they might agree to participate in the interview if it is closely linked to the intake interview used to determine welfare elgibility; or, a person in a public setting may agree to be interviewed out of a sense of peer pressure (e.g., students in a classroom setting). It is imperative that researchers be fully cognizant of and sensitive to the power relations involved in the interview as these may not only affect the quality of the data but reflect larger social processes of which the interview itself is a microcosm.

7. *Symbolic Interaction*

The interview situation is not one which is necessarily clearly defined and unambiguous, especially on the part of respondents. Therefore, one of the key activities of the good interviewer is to negotiate with the respondent in defining the appropriate behaviors and

what can be expected in the interview situation. Drawing on the symbolic interactionist framework (Goffman 1959), the interview may be considered to be a situation in need of mutual definition through the interaction of the interviewer and respondent. At a minimal level is the idea that the interviewer is supposed to ask questions and the respondent is to give answers. But the fine nuances of this somewhat 'artificial' interaction are a negotiated reality in which the interviewer has the task of 'educating' the respondent into the appropriate behavior. For example, a too loquacious respondent might be interrupted in the course of an answer and asked to respond more simply—'strongly agree, agree, neutral, disagree, or strongly disagree.'

The negotiated definition of the situation draws on the past experiences of both interviewer and respondent. The idea of interviewer training focuses on behaviors used to aid in an appropriate definition of the situation such as what to say to gain access, how to present self for gaining agreement to participate, how to develop and maintain rapport and how to terminate an interview, and of course, how to avoid biasing respondents (Billiet and Loosveldt 1988). Some respondents may be familiar with the interview situation from having participated in them previously, while others may have been exposed to the situation vicariously through the media. Some may in fact be 'professional respondents,' that is, those paid to participate in ongoing panel studies in which they have been more thoroughly trained or educated into the respondent's role.

Expectations of the interviewer about the interview process have also been found to influence the nature of the respondents' participation. Some interviewer expectations are formed before the interviewer conducts any interviews, for example, expectations about how difficult or threatening certain questions may be to respondents; while other expectations may develop in the course of an interview as the interviewer begins to form a picture of the respondent through their prior responses, and yet other expectations may emerge as the interviewer completes multiple interviews and begins to form a patterned set of expectations for emerging 'types' of respondents. For example, interviewers who expected that questions about threatening behavior would be easy to ask received higher rates of responding than interviewers who thought the questions would be difficult to ask (Bradburn et al. 1979). It would appear that interviewer behavior in some way reflects expectations and that behavior calls forth different responses on the part of subjects.

Ambiguity in social interaction is a key problematic in the symbolic interactionist framework. Much interaction is seen to be specifically oriented to the reduction of ambiguity in an attempt to arrive at a mutually agreed upon definition of the situation. The issue of ambiguity is also significant in the interaction between interviewer and respondent. If a respondent should ask quizzically, what is meant by a question, often interviewers are simply instructed to repeat the question without further elaboration or clarification of the question so as no to differentially bias one respondent vs. another. On the other hand, if a respondent gives an answer that is limited, partial, or ambiguous, the interviewer is often instructed to 'probe' to get greater clarification. In a classic laboratory experiment, Hyman et al. (1954) demonstrated that interviewers faced with an ambiguous response coded the answer on the basis of previous answers in the questionnaire. Respondents were asked a series of questions about whether the United States should actively intervene or should isolate itself from world affairs. When the response was ambiguous, those who had previously given unambiguously interventionist answers were coded as giving an interventionist answer, while those who had previously given isolationist answers were coded as giving an isolationist answer. In this experiment interviewers were not allowed to probe the ambiguous answer for clarification.

The first phase of an interview involves negotiation in securing the willingness of the respondent to participate. By negotiating a formal 'commitment' from respondents in the form of a signed 'pledge,' to answer 'fully' and 'truthfully' has been found to increase the degree of cooperation by respondents and the completeness of their responses (Cannell et al. 1981). A further mechanism for increasing cooperation is to flexibly tailor the appeal to participate to each individual respondent rather than using a standardized approach. Such individually tailored appeals generate higher levels of cooperation and also experienced interviewers are more likely to obtain such higher rates of cooperation (Groves and Couper 1998).

8. *A Multimethod Strategy*

Interviews in their various forms and formats will continue to be a primary tool in the social scientist's toolkit for generating reliable and valid data. Direct comparisons of the interview to other tools for data generating, such as content analysis of media, or conversational analysis, the use of systematic observation of behavior, or the analysis of archives can only further the understanding of the strengths and limits of the interview in a multimethod strategy. Some but far too little research has been concerned with such comparisons. One example is Janet Lever's (1981) multimethod study of children's play. She found that interviews with kids produced more gender stereotyped responses to the nature of boy's vs. girl's play than observations of their behavior by the researcher or diaries kept by the kids themselves. Throughout the above discussion the multimethod strategy has been mentioned at various points and briefly noted in passing. Bringing the multimethod strategy to the foreground whether narrowly focused on measure-

ment or more broadly on the research process as a whole (Brewer and Hunter 1990) can only lead to a more refined use of the interview in social science research. The shape and function of the interview as a tool can more clearly be delineated as it is compared to these other tools in the same research project. The centrality and the ubiquity of the interview requires much more systematic research fully exploring the social, situational, and methodological dynamics of the interview process. Whether viewed from a post-modern perspective of a greater need for reflexivity within the social sciences or a positivist perspective of understanding the sources of bias and the need to reduce measurement error, much more research on the interview itself is needed. A few lines of inquiry and understanding have been developed as noted, but a great abyss of ignorance remains to be plumbed.

At various points throughout this discussion I refer to data being either 'gathered' or 'generated.' I fully recognize the implications of these two distinct concepts as the former privileges an older classical positivism while the latter speaks to a more agency oriented social constructionist view of science. The distinction will itself become part of our nuance discussion of the interview.

Database, Core: Linguistics and CHILDES

1. History of Data Sharing in Child Language

The Child Language Data Exchange System (CHILDES) was first formally discussed in the summer of 1983, at a meeting of the John D. and Catherine T. MacArthur Foundation funded Network on the Transition from Infancy to Childhood. The MacArthur Foundation had funded this Network, which consisted of five geographically centered nodes of activity, to promote innovative and collaborative work on the age period 1 to 3 years. Within the

network, about a dozen individuals most directly involved in the study of child language attended a working session chaired by Brian MacWhinney (then of the University of Denver) and Catherine Snow (Harvard Graduate School of Education) to plan an effort to promote collaboration by sharing child language transcript data. The level of interest expressed in that initial meeting was sufficiently high that MacWhinney subsequently submitted a proposal to the MacArthur Foundation for funding to establish the data-sharing system.

Child language transcript sharing had been initiated by Roger Brown in the first large longitudinal study of child language in the audiorecording era. Brown's study of children he called Adam, Eve, and Sarah, which established procedures and basic measures that would become standard in the field, had been started in the early 1960s at Harvard. In addition to weekly or biweekly recordings of the children at home, Brown established a seminar of graduate students and colleagues who met to study the newly produced transcripts. To facilitate this effort, the Brown corpus was produced using mimeograph masters. One full (though somewhat faded) set of these transcript copies was still available in 1983, and indeed formed one of the first large corpora entered into the CHILDES system (after being photocopied to improve contrast, scanned, then checked and reformatted extensively to match the CHILDES-prescribed format).

The history of Brown's generous sharing of the Adam, Eve, and Sarah transcripts was crucial to the ready acceptance of the CHILDES proposal by the field of child linguists as well, since it had demonstrated the potential for multiple waves of analysis of a wide variety of phenomena using a single corpus. Dozens of articles and books had been published using the Brown corpus, focusing on topics as diverse as the development of reference to the past (Cromer 1968), maternal teaching techniques (Moerk 1977), conversations about kinship (Goldfield and Snow 1992), and semantic and morphological development (Brown himself 1973). These provided evidence of the utility, efficiency, and feasibility of data sharing.

2. *Design of CHILDES*

Initial funding from MacArthur provided for the development of the basic components of the system. These included a set of transcription conventions, known collectively as CHAT (Codes for the Human Analysis of Transcripts) (see MacWhinney 2000a). The CHAT guidelines were imposed *ex post facto* on important corpora, such as Brown's, that had already been collected, but of course much more importantly came to define one set of expectations for how transcripts should be produced. While considerable discussion concerning the advantages of various transcript formats occurred during the 1980s, and while limitations of the CHAT system for representing conversational features easily are clear, nonetheless the convergence by a large portion of the child language community on a single transcription system had important advantages. The CHAT system was elaborated with suggested procedures for phonetic, morphosyntactic, speech act, and error coding. It is important to note, though, that the vast majority of the CHAT guidelines are merely advisory; a transcript that conforms in certain minimal ways to the CHAT format (minCHAT) can be incorporated into the CHILDES database and analyzed using the CLAN programs. The major inducement for adopting CHAT guidelines was that transcripts that conformed to CHAT were susceptible to analysis by CLAN (Child Language Analysis) programs, a set of programs designed to automate various analytic procedures that had become standard in the field of child language. The earliest CLAN programs produced automatic counts of morphemes, words, utterances, and turns, to generate measures such as Mean Length of Utterance, Mean Length of Turn, and Type-token Ratio. Key word searches were also made possible (KWAL), as were procedures for Boolean searches (Combo). Subsequent expansions added programs to select certain marked portions of the transcript for further analysis (GEM), to calculate contingencies between codes in adjacent turns (Keymap), to code transcript lines for overlap with preceding lines (CHIP), and so forth. In addition, morphological tagging programs have been made available for a number of languages. These various programs are designed in most cases to analyze many files simultaneously and to generate output in a format directly usable by statistical analysis programs.

The CHILDES database is a constantly growing electronic repository of transcript data (see MacWhinney 2000b). Corpora included in the database as of January 2000 represented the acquisition of 26 languages as well as a number of language pairs and triplets (in the Bilingual section). In addition, data from children with language disorders and from narrative elicitation procedures are included in separate sections. Access to files in the database is free to anyone who agrees to use the data in accordance with the guidelines specified, primarily to cite the sources and the CHILDES manual appropriately. Files can be accessed through the website or via CD-ROMs distributed in conjunction with the CHILDES manuals.

3. *Funding History*

After the initial period of funding from the MacArthur Foundation, support for the CHILDES system was provided to Brian MacWhinney and Catherine Snow through the National Institute of Child Health and Human Development (NICHD) and subsequently to MacWhinney from NICHD and the National Science Foundation Linguistics Program.

4. Beyond CHILDES

Since the CHILDES enterprise was designed to promote collection, use, sharing, and analysis of transcript data, it did not optimally accommodate the inclusion of audio or video data. As researchers increasingly turn to such data, and seek methods for annotating, analyzing, and sharing them, a successor system to CHILDES called TalkBank has been founded, with support from the National Science Foundation. TalkBank (*http://www.talkbank.org/*) will provide standards, tools, and support for creating, searching, and publishing video-based language interactions using electronic networks.

Databases, Core: Anthropology and Human Relations Area Files (HRAF)

The Human Relations Area Files (HRAF) databases are collections of full texts that have been complexly indexed to facilitate worldwide comparative studies of human behavior, society, and culture. The motivating idea was to foster comparative research on humans in all their variety so that social scientists could discover which principles and explanations are universally valid, not culture bound. What may be true for one society may not be true for others. The organization known as HRAF was founded to provide data for the cross-cultural testing of hypotheses. The HRAF databases are also useful to researchers, instructors, and students who wish to compare the ethnography and archaeology of particular cultures, traditions, and regions.

Human Relations Area Files, Inc. is the nonprofit membership organization that produces and distributes the HRAF databases. It also organizes and edits encyclopedias and sponsors the quarterly journal *Cross-Cultural Research: The Journal of Comparative Social Science*. HRAF is an international consortium, with nearly 200 member institutions in 25 countries; it is also a financially autonomous research agency of Yale University, where it was founded in 1949. The HRAF databases, which are produced now only in electronic format, are accessible only through HRAF member institutions. The first and larger database is the HRAF *Collection of Ethnography*, which has been building in paper, microfiche, and electronic format for more than 50 years. It includes indexed full-text materials on more than 365 cultures around the world. The electronic version, *eHRAF: Ethnography*, has been building since 1994 and as of 2000 covers a geographically stratified random sample of 60 cultures, plus assorted ethnic groups. The second database is the HRAF *Collection of Archaeology*, which has been building solely in electronic format since 1999. As of 2000, *eHRAF: Archaeology* includes indexed full-text materials on 20 randomly selected major archaeological traditions, and many more subtraditions and sites, around the world.

1. Uniqueness of the HRAF Databases

The task of finding particular kinds of information in the HRAF databases is facilitated by the unique indexing system that HRAF has developed and refined since the 1950s. The HRAF indexing system (the *Outline of Cultural Materials* or OCM) helps the user find information on more than 750 subjects, covering just about anything that might be described in an ethnographic or archaeological document. Searching by one of the categories goes right to the relevant passages, rather than to a pointer to the passages. The efficiency of the indexing derives from the fact that a particular subject may not be identified unambiguously in a source, and even if there is an index (if the source is a book) there may not be an entry for the kind of information sought. And, of course, articles and dissertations do not usually have indexes at all. So a particular kind of information may not be easy to find just by looking through a document, because different documents may refer to what is being looked for in different ways, using different words or under different headings. The HRAF indexing system solves the problem of searching for data in texts that do not employ a standard vocabulary. Using the OCM index categories enables one to find just about any kind of information in seconds, because the categories bring the user to the relevant passages even if the original authors used different words and headings. There is

also an index to the OCM categories; this large list of words points to the relevant OCM categories for finding particular kinds of information.

For example, if you were interested in assessing the degree to which various cultures depend on stored foods, you might search the index to the OCM, where you would find 'Preservation, of food, 251.' This directs you to OCM category 251, 'Preservation and Storage of Food.' Searching the database by OCM 251 will bring you to all of the passages that describe dried, smoked, pickled, refrigerated, frozen, canned, and irradiated foods, and whatever other ways are used to store or preserve food. The analysts at HRAF, who have read through and indexed every page of every text that goes into the HRAF files, have made it possible to find the relevant information, even when you cannot anticipate the particular words (including untranslated native words) the original authors may have used.

The HRAF collections are indexed by subject, but not coded by variable. This is deliberate. There are many kinds of potential comparisons and therefore no one system of coding would suit every user. The OCM indexing system gets the user directly to the text passages that are relevant, whatever the comparative purpose and whatever the information of interest. The eHRAF collections can also be searched by the words that actually appear in the texts. In eHRAF, word searches (including proximity and Boolean searches) are possible with or without specifying OCM subject categories. In any search, the context of the hits is never lost. The sections before and after the retrieved paragraphs can be read easily.

The OCM indexing system is a flexible search tool. The user is always in control, because it is the user who decides exactly how to search and exactly how to deal with the information retrieved. Although it is frequently believed that the qualitative nature of most ethnographic description precludes coding and quantitative measurement, this is not true. It is not difficult, after a little practice, to develop at least ordinal scales that can allow the user to code the words of ethnography into measures, and once done it is easy to use available software to test hypotheses, and compare, combine, and model rival hypotheses. Needless to say, the indexed texts in HRAF are also amenable to qualitative cross-cultural comparisons.

Installment 48 of the HRAF *Collection of Ethnography* (available in 2000) is the sixth annual installment of *eHRAF: Ethnography*. It completes the updating and electronic conversion of the 60-culture Probability Sample Files (PSF) that were built in the 1970s and 1980s. Raoul Naroll planned how the PSF was built. Quality control considerations were used to select a large list of eligible preindustrial and peasant cultures, and then one culture from each of 60 culture areas was randomly selected. Thus, researchers can use the PSF to test hypotheses on a fairly large and unbiased sample of the world's preindustrial and peasant cultures. Correlations and other statistical results are likely to be trustworthy and functional, not due to duplications in the sample because of random diffusion or common ancestry. From 2000 on, *eHRAF: Ethnography* will grow by adding other randomly selected cases (as well as additional contemporary ethnic groups in the USA and elsewhere). The cases will be drawn by simple random sampling from a new sampling frame for the world that has been constructed by HRAF with the aid of external experts on the various regions. The new sampling frame will eventually include national cultures as well as immigrant cultures all over the world.

The results of comparative studies using ethnography may suggest causality, but social scientists would like to go beyond cross-sectional validation. In particular, they would like to see if temporal sequences validate causal theories. A cross-cultural study using ethnography may be able to discover predictors, but it cannot by itself confirm the temporal sequence assumed in a causal theory. Of course, one could try to measure the ethnographic cases for two different points in time. Measuring each case twice may be increasingly possible as the ethnographic record grows and includes more and more cultures that have been re-studied. But for many questions about cultural evolution, the ethnographic (or ethnohistorical) record is unlikely to provide the required time-series data. This dilemma particularly applies to the classical questions about human cultural evolution. How could we test answers to questions about the emergence of agriculture, the rise of social inequality and the first cities, and the origins of the state?

Now there is a research tool that allows us to escape this dilemma. Investigators of cultural evolution can use *eHRAF: Archaeology* to study and model causal sequences. Cross-cultural (comparative ethnographic) studies can provide archaeological indicators of cultural and other (e.g., physical and social environmental) features. Using those indicators, researchers can test many causal ideas about the major events in cultural evolution on the time-series data in the archaeological record. Thus, the data in *eHRAF: Archaeology* can allow researchers to determine whether evolutionary patterns in one region are repeated in others, and to determine whether the presumed causal factors in one region are also important, and antecedent, in other world regions. Comparative ethnography can tell us about cultural statics, what is associated with what in the ethnographic record. Comparative archaeology can tell us about cultural dynamics, what precedes what in the archaeological record.

Compared with conventional library research, retrieval of information from the electronic (eHRAF) collections is like a day compared to a month. When comparing or measuring things about a number of cultures, it is not necessary to devote weeks to building bibliographies for each of your sample cases; to search

for the relevant books and articles and dissertations, which might have to be obtained by interlibrary loan; to read every page of a source that does not have an index to find all of the passages with relevant information; or to bring any sources back to the library. If the researcher's institution belongs to the HRAF consortium, and the culture(s) of interest are included in eHRAF, it is easy to access the text passages that contain the particular kinds of information sought.

2. HRAF and Useful Social Science

The usefulness of social science, the possibility of social engineering or applying knowledge to solve social problems, depends on the validity of social science findings and theories. If a finding or theory is not true under some circumstances, it would be foolhardy to think of applying it to real world situations and problems. Hence there seems to be a growing awareness that social science risks being useless, even parochial, if it does not apply to many times and places. The more a finding or theory fits the world generally, the better for understanding and application. Culture really does make a difference. People in different times and places behave differently at least partly because they have different repertoires of customary ideas and practices. So cultural variation cannot be ignored by social scientists if they want to discover principles and relationships that are universal, which is probably why introductory textbooks in psychology, sociology, political science, and international relations, as well as in anthropology, are now paying more attention to the results of cross-cultural research.

In addition, more and more types of investigators—not just anthropologists—are now doing worldwide cross-cultural research. Psychologists, political scientists, sociologists, and evolutionary biologists now use HRAF to test universal hypotheses. And researchers are now using HRAF to test hypotheses about many new kinds of human variable—not just the standard cultural observables such as where couples typically live after they marry or how people get their food. The new kinds of variable include: psychological variables that are measured from projective materials such as folklore; population (biological) variables that are measured using information found in ethnographic and archaeological reports; and comparative archaeological variables that are measured on the basis of ethnographic data that have archaeological correlations. There are many kinds of information in the ethnographic and archaeological records that can be used to construct and test theories.

Of all the research strategies for testing theory, worldwide cross-cultural research is the strategy that most ensures the generalizability of results. To be sure, not all theories can be tested on data from the ethnographic and archaeological records. If something is not widely described, we cannot measure it. Hence social scientists also have to do comparative field studies, cross-historical and cross-national studies, and simulations to test theory. But if we want to maximize the effectiveness of applied social science, we need to try to see if our theories survive worldwide cross-cultural tests. Why should theories that have been cross-culturally tested and supported be more likely to suggest effective solutions to social problems? The logic of statistical inference tells us. A theory that seems to fit a particular region or a sample of nations may not be true for human societies generally. There is no way to tell without cross-cultural testing. A study in one or a few countries may suggest an explanation or application. So may computer simulations and modeling. But ultimately we have to see if the data in the real world are consistent with what we hypothesize. This is why HRAF was invented in the first place, to enable scientists to test their ideas about cultural variation and evolution on a worldwide basis. How often could an explanation that is not universally valid suggest an application or solution that is generally effective?

Databases, Core: Anthropology and Museums

Anthropological museum collections—including both ethnographic and archaeological materials—comprise an essential source of data for understanding the dynamic uses of material culture, relationships be-

tween human behavior and its material correlates, long-term social processes, and documentation of culture history and change. With the rapid spread of western material culture and technologies, museum holdings have assumed a greater prominence for studies of non-Western lifeways and cultural forms. Because museum holdings provide both longitudinal data documenting cultural change through time, and also synchronic data showing diversity over space, their potential for social scientific research is considerable. This article provides a brief overview of collections and related core databases in anthropology museums, and their associated problems and prospects.

Many different kinds of museums hold significant anthropological collections; these institutions vary in terms of mission, authority, constituency, and level of physical resources available to support collections care and access. Most museum collections were acquired over a considerable period of time, informed by a variety of interests and acquisition strategies, and supported by varying levels of documentation and conservation. While this diversity insures that collections are not limited by the scope of collecting strategies or research interests dominating a particular discipline or period, it also results in a multiplicity of cataloguing systems, descriptive terms, and standards for care, access, and interpretation.

No reliable estimate of the scale of the resource exists, but available collections are enormous, and growing in both volume and significance. The Ethnography Department of the British Museum holds some 350,000 catalogued items from around the world, Vienna's Museum für Völkerkunde 200,000 items, and the National Museum of Ethnography (Minpaku) in Japan some 221,000 items. The scale of archaeological collections is still larger; the US Department of the Interior alone lists more than 30 million items (most archaeological) in its holdings, while the Canadian Museum of Civilization maintains some 300,000 ethnological artifacts and more than 2.5 million archaeological specimens. Extensive resources focus on specific areas of the world. Often these are based on the museum's immediate region, such as Mesa Verde National Park's two million specimens, most from the Wetherill Mesa Archaeological Project, or the Bishop Museum's 1.2 million Pacific and Hawaiian cultural objects. In other cases, however, regionally focused collections are half a world away. Brussels' Koninklijk Museum voor Midden-Afrika, for example, holds some quarter million artifacts from central Africa, along with extensive archival material.

As yet, no single, standard nomenclature has been adopted for categorizing anthropological resources. Most museums categorize collections by ethnic origin (e.g., organized by Murdock's *Ethnographic Atlas* or *Outline of World Cultures*), material type, intended function (e.g., the Chenhall nomenclature for man-made objects), geographic locality (e.g., by site) or time period (e.g., Bartoloni's *Dizionari Terminologici de Materiali dell'eta del Bronzo finale e della prima eta del Ferro* of 1980). Historically, the ability of scholars to access collection information was constrained by cataloguing terminology and data model limitations intrinsic to each approach. Consider the Chenhall nomenclature, for example. A search for the functional set 'skiing gear' would require searches within 'sports equipment' (snow skis), 'clothing—footwear' (ski boots), 'LTE land transportation equipment—human powered' (ski poles), and 'personal gear' (goggles) (Welsh 1990). Conversion of catalogues to electronic form has in some cases lessened these limitations, but introduced new concerns regarding hierarchical terminologies, data integrity, and long-term structural implications and limitations of extant data models. In many areas of the world core catalogue data remains incomplete or inaccessible; AFRICOM, for instance, is an international initiative to document collections in African museums using a common set of descriptors, and to develop common resources and standards for collection documentation and care (see also Roberts 1990).

The availability of information regarding collections varies greatly. Collections at the Chaco National Historical Park are listed in both a published guide and a computerized database available to researchers listing some 65,000 catalogue records, representing more than 1.5 million catalogued items. Such levels of access are, however, the exception rather than the rule. Lacking meaningful data standards, access to collections usually requires either consultation with appropriate staff at each institution, or use of published guides to available collections, often specific to individual collections within a single institution. A draft standard for anthropological metadata (data about data, or a meaningful data model standardizing usage across data sets) has been proposed through the Council for the Preservation of Anthropological Records (CoPAR), although databases using this standard are still in preparation.

Online resources and other emerging technologies promise some relief. Australian resources, for example, are summarized by online directories of museum collections (Australian Museums Online), archives (both the Directory of Archives in Australia and the Register of Australian Archives and Manuscripts, supplemented by the item-level database ANGAM II), and social science resources relating to Asia and the Pacific (through the efforts of the Australian National University's Research School for Social Sciences and Research School for Asia and the Pacific). In practice, however, these are very broad summaries that provide limited access to key collections data.

Other kinds of anthropological resources also support social science research. Many national or regional authorities maintain records documenting the number, location, age, and character of archaeological

sites within their jurisdiction. Denmark's Kulturhistoriske Centralregister, for instance, has recorded more than 140,000 archaeological sites, with a schedule of 55,000 monuments (not including buildings), and the US State of New Mexico currently lists more than 100,000 recorded sites in its automated ARMS site registration system. In addition, international organizations promote the documentation of sites and monuments (e.g., ICOMOS, the International Council on Monuments and Sites), and have taken first steps toward establishing metadata standards.

Field records, notes, and papers—valuable for adding research value to the catalogued physical objects and related documentation held by museums—are often not preserved as archives, although there are exceptions. The British Library holds the papers of many leading anthropologists, including Edward B. Tylor and James G. Frazer (although the extent of anthropological holdings is not recorded separately), the American Philosophical Society maintains some 6.25 million manuscripts with strengths in American ethnology and linguistics, including the papers of Franz Boas, and the National Anthropological Archives, part of the Smithsonian Institution, preserve more than 7,000 linear feet of primary documents, papers, and photographs for anthropological studies worldwide. Many universities maintain archives of the papers of past faculty, although these are rarely integrated or cross-referenced with museum holdings. Photographs and other images have become increasingly valuable in many areas of research. The Musee de l'Homme in Paris holds more than 400,000 black and white photographs, Leiden's Rijksmuseum voor Volkenkunde 300,000 images and related materials, Harvard's Peabody Museum some 500,000 images of all kinds, and the Smithsonian's Human Studies Film Archives more than eight million feet of film and video. Surveys of extant resources (e.g., Dutton 1999), while valuable, are limited in scope and uneven in geographic coverage.

While cultural resource management (CRM) represents one of the most rapidly growing sources of anthropological collections, most data generated from heritage management or CRM studies are reported in unpublished, limited-distribution 'gray literature' reports to regulatory agencies. Attempts are being made currently to standardize access to this literature; the National Archaeological Database (NADB), for example, provides bibliographic control for some quarter-million archaeological planning and management documents for projects within the US, and the Archaeology Data Service provides access to a series of related databases on archaeology and cultural resources in the British Isles, including the 48,000 records in the Excavation Index for England. Metadata standards for the online publishing of field reports are in development (e.g., UCLA's Digital Imprint initiative), but databases based on these standards are not yet available.

For the most part, the value of anthropological collections depends on the preservation of the objects themselves and the associated contextual data necessary to place them within a particular social, temporal, and spatial setting. Threats to the long-term integrity of anthropological collections include unaddressed conservation needs, changing legal and ethical requirements affecting access and treatment, security issues, data integrity concerns, and the cost (in terms of both infrastructure and cash outlay) of adequately housing and curating ethnological and archaeological materials.

The management and conservation of anthropological collections is difficult, however, as many items of human material culture are complex artifacts including different materials requiring different kinds of conservation regimes for their long-term stability. Physical threats to collections come from a number of sources, including: (a) inherent vice (including flaws and instability due to the material from which artifacts were made); (b) improper storage materials or conditions, including acidic or otherwise reactive storage media and off-gassing of cabinets; (c) improper environmental controls, particularly for humidity and temperature; (d) physical damage through neglect, vandalism, and effects of warfare or natural disaster; (e) theft; and (g) damage from pests. In some cases addressing these concerns leads to new ones. In the past some collections were treated with arsenic and other toxins to protect them against pests; these treatments now represent a threat to both the collections and to museum staff and visitors.

In other cases consolidants or other conservation treatments used to stabilize items may now interfere with more recent chemical studies of artifacts and residues. In addition, inadequate curation or collections management practices can result in loss of artifacts, associated documentation, or the link between the two. A more immediate threat to collections care is the relatively high cost in money, space, and time required to adequately curate and conserve anthropological materials, leading to the selective curation of collections and disposal of 'less valuable' objects or sets of objects.

Stewardship remains the most important responsibility of professional museum staff; this is particularly true in anthropology, where curators hold collections in trust, not only for posterity, but in many cases for specific descendant or ethnically-related groups as well. In addition to physical care and monitoring by conservators, many items require other kinds of maintenance mandated by native peoples. The Museum of Indian Arts and Culture in Santa Fe, New Mexico does not fully seal cases containing kachina dolls, because they 'need to breathe,' and the storage facilities for the National Museum of the American Indian, part of the Smithsonian Institution, include a smoking room for the blessing of material objects by native groups. In some cases the intent of the makers

is at odds with physical conservation concerns; the celebrated Zuni War Gods—that were created to be exposed to the elements and gradually decay—are one example.

Many kinds of collection remain subject to claims for repatriation, either by countries of origin or ethnic groups. Several countries have laws requiring repatriation of certain classes of material to native or aboriginal groups. Whether this represents a long-term threat to the integrity of these collections, or merely a long-overdue reallocation of rights and control to native peoples, remains to be seen.

Despite these concerns, there are many encouraging trends in museum anthropology. These include innovative research projects harnessing old data to address new questions, increasing professionalization of the field, recruitment of native peoples to museum staffs, especially as curators, widespread recognition of the need for common metadata standards and improved access to collections information, substantive research on appropriate collections management and conservation procedures, and a growing recognition of both the value of anthropological materials as a unique and irreplaceable resource, as well as an appreciation that they are a fragile legacy requiring the highest standards of management and care.

Anthropological museum collections remain one of the most valuable and underutilized sources for social scientific and behavioral research. As one of the most important means of documenting the material remains, histories, and social trajectories of cultures both extant and extinct, anthropological museum collections represent a comparative database of unparalleled potential—and one of steadily increasing scientific and social significance.

Databases, Core: Demography and Genealogies

Genealogy, according to the Oxford English Dictionary, is defined as an account of one's descent from an ancestor or ancestors by enumeration of the intermediate persons; the investigation of family pedigrees as a department of study or knowledge; lineage, pedigree, family stock; and progeny. In this article, as indicated by its title, the term genealogy is particularly used to refer to the written record of family or lineage members and the discussion is focused on genealogical records as a data source for demographic research.

1. Genealogies

Constructing genealogies has a long history. In the early days of civilization and before written records were made, oral transmission of genealogical information already existed, although this may include only a list of names and the relationships between these people.

The invention of writing and the improvement in keeping written records allowed genealogies to be easily made and better preserved. During early history, however, they were largely compiled for royal and noble lines. Surviving genealogies concerning past ruling and upper class families can still be found in many countries. This is related to the fact that in a society of hereditary monarchy or aristocracy, genealogies were frequently used in determining one's inheritance of office or land, and in establishing a link to a superior social status.

In China, for example, compiling genealogies reached one of the high points of its development during *Wei Jin Nan Bei Chao* (220–589 AD), a period when genealogical information was widely consulted in recruiting government officials and arranging marriages. In addition to the genealogical activities of the individual family or lineage, government genealogical bureaus were set up and responsible for preserving, editing lineage registers, and constructing multilineage genealogies (Pan 1929).

This upper class practice, nonetheless, had a trickle-down effect. The number of genealogies compiled by or for ordinary families or lineages increased during the last few centuries. This was particularly the case in the society where lineage organizations formed an important social institution and the worship of

ancestors was widely encouraged, and in the new frontier where a large number of migrants settled.

The twentieth century has witnessed a continuous increase in genealogical activities throughout the world. Many genealogical societies have been formed and numerous genealogies have been compiled. Recent development in computer technology has brought about a further surge in the study of family history. This has led to an explosion in the number of genealogical databases accessible through the Internet, with some of them providing biographical information for millions of people. Genealogies have increasingly become an important data source for scientific research.

2. Genealogies and Some Other Demographic Data Sources

Like population and vital registers, census and survey data, and church records, genealogies can also provide valuable information for demographic research. However, they differ from the above data sources considerably.

People recorded in genealogies normally have common ancestry and are connected to each other through family relationships, while those included in other data sources are generally not. This gives genealogies a unique character and makes them extremely useful in the study of population genetics, heterogeneity, and social mobility of the family. Indeed, genealogies have already been used by historians, demographers, epidemiologists, and geneticists. Their endeavor has produced some very interesting results (Hollingsworth 1964, Knodel 1988, Bean 1990, Liu 1992).

Population and vital registers and census and survey data are often obtained from a precisely defined territory. Church records also tend to be concerned with religious groups of a certain area, whereas people recorded in genealogies are less, or not at all, restricted by their residence. Accordingly, genealogies can reveal geographic movements of family members and migration patterns. However, people listed in the genealogies may not be the total population of any given region.

Most available parish records, census and survey data, and vital registrations were produced in the last few centuries, and can be used only for the study of recent demographic history. Population counts of earlier periods have been found in some countries, but their reliability is difficult to assess because of the lack of original enumeration and other relevant materials. Furthermore, aggregate figures of this kind do not permit any detailed examination of past demographic regimes. In this context, genealogies covering a very long period may contain extremely useful information for the study of early population history. Some Chinese genealogies, for instance, consist of family or lineage members of more than 80 generations living over a period of more than 2000 years. This gives scholars a rare opportunity to investigate long-term demographic patterns.

Noticeable differences also exist in the process of producing these records. Vital registrations and parish registers are often made soon after certain demographic events take place. Censuses and surveys are also conducted within a well-defined time frame. In collecting these data, rigid rules and instructions are usually followed. In contrast, constructing genealogies can be a series of activities undertaken by people of many generations under different circumstances over a long period. The rules of compiling genealogies or the implementation of such rules may change from time to time. The interval between the time when a certain social demographic event actually happens and when it is recorded by the genealogy compiler can be very long. These characteristics, though to some extent are shared by retrospective and longitudinal surveys, make the genealogies different from other demographic data sources.

3. Descendant Genealogies and Ascendant Genealogies

Conceptually, genealogies can be constructed in two ways. Accordingly, they can be divided into descendant genealogies and ascendant genealogies (Oeppen 1999).

Constructing a descendant genealogy starts with a person (or a group of people) who may be regarded as the founder (or founders) of the family or lineage. Then, descendants of this person (or these people), if there are any, are added into the genealogy generation by generation. Compilation of the genealogy is not conditional on the availability and the survivorship of the members of the descendant generation. When genealogies are produced in this downward manner, the process of accumulating records can be very long. The genealogy may form a primary data source that is derived from direct enumeration.

In contrast, compiling an ascendant genealogy starts with a person of a later generation (the person is often the genealogy compiler). Then his or her ancestors are traced retrospectively generation by generation and entered into the genealogy. When genealogies are constructed in this upward fashion, the recorded family and lineage are those having survived to that later generation. The entries of the ancestors are most likely to be the outcome of genealogical research based on searching church records, vital registrations, or other data sources. The genealogies, therefore, can be viewed as secondary data sources.

Although such a distinction can be made and an ascendant genealogy can be easily identified, descendant genealogies recorded completely in a downward manner are less common. The majority of the

genealogies are more likely to be a combination of the two. Whoever starts to construct a family or lineage genealogy, naturally, would like to trace his or her own family history and accordingly compiles an ascendant genealogy. Thereafter, the compiler may add his or her children, grandchildren, and descendants of the earliest identifiable family or lineage member into the record. Alternatively, the work may be continued by the future generation. As a result, the genealogy will increasingly become a descendant one.

The above distinction is important nevertheless. The extent to which a genealogy is retrospectively constructed and to which the lateral kin are included has a significant impact on whether the recorded family or lineage members can be regarded as an unbiased sample of the general population or a clearly defined substratum of the population.

4. *Genealogies as a Data Source for Demographic Research*

Genealogies have been used in population studies for many years, but they remain a data source of both promise and disappointment. On the one hand, the long time coverage of the record, the richness of the information, and the great potential of integrating genealogical, demographic, and genetic studies make the genealogy a unique research source. On the other hand, biases and under-registration problems make it difficult to use conventional demographic techniques to analyze genealogical data (Willigan and Lynch 1982, Telford et al. 1983, Fogel 1993).

Whether a genealogy is biased for demographic research is affected by the manner of its construction. Descendant genealogies are generally free from the impact of selection. But ascendant genealogies, especially those including only family members of the direct line or the succession, tend to exhibit lower mortality and higher fertility than the general population (Oeppen 1999). This arises from the fact that an ascendant genealogy requires each generation to have at least one member surviving to adulthood and producing at least one child. It is biased towards demographically successful families or lineages, which have a better than average chance of extending their lines to the future generation. For the same reason, nuptiality can also be biased if marriage serves as a precondition for childbearing. Thus, although an ascendant genealogy can document the demographic history of a family well, it may not be an unbiased data source for investigating of the demographic experience of the entire population.

Another difficulty in using genealogies for demographic research comes from under-registration. The amount of information contained in genealogies varies considerably. Some genealogies provide detailed records for all family or lineage members, while others show only names and the relationships between the recorded people. Even within the same genealogy, the completeness of the record can be very different.

One reason leading to such under-registration problems is that genealogies, regardless of the manner of their compilation, are usually constructed for purposes other than demographic research. Because of that, certain family members, for example, children who died young, female descendants who were often regarded as less important to the family in a patrilineal society, and those who brought disgrace to the family, are frequently excluded from the genealogies (Zhao 1994).

In addition to the deliberate omission of certain family members, genealogies suffer from distortions of other kinds. Genealogical records accumulated over a long period could have been affected by changes in the rules and practice of compiling genealogies. While some records may have been damaged or lost, other items and information could have been edited out. When records are gathered from other sources, they could inherit the biases existing in these data and the nominal linkage process is also subject to error. Producing complete and accurate genealogies, therefore, becomes even more difficult.

Knowing where biases come from and what have been or may have been missing is the first step in estimating their impact and using incomplete data. Although these deficiencies create great difficulties in using genealogical data for demographic research, they do not make it impossible. Indeed, considerable progress has been made in recent years. Demographic analysis of genealogical records has and will continue to provide further insights into past demographic process and contemporary population changes.

Databases, Core: Demography and Registers

Population registers are continuous records of the residential context, socioeconomic status, and demographic behavior of the members of a community. They exist for a number of European and Asian locations from as early as the seventeenth century. Though some countries still maintain them, because of confidentiality issues only data from before the middle of the twentieth century appear to be available for public use. Population registers combine features of most of the other sources commonly used in studies of population, family, and society in the past. In contrast with many of these sources, they are especially well suited to the application of event history techniques to study the determinants of demographic and other outcomes. Though they have some limitations, they are nevertheless an important source for the study of social demography, family history, and social mobility in the past.

1. Contents

Population registers, also referred to as household registers, are longitudinal, nominative records of the households and individuals that make up a community. They follow households through time, recording changes in their composition and other characteristics. Registers also follow individuals, recording when and by what means they enter and exit the household or community. They usually record their relationship to the head of the household. In most cases, they measure socioeconomic status at either the household or individual level. European registers, for example, often record the occupation of the household head. In a rural setting they may provide details on landholding, including type of tenancy.

Authorities originally established population registers for diverse reasons. In China, where systematic population registration has perhaps the longest history, successive governments used registers for centuries as tools for administration. In parts of Europe during the nineteenth century, civil authorities also introduced them as a tool for administration. In Japan, the state originally established a nationwide system of local population registers in the late seventeenth century to prevent the spread of Christianity, though of course it quickly found the registers useful for more routine tasks (Cornell and Hayami 1986). In some places, religious authorities maintained population registers. For example, parish priests in Sweden during the nineteenth century compiled catechetical registers every year that listed households and their members to identify candidates for literacy exams. In Italy, churches compiled *status animarum* every year that listed all of the households in the parish along with their members (Manfredini 1996).

Even though registers had diverse origins and purposes, they are broadly similar in terms of format. Almost all of them are organized in one of two ways. Many of the systems established in continental Europe during the nineteenth century were continuous. A register was created that contained a separate entry for each household in a community. Once created, often from the results of a census, it was updated on a continual basis. As events such as births, marriages, occupation changes, migrations, and deaths occurred in a household, annotations were made to its entry. Once annotations accumulated to the point where further updates were impractical, the register was retired and a new one was created containing only current information.

In the remaining locations, mainly in Asia but also in some parts of Europe, households in a community were recorded in census-like fashion at fixed intervals, most commonly annually, but in some cases less frequently. Copying information from the previous register and updating it produced a new register. Entries commonly included additional annotations indicating whether or not demographic events such as birth, migration, marriage, or death had occurred since the last update. Since households and their members were usually listed in roughly the same order in successive updates, entries for individuals and households are easily linked from one register to the next. Demographic events and other changes in status not specifically annotated can be inferred by comparison of entries in successive registers.

Historical studies that use population registers often supplement them with data from other sources. In most European settings, it is possible to use names, ages, and other identifying information to link to baptism, marriage, and burial records in parish registers and obtain additional information about the timing of demographic events. In some locations, links can be made to vital registration data, including birth, death, and marriage certificates. Such linkage can turn up vital events that the population registers missed. In some cases, it is also possible to link to entries in land

and tax registers, yielding richer detail on socioeconomic status.

Population registers combine features of the sources most commonly used to study population and society in the past. Like both genealogies and family reconstitutions from parish registers, population registers are inherently longitudinal. They follow individuals through time, allowing for the reconstruction of life histories. Like parish registers, population registers usually provide a nearly complete record of the vital events occurring in a community. Like censuses, registers describe entire communities, identifying who was present and at risk of experiencing a demographic event or other transition. They also provide details on household characteristics, including composition, socioeconomic status, and members' relationships to each other.

Registers accordingly overcome many of these sources' limitations and allow for new avenues of inquiry. In contrast with genealogies, they cover entire communities, not selected families. Whereas genealogies are usually retrospective, compiled based on the recollections of family members, registers are prospective. In contrast with family reconstitutions and genealogies, registers describe residential context, not just kinship. Finally, unlike most censuses, registers allow for the direct calculation of demographic and other rates because they are longitudinal, and include information on demographic events and other transitions.

2. *Applications*

Registers may be used to examine the determinants of marriage, childbearing, remarriage, and death because like panel studies they allow use of event-history techniques (see *Event History Analysis: Applications*) that measure the effects of time-varying community, household, and individual characteristics on the chances of these and other events (Alter 1988). Registers can also be used to illuminate the links between economic conditions and demographic behavior. Whereas previous studies have been limited to correlating prices and aggregate vital rates at the regional or national level, application of combined time-series (see *Time Series: General*) and event-history techniques to register data allows comparison of the price responses of different subgroups of the population, yielding new insights underlying causal mechanisms (Bengtsson 1993).

Register data lend themselves to the study of household dynamics. Classic studies of historical households were limited to examinations of size and structure by their reliance on cross-sectional census data. Registers, by contrast, follow changes in the structure and composition of households over time. Indeed, one of the first applications of register data was in a study of household dynamics in mid-nineteenth century Belgium (Van de Walle 1976). From register data it is possible to compute the rates at which households with different characteristics dissolve, disappear, or change structure.

Topics such as migration, adoption, and occupational mobility that are difficult or impossible to study with traditional sources for historical demography and family history are ideal for analysis with registers. Studies of adoption have been carried out in several Asian locations, including Japan and Taiwan (Wolf and Huang 1980). As for migration, studies have been carried out in both Europe and Asia. They usually focus on the determinants of the timing of family migration and, especially in Europe, individual home-leaving. Examination of occupational mobility is also possible because through record linkage, it is straightforward to examine the relationship of children's statuses as adults to the statuses of their parents, grandparents, and other kin.

3. *Limitations*

Like all other historical sources, registers suffer from limitations. One of the most common is that they may fail to record short-term movements into and out of a community. While such problems are most common in systems that record the population at fixed intervals because they miss those who enter and exit again between updates, they also exist in continuous registration systems. In-migrants may never be recorded if they are only in the community for a few weeks or months because they leave or die soon after arriving. Similarly, those who reside in the area but who migrate out for a very short time may never be identified as having been away. Infants who die soon after they are born may leave no record of their existence, leading to underestimates of the level of mortality in the first months of life.

Where service migration was part of the life cycle, older adolescents and young adults are often poorly covered from the time they leave their parent's household to the time they marry and form one of their own. If they remain in the area, they are difficult to link to their natal households. Therefore, it is hard to tell whether young persons who leave their natal households are still in the area but living and working in other households, or have left the area completely. For this reason, studies in settings where service migration was common often exclude from consideration older teenagers and young adults who have never married.

Demographic and other events that occur to residents when they are outside the community are unlikely to be recorded. This is not a serious problem, however, because population registers also allow individuals who have left the community to be excluded from consideration starting from the time of their departure. The caveat remains that if the individuals who left the community were selected on some characteristic that affected the chances of the event of

interest, rates computed for those who remained might differ from the ones that would be observed if no one left.

4. Availability

In Asia, historical registers for China, Korea, and Japan are available. Within China, there are at least three types of registers. In Taiwan province, Japanese colonial authorities established a registration system that generated data of extremely high quality from 1895 to 1945 (Wolf and Huang 1980). In northeast China from the mid-eighteenth century to the beginning of the twentieth, triennial registers recorded the residents of state farm systems in great detail (Lee and Campbell 1997). Registers from what is known as the *baojia* system exist for other parts of the country in the eighteenth and nineteenth centuries, but they appear to be of very poor quality (Skinner 1987). In Japan, there are annually updated population registers for many villages from the mid-seventeenth century to the mid-nineteenth century (Cornell and Hayami 1986). In Korea, triennial registers remarkably similar in format to the northeast Chinese ones exist.

In Europe, registers exist for parts of Belgium, Italy, The Netherlands, Sweden, and elsewhere during the eighteenth and nineteenth centuries. Belgian registers are continuous (Alter 1997), as are those from The Netherlands, where there is now an effort underway to use them to compile a nationally representative sample of individuals (Mandemakers 1994). Italian registers, consisting of annual *status animarum*, exist for a number of parishes (Manfredini 1996). In at least one Italian City, Venice, detailed data from a continuous registration system that operated during the middle of the nineteenth century also exist (Derosas 1989). In Sweden, catechetical registers exist for the nineteenth century. Some of these data have already been transcribed into databases at the Demographic Database at Umeå University.

Databases, Core: Linguistics, Online Grammars, and Dictionaries

Before discussing online dictionaries and grammars, we need to define what these are and how they are produced (and used) in their 'non-online' form. A dictionary is a reference book used (a) to look up the *meaning* of a word or a phrase, in a monolingual dictionary, or (b) to look up the *translation* of a word or phrase in another language. For example, if you want to know the meaning of the word *blockbuster*, you would consult an English dictionary; alternatively, if you want to know the translation of this word into French, you would consult an English–French dictionary. A grammar is a description of a language. For the purpose of this article we shall discuss descriptive (or reference) grammars, i.e., books that describe the grammatical system of a language: the syntax, morphology, and phonology—but much of what we shall say also applies to teaching grammars, i.e., books that are intended as learning tools.

Grammars and dictionaries have a number of things in common. They try to explicate aspects of a language (meaning of words, explanations of the structure of the language) in a written form. They also refer to other parts internally; typically, dictionaries contain

cross-references to other parts of the same book to further elaborate the meaning, or aspects of the meaning of a word or a phrase. Reference grammars typically abound in cross-references to related issues discussed elsewhere in the book.

1. *Problems with Traditional Grammars and Dictionaries*

Because of their intended use as reference tools, dictionaries and grammars must be easily accessible. In the case of dictionaries, this is not a problem. After all, they list all the words alphabetically, so users will usually be able to find what they need. But sometimes searching for what you want is a bit more involved, especially looking up the meaning of an expression. For example, if you want to know the meaning of an expression such as *pull your socks up*, do you look under *pull* or under *socks*? In dictionaries of English, the entry for *pull* is quite big, so searching there is quite a task, so you might first want to look under *socks*. But if the expression is not listed there, you need to go through the columns of text where all meanings and uses of *pull* are described.

Another problem for explanatory monolingual dictionaries is that, in many cases, a word is explained more easily by a picture. Also most dictionaries contain several pictures (indeed, there are so-called picture dictionaries, in which virtually all entries are illustrated with a picture) but pictures also take up a relatively large amount of space, so the publisher needs to be as economical as possible and strike a balance between using words and pictures to illustrate words.

Grammars rely crucially on a good table of contents and a good index. After all, reference grammars are used to look things up: they are not intended to be read from cover to cover. Finding what you want is often a challenge in a grammar: via the table of contents and the index, users search and find the topic they wish to know more about, and are typically sent to other parts of the book as well via cross-references.

A practical point about both dictionaries and grammars is that, apart from giving the meanings of words and explanations about the structure of a language, they also try to give an idea how those words and sentences sound. Many dictionaries include, apart from the meaning or the translation of words, indications of how those words sound, and how they should be pronounced. Although there is a standard symbolic system for representing sounds (the alphabet devised by the International Phonetic Association (IPA)), few dictionaries actually use that, and instead use a system of the publisher's (or the editor's) invention. This is a strain on users, as they need to familiarize themselves with the symbols used; and as most dictionaries use different symbols to represent the same sounds, the situation can become quite confusing.

Grammars have this problem as well. Most descriptive grammars contain an account of the sound system of the described language—not only an inventory of the vowels and consonants, but also how these are combined. Academic grammars are usually standardized to use the IPA alphabet, but even such descriptions can be quite daunting.

Another practical problem that publishers of dictionaries and grammars face is that languages change: new words enter a language, others become obsolete; and words may change their meaning. Apart from this, errors need to be corrected and changing insights incorporated. This means that new editions of a dictionary need to be produced periodically. All this also applies to grammars. It is not only the words of a language that change, but the structure of every language—its syntax, morphology, and phonology—changes as well. And these changes, too, necessitate new editions of grammars.

Most of the problems outlined above can be overcome by online dictionaries and grammars, to which we now turn.

2. *Online Grammars and Dictionaries*

By 'online' we mean the World Wide Web (or 'the web,' for short), as this is the best-known online medium that most people will be familiar with. ('Online' can also be taken to include CD-ROM, but increasingly, publications on CD-ROM are identical to those on the web.) Documents can be presented on the web in two forms, as HTML (hypertext markup language) files, or as PDF (portable document format) files. The differences between these two can be ignored here, as it is the similarities that are important: both allow the same facilities, namely, searching, following built-in links, and playing sounds and displaying images. These three facilities are dealt with below. In the rest of this section, dictionaries and grammars will be discussed separately: dictionaries in Sect. 2.1, and grammars in Sect. 2.2.

2.1 *Online Dictionaries*

The main activity of a dictionary-user is searching for a word or an expression, and often, following up cross-references in the entries found, or looking up the meaning of a word in a description. For example, in the Concise Oxford Dictionary (COD), one of the explanations of the meaning of the entry *leg* is 'obeisance made by drawing back one leg and bending another'. If you do not know what *obeisance* means, you have to look up this word elsewhere in the dictionary. (Professional dictionary-users, such as

translators, benefit greatly from online dictionaries for precisely this reason.)

In an online dictionary, searching an entry is straightforward by using the search facilities offered by the browser, and following up references or looking up unknown words in an explanation (such as *obeisance* in the example given above) is speedy.

Online dictionaries shine in their multimedia capabilities. For example, dictionaries typically contain a phonetic representation that indicates how a word should be pronounced. (This is especially the case in English dictionaries as pronunciation is so unpredictable in English.) For example, the COD contains the entry **ăntėnā′tal**, and from the introduction to the dictionary we learn that ă sounds like the 'a' in 'fat'; ė like the 'i' in 'pill'; and ā like the 'a' in 'fate' (the prime symbol, ′, indicates stress). The circularity here, naturally, is that such explanations assume that the user knows how to pronounce 'fat', 'pill', and 'fate'. In an online dictionary, it is possible to link a sound file to each entry, such that when users click on that entry, they will hear the word pronounced. Such a system is exploited in the Interactive Introduction to Linguistics (http://www.hueber-vfd.de). In this CD-ROM-based system, the user can click on a word to hear how it is pronounced.

Especially when there are small differences in pronunciation, explanations in words can be tedious and ineffectual. A language such as English, which has little correspondence between spelling and pronunciation, can benefit from 'spoken' explanations. But other languages can profit from modern technologies as well. For example, Chinese is a language with lexical tone, which means that words with the same spelling can mean up to four totally different things, depending on the tone used. Tone is usually indicated using special symbols, but can be exemplified much better with the use of sound.

Another way in which the multimedia capabilities of the web can be exploited is in its use of pictures. We mentioned earlier that words in a language are often illustrated more easily with a picture than with words, but that publishers have to strike a balance between the use of pictures and words, mainly for reasons of space. With online dictionaries, however, space is hardly an issue. A publisher, then, can decide to add as many pictures as necessary.

2.2 Online Grammars

As is the case with dictionaries, online grammars are used for reference purposes, and therefore need to be easily accessible. We mentioned that traditional grammars depend heavily on the table of contents and the index. But even when the contents and the index are of good quality, finding what you want to know involves a lot of searching. Online grammars, meanwhile, are searchable very easily, thanks to the basic search facilities offered by all browsers. Online grammars, like traditional grammars, typically contain a table of contents and an index, but these are hyperlinked with the body of the text, so that users can jump immediately from the table of contents to the relevant chapter or section. Similarly, when the index entries are hyperlinked to the relevant occurrences in the text, these can be accessed easily through the hyperlinks. And finally, cross-references in the text can be looked up more easily.

Academic descriptive grammars (but non-academic ones as well) often contain a chapter on the phonology (the sound system) of the language, and one or more texts. The audio capabilities of the web make it possible to have the sounds reproduced through the computer's sound system, and can include the spoken version of the texts included in the grammar.

2.3 Other Advantages

Other advantages of online reference works over their 'paper' versions are of a more practical nature. As was mentioned above, languages change all the time, with new words entering the language and others becoming obsolete. With printed dictionaries, this means that new editions need to be produced, which is time-consuming and expensive: not only for the producer, but also for the user. Conversely, online dictionaries are relatively easy to update and maintain.

The relative ease of production is especially beneficial for grammars, which usually take a long time to write. With online grammars, material can be published earlier to make it available to the academic world. In the course of time, more material can be added. Naturally, this only applies to academic grammars, which can be of scientific importance even when not completely finished.

2.4 Disadvantages

Are there disadvantages to online dictionaries and grammars? There are, but these can be overcome. The first issue is quality. As most traditional grammars and dictionaries are published by reputable publishers, there is in most cases a guaranteed degree of editorial control and therefore a degree of quality. On the web, however, this is not necessarily the case: anyone can publish anything on the web, so if the material found here is not endorsed by a reputable publisher, users must be aware of the possible limited reliability.

Second, documents on the web can be updated literally every minute. We mentioned this earlier as an advantage, which in many ways it is, but there is a downside as well. The ease with which web documents

can be updated also makes them less stable. This is a problem especially for academic purposes, where everything that is cited in a publication is accounted for by a full reference (year of publication, edition, page numbers, etc.) so that other people can verify the correctness of cited material and cited claims. With texts on the web being subject to change, it becomes difficult to check the accuracy of a publication.

2.5 Where to Find Online Dictionaries and-Grammars

A good example of an online grammar can be found at http://doma.bicos.de/elevine/YuGrHTML/home.html, a grammar of Yukaghir (a language spoken in Russia) which is being developed on the World Wide Web. An interesting example of an online dictionary project can be found at http://coombs.anu.edu.au/WWWVLPages/AborigPages/LANG/GAMDICT/GAMDICT.HTM, a dictionary of Gamilaraay, a language spoken in Australia. The biggest online dictionary is the Oxford English Dictionary, at http://www.oed.com/public/publications/online.htm. And a useful start is http://www.facstaff.bucknell.edu/rbeard/index.html, which is an index of grammars and dictionaries available on the web.

Databases, Core: Political Science and Political Behavior

1. Data and Databases

Data is information on properties of units of analysis. These units can be individuals (micro), organizations like business firms or political parties (meso) or nations (macro), they can be geographical divisions like cities, counties or states, or they can even be relations like elite networks. Often, units of analysis and units of observation are the same. However, sometimes units of observation, like all family members in a household, can be aggregated if the household is the unit of analysis.

Data in political science come about through a variety of means. They can be process-produced in an administrative environment like macro- or microcensuses for the purposes of societal self-observation and informed policy formation, they are created by scientists according to (more or less) methodologically sophisticated approaches of questioning individuals or other social units, or they are derived from inobtrusive techniques like content analyses of printed or video material as well as group observations. Information on a particular collection of units of observation or analysis placed in time and space is called a dataset. Correspondingly, databases are general or focused collections of datasets, as held, e.g., by data archives.

2. The Beginnings

In his history of the discipline of political science, Almond (1996) has pointed out that in the context of the professionalization of the field in the twentieth century, already in the first decades the empirical study of political phenomena had blossomed, most noteworthy in the Chicago School which is associated with such eminent scholars like Charles E. Merriam, Harold Gosnell, and Harold D. Lasswell. In this article it is emphasized, though, that a major breakthrough in the theory, methodology, and practice of empirical political science research was accomplished after the end of the Second World War. During the war, many of the later leading figures in the social sciences were employed in a variety of US government or related public and private organizations with the task to find answers to questions of critical military and civilian importance in the war context. One case in point is the series of seminal studies of *The American Soldier* directed by Samuel A. Stouffer.

The above war context in the long haul also led to the foundation of the Institute for Social Research (ISR) at the University of Michigan in Ann Arbor by scholars like Angus Campbell, George Katona, Rensis Likert, and Robert Kahn. In 1952, Campbell and Kahn published a small book on the US presidential election of 1948, and this is worth mentioning on various accounts. First, the first election study by the Michigan Survey Research Center (SRC) was one of the very few if not the only one which got it right in that its data showed Truman's win over Dewey. It was innovative in that it was national in scope, used a fairly sophisticated method for selecting respondents, applied a pre–post panel design and operated with a majority of standardized, but also some open-ended questions.

This study is singled out not only because it very well reflects the beginning theoretical and methodological innovations in research on political behavior, but also because it paved the way for one of the most demanding ventures in database construction: the American National Election Studies (NES).

Warren E. Miller (1994, pp. 249–50), in his recapitulation of the NES history, points out that since the outcome of the 1948 presidential election resulted in 'a public embarrassment to the national community of public opinion pollsters' (because of their falsely picking Dewey as the winner), the successful Michigan study gained a remarkable public and scholarly visibility, resulting in a grant to the Social Science Research Council (SSRC) which in turn commissioned the Survey Research Center to also conduct a study of the 1952 presidential election. With the intellectual success of this study (Campbell et al. 1954), the ground was prepared for a continuous series of Michigan-based election studies which finally were transferred in 1977 into the format of the national political science research resource of the American National Election Studies (Miller 1994, pp. 260–2) funded by the National Science Foundation.

The intellectual pull of the Michigan school of electoral research was felt not the least by European political scientists who especially in the 1950s and 1960s came to Ann Arbor to learn about the study of elections and about advanced methods in social research. It is because of this connection that in a fair number of European countries national election studies have by now become institutionalized (for a detailed account of this see Thomassen 1994). What makes this development so pertinent for the topic of this article is that the Michigan–European interaction helped to prepare the ground for the most important development in creating political science databases: the emergence of academic data archives.

3. *Data Archives—A Core Infrastructure for Political Science*

There is agreement in the literature that the oldest general-purpose survey data archive in the world is the Roper Center for Public Opinion Research (Bisco 1966, pp. 96–7). It was founded in 1946 at Williams College and is now located at the University of Connecticut in Storrs. While in many ways it has served as an example for other data archives founded later, the impact of the Inter-University Consortium for Political and Social Research (ICPSR; initially ICPR) at the ISR on the development of data archives in Europe has been more pronounced because it could build on an identity of substantive research interests between American and European scholars (see *Data Archives: International*).

In his recollection of how the ICPR came about, Miller (1989, pp. 152–3) mentions the intersection of two important strands of thought regarding the improvement of political research. The first was the positive impact on the development of at least parts of political science in the US from the Michigan election studies and, more concretely, from two summer seminars held at the SRC in 1954 and 1958 which were sponsored by the SSRC Political Behavior Committee.

'The attraction of the courses was the ability to analyze the Survey Research Center election surveys with state-of-the-art counter-sorters which were not available at most other campuses.' (Weisberg 1987, p. 282)

Second, in the interaction between the SRC and Stein Rokkan, one of the great European social scientists and comparativists, the SRC took up ideas from a Rokkan report to the Ford Foundation in 1957 proposing the establishment of survey data archives particularly to stimulate comparative research (Rokkan 1964, p. 1966).

The establishment of the ICPR in 1962 was preceded in time by that of the Zentralarchiv für Empirische Sozialforschung (ZA) at the University of Cologne, Germany. It was founded in 1960 by Guenther Schmoelders, a professor of public finance, and later directed by Erwin K. Scheuch, a major figure in international cooperation in the social sciences and in comparative research. Both ICPR and ZA were pioneers in academic data archiving and cooperated closely from their early days on. This innovation owed a lot also to the network of the Committee on Political Sociology of the International Political Science Association (IPSA) and of the International Sociological Association (ISA) which brought together scholars like Campbell, Philip E. Converse, Juan Linz, Seymour Martin Lipset, Richard L. Merritt, and Miller from the American and Hans Daalder, Mattei Dogan, S. N. Eisenstadt, Arend Lijphart, Giovanni Sartori, Scheuch, Otto Stammer, and Jerzy J. Wiatr from the European side.

The emergence of academic social science data archives reflects very much the state of empirical political science in the 1950s and 1960s. First, the methodology of social research and particularly survey research had been advanced to a point where it was regarded as a reliable, fruitful way of collecting information on a broad variety of social and political topics found interesting by the research community, but also by social and political elites as well as by the mass media (for example, see Lazarsfeld and Rosenberg 1955, Hyman 1955). However, the time period for which survey studies were then available was still quite short, and therefore one-shot studies, usually of a cross-sectional and not a longitudinal nature, dominated the field. In addition, high-quality surveys were expensive, funding opportunities were limited, and therefore access of the academic community to such information was difficult.

The resulting scarcity of data plus the growing insight that primary investigators were not capable of

completely exhausting the analytical potential of a given dataset paved the road for considerations to make data which were often paid for by public money and therefore in principle a collective property available also to other than the primary investigators after those had had their first good shot at data analysis and publication.

A further consideration is also relevant. Often, data collected by primary researchers under a specific conceptual scheme can be reanalyzed under a vastly different scheme and may lead to new insights. Thus, the logic of secondary analysis (Hyman 1972) of existing data was an important addition to the arsenal of empirical political and social research and triggered an increasing demand for such data.

In sum, data archives were the answer to many concerns resulting from the data needs of empirical political science. Thus, it is little wonder that already in 1966 Ralph L. Bisco (1966, p. 93) could speak 'of a growing movement within the social sciences: the establishment of repositories of social science data.'

4. *The Historiographic Dimension of Longitudinal Data*

In one of his many insightful contributions to the social sciences, Paul F. Lazarsfeld [1972 (1964)] put himself into the role of a 1984 historian and asked about the obligations a 1950 pollster has vis-à-vis this historian. One can carry this torch much farther now in observing that especially data from survey research have opened up a new dimension in historic analysis along the lines of social history. With the advent of representative sample surveys of national population or special subgroups in society the potential for the *ex post* understanding of microphenomena of an attitudinal as well as of a behavioral nature has been vastly enhanced, and examples of excellent historical analysis based on findings from longitudinal sample surveys are increasing in number (see for instance the analysis by Schildt in 1995 on the modernization process in postwar West Germany).

But there is much more to be gained analytically from data which reach back into the past, and this is even more true when the researcher's interest is in more than one country. In the late 1980s, after heated controversies especially in Europe about the future of democratic government, many political scientists felt that the time had come to take stock of the sociopolitical changes in the 1960–1990 period in the nations of Western Europe which could be observed among mass publics. Such a stocktaking took place between 1989 and 1994 through the Beliefs in Government project funded by the European Science Foundation (ESF) and directed by Max Kaase and Kenneth Newton (Kaase and Newton 1995; Abramson and Inglehart 1998). Clearly, this project would not have been possible without systematic recourse to existing databases held in European data archives. Still, at the same time a number of shortcomings and weaknesses in the availability, equivalence (van Deth 1998), and quality of the data showed when becoming longitudinal and at the same time comparative in perspective.

Pitfalls in comparative research can be more easily avoided when the data are collected through primary research, like in the ongoing (1999) project on the Comparative Study of Electoral Systems (CSES) running in 40–50 countries of the world, and in the planned European Social Survey (ESS). This is a Europe-wide extension of the concept of General Social Surveys as developed first by James A. Davis of the National Opinion Research Center (NORC) at the University of Chicago in 1972 and since then conducted almost annually in the US and also, though less frequently, in some European countries. An additional advantage of both surveys will be that they will be amended by systematic macroinformation on political and social arrangements (like the respective electoral laws) in the participating nations, thereby permitting micro–macro (multilevel) analyses.

5. *Core Databases in Social Sciences*

By the turn of the twentieth century, the initial data scarcity in the social sciences has been replaced by a situation of data richness. There are many reasons for this. With economic growth especially in the OECD countries since the end of the Second World War, the number and/or size of educational institutions has risen dramatically with larger student populations (measured by shares in birth cohorts), and with this also the number of researchers both within and outside of institutions of higher learning. This development has, of course, embraced the social sciences too, and with more research money around the number of academically driven data gathering research projects has increased substantially. Also, a large number of empirical social science studies is regularly conducted on behalf of government agencies, the media, and for private business, often with advice from the academic community. Therefore, quite a few of these data also find their way into academia, and this means mostly through data archives. In addition, new survey research methods, and here especially the rise in telephone surveys, has made data production less expensive than in face-to-face interviewing studies. This data richness, however, does not automatically justify the conclusion that these data also satisfy most of the information needs in political science.

A specification of which core databases in political science presently exist has to be taken according to explicit criteria. For the purposes of this article, the main selected criteria are emphasis on microdata stemming from representative sample surveys, longitudinality and international scope; aggregate political

science databases like the one for the World Handbook of Political and Social Indicators (Taylor and Jodice 1983) and the Comparative Party Manifestoes Project (Budge et al. 1987, Klingemann et al. 1994) will be covered in a separate article in this Encyclopedia. In addition, one has to keep in mind that longitudinal national or comparative multipurpose surveys like the General Social Survey (GSS), the International Social Survey Programme (ISSP), and the biannual Eurobarometer surveys in the member states of the European Union (EU) as well as the Latinobarometro for South America regularly contain a variable mix of political and nonpolitical items, thereby preventing an unambiguous classification as political science surveys. They will, though, be included in the following listing, with the first two entries bearing more emphasis on a national than on an international focus. (See Databases Core: for several additional entries covering other disciplines.)

5.1 The National Election Studies

For political scientists the most interesting data come from the various national election studies, in particular from the American NES. They aim at the heart of the democratic political process—elections—and are longitudinal in nature. The opportunity to look at the electoral process comparatively is provided by these data to the extent that there are enough at least functionally equivalent questions asked across nations and different institutional and political settings to make an international comparison meaningful at all (for an inventory of election studies in nine European nations see Mochmann et al. 1998).

5.2 The General Social Surveys (GSS) and Other Surveys

As the analyses by Putnam (1998) on the decline of social capital in the United States show, the data from the GSSs can be and are put to an excellent longitudinal use by political scientists. In addition, there are many national datasets, cross-sectional and/or longitudinal, which are relevant for political scientists, but cannot be specified in detail here because of their number and their numerous national specialities.

Moving on from a more national to a distinctly comparative perspective, the following databases are of core interest to political scientists:

5.3 The Eurobarometers, the New Democracies Barometer, and the Latinobarometros

The Eurobarometers are representative sample surveys with usually about 1000 respondents conducted twice a year since 1974 in all countries of the European Union. As the number of EU member countries has grown over the years, so has the number of nations covered by the Eurobarometer. While many of the questions are concerned with special needs of the European Commission, the data contain enough continuous information on politics to make them very attractive for political scientists (for example, see Kaase and Newton 1995). Also, since the demise of communism, similar surveys have been regularly conducted in Central and Eastern Europe (Eurobarometer East). All Eurobarometer data are accessible through data archives like ICPSR and ZA.

For research on the transition from communist to democratic rule, it is important to know that in addition to the Eurobarometer East, comparable longitudinal representative sample surveys for 11 Central and East European countries have also been conducted in the context of the New Democracies Barometer organized on behalf of the Austrian Paul F. Lazarsfeld Society. Between 1991 and 1998 five such surveys were fielded (Rose et al. 1998). An extension to 20 countries with surveys in 2000 and 2002 is envisaged. Presently, the data for waves one, two, and three (1991, 1992, 1993–94) and wave five (spring 1998) are freely available through the Austrian data archive Wiener Institut für Sozialwissenschaftliche Dokumentation und Methodik (WISDOM). Furthermore, the Centre for the Study of Public Policy at the University of Strathclyde under the direction of Richard Rose has set up a New Russia Barometer since 1992 with seven surveys until the summer of 1998 and a New Baltic Barometer in the three Baltic states since 1993, with three surveys as of the summer of 1999. For both, a continuation is planned. The data are not yet freely accessible (for other pertinent data on the transition topic see also Sect. 5.5).

A Latinobarometer has been modeled after the Eurobarometer and has been conducted annually since 1995 in countries of Central and Latin America (1995: eight countries; since 1996: 17 countries). The Latinobarometro is anchored at the Centró de Estudios de la Realidad Contemporánea in Santiago, Chile, and directed by Marta Lagos (Lagos 1997). The data of this survey as of now (autumn 1999) are not freely available through an academic data archive.

5.4 The International Social Survey Programme (ISSP)

ISSP originated in 1982 from an American–German collaboration in devoting a small part of their GSSs to a common set of questions. It then developed to a four-nation participation in 1985–1986 and by 1998 had grown to 31 participating nations in all parts of the world. ISSP is often attached to a GSS, uses different data collection modes, and in each year

focuses on a particular topic which is replicated from time to time. For example, in the ISSP surveys in 1985–1986, 1990–1991, and 1996/1997/1998, the topic was role of government. These data are, like the Eurobarometers, accessible through data archives.

5.5 The European/World Values Surveys

In 1981, the European Values System Study Group started with surveys in 10 West European societies; this survey was replicated soon in 14 other countries outside of Europe to become the World Values Survey. Its second wave of surveys was coordinated by Ronald Inglehart between 1989 and 1993, the third wave ran between 1995 and 1998 in 53 countries, and the fourth wave of surveys has presently (1999) begun. Not all of the data at the time of writing is accessible; in the long run this study is, however, one of the most interesting for comparatively working political scientists because of its potential for macro–micro analyses (for a major comparative analysis of these data see Inglehart 1997).

Databases, Core: Sociology

A database consists of one or more data sets, such as a sequence of decennial censuses. Databases reach core status for several reasons. One is sheer frequency of use. In the USA, the General Social Survey (GSS), a series of cross-sectional surveys beginning in 1972, is used by more than 200,000 students a year and by hundreds of researchers. The data are freely available to anyone via the Internet (http://www.icpsr.umich.edu/GSS99/, (which gets more than two million hits a year) and are well documented and easily accessible. Other databases

become influential because they yield fundamental results and serve as a research model. The two 'Occupational Change in a Generation' surveys in the US produced benchmark estimates of social mobility and spawned similar mobility surveys around the world (Blau and Duncan 1967, Featherman and Hauser 1978). Still other databases are influential because they provide basic data on social structure (e.g., income shares) which then play into other research. For example, many countries have an annual sociodemographic survey that yields income and employment statistics, which in turn drive research on poverty. To an increasing degree, the most influential databases are those which are based on systematic data collection over both space and time. Repeated data collection provides a fundamental tool for attacking some of sociology's defining problems such as macro–micro linkages and the evolution of social structure. They also provide a framework in which one-time data collections can be understood. This article will argue that over time the core databases in sociology will be those which permit historical and cross-cultural comparisons.

1. *The Impact of Data on the Discipline*

Sociologists have argued for many years about the extent to which the physical sciences, particularly physics and chemistry, provide a model for doing sociology (Lieberson 1985). An argument can be made that geology is perhaps a better model. In that field, the scientific revolution known as the theory of plate tectonics resulted in large part from the study of the sedimentary record. Using deep cores and other tools, geologists have been able to reconstruct the physical history of the earth, along with its climate and biology, going back many millions of years. At the beginning, the data were collected in a somewhat a-theoretical way but as the picture became inductively clear, more focused data collection resulted (Van Andel 1985). This kind of interplay between data collection and theory development characterizes other fields as well. In biology, Darwin's theoretical achievements were based on years of data collection and the theory of natural selection drew heavily on the geological record.

In sociology, the data accumulated over many centuries of human activity are somewhat analogous. While the time scale differs by several orders of magnitude, one can think of accumulated data from human activity in the form of government, religious and commercial records, and more recently from surveys, as the sediments that form the basis for social science research. As these records have become computerized the volume of data, and the ease with which it can be accessed, have increased dramatically. Of course, researchers have used surviving hard-copy data for a long time. Historical demographers have used parish registries to study family formation and economic historians have used commercial and government records to study price levels and other economic phenomena. But until very recently the availability of data was, to a large extent, accidental, based on nature's whim and historical chance. Coverage of topic, region, and time period was erratic and inconsistent. But in the last 50 years of the twentieth century, the information revolution has been laying the basis for a databased social science that is far broader and systematic than has been the case in the past.

There are several aspects of the revolution. First, much primary data are now being created directly in electronic form, thus increasing accessibility. Second, vast amounts of data can be stored at very low cost. Third, with the emergence of the Internet, data can be moved about the world almost at will. Finally, software for accessing the data and analyzing it is becoming easier to use, although much remains to be done. The revolution dates back to the early 1960s. Although there are certainly examples of machine-readable data collected before then, the flood began with the availability of second-generation computers to process data and machine readable tapes on which to store and ship it. Since then, a torrent of data has become available and the breadth and depth of the river is increasing daily. Two processes are going simultaneously. First, hard-copy data from old records and texts are being retrieved and converted to electronic form. For example, in the USA very large samples of decennial census records from 1850 to 1950 have been drawn from the original manuscript data and are available to be used in conjunction with contemporaneously created sample files from 1960 onward. More focused data conversion is also going on. To cite just one example from dozens available, the study of slavery in North America is being revolutionized by the conversion of old records such as courthouse registers and slave ship manifests (Eltis 1999, Hall 1999). Second, various data resources—not just surveys but electronic records of all kinds—are slowly accruing over time. For example, tables of live births by age of mother and race are available for the USA from 1933 to the present.

To see the impact of what is happening, imagine that the information revolution had begun a 100 years earlier, i.e., about 1860 rather than 1960. Suppose that the electronic information that social scientists now work with routinely—surveys, macroeconomic data, administrative records of various kinds, detailed geographic information—had begun to emerge at the beginning of the American Civil War and in the midst of the Industrial Revolution. Events such as the Great Depression would be seen in the light of a number of other economic events for which similar data would exist. In the USA, the 70-year period beginning with the 'Depression' and followed by more than half a century of almost continuous

economic growth would be seen in the light of a far more variable economy in the period from 1860 until 1930. In Europe, the effects of the breakup of the Soviet Union could be studied in light of similar political and social transformations that occurred after World War I. Of course, it cannot be assumed that the data would be perfect or complete, any more than it can be assumed that current systematic data collection will proceed unperturbed in the face of economic upheaval, civil strife, or environmental catastrophe. But even with gaps in coverage and quality, with 140 years of data it would be possible to do a kind of social science which is now only beginning to be visible. Gradually, as the database for social science research grows more sophisticated, sociology and related fields will undergo a databased revolution that will redefine both substance and method.

2. *An Overview of the Emerging Database*

Although any classification is somewhat arbitrary, it is helpful to think in terms of five main categories of databases.

2.1 Cross-sectional Micro Level Social, Economic, and Demographic Data

Many countries conduct national demographic surveys, either as censuses or based on samples, and in some cases both. These surveys tend to focus on core demographic data: family formation, fertility, mortality, and related matters. Increasingly, however, they deal with education, income, health, and other basic social variables. If not full censuses, most of the surveys have relatively large samples sizes. It can be expected that more and more countries will conduct such surveys as the benefits of the data become obvious, and as the technology for doing the survey work becomes more widespread. The 'Integrated Public Use Micro Sample' (IPUMS) project provides access to US Census from 1850 to the present at www.ipums.umn.edu. IPUMS will soon be offering access to other national censuses, with plans to include multiple time points from 21 different countries. The US Current Population Survey is available back to the mid-1960s from www.unicon.com. Many other national statistical agencies carry out similar surveys. The Luxembourg Income Study, begun in 1983, provides somewhat similar data for more than 25 countries (www.lis.ceps.lu).

2.2 Cross-sectional Omnibus Social Surveys Focusing on Social Behavior, Attitudes, and Values

The GSS is perhaps the premier example of an omnibus survey. The International Social Survey Program (ISSP), which currently contains data from 31 countries, is linked closely to the GSS. Data and documentation can be obtained at www.icpsr.umich.edu/GSS99/. An important feature of the GSS/ISSP is its careful replication of measurement and methodology both over time and across countries. A somewhat parallel survey series, known as 'Eurobarometer' has been carried out between two and four times a year since 1974 (see http://europa.eu.int/comm/dg10/epo/org.html). Eurobarometer studies tend to be more topical and less focused on replication than the GSS.

2.3 Macro Level Economic and Social Data

Macro data consists of two kinds; data aggregated up to the micro level such as time and country-specific counts of crimes, and nondisaggregatable data such as balance of payments records. Among other organizations, the World Bank, the United Nations, the International Monetary Fund, and the Organization for Economic Cooperation and Development all provide data files and tables, varying in focus and coverage as do various academic institutions such as The University of Pennsylvania via its Penn World Tables (http://pwt.econ.upenn.edu/).

2.4 Micro Level Longitudinal Surveys of the Life Course

Since the mid-1960s, a number of studies in various countries have followed individuals longitudinally over long periods of time. The article on Economic Micro Databases (*Microdatabases: Economic*) discusses a number of these studies. They are important because they provide data on long periods of the life course within a particular historical context. Increasingly, the studies are being replicated, and one can study the flow of lives under differing social and economic conditions. For instance the US Health and Retirement Survey (www.umich.edu/~hrswww/) provides data on the later life course for cohorts born after about 1920, with new cohorts entering the measurement sequence every five years.

2.5 Administrative Databases

Administrative records maintained by government and other organizations such as insurance companies, are potentially incredibly valuable resources. For example, a number of researchers in the US have been able to analyze survey data from studies of aging in conjunction with information from Health Care Financing Administration (Medicare) records (e.g., Wolinsky et al. 1995). These databases are usually not constructed with research in mind, and thus it is often

time consuming to make effective use of them, but the accumulated data in various administrative databases can offer research opportunities available in no other way.

3. Issues to be Resolved

Thus far, this article has been written as though there are no impediments to a new world of data. However, this is not the case.

3.1 Gaining Access to Data

Access to micro level surveys, particularly those conducted by national statistical bureaus, is often difficult. Some countries refuse access entirely and others sharply restrict it. When data files are released, confidentiality concerns often lead to sharp limitations on the availability of potentially identifying information, particularly geographic data. Researchers can often negotiate access to specific data files, but gaining simultaneous access to multiple data sets in multiple countries is often impossible. There are several approaches to the problem. The US Bureau of the Census has created several Research Data Centers, where closely controlled on-site access to restricted data is available to qualified researchers. Another approach is to devise disclosure limitation methodologies to protect individual identities in publicly available files. A third possibility is to make documentation public but require analyses to be run remotely on the agency's computer with agency control over the analyses. Despite these initiatives, public concerns about confidentiality and privacy continue to impact legislation on data access in many countries. If the promise of the information revolution is to be fully realized, efficient ways of giving researchers access to data while satisfying privacy concerns will have to be found.

3.2 Ease of Use

Anyone who has used a complex data set knows that the cost of getting into the data is high. Even the best data sets tend not be documented in such a way that outside researchers find it easy to use them. The problem has been exacerbated by the use of computer-assisted interviewing. Although computer-based interviews have major advantages in data collection, one of which is to allow very complex survey instruments, they tend not to produce easily used documentation and the very complexity of the questionnaires makes the data difficult to use. Because the 'questionnaire' often consists of a series of computer screens, there is often no traditional hard-copy questionnaire, and producing one after the fact is difficult and time consuming. The research community has recognized the problem and there are various meta data projects under way. One example is the 'Data Documentation Initiative,' an international project involving many social science organizations, which has developed mark up standards for machine-readable documentation (http://www.icpsr.umich.edu/DDI/codebook.html). An application of DDI can be found at FASTER (http://www.nesstar.org/), a joint project of a number of European data and statistical organizations. There is also a good deal of work in progress to produce software that combines data collection, documentation, and analysis tasks. One example, which is freely available, is EpiInfo a software package for public health researchers developed at the US Centers for Disease Control (http://www.cdc.gov/epiinfo/). There are also several competing commercial products under development at this point.

3.3 Design

As noted, with important exceptions, the accumulation of data is largely accidental. Within sociology, there is no grand plan to dictate what kind of data gets collected at what intervals. It is quite tempting to design studies to react to major political and social events, such as the breakup of the Soviet Union. Sometimes there is even ample time to anticipate an event, as was the case with welfare reform in the USA. However, it is becoming increasingly clear that slow, steady, systematic data collection offers the best chance of capturing the effects of unanticipated events and in any case provides an enormously powerful tool. The National Election Studies in the USA (www.umich.edu/nes/) provide a sequence of surveys going back to 1948. As the name implies, the principal use of the data has been to study national elections, but as a 50-year sequence of replicated surveys, the data also offer an almost unparalleled chance to study change in American society. With the exception of census data, it is very hard to find examples of systematic micro data series that go back further. It is very difficult for researchers anywhere to find the resources to maintain these kinds of studies over an extended period of time. But it seems clear that the steady accrual of systematic data while costly and by definition slow, is the only way to be sure that one has the right kind of data at the right time. Trying to spring into the field on short notice with the ideal design to study a particular topic or event is risky. This is not to say that short-term studies are valueless but rather to argue that short-term studies are most effective when a long-term framework of data using standard protocols and methods can support them.

3.4 Replication and Comparability

Perhaps the aspect of design that requires the most attention is measurement. Studying a given topic over the long term using multiple databases requires a certain amount of consistency of measurement. The

Figure 1
Percent opposed to capital punishment, US population age 18 and above. Source: General Social Survey

GSS, for example, has maintained consistency of its basic items since its inception, and some of those items were taken from previous surveys that go back 20 years prior to the start of the GSS. Figure 1 shows GSS results from the US between 1974 and 2000 for the item 'Do you favor or oppose capital punishment for murder.' As the graph shows, opposition to capital punishment has increased since 1995, but is only now reaching levels that were common in the mid-1970s. The trend is too systematic to be accidental, and there are many possible explanations. It is tempting to speculate on the link between this trend and the fact that crime rates, particularly homicide, have fallen in the US for the past several years. The only point to make is that this comparison would have been difficult to impossible, had the wording of the item changed. Unfortunately, some items literally wear out as changing tastes and social conditions make them archaic or irrelevant, if not offensive, and some change is inevitable.

Unfortunately, this kind of measurement and design consistency is rare, particularly for cross-cultural research. Researchers who wish to pool data from multiple surveys are usually faced with enormous inconsistency both within surveys over time and across surveys. Even within a given field, one finds differences in standard items across surveys. Often, there is no particular reason for the inconsistency; researchers just don't think as much as they might about replicability. However, important progress is occurring. As noted, the ISSP has made great strides in obtaining comparable data across countries. There are several other examples such as the SF-36; a scale designed to measure health that is now in use in more than 45 countries (www.sf-36.com). A few fields of sociology, particularly social mobility, have made great progress in dealing with these issues. Ganzeboom et al. (1991) review mobility studies from more than 30 countries showing that it is possible to develop regression models that maintain at least rough comparability.

Despite the obvious advantages of consistency, there is a certain paradox here. Suppose that we find that when one operationalizes a set of constructs in exactly the same way, using exactly the same measurement protocols and survey design, one gets closely comparable results across multiple surveys. Is the similarity due to the 'methods effect' or does it represent true equality of results? In other words, one might like to show that the basic results replicate despite differences in measurement, sampling, etc. The answer to this question depends in large part on how closely one wants to compare results. To answer the question 'have the economic returns to schooling changed over time?' requires a great deal of consistency because answering the question requires exact comparison of regression coefficients. On the other hand, answering the question 'are the relative effects of achievement and ascription the same in most industrial societies?' might be answered, at least approximately, with something less than exact comparability.

3.5 Data Archiving and Preservation

An important aspect of the data revolution is the existence of data archives in many countries of the world. The idea of a data archive developed in the early 1960s when most data sets were in the form of decks of electronic data processing cards, a technology now virtually unknown. The card files were expensive to maintain and quite fragile, so data archives maintained master copies and provided duplicates to researchers. As the computing world moved to storing data on tapes, archives were sill needed as central repositories of data because the task of maintaining the data and making it available to users in a form suitable for their local computing facility, required technical skill and resources. A web-based world map of most of the major academic archives can be found at http://www.nsd.uib.no/cessda/other.html. The InterUniversity Consortium for Political and Social Research (ICPSR) (www.icpsr.umich.edu) is the world's largest academic archive with literally thousands of data sets, but there are a great many specialized archives around the world. A very thorough guide to archives and related facilities is maintained by the Social Sciences Data Collection at the University of California San Diego (http://odwin.ucsd.edu/idata/) where one can find links to hundreds of electronic resources.

The new world of the Internet is leading to radical changes in the nature of data archives. Currently, many data sets are made available directly on the web by the originating investigator or agency. This has obvious advantages in terms of accessibility, but perhaps less obvious disadvantages. Although Internet search tools are powerful, it is far easier to search the holdings of a few data archives than it is to search the whole Internet for data on a given topic. A more important issue is permanency. Archives are committed to maintaining data and related documentation in perpetuity. Data maintained on local web sites is

subject to all sorts of vicissitudes—funding disappears, investigators move or lose interest, servers crash, and technology changes sometimes rendering data unusable. Indeed, archives have to worry about the fact that data on any storage medium deteriorates over time, as many users of compact disks know (see *Data Archives: International*).

4. The Future

Although there is no question that social science will be affected profoundly by the availability of masses of data, a great deal must be done if the data are to be used to maximum advantage. Three issues seem to be the most important. First, the research community needs to pay closer attention to comparability and replication. The Internet has made that task vastly easier because data documentation can be moved about so easily. But the quality of the documentation varies a great deal and finding the information that one needs to know in order to either analyze the data or replicate the study, can be difficult to impossible. The development of efficient and effective electronic documentation and meta data is in the early stages and much remains to be done. Second, means of giving qualified researchers access to data must be worked out. In the current climate of serious concern about privacy, this will be a difficult task. On the other hand, the power of computing, when used properly, makes it easier to guarantee privacy rather than harder. Data can be encrypted, modified for public consumption to prevent disclosure, maintained at a single site to restrict access to qualified people, etc. There are slowly emerging methods and standards for how to do these things, but many issues remain to be resolved. Finally, and most importantly, there is the intellectual task of coming to terms with the stream of data that will be available. Until very recently, most researchers were content to focus their activities on a single data set. But as data accrue, for almost any question one is interested in, there will be multiple data sets available. Not only will there be multiple data sets across time and place, but there will be corresponding macro level data which might be relevant, as in the case of the GSS data on capital punishment, which can only be understood in light of societal level social and political factors.

R. T. Campbell

De Finetti, Bruno (1906–85)

Bruno de Finetti was born in Innsbruck, Austria of Italian parents on June 13, 1906, and died on July 20, 1985 in Rome. He enrolled in the Milan Polytechnic in 1923, and then after discovering that his interests lay more in science, switched to the Faculty of Mathematics of the University of Milan.

He first became interested in probability as a result of reading an article in a popular magazine concerning Mendel's laws of genetics, which stimulated him to write an article of his own on the subject. His article attracted the attention of Corrado Gini and eventually led to a position as head of the Mathematical Office of the Instituto Centrale di Statistica. Later he accepted a position as actuary in the Assicurazioni Generali insurance company in Trieste, where he was concerned with automation of all actuarial, statistical, and bookkeeping operations and calculations. He became a lecturer in mathematics, actuarial mathematics, and probability at the Universities of Trieste and Padova, and later full professor in Trieste and finally at the University of Rome, from which he retired in 1976.

In 1957 he spent a quarter at the University of Chicago at the invitation of Professor Leonard Jimmie Savage (1917–71). They became friends and each stimulated the other in the development of his ideas.

Although there are differences in the presentations of subjective probability by de Finetti and Savage, their basic outlook was the same, and they stood in sharp contrast to other figures in the field, with the exception of Frank Ramsey (1903–30), whose important article *Truth and Probability* (1926) was very much in the same spirit. De Finetti and Savage were the major figures of the twentieth century in the area of subjective probability, and legitimate heirs of the two giants, Émile Borel (1871–1956) and Henri Poincaré (1854–1912), who also viewed probability theory as a serious subject with numerous important real-world applications, rather than as a mathematical exercise. Both de Finetti and Savage were infuriated by the trivializations of the subject as such an exercise, which dominated the field during most of their lifetimes.

Early in his career de Finetti realized that there was something seriously lacking in the way probability and statistics were being developed and taught. The famous remark 'Everybody speaks about Probability, but no one is able to explain clearly to others what meaning probability has according to his own conception,' by the mathematician Garrett Birkhoff (1940), was indicative of serious problems even with the definition of probability. De Finetti found many of the standard assertions confused and meaningless. In his University of Rome farewell address (1977), concerning the contrast between himself and Savage (a mathematician who had been trained in the standard non-Bayesian theory) he said: 'I, of course, was in quite the opposite situation: a layman or barbarian who had the impression that the others were talking nonsense but who virtually does not know where to begin as he cannot imagine the meaning that others are trying to give to the absurdities that it is imposing as dogma.'

De Finetti then attempted to formulate an appropriate meaning for a probability statement. His knowledge of philosophy and logic as well as mathematics, both pure and applied, enabled him to do so. The areas of his work that will be discussed here are his theory of exchangeability, theory of coherency, and theory of finitely additive probability. For him theory and practice were inseparable, and he emphasized the operational meaning of abstract theory, and particularly its role in making probabilistic predictions.

De Finetti rejected the concept of an objective meaning to probability and was convinced that probability evaluations are purely subjective. In his article *Probability and my Life* published in Gani (1982) he wrote: 'The only approach which, as I have always maintained and have confirmed by experience and comparison, leads to the removal of such ambiguities, is that of probability considered—always and exclusively—in its natural meaning of "degree of belief." This is precisely the notion held by every uncontaminated "man in the street." De Finetti then developed a theory of subjective probability, corresponding to its use as an expression of belief or opinion, and for which the primary feature is coherency.

The starting point for his theory is the collection of gambles that one takes on, whether knowingly or unknowingly. These can be either ordinary gambles or conditional gambles, which are called-off if the contingency being conditioned upon does not occur. The simplest type of gamble is one on an event E, in which one receives a monetary stake S if E occurs and nothing otherwise. If a person values such a gamble at the sure amount $p \times S$, then p is defined to be the probability of E for that person. In this evaluation one uses small stakes S so as to avoid utility complications, which distort probabilities evaluated in this way. One can then take linear combinations of such simple gambles to generate gambles in which there are a finite number of possible outcomes. Similarly, a called-off gamble on the event E given F, is such that one receives a monetary stake S if both events occur, nothing if F occurs but not E, and the gamble is called off if F does not occur. The value of such a conditional gamble for a person is called his or her conditional probability for E given F and is denoted by $P(E|F)$.

In the work of de Finetti (1970, 1972, 1974–5) a primary aim is to avoid the possibility of a Dutch book, that is, to avoid sure loss on a finite collection of gambles. Thus suppose one has taken on a finite collection of gambles of any type whatsoever, including such things as investments, insurance, and so on. De Finetti proved that a necessary and sufficient condition for the avoidance of sure loss of a positive amount greater than some $\varepsilon > 0$ on a finite number of unconditional gambles, consists in consistency with the axioms of finitely additive probability theory. These axioms are the usual ones, apart from the fact that the condition of finite additivity replaces that of countable additivity in the third axiom. Let $P(E)$ denote the numerical probability for the event E. Then the axioms are:

1. $P(W) = 1$, where W is the sure event.
2. For any event E, $0 \leqslant P(E) \leqslant 1$.
3. The probability of a finite union of disjoint events is the sum of the probabilities.

Further, if conditional gambles are also included, then to avoid a Dutch book, conditional probabilities must be evaluated in accord with the usual definition:

$$P\{A|B\} = P\{A \text{ and } B\}/P\{B\},$$

provided that $P\{B\} > 0$. See Hill (1998) for further discussion.

In the subjectivistic conception a probability is essentially a price that one will pay for a certain gamble, with the understanding that this price can and will differ from one person to another, even apart from utility considerations. This conception is very close to that of the common person who speaks of probabilities for various real-world events based upon his or her

own experience and judgment. In this case there is no need to confine attention to trials such as arise in games of chance. On the other hand, it is extremely interesting to see what the subjectivist interpretation of such trials might be. By considering this question, de Finetti developed his celebrated exchangeability theorem.

The problem that de Finetti posed and largely solved was that of justifying from a subjective point of view the importance of statistical frequencies in the evaluation of probabilities. Suppose that we have a sequence of events, E_i, for $i = 1,\ldots, N$, each of which may or may not occur, for example where E_i is the result of the ith flip of a coin. For convenience, we can assign the value 1 to heads and 0 to tails. It is natural sometimes to view the order of the flips as irrelevant, so that any permutation of the same sequence of outcomes is given the same probability. This leads to the notion of exchangeability, which is a symmetry condition, specifying that joint distributions of the observable random quantities are invariant under permutations. De Finetti proved a representation theorem which implies that if one regards a sufficiently long sequence of successes and failures as exchangeable, then it necessarily follows that one's opinions can be represented, approximately, by a mixture of Bernoulli sequences, that is, of sequences for which there is a 'true' (but typically unknown) probability P of success, and such that conditional upon $P = p$, the observations are independent with probability p of success on each toss. The proportion of successes, as the number of trials goes to ∞, converges almost surely to P, and the initial or a *priori* distribution for P is also called the de Finetti measure for the process.

This representation in terms of Bernoulli sequences is exact for infinite sequences, and a slight modification holds also for finite sequences, the difference amounting to that between sampling with and without replacement from an urn. It also follows mathematically that provided a sufficiently long sequence has been observed, to a good approximation one will be led to base opinions about a future trial on the past empirical frequency with which the event has occurred, and this constitutes de Finetti's justification for induction. In his work de Finetti emphasized prediction of observable quantities, rather than what is usually called inference about parameters. In other words, he was primarily interested in the posterior distribution of future observable random variables, rather than in the posterior distribution for the parameter P. This point of view has become known as predictivism in modern Bayesian statistics.

The exchangeability theorem of de Finetti allows one to analyze the relationship between subjective probabilities and the frequency theory of probability that developed from the work of Jakob Bernoulli. The fundamental stochastic process is known as a Bernoulli sequence. Such a sequence is by assumption such that on each trial there is a fixed objective probability p for success (1) and $1-p$ for failure (0), whose value may or may not be known, with the trials independent in the probabilistic sense. It is then a mathematical fact, known as the law of large numbers, that as the number of trials grows large the proportion of successes will stabilize at the 'true' probability p in the sense that the proportion of successes will converge almost surely to p; that is, the sequence converges except for a collection of outcomes that has probability 0.

Critics of this theory, such as de Finetti, argue that there are no real-world applications in which either p or the limiting proportion of successes is known to exist. The empirical support for the objectivist theory is merely that there are certain processes, such as coin flipping, dice throwing, card playing, draws from an urn with replacement, and so on, for which in finite sequences of trials the empirical proportions of successes appear to be in conformity with what the objectivist theory suggests. For example, if there are two similar balls in an urn, one red and one white, and if draws are made with replacement after substantial shaking of the urn, then experience suggests that the proportion of red balls in n draws, when n is sufficiently large, is around .5. Of course it is impossible to perform an infinite number of trials, so the limiting proportion, if it exists at all, can never be known. But in finitely many trials not only does the proportion of red balls drawn often seem to settle down to something like .5, but in addition, if say the n trials are repeated I times, then the proportion of these I trials in which there are exactly j red balls in n trials appears also to settle down to $\binom{n}{j}(1/2^n)$, more or less as the theory suggests. One must, however, exclude situations where such settling down does not appear to happen, and these are usually interpreted as meaning that the shaking was not adequate, or the cards not sufficiently well shuffled, and so on. Nonetheless, it appears that when sufficient care is taken, then the proportions appear to be roughly in accord with the objectivistic theory.

Does this imply that there exists a true $p = \frac{1}{2}$ which is the objective probability, for example, that the ball drawn is red, and hence also that the proportion of red balls drawn must converge almost surely to .5? No one knows to this day. However, de Finetti's exchangeability theorem provides an alternative way to describe our experiences with such random events. A probability as before is merely a price that one would pay for a certain gamble. Under the assumption of an equal number of red and white balls, and that the urn is well shaken, symmetry suggests a price of .5 for the gamble in which you receive a dollar if a red ball is drawn, nothing otherwise. Similarly, if you were to be offered a gamble in which you would receive the dollar if the first two draws were red, then again symmetry together with the assumption that the urn is well shaken, suggest that a fair price would be .25. Continuing in this way we see that your prices are in

accord with the usual probability evaluations for such an urn.

It is then a logical consequence of the exchangeability theorem of de Finetti, that you must evaluate your probability that the sample proportion of red balls converges to .5 as unity. Note that this requires no circular definitions or mysterious conventions. There are, however, two important caveats. First, it is necessary that utility considerations be ignored, which necessitates that the prizes are not too large, and for this reason the stake S was taken to be one dollar. Alternatively, utility can be dealt with after the fashion of Ramsey or Savage. Second, the cases where people take this evaluation most seriously are those in which there have already been many draws in the past, indicating no cheating or violation of the apparent symmetry, so that in effect your probabilities are posterior probabilities based upon Bayes' theorem. In other words: just as dice may be loaded so can other games be fixed, and a prudent bettor would not make the above evaluations merely from apparent physical and time symmetry alone, but rather in addition from experience that the game is not rigged and that the perception of symmetry is not mistaken. At any rate, one sees that it is not necessary to introduce the concept of an objective probability, but merely the experience that suggests an evaluation of .5.

The case of a Bernoulli sequence, whether interpreted according to the objectivist or subjectivist theory, is of course a very special example of an exchangeable sequence of random variables. For a Bernoulli sequence with $p = .5$, that is, a degenerate *a priori* distribution for P concentrated at the value .5, the primary difference between the two theories is that the objectivist theory objectifies the .5 which in the subjectivist theory is merely the opinion of the bettor, and similarly the .25 for drawing two red balls, and so on. In circumstances where prudent bettors have learned from experience to bet in accord with symmetry, the objectivist school states that the .5 and the .25 and so on, are the objective or true probabilities, not merely the values that the bettor chooses. Thus the objectivist theory implies that the proportion of successes necessarily converges to .5, while the subjective theory implies that the bettor must believe, with probability 1, that such convergence takes place.

It should be noted that countable additivity, that is, the modification of the third axiom to include also denumerable unions of disjoint events (which corresponds to a denumerable number of gambles) has never been demonstrated within the rigorous approaches to probability theory and, as argued by de Finetti, is merely a particular continuity condition that one may or may not wish to adopt in a particular context, just as with the use of continuous functions in physics. The relaxation of the condition of countable additivity to finite additivity allows one greater freedom in the representation of degrees of belief. For example, the use of adherent mass distributions (which were introduced by de Finetti and are closely related to Dirac functions) allows one to obtain solutions for Bayesian non-parametric inference and prediction. See Hill (1993).

The work of de Finetti played a major role in the resurrection of the classical Bayesian approach to probability, statistics, and decision theory, as founded by Bayes and Laplace and developed by Gauss, Poincaré, and Borel. His work continued the theory of induction of the British empiricists such as David Hume, and provided mathematically sound foundations for the modern-day subjective Bayesian approach.

Death and Dying, Psychology of

1. Attitudes Towards Death and Dying

In the literature, coping with one's own finitude is often understood as a sequence of stages that people pass through in part or completely. Kubler-Ross (1969), for example, distinguishes between an initial phase of denial followed by phases of anger, depression, bargaining, and—finally—acceptance. Though the generalizability of the stages model is debated, an important conclusion that can be drawn from the work of Kubler-Ross and others is that

attitudes toward death and dying can be understood as an outcome variable, reflecting the effectiveness of individual attempts to cope with the last borderline situation of human existence.

Previous research on factors that might influence attitudes toward death and dying focused extensively on fear of death as the variable to be predicted. Other outcome measures in recent studies are the desire to prolong life (e.g., Mutran et al. 1997), frequency of thoughts about death (e.g., Rao et al. 1998), and valuation of life (Lawton et al. 1999). The literature suggests that age, gender, and ethnicity may be variables associated with fear of death. The likelihood of fearing death appears to be slightly higher for younger persons, for women, and for African-Americans compared with Whites (Mutran et al. 1997).

1.1 The Role of Religious Activity

Religious activity has been a prominent topic in previous research. Studies have shown that people who engage into devotional activities experience less fear of death (Musick et al. 1998). Trying to explain this relationship, some authors focus on processes of primary appraisal, emphasizing that looking forward to an afterlife that is better than the current situation makes religious people less likely to see their disease as harmful. Focusing on processes of secondary appraisal, others have suggested that feeling close to God is seen as a source of power and strength that can be used in times of trouble. According to Filipp (1999), when processing bad news, religious beliefs may enable people to construct an interpretative reality, i.e., to ascribe subjective meaning and to re-establish a better world to live in. From the perspective of the social cohesiveness hypothesis (Idler 1987) religion can benefit individuals by providing support from clergy or fellow church members. However, studies show that the effects of religious activity are not the same for African-Americans as for Whites. To account for this difference it has been argued that, because the former face greater discrimination and barriers to institutions and status, they must find alternative avenues to success and well-being, and that one such alternative avenue is the church (Hummer 1996). Proceeding from the assumption that church and religious activity serve a special place in the lives of African-Americans, religious activity should have a greater effect for them than for Whites.

1.2 The Role of Social Support

Given that Kubler-Ross emphasized that processes of coping with death and dying can be assisted by social interaction and that the relationship between social support and health in general is the subject of numerous studies, it is noteworthy that until recently only a few studies investigated the relationship between supportive networks and attitudes toward death and dying.

Mutran et al. (1997) investigated the potential mediating and moderating effects of social support on the desire to prolong life, an aspect of attitudes toward death and dying that is related to, but not identical with, fear of death. In this study, two alternative models were tested in a hospitalized sample of 212 persons with an average life expectancy of six to 12 months. The first model proceeds on the assumption that those who wish to prolong life are characterized by unfinished business and fear of death, two stressors that are influenced by a number of background variables (e.g., education, gender, health, ethnicity). According to this model, the two stressors lead to the mobilization of family support, i.e., increased frequency of contact with family members and increased family salience, two variables which in turn mediate the impact of background variables on the desire to prolong life. In the second model it is hypothesized that contact with family members moderates the relationship between the two stressors and the desire to prolong life only in the case of family salience, a variable which in turn is associated with background variables like education, gender, health, or ethnicity. The results support the second model, indicating that family salience and family contact contribute to the definition of the context in which the stressors of unfinished business and fear of death prompt desires to prolong life, and that family contact has a different impact on attitudes toward death and dying for different ethnic groups.

1.3 Finitude and Valuation of Life

Rao et al. (1998) emphasize the influence of low spirits and social factors on attitudes toward death and dying. In a sample of community residents aged 81 years and older, those who thought about death more frequently were more likely to be unmarried and to manifest a greater severity of depressive symptoms. In interpreting their results the authors suggest a closer examination of attitudes toward death and dying would be useful in the assessment of depression and suicidal risk. Similarly, from the study of self-definition and time horizon in old age there is evidence that only in a minority of older people are feelings of finitude and finiteness predominant in their conceptualization of their future time perspective (Smith and Baltes 1999, Thomae 1981). An increase in feelings of finitude and finiteness is observed only in cases where life is subjectively supposed to be determined by limits and losses (Kruse 2000).

Lawton et al. (1999) proposed that the relationship between quality of life and years of desired life is mediated by an intervening cognitive-affective schema,

'valuation of life,' that may be defined as 'the extent to which the person is attached to his or her present life, for reasons related to a sense not only of enjoyment and the absence of distress, but also hope, futurity, purpose, meaningfulness, persistence, and self-efficacy' (p. 407). Since the usefulness of this concept was affirmed in an empirical study of 600 healthy and chronically ill older people aged 70 and older, further research is required in order to understand how health, cultural, social, and psychological factors become transformed into strong or weak valuations of life.

2. *Assisting Coping Processes in Institutional Settings*

In the last few years, the field of palliative medicine and care has developed new insights and concepts that could be used to improve treatment and care of dying people. However, the currently existing care systems are not sufficient.

Empirical research on factors influencing coping with death and dying underscore the demand for giving more attention to (a) pain therapy (most dying persons could be free from pain or at least be relieved from severe pain when therapy is offered), (b) activating care that enables people to continue to lead an independent and responsible life, even in the final stage of disease, and (c) ambulant care services that offer instrumental and emotional support for the family (Kruse 1991).

Giving assistance for coping with one's own finitude is complicated when the dying person is suffering from psychiatric disorders. This is especially the case since in the so-called fourth age (from 75–80 years on) vulnerability to chronic physical and psychological diseases increases, and changes in life expectancy go together with a steadily growing number of people dying from long-lasting illness instead of an acute health crisis. As a consequence, institutional care for the dying should be able to rely on psychiatric and psychological expertise. In this context it should be noted that psychiatric disorder (as a kind of serious illness) and the psychological reactions associated with the consciousness of finitude, death, and dying must be differentiated. It is important to distinguish between states of anxiety, despondency, resignation, and despair resulting from the confrontation with one's own finitude and similar emotional states resulting from psychiatric disorders since the diagnosis of a psychiatric disorder might suggest medical treatment. In contrast, the diagnosis of psychological reactions to the confrontation with one's own finitude suggests nonmedical treatment aimed at optimizing active and self-reflexive coping processes. Since coping with one's own finitude is an existential challenge for human beings, the temporary psychological reactions that occur during the process of active coping must not be interrupted by medical treatment. However, practitioners are obliged to provide adequate medical treatment when a changing of emotional state helps the patient's coping process. For adequate medication, differentiated knowledge about the development of psychological symptoms is needed. In order to be able to gain such differentiated knowledge, medical practitioners have to rely on information from caregivers. For this reason, there is a need for cooperation between medicine and care in institutional services trying to give assistance for dying people.

3. *Maintaining Self-responsibility*

The treatment and care of dying people suffering from changes of consciousness that prevent them from leading a self-responsible life should be based on the preferences and values articulated or supposed to be held by the patient before the occurrence of changes in consciousness. Medical ethics insist on enhancing the possibility for patients to lead a self-responsible life as long as possible. Self-responsibility can be interpreted in different ways; and at least five aspects of self-responsibility should be distinguished (Kruse 1991).

3.1 *Self-responsibility as Independence in Performing the Activities of Daily Living*

This aspect is too often neglected in discussing the possibilities for helping people cope with their own finitude, since the former is centered around illness and the corresponding possibilities and limits of therapy. However, Kruse (1987) found a close relationship between independence in performing the activities of daily living and the ability to cope with one's own finitude.

3.2 *Self-responsibility as Self-determination in Organizing Everyday Activities and Realizing Personally Meaningful Interests*

It should be considered that even in the process of dying, most people look for positive emotions and experiences that correspond with a feeling of participation from which they gain support for coping with dying. Studies show that religious activities can be helpful in this context (Musick et al. 1998).

3.3 *Self-responsibility as Autonomy in Choosing Social Contact and Managing Social Relationships*

Even if most people wish to die at home, it should be noted that what is to be regarded as an adequate amount of closeness to or distance from family members and relatives can be determined only by patients themselves (Baltes 1996).

3.4 Self-responsibility as the Ability to Understand the Development of Illness and the Effect of the Chosen Therapy

The quality of the interaction between the patient and the medical practitioner is an essential factor for the effectiveness of pain therapy (Lohmann et al. 1998).

3.5 Self-responsibility as the Opportunity to Decide Where to Die

Individuals cope best when they decide which kind of therapy or care to take and—especially when therapy leads to an extension of the process of dying—to terminate life-sustaining measures.

4. The Problem of Surrogate Decisions Concerning Life-sustaining Measures

In medical practice the question often is not whether prolonging life is possible but whether it is justified to provide life-sustaining measures for older people. When the patient is no longer competent, the offspring have to make the decision. According to Cooper-Kazaz et al. (1999) such surrogate decisions often do not reflect the patient's autonomous wishes, but rather the current feelings of the decision-maker. This is often an emotional reaction which sometimes is not even consistent with the offspring's own ethical outlook. In a study by Sonnenblick et al. (1993), approximately 50 percent of the offspring believed they knew their parent's wishes, but most of them did not comply with the previously stated wishes of their parent. Cooper-Kazaz et al. (1999) argue that attitudes toward the dying patient and the treatment appropriate are influenced by cultural, intuitive, and emotional factors. Moreover, exposure to the critical event (when parents become terminally ill) seems to have an impact on the children's judgement about life-sustaining measures. Those with terminally ill parents were significantly more likely to request the initiation of resuscitation and less likely to prefer that the decision be made by the physician than those who had no terminally ill parents. We therefore need more studies that investigate solutions not only of theoretical dilemmas, but of processes of decision-making under real-time conditions as well as more research on the factors which might influence the decisions of offspring.

5. Future Directions

Recent research suggests that the scope of the stages model is too narrow to account for individual differences in experiencing and coping with death and dying. It could be shown that coping processes depend on a number of personal and environmental factors, e.g., age, gender, ethnicity, social support, and religious activity. However, more research is needed to understand the complex interaction between these factors. Moreover, previous research has concentrated much on explaining interindividual differences in fear of death. However, advances in medical technology in particular point to the significance of other outcome variables that have been neglected too long. A broader perspective on attitudes toward death and dying should be helpful to integrate research on attitudes toward death and dying, thus assisting patients to cope in institutional settings, and to maintain self-responsibility and addressing the problem of surrogate decisions concerning life-sustaining measures. This integration is seen as an essential challenge for the psychology of death and dying.
