Judaism is generally tolerant of the public policy of choice in abortion but teaches that abortion should be chosen only for compelling reasons. It does not regard abortion as murder, however, and it is open to the prospect of using human embryos in research and therapy because it regards the embryo outside the body as having no legal standing. In fact, even in the body, the embryo's status for the first forty days, according to the Talmud, is "as if it were simply water" (Dorff, 2002). As a result, Judaism is supportive not just of in vitro fertilization but of more recent developments such as preimplantation genetic diagnosis.

Islam bases its understanding of developing human life on the section in the Koran (23:12–16) that describes human creation as beginning with a tiny drop from which the larger and more complex structure of the fetus is fashioned by God the creator, who breathes life into what is formed. Islam thus sees each human life as created by God through a developmental process. Islamic scholars sometimes distinguish between the ensouled and the unensouled fetus, often arriving at the end of the fourth month as the point in fetal development when abortion is no longer permissible for any reason.

Other Islamic scholars argue that recent scientific discoveries demonstrate that the embryo is alive from the earliest moment and thus deserves full protection, but the more common and traditional view is to accord legal status as a person only after the form is recognizable and movement is voluntary. When it comes to the use of genetic or reproductive technology, Islam is guided primarily by the general context in which the technology is applied rather than by the technology considered abstractly. If reproductive technology serves the goal of health within the context of marriage, it is permitted; if not, it is rejected.

Detailed theological and moral discussion of topics such as abortion, the beginning of life, and embryo research is far more characteristic of the Western monotheisms (particularly Christianity) than of the other great religions. In Buddhism, however, rich conceptual and practical traditions have made it possible for some countries such as Japan to address abortion without the divisiveness characteristic of the West. The first of the Five Precepts of Buddhism is the prohibition against taking life, including embryonic life. While there is some traditional debate in Buddhism about when reincarnate life is present in the developing fetus, for the most part Buddhists agree that abortion is always wrong. At the same time, what is wrong is also sometimes necessary, but that does not make the act less wrong or the loss less tragic. On the one hand, there is the moral teaching, quoted by James Hughes as follows: "It is the woman carrying the fetus, and no one else, who must in the end make this most difficult decision and live with it for the rest of her life. As Buddhists, we can only encourage her to make a decision that is both thoughtful and compassionate" (Hughes, p. 191). But on the other hand, in Japan in particular, fetal loss of any sort is mourned and observed with ritual and remembrance (*mizuko*) far more than in the Christian West. Similar traditions are found in Thailand and Vietnam. Far from legitimizing abortion through religious sanction, these

rituals help to maintain the Buddhist prohibition against taking even fetal life even in a social context that occasionally requires just this act.

New Technologies

Religious ideas about nascent human life were developed long before modern science opened up the fields of genetics or embryology and prior to technology making the embryo an object of manipulation. These new developments bear on religious understandings, and religious perspectives are likewise brought to bear in assessing the legitimacy of various technological options, such as in vitro fertilization, prenatal genetic testing, preimplantation genetic diagnosis, cloning, and embryonic stem cells.

The responses of various religious traditions to these developments are largely outgrowths of classic positions and thus predictable. Catholic teaching objects to any attempt to move procreation outside its natural context and thus opposes in vitro fertilization. Because of its uncompromising objection to abortion, *Donum vitae* objects to prenatal genetic diagnosis unless limited to healing the individual: "But this diagnosis is gravely opposed to the moral law when it is done with the thought of possibly inducing an abortion" (part I, no. 2). Judaism, Islam, and Protestantism generally permit in vitro procedures and also allow, with practical reservations, prenatal genetic diagnosis.

Preimplantation genetic diagnosis, which involves in vitro fertilization followed by a genetic test of the embryos to determine the most healthy for implantation, is likewise rejected by Catholic teaching but accepted by others, although the cost factor raises religious concerns for social justice.

Cloned Embryos

Reproductive cloning is widely condemned by religious institutions and by nearly all religious scholars, but use of the cloning technique (somatic cell nuclear transfer) to create embryos for research purposes is permitted under some religious grounds while being strongly condemned under others. Catholic teaching clearly forbids any form of embryo research that destroys the embryo, cloned or otherwise. According to the Pontifical Academy for Life, "The ablation of the inner cell mass (ICM) of the blastocyst, which critically and irremediably damages the human embryo, curtailing its development, is a gravely immoral act and consequently is gravely illicit."

In similar terms, the conservative Protestant Southern Baptist Convention, at its national meeting in 1999, stated: "[we] reaffirm our vigorous opposition to the destruction of innocent human life, including the destruction of human embryos." The opposite position, however, is taken by the Presbyterian Church (U.S.A.), which declared in 2001: "With careful regulation, we affirm the use of human stem cell tissue for research that may result in the restoring of health to those suffering from serious illness. We affirm our support for stem cell research, recognizing that this research moves to a new and challenging frontier."

On this, the Presbyterian position (shared by some other similar denominations) is substantially indistinguishable from that of Judaism. An example of the latter is found in a joint statement offered by the heads of the various branches of Judaism in the United States. This statement begins by stressing the God-given human role in mending the creation: "The Torah commands us to treat and cure the ill and to defeat disease wherever possible; to do this is to be the Creator's partner in safeguarding the created" (Union of Orthodox Jewish Congregations of America and the Rabbinical Council of America, 2002). To this end, humans are permitted to use human embryos in research, for "our tradition states that an embryo in vitro does not enjoy the full status of human-hood and its attendant protections. Thus, if cloning technology research advances our ability to heal humans with greater success, it ought to be pursued since it does not require or encourage the destruction of life in the process" (Union of Orthodox Jewish Congregations of America and the Rabbinical Council of America, 2002). Reproductive cloning, however, is opposed, and therefore careful oversight of research must be in place.

At the beginning of the twenty-first century, it appears possible to create human embryos by nuclear transfer, embryo splitting, or by a process usually called parthenogenesis by which researchers induce an egg to start dividing like an embryo without fertilization. In each of these processes, something like an embryo comes into existence without fertilization or conception in the usual sense. If an embryo strictly speaking is the result of conception, then these entities are not embryos. One cannot imagine, however, that those who hold passionately to the slogan that "life begins at conception" will not modify their rhetoric to say that life begins at conception or anything that replaces conception.

A deeper issue is whether these entities, even if implanted, have the biological potential to develop into a human life. In some cases, probably most, it will turn out that they lack this potential. If so, will they be seen as embryo-like but as sub-embryos, morally speaking? Surely, some out of religious conviction will defend their status as "one of us" or as fully human. In time, however, technology may find even more ways to create entities that function in some ways like embryos but in other ways fail as their

biological equivalent, and so religious, moral, and policy distinctions are inevitable.

Conclusion

Far from being relics of a prescientific era, the religions today, even in their disagreements, serve to focus both our awe at the mysteries of our humanity and our anxieties about our future. Religious traditions, which are anything but changeless, will probably continue to adapt to our changing knowledge of ourselves and our growing powers to modify our nature. In so doing, through doctrinal argument and moral warning, they will perhaps shed some light on our biological origins and on our technological destiny.

EMOTIONS

• • •

In bioethics, as in ethics more generally, there is much debate about the significance of emotions in an account of moral character. Intuitively speaking, emotions are important because as moral beings we care not only about how we act but also about how we feel—what our moods are, as well as our attitudes and affects. Within the practice of healthcare, the emotions of compassion and empathy seem to have a particularly important place in a full description of decent and ethical treatment of a patient. The general point is not that emotion is internal and action external, because both action and emotion have exterior moments that point to deeper interior states, commonly thought of as character. Rather, emotions are important as modes of sensitivity that record what is morally salient and that then communicate those concerns to self and others. Thus, to grieve, pity, show empathy, or love is to focus on an aspect of self or other and to grasp information to which purer cognition or thought may not have access. Generally put, different emotions are sensitive to different kinds of salience. In the case of grief, what is salient is that humans suffer and face loss; in the case of pity, that they sometimes fail through blameless ignorance, duress, sickness, or accident; in the case of empathy, that they need the expressed support and union of others who can understand and identify with them; and in the case of love that they find certain individuals attractive and worthy of their time and attention.

In relations in which caring for others is definitive, emotional sensitivity plays a powerful role. In choosing physicians, for example, people tend to value medical skill and ability deeply, but value character and judgment as well. And part of what people look for in character and judgment is not just reliable and principled action but also a certain range of emotional responsiveness. Medical care ministered without human gesture may simply not be received in the same way as that conveyed through compassion and empathy. A physician's sensitivity to a patient's needs, worries, and fears is often also relevant to diagnosis, just as the physician's communication of emotions may be relevant to how a patient confronts illness and recovery. As in any relationship, emotional interaction is part of the exchange. In more intimate friendships, we hope that loved ones will be able to respond to our joy and suffering in more than merely intellectual ways and that they will communicate feelings through spontaneous affect and gesture as well as more deliberate action.

What Are Emotions?

In general terms, then, emotional sensitivity is a moral feature of personal interaction. But what are emotions? It is useful to first review some alternative views.

The first is the commonsense view in which emotion is thought to be an irreducible quality of feeling or sensation. It may be caused by physical states, but the emotion itself is the sensation we feel when we are in that state. It is a felt affect, a distinctive feeling, but not something dependent upon thought content or appraisals of situations. This view quickly appears faulty, however, when one realizes that on this view emotions become no more than private states—sensations such as itches and tickles that have little to do with what the emotions are about and how a person construes or represents those affairs.

A second view, associated with the American psychologist and philosopher William James and Danish physiologist Carl Lange is that emotions are an awareness of bodily changes in the musculature and viscera. We are afraid because we tremble or flee, not the other way around; likewise, we are angry because of the knots in our stomachs. This view, though rather counterintuitive, nonetheless captures the idea that emotions, more than other mental states, seem to have conspicuous physiological and kinesthetic components. These often dominate children's and adults' reports of their emotional experiences. They dominate the literary world, too. Consider in this vein the lines of the Greek poet Sappho composed around 600 B.C.E.:

When I see you, my voice fails,
my tongue is paralyzed,
a fiery fever runs through my whole body
my eyes are swimming,
and can see nothing
my ears are filled with a throbbing din
I am shivering all over …

Literary history, social convention, and perhaps evolution conspire to tell us this is love. But even here it is not hard to imagine that what is described could be dread or awe or perhaps, mystical inspiration. Even well-honed physiological feelings do not easily identify specific emotions. An awareness of our skin tingling or our chest constricting or our readiness to flee or fight do not specify just what emotion we are feeling. Many distinct emotions share these features, and without contextual clues and thoughts that dwell on those clues, we are in the dark about what we are experiencing (Schacter and Singer). The chief burden of the work of the American physiologist Walter B. Cannon was to show that many physiological affects are virtually identical across manifestly different states. While more current research suggests a tighter fit between specific emotions and specific autonomic system responses (such as skin temperature and heart rate), visceral responses such as these nevertheless have slow response times, too slow to determine what emotion one is actually feeling at a given time (LeDoux). So Cannon's general insight about the indeterminacy of the "feel" of an emotion still holds, though for different reasons than the ones he offered.

A third view with some kinship to the James-Lange view holds that emotions are felt action tendencies (Arnold). They are modes of readiness to act or, in the different idiom of psychoanalysis, discharge impulses. Supporting this view is the tendency of people to describe emotions in terms of dispositions to concrete behavior, for example, "I felt like hitting him," "I could have exploded," "I wanted to spit," and "I wanted to be alone with him, wrapped in his embrace." Nevertheless, the action tendency view seems at best a partial account of emotion. The basic issue here is not that some emotions such as apathy, inhibition, and depression seem to lack activation modes—while others are more a matter of the rich movement of thought so well depicted, for example, in Henry James's novels. It is rather that emotions are about something (internal or external) that people represent in thought. As such, emotions have propositional or cognitive content. They are identified by that content, by what we dwell on, whether fleetingly or with concentrated attention.

According to a fourth and most plausible view, emotions are constituted by appraisals or cognitive evaluations. (This is the view the fourth-century B.C.E. Greek philosopher Aristotle developed in the *Rhetoric,* and a view the Stoics put forth in more radical form. It is the clear favorite of most philosophers of the late twentieth and early twenty-first centuries—for a sampling, see de Sousa, 1987; Stocker; Goldie; Nussbaum, 2001. It is also the reigning view in cognitive psychology—see Lazarus; Oatley; Frijda; Scherer, and for an important criticism, see Zajonc.) Such an account need not exclude other features of emotion, such as awareness of physiological and behavioral responses or a particular phenomenological feel. But these, when present, are dependent on the appraisals of circumstances that capture what the emotion is about. Moreover, it is compatible with this view that emotions have complex neuropsychological structures that can be investigated by science.

To be more precise, an appraisal, on this view, is a belief or evaluation about the goodness or badness of some perceived or imagined event. Anger requires an evaluation that one has been unjustly slighted by another, fear that there is present harm or danger, grief that something valuable has been lost, love that one values a person as supremely important in one's life. On the Aristotelian view, the evaluation is experienced with pleasure or pain, and in some, but not all, cases with a reactive desire, not unlike the earlier mentioned action tendency. According to Aristotle, "Anger is a desire [*orexis*] accompanied by pain toward the revenge of what one regards as a slight toward oneself or one's friends that is unwarranted" (*Rhetoric,* 1378a30–32).

The appraisals constitutive of emotions can be weaker than strict beliefs (P. Greenspan). Thus, many of the thoughts that ground emotions are not judgments to which we would give assent, but are rather thoughts, perceptions, imaginings, and construals (*phantasiai,* Aristotle would say) that we dwell on in compelling ways, though without concern about "objective truth." Familiar sorts of examples illustrate the point. Juan may fear spiders, even though he knows that most spiders he is likely to encounter are harmless; or Clarissa may know that Joe is a no-good lover for her, but she still finds herself yearning for him. In these cases emotions have thought contents or appraisals, though ones that are at odds with more circumspect judgment. They are mental states that seem to lag behind what a person is ready to grasp through belief.

On an Aristotelian view, appraisals constitutive of emotions have a qualitative flavor—a feeling of pleasure or pain. The flavor may be intense or mild, present to consciousness or hidden somewhere as background noise. So, for example, a patient reflecting on her illness may have fears that all may not turn out well, even though she never feels any strong or noticeable tension when she focuses on that thought. Some emotions may be felt as a mix of both pleasure and pain. Even a quick "flash" of emotion, such as a

"twinge" of envy, can seem to oscillate quickly from one affective pole to another, from pain at another's good fortune to pleasure at being in a position to slight that person.

Aristotle suggests that many emotions have a motivational aspect, that is, they involve a reason or motive for action. Again, recognition of the diversity and variety of emotions is crucial here. Some emotions, such as calmness, confidence, and equanimity do not in an obvious way involve desires for action. In contrast, anger often involves a desire for revenge, just as envy seems to involve a desire to thwart others from having various goods. These sorts of desires can go on to constitute a motive or reason for full-fledged action, although often we train ourselves not to act, and not to take as a motive for action all our impulses and desires. In some cases, we act out our emotions only in our minds, as when out of anger, we slay the object of our anger in our fantasy life. Here impulses and urgings are present, but they are not taken up as reasons for action.

At yet other times we do externally act out our emotions but in a way in which that emotion still seems to fall short of constituting a full-fledged reason or motive for action. In anger, we sometimes act impulsively, slamming doors and storming out of rooms. This is a venting, a way of letting out tension, not a strategy for sweet revenge. Defiling a photograph of an ex-lover comes closer to the mark, for here at least there is symbolic aim. Nevertheless, these cases of anger do not really aim at effective revenge. They are reactive more than purposeful. And yet, they seem to be voluntary. They are certainly not the involuntary responses of the viscera. Like stroking a patient's brow or tousling a child's hair, emotion motivates the action. These two actions are likely done out of compassion and affection. But it seems strained, at least in some of these cases, to say that one does these actions in order to show compassion or affection—which is the common pattern a demand for reasons often takes. The gesture just expresses compassion or affection. The explanation stops there. It is not like drinking in order to slake thirst, in which drinking strategically promotes that end (Hursthouse).

Emotions and the Brain

In recent years neurophysiologists have turned to an analysis of emotions and the underlying brain structures of specific emotions and emotional pathologies. Two of the leading researchers in this field are Joseph E. LeDoux and Antonio R. Damasio.

In his 1996 book, *The Emotional Brain,* LeDoux makes three central points. First, he contends that emotions form a two-track response system. One track involves the "low road," or fast route where information travels directly from the thalamus, a subcortical "relay station" in the brain that mediates between external stimuli and specialized parts of the brain that process information, to the amygdala, a small region in the forebrain which generates the behavioral, autonomic and endocrine responses which make up an emotional reaction. The other track involves a "high road," or slow route where information takes a detour through the cortex, the more recently evolved part of the brain which supports higher cognitive functioning, including thinking, reasoning and consciousness. The first, subcortical pathway is a primitive survival mechanism, fast but "quick and dirty" and often filled with errors. It is the basis of the human fear response not only to snakes but also to slimy, bent sticks that look like snakes. The second cortical pathway is slower, but more precise, correcting for errors in overreaction and adding the advantages of conscious judgment and more fine-tuned discernment. The very slowness that makes it a poor defense mechanism suits it well for leisurely appraisal.

LeDoux notes, secondly, that memories of emotional situations are laid down by a two-track memory system. One system involves implicit or procedural memory, another explicit or declarative memory. So LeDoux asks us to imagine being in a horrific car accident, in which the horn gets stuck on. Later, when you hear a horn your body may automatically have a conditioned fear response—you break out in sweats, have a fast heartbeat, and so on. Procedural memory is at work, bringing information directly from the auditory system to the amygdala and opening the floodgates of emotional arousal. But in hearing the horn you also may remember the accident, consciously remembering the intersection where it happened, who was with you at the time, where you were headed, and so on. The two kinds of memories are of the same event, though one is emotion drenched, the other, cool and calm. Research by Larry R. Squire and Daniel Schacter, among others, suggests that the two memory systems are physically housed in different parts of the brain, though the memories, in normal cases, are "seamlessly fused" as one conscious, unified experience of the moment. The fusion results in memories that are "emotional." In those moments when we have arousal without declarative memory, we may experience intense emotions without knowing why. (This may be one explanation of the notion of "objectless" emotions.) Conversely, declarative memories without the emotional arousal of implicit memory may be experienced as emotionally flat.

In his third point, LeDoux focuses on our primitive fear response, suggesting that the brain system responsible for this mechanism can bypass higher, cognitive brain systems. But this leaves to the side questions about more complex, socially constructed emotions, such as indignation, compassion, pity, or shame. Do they operate solely through the high

road, or do they have low-road counterparts, which they routinely correct and educate? Again, are memories of feeling compassion or indignation marked by a two-tier system—the fusion of an awareness of a present arousal with a conscious evaluation of the situation that invoked arousal? These sorts of questions raise a more general concern about how to generalize from LeDoux's important study of the fear defense mechanism to the wide array of emotions that characterize people's waking and dreaming lives.

In his 1994 book, *Descartes' Error,* Damasio argues that a wide range of emotional behavior is not primarily subcortical but is a function of the frontal lobe of the brain, typically associated with reasoning and decision making. Indeed, Damasio's research suggests that the prefrontal cortex is involved in both emotional arousal and rational decision making and that the emotion centers and the reasoning centers in the frontal lobe are intimately related. Damasio begins his account with the famous case of Phineas Gage, a mid-nineteenth-century railroad worker whose frontal lobe was pierced by an iron tamping rod in an accident that occurred while Gage was blasting stone to make way for a straight rail track. To the surprise of his doctors at the time, Gage's severe brain injury (the rod exited the front of his brain and landed more than a hundred feet away) affected not just his reasoning capacities, but his emotional character as well. A calm and polite man prior to the injury, Gage became irreverent and foul mouthed, obstinate and capricious, and full of plans quickly hatched and soon abandoned. A similar pattern had been repeated in others with prefrontal lobe damage. While patients were able to generate emotional responses that travel subcortical, "low-road" paths ("primary emotions," as Damasio calls them), they could not generate "secondary emotions" that require evaluation of stimuli (LeDoux's "high-road" emotional responses). On the basis of a series of related experiments, Damasio concludes that prefrontally damaged patients are unable to have normal, automatic emotional responses. Though they may understand abstractly the emotional significance of some stimuli (such as the punitive side of the risky moves they repeatedly make), they fail to correct their strategies, Damasio argues, because they seem unable to pair that understanding with a mechanism to reenact, in this case, a negative emotional response. They lack what Damasio calls a "somatic marker" mechanism that stamps the appraisal with its appropriate emotional flavor.

Both LeDoux's and Damasio's work shed important light on the interdependence of emotion and reason in emotional behavior—LeDoux through his notion of "high-road" emotional pathways that stand ready to correct "quick and dirty" subcortical responses, Damasio through his analysis of prefrontal responses that embody pairings between representations of situations and appropriate emotional dispositions.

Control and Responsibility

Emotions are reactive responses. But in what sense are we human beings able to choose their emotional responses? How, if at all, can the will intervene in emotional behavior?

Aristotle is once again helpful here. Both action and emotion, he holds, are subject to choice in the following sense. We choose to develop a state of character that stabilizes certain dispositions toward action and emotion. Accordingly, how one feels (and acts) may be less a matter of choice at the moment than the indirect effect of choice over time. In the case of emotion, especially, there are few shortcuts. For unlike action, emotion does not seem to engage choice (or will) in each episode. At a given moment, we may simply not be able to will to feel a certain way however skilled we are at posing appropriate emotional, facial expressions, such as a polite smile or a look of interest.

Common parlance includes many expressions presuming that emotions are "up to us" in various ways. We exhort ourselves and others by such phrases as "pull yourself together," "snap out of it," "put on a good face," "lighten up," "be cheerful," "think positive," and "keep a stiff upper lip." In many of these cases, what the person is being implored to do is to take on the semblance of an emotion with the hope that it might "take hold" and rub off on the person's inner state. Practice as if you believe and you will believe. Or, as de Sousa put it, "earnest pretense is the royal road to sincere faith" (de Sousa, 1988, p. 324; also see Ekman; and Tomkins on posed expressions and facial feedback mechanisms). Similarly, we can sometimes fuel the flames of a sincerely felt emotion by allowing it bodily expression. To weep may intensify our grief or make us more conscious of its presence. The James-Lange theory, and its notion of proprioceptive feedback from the expression of emotion, may be in the background here. There are other sorts of actions a person might take that are not a matter of body language or putting on a new face. A person may try to talk herself out of love, but discover that only when she changes locales do the old ways begin to lose their grip. Other times, it is more trial by fire: staying put and exposing herself to what is painful in order to become inured. The latter process involves desensitization.

Sometimes changing one's mood may be more a matter of mental or perceptual strategy. It may be a matter of bringing oneself to focus on different objects and thoughts—trying to see things under a new gestalt or recomposing the scene. Exhortation and persuasion play an important role here. A patient depressed by the possibility of relapse might

be reminded of the favorable statistics and the steady progress she has made to date. Seeing things in a new light, with new emphases and stresses, helps to allay the fear. In a different vein, anger at a child may subside when one focuses less on minor annoyances and more on admirable traits. One may work on a more forgiving attitude in general by choosing to play down others' perceived faults or foibles. In certain cases, experiencing emotions is a matter of giving inner assent—of allowing oneself to feel angry or giving the green light to a new interest or love. It is as if something grabs hold, and then it is our turn to have some influence.

Mental training can of course follow a more methodical and introspective model. An individual can learn to take more careful note of the onset of certain emotions and of the movement of mind from one perceived object of importance to another. So Buddhists speak of a watchful mindfulness, an intensification of consciousness such that through awareness and knowledge, one comes to be more in charge (Thera).

There are other methods of effecting emotional change that depend upon so-called "deep" psychology. In psychoanalysis the recapitulation of patterns of emotional response through transference onto an analyst is intended to be a way of seeing at a detached level. The patient relives an emotional experience at the same time as he watches and interprets it. This is the putative advantage of an empathetic, clinical setting: A patient can come to see an emotional pattern in a detached way, free from judgment and accusation and from the crippling emotions that those stances often involve. In some cases, a patient tries to relieve the pain of present disabling emotions, such as anger, anxiety, or shame by coming to see their roots in primitive conflicts and frustrations that may have long been repressed. The goal is not to remove the patient from the vulnerabilities of emotion, but rather to make possible a way of experiencing emotions, including shame and anger, that is less crippling and self-destructive.

More Radical Extirpation or Removal of Emotions

Because emotions are valued as modes of attention, motivation, communication, and knowledge, we tend to put up with their messiness while at the same time attempting their reform. But there are venerable traditions in which moderating emotions through transformation and education is viewed as an inadequate therapy and an inadequate way of training moral character and agency. The Stoic view, which influenced later Kantian views and bears rough similarities to certain Eastern traditions, argues that the surges and delusions of emotion warrant their extirpation. Investment in objects and events we cannot control is the source of our suffering, and modification of our beliefs about these values is the source of our cure. In Stoic theory, virtue comes to be rooted in reason alone, for it is reason alone that is most appropriate to our nature and under our true dominion.

The attraction of the Stoic view rests in its powerful description of the anguish of the engaged emotional life. Many emotions (though not all) lead to attachment, but objects of attachment are never perfectly stable. Abandonment, separation, failure, and loss are the constant costs of love, effort, and friendship. The more tightly we cling to our investments, the more dependent we become upon what is uncontrolled and outside our own mastery. Self-reproach and persecution are often responses to lack of control. In our relations with others, the same clinginess of emotions can lead to stepping beyond what is appropriate, just as it can lead to exclusionary preferences and partialities. Provincialism can grow out of stubborn preference for what is familiar and comfortable according to class lines or other restrictive values.

This is a reasonable portrait of some moments of the life lived through emotion. Detachment and watchful awareness directed toward the emotions are important therapeutic stances in such a life. In addition, detachment and watchful awareness should be directed toward reason itself and its own tendencies toward egoism and imperious control. This is clearly at odds with Stoic practice though more in line with Eastern practices such as Buddhism. But it is difficult to see how a thoroughgoing rejection of the emotions can be compatible with what is a human life. Emotions, for all their selectivity, intensity, and stirring, enable us, through those very vulnerabilities, to attend, see, know, and experience in a way that pure cognition cannot. Some of that way of knowing and being known anguishes beyond words. Poetry and literature can only begin to express the reality. But even if at times unruled by reason's measure, emotion must not, on that account, be an outlawed feature of human life. Nor must it be an outlawed feature of morality. How we care for others, and what we notice and reveal, depends greatly on the subtlety, fineness, and often deep truth of our emotional readings of the world.

Conclusion

From the above, it should be clear that emotions play an expanded role within bioethics and within the moral practices of healthcare professionals. Emotional sensitivity is important for discerning the complexity of situations and for appreciating the competing needs and interests of various parties. A simple matter of noticing a patient's distress or displeasure, perhaps by attending to her facial expressions

and bodily gestures, could figure importantly in assessing a case. But by the same token, it is important to communicate emotions and not just record those of others. Conveying compassion to a patient can be a significant part of therapeutic treatment and, in general, be an important part of establishing a relationship in which medical counsel can be trusted and followed. Again, emotions figure in deliberation of choices. Compassion toward a patient can ground a reason for telling a patient the true nature of her condition in a tone that respects the patient's fragile, emotional state. The relevant choice a caretaker faces may not be whether to withhold or not withhold the truth, but rather how to tell the truth in a way that respects both a patient's autonomy and feelings. It is here that healthcare providers' own feelings of compassion and sympathy can importantly ground the specific choices she makes. Finally, healthcare providers, as morally responsible agents, need to have ready access to their own emotions, so that emotions help rather than hinder effective care. In cases, for example, in which fears and prejudice cloud more circumspect judgment, healthcare providers must recognize such fears and prejudice as emotional impediments standing in the way of delivering quality care. In general, a reflective stance toward one's own emotions becomes an important part of caring for others.

EMPIRICAL METHODS IN BIOETHICS

• • •

The period since 1970 has seen the development and maturation of the field of bioethics into a major area of scholarly inquiry. Scholarship in bioethics has traditionally relied on the discipline of moral philosophy and has taken a normative or prescriptive stance. However, bioethics is primarily a field of *practical* and *applied* study as well as a theoretical one. As such, to be relevant and useful to the providers and consumers of healthcare, bioethics must address questions and recommend solutions in the real world. Empirically-based studies provide an understanding of public and professional attitudes, practices, and the implications and intersections of practice and policy. These studies can provide information about the level at which purported problems actually exist and can be described and quantified. Similarly, they can measure the success or failure of public policies designed to help solve bioethics problems.

Employing the qualitative and quantitative methodologies of the social sciences and public health, bioethics scholars, often in collaboration with clinicians and scientists, have shed light on important bioethics questions such as:

- Patient and family preferences for treatment at the end of life;
- Nature and quality of communication between patients and physicians;
- Attitudes and understanding of informed consent by investigators and research subjects;
- Competency and the robustness of individual's stated wishes about end of life treatment;
- Why policy and legislative initiatives have failed to increase consent rates to organ donation;
- Impact of new genetic information on individuals, families, and society;
- Equity in allocation of scarce resources such as dialysis and organ transplantation;
- Disparities in the provision of care to ethnic minorities.

Research Methods

The methods used by researchers engaged in the empirical study of bioethics range from the quantitative to the qualitative, and often combine the two to provide a richer description of phenomenon and to answer research questions. Empirical research methods of all types comprise those that can be used to describe valid and reliable inquiries into phenomenon, including human behavior. Quantitative methods are used to answer hypotheses or to provide generalizable descriptions of populations and the incidence and prevalence of behaviors and problems within a population. Traditional quantitative methods in the social sciences include controlled experiments to compare the effects of an intervention on a sample population and measurement of subject characteristics. These measurements can include characterizing attitudes, behaviors, or physical characteristics. They are distinguished by the use of measurement tools that can provide reliable and replicable descriptions, usually in the form of numeric signifiers. Examples of such measurements are the use of psychometric tools to measure cognitive traits (e.g., anxiety, coping style, depression) and attitudes (trust in the healthcare system, fatalism). Psychometric techniques can also be sued to the measurement of physical traits such as

health status (using measurements like the SF–36 or activities of daily living). Most of these measurements take place within structured interviews (either interviewer-administered or self-administered) in which the responses of subjects are strictly prescribed. The phrasing of questions is regimented and the respondent is provided with what are called forced choice responses in which information is produced as standardized coded information. Aside from obtaining information directly from subjects, another major source of quantitative data is secondary sources, such as administrative databases (such as the Medicare database) and medical records. The advantages of quantitative methods are that they enable collection of data from large sample sizes in standardized ways that permit comparisons across various populations and time periods. They also allow for controlled interventions or controlled introduction of conditions to subjects. These methods have allowed the documentation of racial and gender disparities in the provision of healthcare services.

Bioethics researchers have generally used qualitative methods in the generation of hypotheses rather than in the testing of hypotheses. Deduction characterizes qualitative methods, whereas induction characterizes research using quantitative methods. Qualitative methods permit detailed, and sometimes more accurate, observation of behaviors and contribute to the understanding of underlying social and cultural characteristics associated with specific patterns of behaviors. Moreover, qualitative methods allow discovery of subjects' perspectives rather than imposing a pre-existing framework. Qualitative methods can allow researchers to access areas of investigation not amenable to quantitative research, and to explore areas that have been little researched in the past. For example, how infertile couples have experienced new reproductive technologies and how they have incorporated traditional understandings of parenthood into their conceptual models of the rights and obligations of parents.

Qualitative methods include a variety of techniques. Subject interviews that incorporate wholly or partly open-ended questions are commonly used. These allow respondents to provide answers to questions in their own words, and allow interviewers to probe or follow up on information provided by respondents. More formative interviewing, in which the interviewer uses a guide to begin discussion about the research topic but does not structure the questions that follow, can also be used. In this type of interview, the subject creates a narrative and engages in a dialogue with the interviewer that informs the researcher about the topic under investigation. A similar technique, the focus group, uses six to twelve informants gathered to discuss a particular issue. For example, a study of the social and ethical consequences of genetic testing for Huntington's Disease might gather individuals from families affected by Huntington's Disease to discuss their attitudes, preferences, and intentions about genetic testing.

Qualitative methods can also include direct observation of healthcare situations and populations. For example, studies of informed consent to clinical trials have included directly observing and audio- or videotaping the consent conversation. Conversations can be examined as narratives and themes explored, or behaviors can be coded to extract quantitative data. For example, a trained observer can use 0, 1 coding to measure whether certain behaviors (e.g., explaining that trial participation is voluntary) occur or not. Participant observation—in which the observer actually participates in and observes the daily activities of a setting of interest (for example, observing a primary care setting to understand how or when advance directives are discussed with elderly patients)—can also generate a variety of data types. Personal diaries in which individuals are asked to keep records of activities and behaviors are another technique.

Historically, social sciences researchers have strictly divided themselves into researchers using quantitative methods (i.e., psychologists) or qualitative methods (i.e., anthropologists). However, in recent years there has been a blurring of these distinctions and an increasing enthusiasm for multimethod research. Whereas qualitative research begins by acknowledging that there is a range of different ways of making sense of the world, and approaches its subject matter in a naturalistic, interpretive way, quantitative research overlays hypothesized paradigms on the research phenomena of interest and collects data that can help determine the distributions of characteristics and behaviors in populations and settings. For example, quantitative studies have established how frequently dying patients are treated with futile therapies, but have not been especially successful in explaining why.

Conclusion

Ultimately, scholarship in bioethics can benefit from the methodologies of both the humanities and the empirical sciences. Normative bioethics provides a framework and guideposts for suggesting how healthcare services ought to be delivered, and what the fiduciary responsibilities of clinicians to patients are. However, normative bioethics is unable to describe and explain how these play out in real life. Moreover, the value placed in the principles of bioethics and the use made of these principals by actors in healthcare settings can only be illuminated using empirical methods. In

the final analysis, the best empirical research in bioethics will always be based on a sophisticated understanding of the historical, philosophical, and cultural contexts of the delivery and consumption of healthcare services. Similarly, philosophical debate can often be enriched by an awareness of empirical data.

ENDANGERED SPECIES AND BIODIVERSITY

• • •

Although projections vary, reliable estimates are that about 20 percent of Earth's species may be lost within a few decades, if present trends go unreversed. These losses will be about evenly distributed through major groups of plants and animals in both developed and developing nations, with special concerns over tropical forests (Ehrlich and Ehrlich; Wilson).

The United Nations at the 1992 Earth Summit in Rio de Janeiro launched the Convention on Biological Diversity, signed by 153 nations that are "concerned that biological diversity is being significantly reduced by certain human activities" and who are "conscious of the intrinsic value of biological diversity and of the ecological, genetic, social, economic, scientific, educational, cultural, recreational and aesthetic values of biological diversity," and "conscious also of the importance of biological diversity for evolution and for maintaining life sustaining systems of the biosphere" (United Nations, Preamble).

The U.S. Congress has lamented the lack of "adequate concern [for] and conservation [of]" species, and has sought to protect species through the Endangered Species Act, as well as through the Convention on International Trade in Endangered Species (U.S. Congress, Sec. 2(a) (1)). About five hundred species, subspecies, and varieties of fauna have been lost since 1600 in what is now the continental United States. The natural rate would have been about ten (Opler). In Hawaii, of sixty-eight species of birds unique to the islands, forty-one are extinct or virtually so. Half of the twenty-two hundred native plants are endangered or threatened. A candidate list for all states contains over two thousand taxa (species and significant subspecies and forms) considered to be endangered, threatened, or of concern, three categories used to rank degree of jeopardy (U.S. Fish and Wildlife Service). Human-caused extinctions threaten to approach and even exceed the catastrophic extinction rates of the geological past.

Even where species are not endangered, almost all inhabited lands are impoverished of their native fauna and flora, owing to development, loss of habitat, hunting, collection, trade in fauna and flora, toxic pollutants, introduction of exotic species, and other disturbances produced by humans. Sustainable biodiversity, the use of biotic resources so as to leave them unimpaired for future generations, is an increasing concern. Another concern is the loss of wetlands, permanently or periodically flooded or wet areas, which at the end of the twentieth century in many areas are less than 10 percent of their original area. There is hardly a forest, grassland, or desert system in the developed world that is not impoverished of its once-native fauna and flora. Old-growth or pristine forests have been cut rapidly, as have tropical rain forests. Island ecosystems, often with species peculiar to that location and found nowhere else, are particularly at risk.

In the conservation of endangered species and biodiversity, bioethics in principle and in practice involves an unprecedented mix of science and conscience, especially since the species and ecosystem levels seldom figured in earlier ethical deliberations. A rationale for saving species that centers on their worth to persons is anthropocentric; a

rationale that includes their intrinsic and ecosystemic values, in addition to or independently of persons, is naturalistic.

On an anthropocentric account, the duties involved are to persons; there are no duties to endangered species, though duties may concern species. Persons have a strong duty of nonmaleficence—not to harm others—and a weaker, though important, duty of beneficence—to help others. Many endangered species—which ones we may not now know—are expected to have agricultural, industrial, and medical benefits. They may be of scientific value, serve as indicators of ecosystem health, or provide genetic breeding stock for improvement of cultivated plants. Humans ought to conserve their global resources, a matter of prudence and enlightened self-interest in general, but a matter of moral concern when some persons threaten the benefits of these resources for other persons. Nonrenewable resources may have to be mined and consumed, but biological resources can be perennially renewable.

A developing concern between the species-rich, often underdeveloped countries and the developed countries, which are frequently responsible in part for environmental degradation, is who should bear the costs of saving species relative to benefits gained. Historically, native plant species, seeds, and germ plasm have been considered not to be owned by any nation. Developing nations are claiming ownership by the country of origin, arguing that these resources cannot be used by those in other nations without negotiating compensation. At the same time, developing nations claim that their biological resources are being conserved for the benefit of other nations, and that the developed nations ought to pay developing nations not only for new conservation measures put into effect there but also for the lost opportunity costs of development in such conserved areas.

The Convention on Biological Diversity states: "States have sovereign rights over their own biological resources" (United Nations, Preamble) and continues, "Recognizing the sovereign rights of States over their natural resources, the authority to determine access to genetic resources rests with the national governments and is subject to national legislation" (Art. 15). Nevertheless, the problem of reconciling biodiversity as a common heritage of humankind with biodiversity as a national resource remains unresolved. States may control access to biodiversity, but this does not imply ownership. The United States refused to sign the Convention over questions of ownership, both of the wild biodiversity and of beneficial technology derived from it.

On the harm side, the loss of a few species may have no evident results now, but the loss of many species imperils the resilience and stability of the ecosystems on which humans depend. The danger increases with subtractions from the ecosystem, a slippery slope into serious troubles. Many species that have no direct value to humans are part of the biodiversity that keeps ecosystems healthy. On the benefits side again, there are less tangible benefits. Species that are too rare to play roles in ecosystems can have recreational and aesthetic value—even, for many persons, religious value. Species can be curiosities. They can be clues to understanding natural history. Destroying species is like tearing pages out of an unread book, written in a language humans hardly know how to read, about the place where they live. Humans need insight into the full text of natural history.

Such anthropic reasons are pragmatic and impressive. They are also moral, since persons are benefited or hurt. But can all duties concerning species be analyzed as duties to persons? Many endangered species have no resource value, nor are they particularly important for the other reasons given above. Are there worthless species? As curiosities and relics of the past, perhaps all species can be given an umbrella protection by saying that humans ought to preserve an environment adequate to match their capacity to wonder. Nature is a kind of wonderland. But this introduces the question of whether preserving resources for wonder is not better seen as preserving a remarkable natural history that has objective worth—an evolutionary process that has spontaneously assembled millions of species. A naturalistic account values species and speciation directly.

A further rationale is that humans of decent character will refrain from needless destruction of all kinds, including destruction of any species. Such a prohibition seems to depend, however, on some value in the species as such, for there need be no prohibition against destroying a valueless thing. The deeper problem with the anthropocentric rationale is that its justifications are less than fully moral, fundamentally exploitive, and self-serving, even if subtly so. This is not true intraspecifically among humans, when out of a sense of duty an individual defers to the values of other persons. But it is true interspecifically, since *Homo sapiens* treats all other species as resources. Ethics has always involved partners with entwined destinies. But ethics has never been very convincing when pleaded as enlightened self-interest (that one ought always to do what is in one's intelligent self-interest), including class self-interest, even though in practice altruistic ethics often needs to be reinforced by self-interest. To value all other species only in terms of human interests is rather like a nation's arguing all its foreign policy in terms of national self-interest. Neither seems to be completely moral.

It is safe to say that in the decades ahead, the quality of life will decline in proportion to the loss of biotic diversity, though it is often thought that one must sacrifice that diversity to improve human life. So there is a sense in which

humans will not be losers if we save endangered species. Humans who protect endangered species will, if and when they change their value priorities, be better persons for their admiring respect for other forms of life. But this should not obscure the fact that humans can be short-term losers. Sometimes we do have to make genuine sacrifices, at least in terms of what we presently value, to preserve species. If, for instance, Americans wish to save the spotted owl, they will have to pay higher prices for timber and accept some job losses and relocations.

Dealing with a problem correctly requires an appropriate way of thinking about it. On the scale of evolutionary time, humans appear late and suddenly. Even later and more suddenly they increase the extinction rate dramatically. What is offensive in such conduct is not merely the loss of resources but also the maelstrom of killing and insensitivity to forms of life. What is required is not prudence but principled responsibility to the biospheric Earth.

There are problems at two levels when considering duties to species; one is about facts (a scientific issue), and one is about values (an ethical issue). First, what sort of biological entity is a species? Indeed, do species exist at all? No one doubts that individual organisms exist, but species can have a more controversial factual reality. Taxonomists regularly revise species designations and routinely put after a species the name of the "author" who, they say, "erected" the taxon. If a species is only a category or class, boundary lines may be arbitrarily drawn, and the species is nothing more than a convenient grouping of its members, an artifact of taxonomists. Some natural properties are used—reproductive structures, bones, teeth. But which properties are selected and where the lines are drawn vary with taxonomists.

If this approach is pressed, species can become a conventional concept, a mapping device, that is only theoretical, something like the lines of longitude and latitude. Sometimes endangered species designations have altered when taxonomists have decided to lump or split previous groupings. To whatever degree species are artifacts of taxonomists, duties to save them seem unconvincing. No one proposes duties to genera, families, orders, phyla; biologists concede that these do not exist in nature.

On a more realist account, a biological species is not just a class; it is a living historical form (Latin *species,* a natural kind), propagated in individual organisms, that flows dynamically over generations. Species are dynamic natural kinds, historically particular lineages. A species is a coherent, ongoing form of life expressed in organisms, encoded in gene flow, and shaped by the environment. In this sense, species are objectively there as living processes in the evolutionary ecosystem—found, not made, by taxonomists. The claim that there are specific forms of life historically maintained in their environments over time does not seem arbitrary but, rather, as certain as anything else we believe about the empirical world, even though at times scientists revise the theories and taxa with which they map these forms.

Species are not so much like lines of latitude and longitude as like mountains and rivers, phenomena objectively there to be mapped. The edges of such natural kinds will sometimes be fuzzy, to some extent discretionary. We can expect that one species will slide into another over evolutionary time. But it does not follow from the fact that speciation is sometimes in progress that species are merely made up, instead of found as evolutionary lines articulated into diverse forms, each with its more or less distinct integrity, breeding population, gene pool, and role in its ecosystem (Rojas).

Having recognized what a species is, the next question is why species ought to be protected. The naturalistic answer is that humans ought to respect these dynamic life forms preserved in historical lines, vital informational processes that persist genetically over millions of years, overleaping short-lived individuals. It is not *form* (species) as mere morphology, but the *formative* (speciating) process that humans ought to preserve, although the process cannot be preserved without its products. Endangered "species" is a convenient and realistic way of tagging this process, but protection can be interpreted (as the Endangered Species Act permits) in terms of subspecies, variety, or other taxa or categories that point out the diverse forms of life.

A consideration of species is both revealing and challenging because it offers a biologically based counterexample to the focus on individuals—typically sentient and usually persons—so characteristic in Western ethics. In an evolutionary ecosystem, it is not mere individuality that counts; the species is also significant because it is a dynamic life form maintained over time by an informed genetic flow. The individual represents (re-presents) a species in each new generation. It is a token of a type, and the type is more important than the token. A biological identity—a kind of value—is here defended. The dignity resides in the dynamic form; the individual inherits this, exemplifies it, and passes it on.

A species lacks moral agency, reflective self-awareness, sentience, and organic individuality. Some have been tempted to say that species-level processes cannot count morally. But each ongoing species defends a form of life, and these diverse species are, on the whole, good kinds. Such speciation has achieved all the planetary richness of life. All ethicists say that in *Homo sapiens* one species has appeared that not only exists but also ought to exist. A naturalistic ethic refuses to

say this exclusively of a late-coming, highly developed form, and extends this duty more broadly to the other species—though not with equal intensity over them all, in view of varied levels of evolutionary achievement. Only the human species contains moral agents, but conscience ought not to be used to exempt every other form of life from consideration, with the resulting paradox that the sole moral species acts only in its collective self-interest toward all the rest.

Extinction shuts down the generative processes. The wrong that humans are doing, or allowing to happen through carelessness, is stopping the historical gene flow on which the vitality of life is based, and which, viewed at another level, is the same as the flow of natural kinds. Every extinction is an incremental decay in this stopping of life. Every extinction is a kind of superkilling. It kills forms (species) beyond individuals. It kills "essences" beyond "existences," the "soul" as well as the "body." It kills collectively, not just distributively. We do not merely lament the loss of potential human information; we lament the loss of biological information, present independently of instrumental human uses of it. A shutdown of the life stream on Earth is the most destructive event possible. Each human-caused extinction edges us further in this direction; already the rate may be catastrophic.

A consideration of species strains any ethic fixed on individual organisms, much less on sentience or persons. But the result can be biologically sounder, though it revises what was formerly thought to be logically permissible or ethically binding. When ethics is informed by this kind of biology, it is appropriate to attach duty dynamically to the specific form of life. The species line is the more fundamental living system, the whole of which individual organisms are the essential parts. The species, too, has its integrity, its individuality; and it is more important to protect this than to protect individual integrity. The appropriate survival unit is the appropriate level of moral concern.

A species is what it is inseparably from the environmental niche into which it fits. Particular species may not be essential in the sense that the ecosystem can survive the loss of individual species without adverse effect. But habitats are essential to species, and an endangered species typically means an endangered habitat. Species play lesser or greater roles in their habitats. This leads to an enlarged concern for the preservation of species in the system. It is not merely *what* they are, but *where* they are that one must value correctly. This limits the otherwise important role that zoos and botanical gardens can play in the conservation of species. They can provide research, a refuge for species, breeding programs, aid for public education, and so forth, but they cannot simulate the ongoing dynamism of gene flow over time under the selection pressures in a wild ecosystem. They amputate the species from its habitat.

Extinction is a quite natural event, but there are important theoretical and practical differences between natural and anthropogenic (human-caused) extinctions. Artificial extinction, caused by human encroachments, is radically different from natural extinction. Relevant differences make the two as morally distinct as death by natural causes is from murder. Though harmful to a species, extinction in nature is seldom an evil in the system. It is, rather, the key to tomorrow. The species is employed in, but abandoned to, the larger historical evolution of life. There are replacements. Such extinction is normal turnover in ongoing speciation.

Anthropogenic extinction differs from evolutionary extinction in that hundreds of thousands of species will perish because of culturally altered environments that are radically different from the spontaneous environments in which such species are naturally selected and in which they sometimes go extinct. In natural extinction, nature takes away life when it has become unfit in habitat, or when the habitat alters, and typically supplies other life in its place. Artificial extinction shuts down tomorrow, because it shuts down speciation. Natural extinction typically occurs with transformation, either of the extinct line or of related or competing lines. Artificial extinction is without issue. One opens doors; the other closes them. In artificial extinctions, humans generate and regenerate nothing; they only dead-end these lines.

Through evolutionary time nature has provided new species at a net higher rate than the extinction rate; hence the accumulated global diversity. There have been infrequent catastrophic extinction events, anomalies in the record, each succeeded by a recovery of previous diversity. Although natural events, these extinctions so deviate from the normal trends that many paleontologists look for causes external to the evolutionary ecosystem—supernovas or collisions with asteroids. Typically, however, the biological processes that characterize Earth are both prolific and have considerable powers of recovery after catastrophe. Uninterrupted by accident, or even interrupted so, they steadily increase the numbers of species.

An ethicist has to be circumspect. An argument may commit what logicians call the genetic fallacy in supposing that present value depends upon origins. Species judged today to have intrinsic value may have arisen anciently and anomalously from a valueless context, akin to the way in which life arose mysteriously from nonliving materials. But in an ecosystem, what a thing is differentiates poorly from the generating and sustaining matrix. The individual and the

species have their value inevitably in the context of the forces that beget them. There is something awesome about an Earth that begins with zero and runs up toward five to ten million species in several billion years, setbacks notwithstanding.

Several billion years' worth of creative toil, several million species of teeming life, have been handed over to the care of the late-coming species in which mind has flowered and morals have emerged. On the humanistic account, such species ought to be saved for their benefits to humans. On the naturalistic account, the sole moral species has a duty to do something less self-interested than count all the products of an evolutionary ecosystem as human resources; rather, this host of species has a claim to care in its own right. There is something Newtonian, not yet Einsteinian, as well as something morally naive, about living in a reference frame where one species takes itself as absolute and values everything else relative to its utility.

In addition to the deeper ethical principles at issue in conservation of species, questions of pragmatic strategy arise. One strategy proposed when there are limited resources is to sort jeopardized species into three groups: those that are probably going extinct even if we try hard to save them, those that will probably survive without our help, and those that will probably go extinct unless we intervene. This strategy is called triage. An alternative, or complementary, strategy is to focus more on endangered ecosystems than on single species, an approach that may result both in more effective management and in more efficient use of resources. Another strategy discourages claiming biodiversity as a national resource while thinking of conservation in other nations in terms of foreign policy, for if biodiversity is the common heritage of humankind, all nations share duties to protect it.

ENHANCEMENT USES OF MEDICAL TECHNOLOGY

• • •

In bioethics, one frequently encounters the belief that there is an important moral distinction between using biomedical tools and products to combat human disease and attempting to use them to "enhance" human traits. Thus, people argue that using biosynthetic human growth hormone to treat an inborn growth-hormone deficiency is praiseworthy, but that the use of the same product to increase the height of a short but hormonally normal child is not (Daniels, 1992). Similarly, while the use of human gene-transfer techniques to treat disease enjoys widespread support from secular and religious moral authorities, a line is usually drawn at using the same protocols to attempt to improve upon otherwise healthy traits (Anderson; Baird).

Even those unwilling to condemn the enhancement uses of biomedicine outright generally concur that ethics demands that therapeutic applications of these tools be given priority for research and development (Walters and Palmer). As a result, this distinction has been enshrined in policies at both professional and governmental levels, and it continues to inform much of the public discussion of new biomedical advances (Parens, 1998). The distinction is explicated in several different ways, however, which have different merits as moral boundary markers for medical research and practice. In fact, it often seems in danger of evaporating entirely under conceptual critiques even before the question of its moral merits is entertained.

Professional Domain Approaches

One approach to the enhancement/treatment distinction is to define it in terms of the accepted limits of professional medical practice. Under this view, *treatments* are any interventions that physicians and their patients agree are useful and proper, while *enhancements* are simply interventions that are considered to fall beyond a physician's professional purview. Thus, physician-prescribed physical therapy to improve muscle strength would be considered legitimate medical treatment, while weight lifting under a coach's supervision to achieve a particular physique would be considered an enhancement. This view resonates well with a number of contemporary social-scientific critiques of biomedicine, which suggest that medicine has no natural domain of practice beyond that which it negotiates with society (Good). It also provides a simple normative lesson for professionals concerned about their obligations in specific cases. Given medicine's fundamentally patient-centered ethos, one takes one's cues from the patient's value system, and thus negotiates toward interventions that can help achieve the patient's vision of human flourishing (Engelhardt).

Unfortunately, these same features also deny this approach the ability to be of help to those attempting to use the treatment/enhancement distinction in order to regulate biomedical research. Some argue that medicine's lack of an essential domain of practice means that a coherent distinction between medical and nonmedical services can never be drawn in the first place (Davis). Others accept the distinction between treating and enhancing, but question traditional values of medicine by arguing that privileging treatment over enhancement is itself wrong (Silvers). Still others argue that, for psychological and economic reasons, a professional medical line between treatment and enhancement will be impossible to maintain in practice (Gardner). To the extent that useful "upper-boundary" concepts are required at the policy level—for societies making healthcare research allocation decisions, for example—this impotence is an important weakness.

The Normalcy Approach

Fortunately, another approach to interpreting the treatment/enhancement distinction is framed explicitly as a policy tool for separating legitimate healthcare needs from luxury services. The most developed exposition of this view is Sabin and Daniel's endorsement of what they call the "normal function" standard for determining the limits of "medically necessary" (and therefore socially underwritten) health services (p. 13). Sabin and Daniels argue that an appropriate boundary between medically necessary treatments and optional enhancements can be drawn by thinking about how to provide medical services fairly within a population. Following Daniels' earlier work, they construe healthcare as one of society's means for preserving equality of opportunity for its citizens, and they define "healthcare needs" as those services that allow individuals to enjoy the portion of the society's "normal opportunity range" to which their full array of skills and talents would give them access. This is done by restoring or improving the patient's

abilities to the range of functional capacities typical for members of his or her reference class (e.g., age and gender) within the human species. Any interventions that would expand an individual's range of functional capacities beyond the range typical for his or her reference class would be deemed a medically unnecessary enhancement. Others have used similar understandings of human malady to help explicate a distinction between "negative" (e.g., therapeutic) and "positive" (e.g., enhancing) human genetic engineering (Berger and Gert).

The advantage of the normal-function approach is that it provides one relatively unified goal for healthcare, toward which the burdens and benefits of various interventions can be relatively objectively titrated (measured against one another), balanced, and integrated. The normal-function approach comes close to accurately reconstructing the rationale behind many actual "line drawing" judgments by healthcare coverage plans and professional societies (Brock et al.). Unfortunately, this approach also faces conceptual challenges in an important way. The first serious problem is that of prevention. While efforts at generic "health promotion" straddle the border of biomedicine, efforts to prevent the manifestation of specific maladies in individuals are always accepted as legitimate parts of biomedicine, and thus are automatically located on the treatment side of the enhancement boundary. On the other hand, one of the ways one can prevent a disease is to strengthen the body's ability to resist it long before any diagnosable problem appears. These forms of prevention attempt to elevate bodily functions above the normal range for the individual (and in some cases the species), and to that extent seem to slide into enhancement (Juengst). If human gene–transfer protocols like these are acceptable as forms of preventive medicine, how can it be claimed that healthcare practitioners should be "drawing the line" at enhancement?

Disease-Based Approaches

Probably the most common rejoinder to the problem of prevention is to distinquish the problems to which prevention efforts respond. Treatments are interventions that address the health problems created by diseases and disabilities ("maladies" in the helpful language of Clouser, Culver, and Gert). Enhancements, on the other hand, are interventions aimed at healthy systems and normal traits. Thus, prescribing biosynthetic growth hormone to rectify a diagnosable growth-hormone deficiency is legitimate treatment, while prescribing it for patients with normal growth-hormone levels would be an attempt at "positive genetic engineering," or enhancement (Berger and Gert). Thus, to justify an intervention as appropriate medicine means to be able to identify a pathological problem in the patient. If no medically recognizable malady can be diagnosed, the intervention cannot be "medically necessary," and is thus suspect as an enhancement.

This interpretation has the advantages of being simple, intuitively appealing, and consistent with a good bit of biomedical behavior. Maladies are both objectively observable phenomena and the traditional target of medical intervention. They can be discovered through diagnosis, and it will be clear when one has gone beyond medicine when no pathology can be identified (Juengst). This interpretation is used by professionals working at the boundary, like cosmetic surgeons, to justify their services in terms of relieving "diagnosable" psychological suffering rather than satisfying the aesthetic tastes of their clients (Morgan), and it is also used when insurance companies insist on being provided with a diagnosis before providing coverage for surgery.

However, this interpretation does also face at least two major difficulties. The first problem that any disease-based interpretation of the enhancement boundary faces is, of course, biomedicine's infamous nosological elasticity. It is not that hard to coin new maladies for the purposes of justifying the use of enhancement interventions. By interpreting the boundary of medicine in terms of maladies, this approach puts the power for drawing that boundary squarely in the profession's hands, with the corresponding potential for abuse.

The more important problem, however, is that no matter where the line is drawn, most biotechnological interventions that could become problematic as enhancement interventions would not have to cross that line in order to be developed and approved for clinical use, because they will also have legitimate therapeutic applications. In fact, most biosynthetic biologicals and gene-transfer protocols with potential for enhancement uses will first emerge as therapeutic agents. General cognitive-enhancement interventions, for example, are likely to be approved for use only in patients with neurological diseases (Whitehouse et al.). However, to the extent that they are in high demand by individuals who are merely suffering the effects of normal aging, the risk of unapproved, or "off-label," uses of these products will be high (Mehlman). This last point is critical for policy purposes, because it suggests that the real challenge to regulation in this area may not be the development of enhancement interventions or "enhancement research," but downstream off-label uses of gene therapies for nonmedical enhancement purposes. The policy problem then becomes controlling access and use of the technologies, not their

research and development. This presents another set of challenges for the law, since the novelty of enhancement technologies will make it difficult for judges and juries to ascertain the reasonableness of physician behavior (Mehlman).

These realities have pressed those who would use the treatment/enhancement distinction for policy purposes to articulate the moral dangers of genetic enhancement more clearly. After all, personal improvement is praised in many spheres of human endeavor, and biomedical interventions such as cosmetic surgery are well accepted, at lease in American society, as means to achieving personal improvement goals.

The Moral Dangers of Enhancement

There are two lines of thought that have emerged from this work. The first focuses on the idea that biomedical enhancements are a form of social cheating. In this view, taking the biomedical shortcut erodes the specific social practices that make the analogous human achievement valuable in the first place. Thus, some argue that it defeats the purpose of the contest for the marathon runner to gain endurance chemically rather than through training, and it misses the point of meditation if one can gain Nirvana through psychosurgery. In both cases, the value of the improvements lie in the achievements they reward as well as the benefits they bring. The achievements (successful training or disciplined meditation) add value to the improvements because they are understood to be admirable social practices in themselves. Wherever a biomedical intervention is used to bypass an admirable social practice, then, the improvement's social value (the value of a runner's physical endurance or a mystic's visions) is weakened accordingly. To preserve the value of the social practices considered to be "enhancing," it may be in society's interest to impose a means-based limit on biomedical enhancement efforts.

Interpreting enhancement interventions as those that short-circuit admirable human practices has special utility for policy analysis. To the extent that biomedical shortcuts allow specific accomplishments to be divorced from the admirable practices they were designed to signal, the social value of those accomplishments will be undermined. Not only will the intrinsic value be diminished for everyone that takes the shortcut, but the resulting disparity between the enhanced and unenhanced will call the fairness of the whole game—be it educational, recreational, or professional—into question. If the extrinsic value of being causally responsible for certain accomplishments is high enough (like professional sports salaries), the intrinsic value of the admirable practices that a particular institution was designed to foster may start to be called into question (Murray). For institutions interested in continuing to foster the social values for which they have traditionally been the guardians, a choice will have to be made. Either they must redesign the game (of education, sports, etc.) to find new ways to evaluate excellence in the admirable practices that are not affected by available enhancements, or they must prohibit the use of the enhancing shortcuts. Which route an institution should take depends on the possibility and practicality of taking either, because ethically they are equivalent.

Unfortunately, some of the social games people can play (and cheat at) do not turn on participants' achievements at all, but on traits over which individuals have little control, such as stature, shape, and skin color. The social games of stigmatization, discrimination, and exclusion use these traits in the same manner that other practices use achievements: as intrinsically valuable keys to extrinsic goods. It is becoming increasingly possible to seek biomedical help in changing these traits in order to short-circuit these games as well. The biomedical interventions involved, such as skin lighteners or stature increasers, are enhancements because they serve to improve the recipient's social standing, but only by perpetuating the social bias that inspired their use. When *enhancement* is understood in this way, it warns of still another set of moral concerns.

What makes the provision of human growth hormone to a short child a morally suspicious enhancement is not the absence of a diagnosable disease or the "species atypical " hormone level that would result—it is the intent to improve the child's social status by changing the child, rather than by changing her social environment, that is questionable (White). Such enhancement interventions are almost always wrongheaded, because the source of the social status they seek to improve is, by definition, the social group and not the individual. Attempting to improve that status in the individual amounts to a moral mistake akin to "blaming the victim": it misattributes causality, is ultimately futile, and can have harmful consequences. This is the interpretation of enhancement that seems to be at work when people argue that to use Ritalin to induce cooperative behavior in the classroom inappropriately "medicalizes" a social problem. In such cases, the critics dispute the assumption that the human need in question is one that is created by, and quenchable through, the human body, asserting instead that both its source and solution really lie in quite a different sphere of human experience.

This interpretation of the enhancement concept is useful to those interested in the ethics of personal improvement because it warns of a number of moral pitfalls beyond the baseline considerations that the enhancement/treatment distinction provides. Attempting to improve social status by

changing the individual risks being self-defeating (by inflating expectations), futile (if the individual's comparative gains are neutralized by the enhancement's availability to the whole social group), unfair (if the whole group does not have access to the enhancement), or complicit with unjust social prejudices (by forcing people into a range of variation dictated by biases that favor one group over others). For those faced with decisions about whether to attempt to enhance themselves or their children through gene transfer, this way of understanding enhancement is much more illuminating than attempts to distinquishing it from medical treatment, because it points to the real values at stake. Ideally, gene transfer should not make an existing social problem worse, even if exacerbating injustice would further one's own interests.

On the other hand, protecting these values is difficult in a pluralistic society, because it means developing ways to police individuals' complicity with suspect social norms (Little). Under the historical shadow of state-sponsored eugenics programs, the U.S. government is unlikely to promulgate lists of acceptable and unacceptable enhancements, even if the intent of the lists are to protect the interests of those who are unenhanced.

Policy Implications

Clearly, all of the ways of understanding enhancement as a moral concept reviewed here have limitations. However, all these interpretations do seem to be alive and well and mixed together in the literature on the topic. It is not possible to cleanly assign the different interpretations of enhancement to different spheres of ethical analysis. But there do seem to be some rough correlations that might be made. Thus, the interpretations that contrast enhancement interventions with treatments seem most useful where it is the limits of medicine's expertise that are at issue. Whether medicine's boundary is defined in terms of concepts of disease, or in sociological terms as the scope of medical practice, or in terms of some theory of the human norm, this interpretation at least provides tools to draw that boundary. Moreover, all other considerations being equal, the line that it draws is the boundary of medical obligation, not the boundary of medical tolerance. Using this tool, enhancement interventions such as cosmetic surgery can still be permissable for physicians to perform, but it is also permissable to deny them to patients.

This has important implications for social policymaking about healthcare coverage, to the extent that society relies on medicine's sense of the medically necessary to define the limits of its obligations to underwrite care. Again, all other considerations being equal, this interpretation of the concept suggests that few enhancement interventions should be actively prohibited by society or foregone by individuals, even when they are not underwritten as a part of healthcare, since there is nothing intrinsically wrong with seeking self-improvements beyond good health.

In contrast, the interpretations of enhancement that focus on the misuse of biomedical tools in efforts at self-improvement seem the most relevant to issues of personal, rather than professional, ethics. Concerns about the authenticity of particular accomplishments are moral challenges to the individual, but find little purchase in the professional ethics of biomedicine, with its focus on the physical safety and efficacy of its tools. The primary policy implications of this interpretation are for the social institutions charged with fostering particular admirable practices, for enhancement interventions that offer biomedical shortcuts to achievement force reassessments of the values these institutions stand for, as well as the practices designed to foster them.

Finally, at the other end of the spectrum, enhancement interventions that seem to commit the moral mistake of trying to address social problems through the bodies of the potentially oppressed do seem to mark a stronger set of moral boundaries for all concerned. For biomedicine, this concept marks an epistemic limit beyond which medical approaches to problem solving are not only unnecessary, but conceptually wrong-headed. For individuals, parents, and society, these kinds of enhancement interventions risk either backfiring (by exacerbating the social problems they are intended to address) or being futile (if they merely result in a shift of the normal range for a given social trait).

ENVIRONMENTAL ETHICS

• • •

I. OVERVIEW

The magnitude and urgency of contemporary environmental problems—collectively known as the environmental crisis—form the mandate for environmental ethics: a reexamination of the human attitudes and values that influence individual behavior and government policy toward nature. The principal approaches to environmental ethics are "anthropocentrism," or the human-centered approach; "biocentrism," or the life-centered approach; and "ecocentrism," or the ecosystem-centered approach. Variously related to these main currents of environmental ethics are "ecofeminism" and "deep ecology." Moral "pluralism" in environmental ethics urges that we endorse all of these approaches and employ any one of them as circumstances necessitate.

Anthropocentrism

An anthropocentric environmental ethic grants moral standing exclusively to human beings and considers nonhuman natural entities and nature as a whole to be only a means for human ends. In one sense, any human outlook is necessarily anthropocentric, since we can apprehend the world only through our own senses and conceptual categories. Accordingly, some advocates of anthropocentric environmental ethics have tried to preempt further debate by arguing that a non-anthropocentric environmental ethic is therefore an oxymoron. But the question at issue is not, "Can we apprehend nature from a nonhuman point of view?" Of course we cannot. The question is, rather, "Should we extend moral consideration to nonhuman natural entities or nature as a whole?" And that question, of course, is entirely open.

In the mainstream of the Western cultural tradition, only human beings have been treated morally. Thus—at least for those working in that tradition—anthropocentrism

is the most conservative approach to environmental ethics. Nevertheless, anthropocentric environmental ethicists have had to assume a more reactive than proactive posture and devote considerable effort to defending traditional Western moral philosophy against calls by bolder thinkers to widen the purview of ethics to encompass nonhuman natural entities and nature as a whole.

John Passmore and Kristin Shrader-Frechette were among the first to advocate a strictly anthropocentric approach to environmental ethics. Shrader-Frechette finds it "difficult to think of an action which would do irreparable harm to the environment or ecosystem, but which would not also threaten human well-being" (Shrader-Frechette, p. 17). Since many of the anthropocentric ethics in the Western canon censure behavior that threatens human well-being (utilitarianism, most directly), she argues that there is therefore no need to develop a newfangled non-anthropocentric environmental ethic.

Some of the damage that people have done to the environment certainly does threaten human well-being. Global warming and the depletion of the ozone layer are notorious examples. But it is easy to think of other instances of environmental vandalism that do not materially threaten human well-being. David Ehrenfeld asks us to contemplate the probable demise of the endangered Houston toad, a victim of urban sprawl, that "has no demonstrated or conjectural resource value to man" (p. 650). But, as Ehrenfeld points out, the Houston toad is not unique in this respect. Thousands of other species in harm's way are nondescript "non-resources."

To morally censure the extinction of such species and other kinds of environmental destruction that do not materially threaten human well-being, must we abandon anthropocentrism? Amplifying the work of Mark Sagoff (1988) and Eugene C. Hargrove (1989), Bryan Norton (1987), the leading contemporary apologist for anthropocentric environmental ethics, argues that we should enlarge our conception of human well-being instead. In addition to goods (energy, foods, medicines, raw materials for manufacture) and services (crop pollination, oxygen replenishment, water purification), an undegraded natural environment contributes to human well-being in important psychological, spiritual, and scientific ways. Scenery unmarred by strip mines or clear cuts and undimmed by dirty air is important to human aesthetic satisfaction. Clean air and water, open spaces and green belts, complex and diverse landscapes, national parks and wilderness playgrounds are important human "amenities." Experiencing the solitude of wilderness and the otherness of wild things is an important aspect of human religious experience. Even if no one will be materially worse off after the extinction of "non-resource" species before science has a chance to discover and study them, important subject matter for pure, disinterested human knowledge will nevertheless have been irredeemably lost. Norton also suggests that contact with and care for the integrity of the natural environment can also be "transformative"; it can make better people of us.

Additionally, Norton argues that we should, as a matter of intergenerational justice, ensure that future human beings will be able to enjoy bountiful natural resources, a whole and functioning ecosystem, the full spectrum of environmental amenities, and the opportunity to partake of the psychospiritual experiences afforded by nature and to explore ecology and taxonomy intellectually. If we make our conception of human well-being both wide and long, he thinks that we may ground an adequate and effective environmental ethic without sailing off into the unfamiliar and treacherous waters of non-anthropocentrism.

The principal reason Norton offers for preferring an anthropocentic approach to environmental ethics is pragmatic. Anthropocentrism and non-anthropocentrism, he argues, support the same environmental policies. Norton (1991) calls this practical equivalence of anthropocentrism and non-anthropocentrism the "convergence hypothesis." Why then advocate non-anthropocentrism? Most people, including most environmentalists, he claims, accept the familiar and venerable idea that human beings are ends-in-themselves deserving moral standing. On the other hand, the suggestion that all living beings (and species and ecosystems) ought to be granted a similar status is unfamiliar and controversial. If we rest environmental ethics on as broad and firm a foundation as possible, we can best ensure its rapid implementation. Indeed, Norton suggests that the vigorous philosophical effort to develop non-anthropocentric approaches to environmental ethics has actually done the beleaguered environment a disservice. The environmental movement, as a result, has been divided over purely intellectual issues that have little if any practical import.

Norton's empirical claim that most people and even most environmentalists are anthropocentrists is supported only anecdotally. But opinion polls and the outcome of political contests suggest that most people probably have narrower allegiances—to self-interest, to institutional interests, to class interests, or to national interests—than to present and future collective or general human interests, very broadly construed. On the other hand, a growing minority of environmentalists seem to doubt the philosophical foundations of anthropocentrism. Are human beings really created in the image of God—the idea upon which anthropocentrism in Western religious ethics is founded? Are we uniquely self-conscious, rational, autonomous (some of the foundations of anthropocentrism in Western moral

philosophy)? Must every being possess such characteristics to qualify for moral treatment? One may agree with the convergence hypothesis—that practical environmental goals are as well served by anthropocentric as by non-anthropocentric environmental ethics—but disagree that anthropocentrism is philosophically defensible. Hence, the question of the philosophical merits—the truth, as it were, of anthropocentrism—remains open.

Norton's convergence hypothesis, furthermore, overlooks an important difference between the way anthropocentric and non-anthropocentric environmental ethics support the same environmental policies. Suppose, as non-anthropocentrists variously argue, that the environment is "intrinsically" as well as "instrumentally" valuable—that is, that the environment is valuable for its own sake as well as for all the benefits, tangible and intangible, that it provides human beings. Warwick Fox decisively argues that such a supposition would shift the burden of proof from those who would disinterestedly preserve the environment to those who would destroy it for personal gain:

> If the nonhuman world is only considered to be instrumentally valuable then people are permitted to use and otherwise interfere with it for whatever reasons they wish.… If anyone objects to such interference then, within this framework of reference, the onus is clearly on the person who objects to justify why it is *more useful* to humans to leave that aspect of the nonhuman world alone. If, however, the nonhuman world is considered intrinsically valuable then the onus shifts to the person who would want to interfere with it to justify why they should be allowed to do so; anyone who wants to interfere with any entity that is intrinsically valuable is morally obliged to be able to offer *sufficient justification* for their actions. (Fox, 1993, p. 101)

Norton, for example, might object to lumber companies cutting down redwood forests because the remaining redwood forests are of greater benefit to present and future human generations as amenities than as raw material for decks and hot tubs. But to preserve the remaining redwood forests, Norton would have to persuade a court to issue an injunction preventing lumber companies from harvesting redwoods, based on the assertion that the trees, while living, are more useful to human beings as psycho-spiritual and transformative resources than cut down and sawed up as consumptive resources. If, on the other hand, the trees were regarded as being intrinsically valuable, then a lumber company would have to make a case in court that the utility of redwood forests as raw material is so enormous as to justify their destruction. Thus, although Norton may be correct in claiming that a long and wide anthropocentric environmental ethic supports the same policies as non-anthropocentric environmental ethics—in the case at hand, the policy of preserving redwood forests—he cannot correctly claim that it would do so as forcefully.

Biocentrism

At first, theories of environmental ethics that morally enfranchise both individual living beings and natural wholes, such as species and ecosystems, were called "biocentric." Then, Paul W. Taylor (1986) commandeered the term to characterize his militantly individualistic theory of environmental ethics. Not only in deference to Taylor's influence and authority, but in deference to the literal sense of the term ("life-centered"), "biocentrism" in this discussion refers to theories of environmental ethics that morally enfranchise living beings only. Since species and ecosystems are not, per se, living beings, a biocentric theory would not accord them any moral standing.

Although animal welfare ethics and environmental ethics are by no means the same, biocentrism is launched from a platform provided by animal welfare ethics. Both attempt to extend our basic anthropocentric ethics—which, generally speaking, prohibit harming human "others" or violating their rights—to a more inclusive class of individuals: animal welfare ethics to various kinds of animals, biocentric environmental ethics to all living beings.

Peter Singer and Tom Regan, the principal architects of contemporary animal welfare ethics, exposed anthropocentric ethics to a dilemma. If the criterion for moral standing is pitched high enough to exclude all nonhuman beings, it will also exclude some human beings; but if it is pitched low enough to include all human beings, it will also include a large and diverse group of nonhuman animals.

An anthropocentrist may follow such philosophers as René Descartes and Immanuel Kant and proffer some highly esteemed and peculiarly human capacity—such as the capacity to reason, to speak, or to be a moral agent—as the qualification a being must possess to deserve ethical consideration. However, if practice is to be consistent with theory, anthropocentrism, so justified, should permit people who cannot reason or speak or who are not morally accountable for their behavior—human infants, the severely retarded, and the abjectly senile, for example—to be treated in the same ways that it permits animals to be treated: used as experimental subjects in painful biomedical research, hunted for sport, slaughtered and processed into dog food, and so on. To obviate these repugnant implications, Singer (1975) suggests that we follow Jeremy Bentham, the founder of utilitarian ethics, and settle upon sentience, the capacity to

experience pleasure and pain, as a less hypocritical—and arguably a more relevant—qualification for moral consideration. That standard would secure the ethical standing of the so-called marginal cases, since irrational, unintelligent, or irresponsible people are all capable of experiencing pleasure and pain. But it would open membership in the moral community to all other sentient beings as well. If, as Bentham asserted, pleasure is good and pain is evil, and if, as Bentham also asserted, we should try to maximize the one and minimize the other irrespective of who experiences them, then animal pleasure and pain should count equally with human pleasure and pain in all our moral deliberations.

Singer vigorously advocates vegetarianism. Ironically, however, Singer's Benthamic animal welfare ethic is powerless to censure raising animals in comfort and slaughtering them painlessly to satisfy human dietary preferences. Indeed, one might even deduce from Singer's premises that people have a positive moral obligation to eat meat, provided that the animals bred for human consumption experience a greater balance of pleasure over pain during their short lives. For if everyone became a vegetarian, many fewer cows, pigs, chickens, and other domestic animals would be kept and thus many fewer animals would have the opportunity, for a brief time, to pursue happiness.

Recognizing these (and other) inadequacies of Singer's theory in relation to the moral problems of the treatment of animals, Tom Regan (1983) advocates a "rights approach." He argues that some individual animals have "inherent value" because they are, like ourselves, not only sentient but "subjects of a life"—beings that are self-conscious, experience desire and frustration, and that anticipate future states of consciousness—that from their point of view can be better or worse. Inherent value, in turn, may be the grounds for basic moral rights.

Neither Singer's nor Regan's prototype of animal welfare ethics will also serve as environmental ethics. For one thing, neither provides moral standing for plants and all the many animals that may be neither sentient nor, more restrictively still, subjects of a life—let alone for the atmosphere and oceans, species and ecosystems. Moreover, concern for animal welfare, on the one hand, and concern for the larger environment, on the other, often lead to contradictory indications in practice and policy. Examples follow: Advocates of animal liberation and rights frequently oppose the extermination of feral animals competing with native wildlife and degrading plant communities on the public ranges; they characteristically demand an end to hunting and trapping, whether environmentally benign or necessary; and they may prefer to let endangered plant species become extinct, rather than save them by killing sentient or subject-of-a-life animal pests.

On the other hand, animal welfare ethics and environmental ethics lead to convergent indications on other points of practice and policy. Both should resolutely oppose "factory farming": animal welfare ethics because of the enormous amount of animal suffering and killing involved; environmental ethics because of the enormous amount of water used and soil eroded in meat production. Both should staunchly support the preservation of wildlife habitat: animal welfare ethics because nature reserves provide habitat for sentient subjects; environmental ethics because many other forms of life, rare and endangered species, and the health and integrity of ecosystems are accommodated as well.

Despite the differences, animal welfare ethics may be regarded as "on the way to becoming" full-fledged environmental ethics, according to Regan (1983, p. 187). Animal welfare ethicists went the first leg of the philosophical journey by plausibly lowering the qualifying attribute for moral consideration. Albert Schweitzer (1989), Kenneth Goodpaster (1978), Robin Attfield (1983), and Paul Taylor (1986) variously suggest pitching it lower still—from being sentient to being alive.

Schweitzer, writing long before the efflorescence of contemporary animal welfare and environmental ethics literature, appears to ground his "reverence for life" ethic in the voluntarism of Arthur Schopenhauer:

> Just as in my own will-to-live there is a yearning for more life … so the same obtains in all the will-to-live around me, equally whether it can express itself to my comprehension or whether it remains unvoiced.
>
> Ethics consists in this, that I experience the necessity of practising the same reverence for life toward all will-to-live, as toward my own. (Schweitzer, 1989, pp. 32–33)

Contemporary biocentrism appears to have been inspired by Joel Feinberg's observations about the moral importance of interests and the range of entities to which interests may be attributed. The foundational role of the concept of "conation" (an often unconscious striving, reified by Schopenhauer as the "will-to-live") in Feinberg's characterization of interests unifies contemporary Anglo-American biocentric environmental ethics with Schweitzer's version. According to Feinberg:

> A mere thing, however valuable to others, has no good of its own … [because] mere things have no conative life: no conscious wishes, desires, and hopes; or urges or impulses; or unconscious drives, aims, and goals; or latent tendencies, directions of growth, and natural fulfillments. Interests must be compounded somehow out of conations; hence

> mere things have no interests, *A fortiori,* they have no interests to be protected by legal or moral rules. Without interests a creature can have no "good" of its own the achievement of which can be its due. Mere things are not loci of value in their own right, but rather their value consists entirely in their being objects of other beings' interests. (Feinberg, pp. 49–50)

The clear implication of this passage is that the "insuperable line," as Bentham called the boundary separating beings who qualify for moral consideration from those who do not, falls between living beings and nonliving things, not between sentient animals and insentient animals and plants. Why? Because even plants have "unconscious drives, aims, and goals; or latent tendencies, directions of growth, and natural fulfillments." Feinberg, nevertheless, goes on to deny that plants have interests of their own. His reasons for doing so, however, appear to be less clear and decisive than his derivation of interests from conations and his argument that beings who have interests deserve moral consideration.

Kenneth Goodpaster (1978) argues that all living beings, plants as well as animals, have interests. And he argues, appealing to Feinberg as an authority, that beings who have interests deserve "moral considerability"—a term that Goodpaster uses to indicate precisely the ethical status of moral patients (those on the receiving end of an action), as distinct from moral agents (those who commit an act). Goodpaster agrees with Singer that their sentience is a sufficient condition for extending moral considerability to animals, but he disagrees that it is a necessary one, because sentience evolved to serve something more fundamental—life: "Biologically, it appears that sentience is an adaptive characteristic of living organisms that provides them with a better capacity to anticipate, and so avoid, threats to life.… [T]he capacities to suffer and enjoy are ancillary to something more important, rather than tickets to considerability in their own right" (p. 316).

Goodpaster's life-principle ethic is modest. All living beings are morally considerable, but all may not be of equal moral "significance." He leaves open the question of how much weight we should give to a plant's interests when they conflict with a sentient creature's or with our own. Paul Taylor (1986) has struck a much stronger and bolder stance and argued that all living beings are of equal "inherent worth."

Taylor bases a living being's inherent worth on the fact that it has a good of its own, quite independent of our anthropocentric instrumental valuation of it and quite independent of whether the organism is sentient or cares. Light, warmth, water, and rich soil are good for a sprig of poison ivy, though poison ivy may not be good for us. Unlike machines and other purposeful artifacts that we design to serve our own ends, organisms are ends-in-themselves. Most generally, they strive to reach a state of maturity and to reproduce. Therefore, just as we insist that others not interfere with our own striving and thriving, so, Taylor urges, expressly patterning his reasoning on Kant's, we should respect the striving and thriving of all other "teleological centers of life." Kant argued that we should respect, as individuals-in-themselves, all rational, autonomous beings equally. And Taylor argues that we should respect equally all living beings because they too are ends-in-themselves.

Because biocentrism is concerned exclusively with biological individuals, not biological wholes, it is an approach to environmental ethics that seems at once so restrictive that it would be impossible to practice, and an approach that has scant relevance to the set of problems constituting the environmental crisis. How can we do anything at all, if, before we act, we are obliged to consider the interests of each and every living being that we might affect? Why should we feel compelled to do so for the sake of the environment? Environmental concern focuses primarily on the spasm of abrupt massive species extinction and the loss of biodiversity generally, on rapid global warming and the erosion of stratospheric ozone, on soil erosion, water pollution, and the like; not on the welfare of individual grubs, bugs, and shrubs.

Schweitzer and Goodpaster frankly acknowledge the difficulty in practicing biocentrism. Schweitzer writes, "It remains a painful enigma how I am to live by the rule of reverence for life in a world ruled by creative will which is at the same time destructive will" (1989, p. 35). And Goodpaster writes:

> The clearest and most decisive refutation of the principle of respect for life is that one cannot *live* according to it, nor is there any indication in nature that we were intended to. We must eat, experiment to gain knowledge, protect ourselves from predation.… To take seriously the criterion being defended, all these things must be seen as somehow morally wrong. (p. 310)

Both reasonably suggest that we can at least respect the interests of other living beings when they do not conflict with our own. According to Goodpaster, biocentrism is not suicidal. It requires only that we use living beings considerately and sensitively. Schweitzer thinks that biocentrism permits us to injure or destroy other forms of life, but only when doing so is necessary and unavoidable.

Taylor's egalitarianism renders the practicability problem of biocentrism virtually insurmountable (Wenz). Starting with any individual's right to self-defense, he rationalizes our annihilating disease organisms with medicines and goes on from there to defend our killing and eating other living

beings to feed ourselves. But the satisfaction of any "nonbasic" human interest, according to Taylor, must be forgone if it violates the basic interests of another teleological center of life. So it would seem that strict adherence to biocentric egalitarianism would require one to live a life of sacrifice that would make a monk's life appear opulent.

Writing before the advent of the environmental crisis, Schweitzer was not intending to address its problems. He seems genuinely concerned, rather, with the welfare of individual living beings. Thus, it would be unfair and anachronistic to criticize his reverence-for-life ethic for being largely irrelevant to the set of problems constituting the environmental crisis. Taylor, on the other hand, represents his biocentric ethic as an environmental ethic. And he is clearly aware that contemporary environmental concerns focus on such things as species loss and ecosystem deterioration. But he remains antagonistic to the holistic environmental ethics crafted in response to such concerns. He prefers to think of the extinction of species and destruction of ecosystems in anthropocentric, rather than in biocentric or ecocentric terms. Goodpaster, on the other hand, invokes "concern felt by most person about 'the environment'" as a reason for trying to extend moral considerability to all living beings (p. 309). He seems, moreover, to be aware that to actually reach the concern felt by most persons about the environment, biocentrism would have to "admit of application to … systems of entities heretofore unimagined as claimants on our moral attention (such as the biosystem itself)" (p. 310). Having once mentioned systems of entities, however, Goodpaster lavishes all his attention on individual living beings and has nothing at all to say about how biocentrism might actually admit of application to species, ecosystems, and the biosphere as a whole.

Biocentrism may be not only irrelevant to actual environmental concerns, it could aggravate them. Biocentrism can lead its proponents to a revulsion toward nature—giving an ironic twist to Taylor's title, *Respect for Nature*—because nature seems as indifferent to the welfare of individual living beings as it is fecund. Schweitzer, for example, comments that

> the great struggle for survival by which nature is maintained is a strange contradiction within itself. Creatures live at the expense of other creatures. Nature permits the most horrible cruelties.… Nature looks beautiful and marvelous when you view it from the outside. But when you read its pages like a book, it is horrible. (1969, p. 120)

Ecocentrism

Though the term "ecocentrism" is a contradiction of the phrase "ecosystem-centered," ecocentrism would provide moral considerability for a spectrum of nonindividual environmental entities, including the biosphere as a totality, species, land, water, and air, as well as ecosystems. The various ecologically informed holistic environmental ethics that may appropriately be called ecocentric are less closely related, theoretically, than either the anthropocentric or biocentric families of environmental ethics.

Lawrence E. Johnson has attempted to generate an environmental ethic that reaches species and ecosystems by a further extension of the biocentric approach. He does this not by making the criterion for moral considerability more inclusive but by attributing interests to species and ecosystems. Extensively developing the line of thought that Feinberg (1974) tentatively and ambiguously initiated, Johnson concludes that we should "give *due* respect to all the interests of all beings that have interests, in proportion to their interests" (p. 118). As this, his summary moral principle, suggests, Johnson follows Goodpaster in allowing that all interests are not equal and thus that all interested beings, though morally considerable, are not of equal moral significance. Johnson, however, provides no principle or method for hierarchically ordering interests and the beings who possess them; nor does he provide an ethical procedure for adjudicating conflicts of interest between people, animals, and plants, and, more difficult still, between all such individuals and environmental wholes.

In arguing that species have interests, Johnson exploits the fact that some biologists and philosophers of biology regard species not as classes of organisms but as spatially and temporally protracted individuals. To plausibly assign them interests, in other words, Johnson assimilates species to individual organisms. During the first quarter of the twentieth century, ecosystems (though then they were not so denominated) were represented in ecology as supraorganisms. Johnson adopts this characterization of ecosystems, as doing so allows him to attribute interests to ecosystems by assimilating them to individual organisms, just as in the case of species. Finally, Johnson points out that James Lovelock (1979) has suggested that the Earth as a whole is an integrated living being (named Gaia); if so, it (she) too may have interests and thus may be morally considerable. Adopting nonstandard, obsolete, or highly controversial scientific models of species, ecosystems, and the biosphere is the price Johnson pays to purchase moral considerability for these natural wholes. His attempt to add an ecocentric dimension to his essentially biocentric approach to environmental ethics is thus seriously compromised.

Holmes Rolston's ecocentric environmental ethic, like Johnson's, is launched from a biocentric platform. Rolston (1988) endorses the central tenet of biocentrism that each living being has a good of its own and that having a good of

its own is the ground of a being's intrinsic value. And upon the existence of intrinsic value in nature he founds our duties to the natural world in all its aspects.

Rolston's biocentrism, in sharp contrast to Taylor's, is inegalitarian. Rolston finds more intrinsic value in beings that sense their own good, that feel hurt when harmed, than in those that lack consciousness. And Rolston finds the most intrinsic value of all in normal adult human beings because we are rational and fully self-conscious as well as conative and sentient.

Rolston avoids the scientifically suspect route that Johnson takes to enfranchise ethically such environmental wholes as species and ecosystems. Rolston argues instead that since the most basic telos of a teleological center of life is to be "good of its kind" and to reproduce its species, then its kind or species is its primary good. Species per se do not have a good of their own, but as the most basic good of beings that do have a good of their own, they too can be said to possess intrinsic value. The myriad natural kinds or species, however, evolved not in isolation but in a complex matrix of relationships—that is, in ecosystems. Thus, though not themselves teleological centers of life, either, some intrinsic value rubs off on ecosystems in Rolston's theory of environmental ethics. Rolston coins a special term, "systemic value," to characterize the value of ecosystems.

Systemic value does not seem to be entirely parallel, logically or conceptually speaking, to intrinsic value in Rolston's theory of environmental ethics. Rather, it seems that a necessary condition for the existence of the things that he believes do have intrinsic value—beings with a good of their own and the goods (their kinds or species) that such beings strive to actualize and perpetuate—is the existence of their natural contexts or matrices. Like the moon that shines by a borrowed light, systemic value seems to be a kind of reflected intrinsic value. Rolston finds a similar sort of derivative intrinsic value, "projective value," in elemental and organic evolutionary processes going all the way back to the Big Bang, since such processes eventually produced (or "projected") living beings with goods of their own.

Rolston's theory of environmental ethics hierarchically orders intrinsically valuable individuals in a familiar and conventional way. Human beings are at the pinnacle of the value hierarchy, followed by the higher animals, and so on, pretty much as in the Great Chain of Being envisioned by many Western philosophers of yore. Rolston is prepared to invoke his hierarchical arrangement of intrinsically valuable kinds of beings to resolve biocentric moral conundrums. For example, he expressly argues that it is morally permissible for people to kill and eat animals and for animals to kill and eat plants. Though such a hierarchical ordering of intrinsically valuable beings jibes with tradition and uncultivated common sense, it may not always jibe with, and hence may not adequately justify, our considered environmental priorities. Most environmentalists, faced with the hard choice of saving a sensitive, subjective dog or an unconscious, merely conative thousand-year-old redwood tree, would probably opt for the tree—and not only because redwoods are becoming rare. Pressed for good reasons for making this choice, Rolston might answer that an environmentally ethical agent is perfectly free, in reaching a decision to give priority to the redwood over the dog, to add to their intrinsic value the way standing redwoods are valued anthropocentrically and the way they serve the systemic value of ecosystems. The ethical agent can legitimately add the redwood's economic value to its systematic value, intrinsic value, aesthetic value, or religious value. How the intrinsic value of species and the systemic value of ecosystems fits into Rolston's value hierarchy is not entirely clear. Is a plant species more or less intrinsically valuable than a specimen of *Homo sapiens*, or than a specimen of *Ovis aries* (domestic sheep)?

According to Regan (1981) the very possibility of an environmental ethic turns on constructing a plausible theory of intrinsic (or "inherent") value in nature. He argues that anthropocentric environmental ethics are "management ethics," ethics for the "use" of the environment, not environmental ethics proper. Regan sets clear and stringent conditions for such value: first, it must be strictly objective, independent of any valuing consciousness; second, it must attend some property or set of properties that natural entities possess; and third, it must be normative, it must command ethical respect or moral considerability.

Rolston's basing a being's intrinsic value on its having a good of its own seems to meet the first two of these conditions, but possibly not the third. Before consciousness evolved, living beings had goods of their own; they could be harmed if not hurt; they had interests, whether they cared or not. The move, however, from the hardly disputable fact that living beings objectively possess goods of their own to the assertion that they have objective intrinsic value may turn on an ambiguity in the meaning of "good."

The word "good" has a teleological as well as a normative sense. All living beings have goods of their own in the teleological sense. They have, in other words, ends that were not imposed upon them—as the goods or ends of machines and other artifacts are—by beings other than themselves. But it is still possible to ask if such teleological goods generate normative goods. At this point in the argument, the smallpox and AIDS viruses are usually invoked as examples of organisms that have goods of their own in the teleological sense of the term, but organisms that one would be loath to say are good in the normative sense of the term.

However this particular conceptual issue may be resolved, another, moral general one casts a very large and dark shadow on Rolston's claim of finding objective intrinsic value in nature. While Rolston is very careful not to buck prevailing scientific opinion on the sort of reality possessed by species, ecosystems, and evolutionary processes, his argument that intrinsic value exists objectively in nature does buck more general assumption of modern science. From the modern scientific point of view, nature is value-free. Goodness and badness, like beauty and ugliness, are in the eye of the beholder. According to this entrenched dogma of modern science, there can be no valuees without valuers. Nothing under the sun—no rational self-conscious person, no sentient animal, no vegetable, no mineral—has value of any kind, either as a means or an end, unless it is valued by some valuing subject.

The crisp objective/subjective distinction in modern science, however, has been undermined by the Heisenberg Uncertainty Principle in quantum physics, as the observation of subatomic entities unavoidably affects their state of being. Therefore, the modern scientific worldview has become problematic. Seizing upon this circumstance, J. Baird Callicott (1989), among others, has broached a value theory for environmental ethics that is neither subjective nor objective. Just as experimental physicists actualize the potential of an electron to be at a particular place by observing it, so, Callicott suggests, the potential value of an entity, both instrumental and intrinsic, is actualized by a valuer appreciating it.

Although it may eventually give way to a postmodern scientific worldview, the modern scientific worldview continues to reign supreme. The "land ethic" sketched by Aldo Leopold (1949) has been the moral inspiration of the nonanthropocentric wing of the contemporary popular environmental movement, in part because Leopold respects the subjectivity of value required by the modern scientific world view without at the same time reducing nature to natural resources.

Callicott (1987) claims that Leopold's ecocentric environmental ethic may be traced to the eighteenth-century moral philosophy of David Hume and Adam Smith, who think that feelings lie at the foundations of value judgments. While feelings fall on the subjective side of the great subject/object divide, Hume and Smith also point out that our feelings may be altruistic or other-oriented as well as selfish. Hence we may value others for their own sakes, as ends-in-themselves. Further, Hume and Smith note that in addition to sympathy for others, respectively, we also experience a "public affection" and, accordingly, value the "interests of society even on their own account."

In *The Descent of Man,* Charles Darwin (1874) adopted the moral psychology of Hume and Smith and argued that the "moral sentiments" evolved among human beings in conjunction with the evolution of society, growing in compass and refinement along with the growth and refinement of human communities. He also developed the incipient holism of Hume and Smith, flatly stating that primeval ethical affections centered on the tribe not its individual members.

Leopold, building directly on Darwin's theory of the origin and evolution of ethics, points out that ecology represents human beings to be members not only of multiple human communities but also of the "biotic community." Hence, "the land ethic simply enlarges the boundaries of the community to include soils, waters, plants, and animals, or collectively: the land.… It implies respect for … fellow members and also respect for the community as such" (Leopold, p. 204).

Animal welfare ethicists and biocentrists claim that Leopold's ecocentrism is tantamount to "environmental fascism." Leopold wrote—and his exponents affirm—that "a thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community [and] wrong when it tends otherwise" (pp. 224–225). If this is true, then not only would it be right deliberately to kill deer and burn bushes for the good of the biotic community, it would also be right to undertake draconian measures to reduce human overpopulation—the underlying cause, according to conventional environmental wisdom, of all environmental ills.

Providing for the possibility of moral consideration of wholes, however, does not necessarily disenfranchise individuals. The land ethic is holistic as well as (not instead of) individualistic, although in the case of the biotic community and its nonhuman members holistic concerns may eclipse individualistic ones. Nor does the land ethic replace or cancel previous socially generated human-oriented duties—to family and family members, to neighbors and neighborhood, to all human beings and humanity. Human social evolution consists of a series of additions rather than replacements. The moral sphere, growing in circumference with each stage of social development, does not expand like a balloon—leaving no trace of its previous boundaries. It adds, rather, new rings, new "accretions," as Leopold called each emergent social-ethical community. The discovery of the biotic community simply adds several new outer orbits of membership and attendant obligation. Our more intimate social bonds and their attendant obligations remain intact. Thus we may weigh and balance our more recently discovered duties to the biotic community and its members with our more venerable and insistent social obligations in ways that are entirely familiar, reasonable, and humane.

Ecofeminism

The term "ecofeminism" is a contraction of the phrase "ecological feminism," which may be understood as an analysis of environmental issues and concerns from a feminist point of view and, vice versa, as an enrichment and complication of feminism with insights drawn from ecology. Ecofeminism is both an approach to environmental ethics and an alternative feminism.

An axiom of ecofeminism is that, both historically and globally, men have dominated women and "man" has dominated nature. Further, many male-centered, culture-defining texts, such as the epics of Homer and Hesiod, the works of the ancient philosophers, and so forth, have associated women with nature and personified the Earth and nature generally as female (Griffin). The domination of women and nature appears to stem from a single source: patriarchy (literally, father-rule). Criticize and overcome patriarchy, the principal ideological force responsible for the domination of women, and one will at the same time have criticized and overcome the principal ideological force responsible for the degradation and destruction of nature. According to Marti Kheel, "for deep ecologists, it is the anthropocentric worldview that is foremost to blame.… Ecofeminists, on the other hand, argue that it is the androcentric worldview that deserves the primary blame" for the environmental crisis (p. 129).

Some environmentalists suspect such an analysis to be a thinly disguised ploy to divert the energies of the environmental movement into the feminist movement. Deep ecologist Warwick Fox (1989), for example, argues that a feminist environmental ethic focused on abolishing patriarchy is too self-serving, simplistic, and facile to be taken seriously as a panacea for environmental ills. Other movements, he points out, can make, and have made, the same implausible claim: If we only abolish the ideology of racism, capitalism, imperialism, and so on, then we will usher in the millennium and all will be right with the world, natural as well as social.

Karen J. Warren (1990) does not follow Kheel and blame the domination and subordination of nature by "man" on the domination and subordination of women by men. Rather, she argues, both forms of "oppression" are "twin" expressions of hierarchically ordered "value dualisms" reinforced with a "logic of domination." Critiques of anthropocentrism and androcentrism are mutually illuminating and complementary. A person opposed to the one ought to be opposed to the other—because subordination, domination, and oppression are wrong, whether of women by men or of nature by "man." Environmentalists should also be feminists and feminists, environmentalists. Ecofeminism is the union of the two.

An ecofeminist approach seeks to correct an alleged "male bias" in environmental ethical theory—a selection of concepts and methodology that ignores, discounts, or denigrates women's issues, concerns, and experience. Alison M. Jagger has suggested that modern Western ethics, "Enlightenment moral theory," is thoroughly male-biased since it portrays moral agents as being "disembodied, asocial, autonomous, unified, rational, and essentially similar to all other" agents (p. 367). In short, it abstracts, generalizes, universalizes. Intimately associated with this "Cartesian" moral psychology are such commonplaces of modern Western ethics as universal application of abstract principles and rules, impartiality, objectivity, rights, and the victory of synoptic and dispassionate reason over myopic and prejudicial feelings. Warren argues, accordingly, that "ecofeminism … involves a shift *from* a conception of ethics as primarily a matter of rights, rules, or principles predetermined and applied in specific cases to entities viewed as competitors in the contest of moral standing, *to* a conception of ethics as growing out of … defining relationships … and community" (pp. 141–142). She notes further that "ecofeminism makes a central place for [the more feminine, less male] values of care, friendship, trust, and appropriate reciprocity—values that presuppose that our relationships to others are central to our understanding of who we are" (p. 143).

It is surprising that ecofeminists have not warmly endorsed the Aldo Leopold land ethic, which grounds morality in such sentiments as love, sympathy, and fellow-feeling. The *locus classicus* for an environmental ethic growing out of "defining relationships" and "community" is found in Leopold's *A Sand County Almanac* (1949). Marti Kheel, however, castigates Leopold's land ethic, arguing that it epitomizes male bias. Leopold endorses hunting, historically a predominantly male activity, as a means not only of ecological management but also of experiencing our defining relationships with nature and cultivating a "love and respect" for "things natural, wild, and free."

Deep Ecology

Just as there are Democrats (with a capital "D," members of one of the two major political parties in the United States) and democrats (with a lower-case "d," persons, irrespective of party affiliation, who agree with Winston Churchill that democracy is the worst form of government except for all the others), so there are Deep Ecologists (with a capital "D" and "E") and deep ecologists (with a lower-case "d" and "e"). The latter, such as Aldo Leopold, think that ecology has profound philosophical implications that it transforms our understanding of the world in which we live and what it means to be a human being. Deep Ecologists, on the other

hand, endorse the eight-point "platform" of Deep Ecology that Arne Naess co-authored with George Sessions (Devall and Sessions). Moreover, they downplay the importance of environmental *ethics*, and advocate "Self-[with a capital 'S'] realization," instead. In short, deep ecology is a philosophical orientation; Deep Ecology is an ideology.

Ethics per se, Deep Ecologists allege, assumes "social atomism," a conception of each individual self as externally related to all other selves and to unselfconscious nature (Fox, 1990). Therefore, Deep Ecologists suppose that an ethical act on the part of an atomic moral agent involves grudgingly considering the interests of other morally considerable beings equally and impartially with his or her own. But for people actually and consistently to behave ethically—as thus characterized—is as rare as it is noble. Therefore, even if environmental ethics could be broadly infused, environmental destruction and degradation would be little abated.

However, the metaphysical implications of ecology undermine the social atomism upon which ethics is supposedly premised. We human beings are internally, not externally, related to one another and to non-human natural entities and nature as a whole. "Others" cannot be cleanly and neatly distinguished from ourselves. Our relationships, natural as well as social, with "them" are mutually defining. We are embedded in communities, biotic as well as human. If we could only realize that the environing world is ultimately indistinguishable from ourselves, then we could enlist the powerful and reliable motive of self-interest in the effort to reverse environmental degradation and destruction (Naess).

The process of Deep Ecological Self-realization is experiential as well as intellectual. Through practice as well as study, we should cultivate a palpable sense of identification with the world. Nature-protecting behavior will flow from experiential identification with nature. Warwick Fox (1990) has suggested that Deep Ecology should actually be renamed "transpersonal ecology," since, as in transpersonal psychology, the goal of Self-(with a capital "S") realization involves self-(with a lower-case "s") transcendence.

Deep Ecology's suspicions about the efficacy of environmental ethics seems to be based upon a narrow characterization of ethics that excludes sentiment-based communitarian ethics like the Leopold land ethic and its ecofeminist correspondents. Ecofeminists have also sharply criticized Deep Ecology because it seems to "totalize" and "colonize" the "other" (Cheney; Plumwood). With the important exception of Naess, Deep Ecologists either explicitly or implicitly claim that the integrated, systemic ecological world view is true and regard other ways of constructing nature and the relationship of people to nature to be false. A cornerstone of feminism is openness to the experience of women, experience that is quite varied. The experience of all or even of most women may not jibe well with Deep Ecological Self-realization. Hence the Deep Ecologists' often doctrinaire assertions about how the world is really and truly organized and how we *ought* to experience it are anathema to most ecofeminists.

Pluralism

The term "pluralism" in ethics characterizes two things equally well.

What we might call "social pluralism" is the view that diverse and often mutually inconsistent ethical outlooks should be respected and that there may not be any single moral principle or set of principles, however basic, that all moral agents must acknowledge. Human rights, for example, may be widely acknowledged in the West, but not in other parts of the world; hence, from a social pluralist's point of view, for Western governments to try to impose standards of human rights upon non-Western societies is inappropriate.

Personal pluralism, on the other hand, is the view that a single moral agent may endorse a variety of different moral principles, some of which may be mutually inconsistent, and employ one or another in different morally charged situations. For example, in resolving ethical questions about diet, a personal pluralist might apply Singer's principle that one should not cause sentient beings unnecessary suffering and therefore decide not to eat factory-farmed meat. In resolving ethical questions about abortion, he or she might apply Schweitzer's reverence-for-life principle and vote for an anti-abortion candidate for public office. And, in resolving ethical questions about species conservation, the same person might embrace Leopold's principle that one should preserve the integrity, stability, and beauty of the biotic community and help save an endemic plant species by shooting the feral goats or pigs threatening it.

Social pluralism appears attractive because it seems to imply inclusiveness and tolerance. In extremis, however, social pluralism is vulnerable to the same sort of criticism that ethical relativism, in extremis, has attracted. A social pluralist recognizes no universal ethical values or principles, he or she has no means of ethically challenging any one else's sincerely held moral beliefs. Further, if there are no universal ethical values or principles upon which to base agreement, then radical and intractable differences of moral outlook are irreconcilable. How then can they be resolved except by coercion?

Personal pluralism arose in environmental ethics because finding a single moral principle that could guide our

actions in respect to other people, animals, plants, species, ecosystems, the atmosphere, the oceans, and the biosphere proved difficult (Stone). Moreover, our inherently rich and complicated moral lives may be distorted if reduced to a single master principle of action and we are frequently misled if we try rigorously to follow one (Brennan). According to Mary Midgley (1992), we may read the history of Western ethical theory, from Plato and Aristotle to Singer and Leopold, not as a series of formulations of and justifications for competing master principles of action, but as a series of illuminating insights into human ethical experience that can deepen our moral reflection and help us to make wise practical choices.

Proponents and critics alike of personal pluralism have noted some obvious problems. An agent who has a variety of principles and their theoretical justifications at the ready, with no faithful commitment to any of them required, may be tempted to choose the most convenient or self-serving. But all ethics, whether pluralistic or unitary, assume good will on the part of moral agents. A more difficult problem is how to select which principle to apply when more than one is relevant at some moment of decision, and when those that are relevant indicate different and incompatible courses of action. But to demand an algorithmic solution to this problem is to beg the question against personal pluralism.

Moral principles, however, do not exist in an intellectual vacuum (Callicott, 1990). They are often derived from and are always associated with a complex of supporting ideas—usually an ethical theory, which is in turn supported by a moral philosophy. In choosing to act upon a moral principle, a personal moral pluralist thus also endorses—whether consciously or not—the ethical theory and ultimately the moral philosophy supporting it. But the ethical theories and moral philosophies supporting such popular principles as the Christian golden rule, the Aristotelian golden mean, the Kantian categorical imperative, the utilitarian greatest-happiness principle, and so on, offer radically different visions of nature and human nature. Are we morally autonomous rational ends-in-ourselves for whom nature exists only as means, as Kant argues; or are we vessels of pleasure and pain, equal in this morally relevant respect to all other sentient animals, as Singer holds? How can we be both at once?

Communitarianism

A communitarian moral philosophy might provide a coherent sense of self and world without compromising the richness and complexity of our moral lives or attempting to derive all ethical actions from a single principle. Suppose that ethics, as Darwin argued, is correlative to society; that at this stage of human social evolution, we are simultaneously members of many communities or societies, including families, neighborhoods, towns or cities, nation-states, the global human community, the mixed human-domestic animal community, and the biotic community; and that a spectrum of different and not always compatible duties and obligations grow out of our various social relationships—for example, to provide our children with affection, to watch our neighbors' houses when they are away on vacation, to donate old clothes to the Salvation Army, to pay our taxes, to relieve world hunger, to boycott factory-farmed meat, and to help preserve biodiversity.

Right and wrong behavior in respect to family and family members, humanity and human beings, the biotic community and wild animals and plants, grows out of the very different kinds of communal relationships that we bear in these very different cases. Hence what is right in the context of one kind of community (feeding domestic animals, who are members of the "mixed community," for example) may be wrong in another (feeding wild animals, who are members of the biotic community). A multiplicity of community-generated principles guides our actions, but this multiplicity is united and coordinated by a single general understanding of how our various duties arise and to whom they apply. A coherent moral outlook like this certainly does not automatically determine the best course of action when one's multiple duties conflict. But one can at least hope rationally to decide, in circumstances of hard choice, which of several relevant but conflicting duties is the most pressing because they can all be expressed in comparable and commensurable terms.

II. DEEP ECOLOGY

Deep ecology is a comprehensive worldview of humans in harmony with nature, an "ecosophy" ("ecowisdom") that responds to ecological crisis. It is also a movement to translate this worldview into radical societal reform. Supporters of the deep ecology movement contrast their position with "shallow" reform movements, holding that every living being has intrinsic or inherent value that gives it the right to flourish, independent of its usefulness for humans. All life is interrelated, and living things, humans included, depend on the support of others. For supporters of deep ecology, who tend to oppose the degradation of nature except to satisfy vital needs, the long-range integrity and health of the ecosystems of Earth are of fundamental ethical importance.

The ecological crisis has deep roots in misguided, anthropocentric attitudes about the dominion of humans on Earth. These exploitative, consumptive attitudes, according to the position of deep ecology, cannot be overcome without significant social changes, including changes in the lifestyles of those who live in the rich countries. Such changes can emerge only from a philosophical or religious basis that nurtures a sense of personal responsibility, not simply to persons living now but also to future human generations as well as fauna and flora. The current human population is already too large in many countries; further human population increases will lower the quality of life for both humans and nonhuman forms of life. A smaller human population is desirable and can be achieved by reduced birthrates over several centuries.

The position of the deep ecology movement can be illuminated by contrasting it with the position of so-called shallow ecology. The shallow position considers it unnecessary or even counterproductive to take up philosophical or religious questions to solve the ecological crisis. Its supporters argue that reforms of existing practices are needed, but reforms of basic principles are unnecessary. Those who advocate the shallow position do not find intrinsic value in nonhuman life forms, nor do they find the consumptive economic system problematic. Humans ought to exploit nature, though prudently. High standards of living are not objectionable, and can be raised even further by concentrating on investment in science and technology. Attempts should be made to bring less-developed nations up to this standard.

The deep ecology movement's historic forebears include Henry David Thoreau and John Muir. Aldo Leopold and Rachel Carson, also of the United States, are more recent pivotal figures. In 1962 Carson's book *Silent Spring* set off an ecological alarm. Starting with practical issues related to pesticides, Carson probed the philosophical assumptions underlying this attack on pests that stood in the way of human progress. In Europe such ecological concerns joined with the peace and social justice movements to create the first wave of the "green movement." Australians also became involved. In eastern Europe, ecologists were judged hostile to state-sponsored industrial development, and were banned. In the Third World, long-term ecological sustainability often had to take second place to short-term economic survival.

The deep ecology movement argues for ecological sustainability, human development that conserves the richness and diversity of life forms on Earth. This position, often said to be biocentric (centered on life) rather than anthropocentric (centered on human life only), includes what Leopold called "the land": the whole community of life on the landscape—rivers, mountains, canyons, forests, grasslands, and estuaries. Reforestation, for example, does not mean large tree plantations, producing timber and fiber for humans. Such plantations, which lack the biodiversity, complexity, health, and integrity of spontaneous natural ecosystems, are not genuine biological communities.

Those who advocate deep ecology and the more shallow reformers must learn to cooperate. Some strengths of each approach can be combined; some weakness of each, offset. The former sometimes become lost in utopian visions of a "green world"; the latter may be too absorbed in ad hoc, short-range solutions. The former can press for, and practice, more modest standards of living and support higher prices for nonvital products. Those who are less "deep" can be more pragmatic, willing to respond to what is currently politically realizable reform. Through such cooperation the supporters of both movements may help avoid crises likely to occur if ecologically responsible policies are forced too soon and too fast on populations that are not prepared for

them. The deep premises of argumentation add to the utilitarian arguments, which are shallow in relation to philosophical and religious premises, needing more depth of analysis of the problem.

The discussions surrounding deep ecology have implications for the medical area of bioethics as well. "Rich life, simple means," an aphorism of the deep ecology movement, suggests for medical bioethics a strengthening of preventive medicine and a reduced reliance on technically advanced treatments, especially if they require large investments of resources and energy. Medical bioethics can learn from ecological bioethics the need for a moral vision that can reorder its priorities.

III. LAND ETHICS

After graduating from the Yale Forest School, Aldo Leopold (1887–1948) joined the U.S. Forest Service in 1909 and served for fifteen years. He resigned to pursue his interest in wildlife ecology and management; in 1933 he was named Professor of Game Management and inaugurated a doctoral program in the subject at the University of Wisconsin. Over the course of his multifaceted career, Leopold came to believe that human harmony with nature could be achieved only if, in addition to governmental management and regulation, private citizens (and property owners in particular) acquired a "land ethic." Such an ethic would make ecosystems and their parts direct beneficiaries of human morality: "A land ethic changes the role of Homo sapiens from conqueror of the land community to plain member and citizen of it. It implies respect for his fellow-members, and also respect for the community as such" (Leopold, 1949, p. 204).

Leopold is routinely called a modern American "prophet." *A Sand County Almanac,* his slender book of literary and philosophical essays, has become the "bible" of the contemporary environmental movement in the United States. And his land ethic is the environmental ethic of choice among most American environmentalists and conservationists, both amateur and professional. It rests upon secular scientific, not sectarian or supernatural religious, foundations. It is less rigidly doctrinaire than deep ecology's eight-point ethical "platform." Unlike ecofeminism, it focuses directly on the human-nature relationship, unrefracted by the alleged historical oppression of women by men. And, in sharp contrast to Western ethical paradigms, it has a holistic dimension that can ground environmental policy and law respecting endangered species and biodiversity.

In the foreword to *A Sand County Almanac,* Leopold (1949, pp. viii–ix) identifies the central eco-axiological theme: "That land is a community is the basic concept of ecology, but that land is to be loved and respected is an extension of ethics. That land yields a cultural harvest is a fact long known, but latterly often forgotten. These essays attempt to weld these three concepts." Its forty-odd essays document two decades of Leopold's reflective intimacy with the natural world; they span the North American continent from Mexico to Canada and from the Southwest to the Midwest; and they range in style from pastoral vignettes to didactic sermonettes. Part One introduces the basic ecological concept of a biotic community (or ecosystem) personally and experientially through artful seasonal sketches of Leopold's beloved 120 acres of Wisconsin River bottomland. The regional sketches of Part Two develop the community concept in ecology more intellectually, generally, and abstractly. The prescriptive essays of Part Three frankly and forcefully explore the ethical and aesthetic implications of the community concept in ecology. The final essay, "The Land Ethic," is the book's philosophical climax and consummation.

The Biological Paradigm

Though liberally educated, Leopold was primarily a student of biology, not of philosophy. Hence his thinking about

ethics was influenced more by Charles Darwin than by Immanuel Kant and Jeremy Bentham, the fountainheads of the two major modern paradigms in ethics—deontology and utilitarianism, respectively—both of which proceed somewhat as follows: I demand that others dutifully respect my rights (in the deontological tradition) or take full account of how the consequences of their actions affect my interests (in the utilitarian). To defend that demand, I identify a characteristic I possess that arguably justifies my claim to moral rights or to consideration of my interests. According to Kant, it is rationality; according to Bentham, sentience. If I am to be consistent in my moral reasoning, then I must acknowledge that those who possess the same morally enfranchising property are entitled to the same regard from me as I demand of them. In short, the prevailing modern paradigms reach the moral standing of others starting from one's claim against others of one's own moral standing.

In sharp contrast, the biological paradigm, the paradigm in which Leopold works, starts with altruism, not egoism. Human beings are bonded to their fellows through sympathetic feelings and what David Hume and Adam Smith call the moral sentiments. The prehuman ancestors of Homo sapiens, whose survival and reproductive success greatly depended upon communal living, sympathy, and the other moral sentiments, were strengthened by natural selection and ever more broadly cast through social expansion. With the evolution of the powers of speech and reflection, forms of behavior that accorded with altruistic and social sensibilities were articulated in codes of conduct. As clans merged into tribes, tribes into nations, and so on, such codes were extended to each emergent social whole and its members. Leopold (1949, p. 202) comments that "Ethics, so far studied only by philosophers, is actually a process in ecological evolution." And he alludes to natural selection when he defines an ethic from a biological point of view "as a limitation on freedom of action in the struggle for existence." That he built directly and self-consciously upon this scenario of ethics arising out of community membership, which Darwin had fully articulated in the Descent of Man, therefore, seems certain. To the evolutionary foundation laid by Darwin, Leopold adds crucial material from ecology—the "community concept," especially—in order to erect his land ethic.

In Leopold's (1949, p. 203) own words: "All ethics so far evolved rest upon a single premise: that the individual is a member of a community of interdependent parts." That is Darwin's account of the origin and development of ethics in a nutshell. Ecology "simply enlarges the boundaries of the community to include soils, waters, plants, and animals, or collectively: the land" (p. 204). When this novel ecological insight is added to Darwin's classic evolutionary account of ethics, Leopold believes that the land ethic follows. Therefore, he writes, "A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise" (pp. 224–225).

Most contemporary environmental philosophers follow another path to an environmental ethic. They work well within either deontology or utilitarianism, and proceed to extend ethical standing to nonhuman beings by lowering the qualifications for moral rights or for consideration of interests. "Animal liberation" follows from Bentham's first principles virtually without modification, if we acknowledge that most animals are sentient. And "animal rights" follows from Kant's first principles if we acknowledge that while few, if any, animals may be rational, many have sufficiently robust mental capacities to support claims of rights on their behalf. Of course, animal welfare ethics are not the same as environmental ethics. But, taking the next step along these parallel paths, other philosophers have variously argued that all things having interests, broadly construed, or goods of their own—that is, all living beings—deserve, if not rights, then either dutiful respect (according to the deontologists) or moral consideration (according to the utilitarians).

From Facts to Values

To most moral philosophers, the biological paradigm seems to be more a scientific theory about ethics than a normative theory of ethics. And Leopold's facile move from an ecological "is" (that Homo sapiens is a plain member and citizen of the biotic community) to an environmental "ought" (that therefore we ought to preserve the integrity, stability, and beauty of the biotic community) seems to commit the naturalistic fallacy—the fallacy (named by G. E. Moore, but attributed to David Hume) of deducing prescriptive statements about our moral obligations and ethical values exclusively from descriptive statements about the way things in fact are.

The two major modern philosophical paradigms, on the other hand, seem strained to the breaking point when one attempts to extend rights or entitlements to an entire species or to whole ecosystems, let alone "soils and waters." The Leopold land ethic, grounded in feeling and community, better accords with the holistic focus of contemporary environmental concerns. Environmentalists and conservationists are not too concerned about the well-being of individual grubs, bugs, and shrubs. They are concerned, rather, about what pollution is doing to Earth's atmosphere, fresh waters, and oceans; about what fragmentation is doing to ecosystems; about endangered species and biological diversity.

Contemporary environmental philosophers thus face a theoretical dilemma. Cling to the modern paradigm and remain out of phase with the more holistic character of genuine environmental concerns, or give up the intellectual security and familiarity of the modern paradigm, follow Leopold's application of the biological paradigm to environmental concerns, and work to solve the daunting problem of deriving environmental ethical values from facts about human moral psychology, evolutionary biology, and ecology.

Ironically, Hume himself may provide the key to bridging the lacuna between "is" and "ought," fact and value, and thus clear the way for environmental philosophers to embrace the biological paradigm of ethical theory that the land ethic extends. "Reason," our tool for determining facts, according to Hume (1960, p. 469), "in a strict and philosophical sense can have influence on conduct only after two ways: either when it excites a passion [such as the love and respect that Leopold identifies with ethics] by informing us of the existence of something which is a proper object of it; or when it discovers the connexion of causes and effects, so as to afford us means of exerting any passion." Dispassionate, descriptive evolutionary biology, a product of what Hume calls "reason," has discovered that human beings and other extant forms of life are descended from common ancestors. Evolutionary biology thus discloses a previously unknown fact: that we are literally kin to "our fellow-voyagers … in the odyssey of evolution," as Leopold (1949, p. 109) characterizes them. The discovery of the fact excites the passions—love and respect—we feel for our kin. Equally dispassionate and descriptive ecological biology has discovered the existence of the biotic community, of which we are no less members than of our various human communities. And the discovery of that fact excites the passions—loyalty and patriotism in this case—that we feel for the social wholes to which we belong. Thus may we move from facts to values, from "ises" to "oughts," in the land ethic, after a manner, according to Hume, that is so strict and philosophical.

IV. ECOFEMINISM

"Environmental ethics" refers to a wide range of normative positions, from traditional Western, utilitarian, rights- and justice-based ethics to nontraditional and non-Western ethics. Feminist concerns in environmental ethics span this broad range of positions. However, one feminist position is distinctive: ecological feminism.

"Ecofeminism" is expressly committed to making visible the nature and significance of connections between the treatment of women and the treatment of nonhuman nature, or "women-nature connections." Ecofeminism claims that understanding women-nature connections is essential to any adequate feminism or environmental ethic.

Varieties of Ecofeminism

Just as there is not one feminism, so there is not one ecofeminism. "Ecofeminism" is a term that refers collectively to various environmental perspectives with roots in different feminisms: liberal feminism, traditional Marxist feminism, radical feminism, socialist feminism, and Third World feminism. These roots give rise to different, sometimes competing, ecofeminist positions on the nature and

resolution of contemporary environmental problems. What makes them ecofeminist is their explicit focus on "women-nature connections."

Consider the range of women-nature connections explored by ecofeminism (see Warren, 1993). Some ecofeminists discuss *historical* connections: for example, the role rationalism has played in Western philosophy and science in justifying the inferiorization of what is associated with female nature (Plumwood). They argue that to the extent that either the concept or the ascription of reason historically has been applied only to (some) human males, rationalism has been male-gender-biased. The male-gender bias arises from the mistaken assumption that women (and, typically, men of color) are incapable of the impartial, objective, abstract, universalizable reason by virtue of which rational men are both distinguished from and superior to nonrational "nature" (see Warren, 1989). These ecofeminists argue that philosophical conceptions of the human self, ethics, and culture that rely on Western historical conceptions of reason will thereby be male-gender biased (see Warren, 1989).

Some ecofeminists discuss *conceptual* women-nature connections: for example, the way women and nature have been conceived as inferior to male-identified reason and culture. Many ecofeminists claim that the twin dominations of women and nature grow out of and reflect oppressive ways of thinking. These are characterized at least minimally by value dualisms (mind/body, reason/emotion, man/woman, culture/nature), value hierarchies (assigning greater status, value, or prestige to what is "up" in "up-down" hierarchies), conceptions of power as power of "ups" over "downs," conceptions of privilege that systematically favor the "ups," and a logic of domination (the assumption that superiority justifies subordination) (Warren, 1990). On this view, oppressive patriarchal conceptual frameworks sanction behaviors that maintain the domination of women and nature.

Ecofeminists discuss *empirical* women-nature connections: for example, Third World women as managers of domestic households, primary gatherers of food and fuel (typically wood), and collectors and distributors of water (see Warren, 1992). These women must walk further for fuel and suffer greater exposure to contaminated water; in Western countries, poor women, men, and children of color face increased health risks associated with radioactive waste and hazardous waste incinerators (Warren, 1992; Commission for Racial Justice, 1987). Development policies and practices do not recognize the distinct gendered division of labor experienced by Third World women, or the gender, race, and class factors that contribute, even if unconsciously and unintentionally, to the subordination of women and people of color cross-culturally.

Ecofeminists also are interested in *epistemological* and *methodological* women-nature connections. At least 80 percent of the farmers in Africa are women, and women grow about 60 percent of the world's food (see Warren, 1992). A study in Sierra Leone showed that while local men could name an average of eight products of nearby bushes and trees, local women could identify thirty-one (see Warren, 1992). Such data suggest that women often have "indigenous technical knowledge" (ITK) or farming and forestry due to their gendered-role responsibilities in these areas (see Warren, 1992). Consequently, issues of epistemology and methodology in framing environmental ethics, policy, and decision making must ask not simply "What is known?" but "Who has the requisite knowledge and expertise?" According to ecofeminism, what women know as household managers of domestic economies, forests, and agriculture is important to the development of environmental ethics.

Symbolic associations between women and nature appear in art, literature, religion, and philosophy. This is especially evident in the sexist, naturist, and ageist language used to describe women and nonhuman nature. Women are characterized frequently as cows, sows, foxes, chicks, bitches, beavers, dogs, mares, dingbats, old bats, pussycats, birdbrains, harebrains, and serpents. They are pets, dolls, babes, childlike, whiny, "domesticated creatures." Nature is raped, mastered, mined, penetrated, domesticated, manipulated, conquered, and controlled by "the man of science." Virgin timber is felled, cut down; land that lies fallow is barren and useless (not "impotent" and "sterile"). (Similarly, men of color are disproportionately described in the subordinating language of the "downs" as animals, studs, dicks, weasels, wolves, unruly and dangerous "savages" driven by "animalistic instinct"; as docile, wimpy, sissy, childish, or childlike, and not fully rational; as childlike, simple [nonrational] "slaves" who need the guidance and protection of the paternalistic master, the "up.") In a patriarchal context, whatever is woman-, animal-, nature-, or even child-identified has historically been inferior ("down") to what is man-, male-, human-, adult-, or culture-identified. Thus language that feminizes animals and nature, animalizes and naturalizes women (and some men), or describes women, nature, and some men as domesticated pets or children, serves to reflect and reinforce their inferiorization.

What, then, about the allegedly positive connotations of "Mother Nature" or "Mother Earth"? Ecofeminists disagree about whether such female-gendered language truly liberates or merely reinforces harmful gender stereotypes (see Roach). However, all ecofeminists agree that within a patriarchal context, where gendered language has functioned historically to elevate that which is associated with

men and male culture, its uncritical continued use in the prefeminist present is problematic.

Finally, there are *political* ("*praxis*") women-nature connections. The term "ecofeminism," coined by Françoise d'Eaubonne in 1974, has always referred to grass-roots activism by local women interested in bringing together feminist environmental concerns. Whether it is the Chipko women in India, who are attempting to save trees from commercial fiber producers by hugging the trees, or Native American women, who are protesting the dumping of uranium mining residue on their lands, or the thousands of women from various cultures who gathered to develop strategies for policy and community organizing to combat water pollution, soil erosion, deforestation, and desertification at planning sessions, conferences, and seminars in conjunction with the Earth Summit in Rio de Janeiro in 1992, ecofeminism has always been grounded in grass-roots, local community political organizing (see Lahar). Properly understood, then, ecofeminist ethics is largely a theoretical response to such grass-roots political concerns involving women's lives globally.

Contributions of Ecofeminism

One might summarize ecofeminism's contributions to environmental ethics as threefold: First, ecofeminism challenges male-gender bias wherever and whenever it occurs. Second, ecofeminism offers a corrective lens to oppressive male-gender bias by self-consciously attempting to develop environmental analyses and positions that are not male-gender-biased. Third, ecofeminism offers a transformative perspective in environmental ethics, one that builds on but goes beyond both feminisms that do not have an adequate environmental component and environmental ethics that does not have a distinctly feminist component.

Ecofeminism does this by using a feminist lens to form different insights about women-nature connections; those environmental ethics that do not include (eco)feminist insights are viewed by ecofeminists as either antifeminist or nonfeminist. Nonfeminist environmental ethics, unlike antifeminist environmental ethics, is not ipso facto male-biased; its claims and conclusions might be quite compatible with and supportive of ecofeminist ethics. What an explicitly (eco)feminist environmental ethic does is overtly challenge androcentric (male-centered) bias in the way environmental ethics is conceived and practiced. For this reason, many ecofeminists criticize other environmental ethics (e.g., deep ecology, traditional Western ethics) for either their androcentric bias or their inattention (however inadvertent or unintentional) to important historical and empirical data about women-nature connections. Ecofeminists insist that within the intellectual traditions of the past few thousand years and at least of Western cultures, anthropocentrism (human-centeredness) has functioned historically as androcentrism (male-centeredness); failure to see this results in a gender blindness that is harmful to the framing of an environmental ethic or philosophy.

Similarly, ecofeminist conceptual concerns challenge the dominant notions of reason, knowledge, and objectivity, as well as the dominant notions of the human self that underlie them, that have been a mainstay of Western philosophical and environmental ethics. What ecofeminists seek is the development of different, nonoppressive notions of each that change or expand how the notions of reason, knowledge, objectivity, and the human self are conceived. In this vein, many ecofeminists challenge the extension of rights by animal-rights ethics to some nonhuman animals because those rights are based on historically intact, unrevised (and hence problematic) notions of the human self as moral agent (claimant, right holder, interest carrier) separate from and superior to lower plant and inorganic life.

Ecofeminist epistemological concerns raise related issues about the underrepresentation of women's voices in environmental ethics. Such concerns prompt ecofeminists to criticize, for example, land ethicists for their apparent lack of interest in gender issues. Ecofeminist concerns about gendered language and nature symbols (e.g., Mother Earth) challenge those environmental ethics (e.g., stewardship ethics) that uncritically adopt or perpetuate gender-exclusive or gender-problematic language and symbol systems (see Adams). Ecofeminist political concerns about unequal distributions of power and privilege in maintaining systems of domination (e.g., domination over women and nature) challenge any environmental ethic uncorrected by feminism to pay more attention to power and privilege in discussions of environmental ethics (see Warren, 1990).

Concluding Remarks

In conclusion, ecofeminist ethics is a self-consciously feminist-biased ethics insofar as it consciously, intentionally, and explicitly adopts a feminist perspective as the organizing lens through which any environmental ethic is constructed. Despite their critics (see Biehl; Fox), ecofeminists argue that in contemporary patriarchal society, the label "feminist" *does* add something important to the nature and description of environmental ethics; in a nonpatriarchal context, "feminist" concerns may well be unnecessary and the label "feminist" may drop away (see Warren, 1990). But for now, ecofeminist ethics reminds us that in contemporary patriarchal culture, there are important ways in which the domination of nature and the domination of women are linked, and

that failure to acknowledge such links perpetuates the mistaken view that feminism does not contribute anything significant to any environmental or biocentric ethics.

ENVIRONMENTAL HEALTH

• • •

Environmental health is "the segment of public health that is concerned with assessing, understanding, and controlling the impacts of people on their environment and the impacts of the environment on them" (Moeller, p. 1). The importance of environmental health has received increasing attention since the early 1990s as the connections between health and environment have come to be better understood and environmental challenges to health have become more pronounced.

Environmental health problems arise from poor air quality, lack of clean water, unhygienic living conditions, dangerous workplaces, unsafe food, careless disposal and treatment of wastes, and toxic pollution. A number of longer-range and more globally dispersed problems also pose significant challenges to health, including global climate change, depletion of the ozone layer, acid rain, nitrogen loading, loss of biodiversity, deforestation, loss of topsoil, increased pressure on resources as a result of changing patterns of consumption, and a rapid increase in the human population (McMichael, 2001; McCally, 2002).

The Global Environmental Health Picture

Although health around the world improved on average over the last half century—due mainly to improvements in environmental health fundamentals such as access to clean water, nutritious food, and adequate sanitation, alongside public health basics such as prenatal care and immunizations—it is likely that these gains will be lost if the environmental foundation for health continues to deteriorate. Billions of people already suffer from the effects of degraded environments: At the beginning of the twenty-first century fully one-third of the global burden of disease was attributed to environmental factors (Murray and Lopez).

Lack of clean water for drinking, inadequate sanitation, and lack of hygiene affect a third to a half of the world's population and are responsible for 7 percent of all death and disease globally. Chemical agents, particularly in the form of air pollution, are considered major causative factors in increased rates of bronchitis, heart disease, and cancer. The incidence of asthma is mushrooming. Certain forms of cancer are on the rise. The health of people around the world is diminished by exposure to toxic substances such as lead, mercury, arsenic, cadmium, and dioxins. As local and global ecosystems show increasing signs of stress, human health is likely to become far less stable and far more difficult to maintain. Children are hit especially hard by environmental health problems: The World Health Organization estimates that environmental hazards kill at least 3 million children under age five each year (United Nations Environment Programme).

There is a broad international consensus that the earth's ecosystems are under considerable strain, and global environmental decline will be the defining public health context in the twenty-first century (McMichael, 2001). According to an international report, the overall health of the earth's natural systems declined by 37 percent in the 1990s (World Wildlife Fund), fueled largely by population growth combined with unsustainable levels of consumption and production, which have increased in aggregate even more quickly than have human numbers.

Environmental Health in the United States

Concern with environmental health in the United States has long focused almost exclusively on the problem of toxic pollution, and concern about toxins has shaped the American regulatory, legislative, and philosophical approach to environmental health. Since the publication of *Silent Spring* (Carson) the country has been alerted to the mortal danger of exposing human beings and other life-forms to many products and by-products of an industrialized lifestyle. Although the negative effects of environmental pollution on human health cannot be denied, the existence and magnitude of danger associated with particular processes and products remain controversial.

One reason for the controversy is that powerful interests typically have a stake in denying that their industries create health hazards. Nuclear industries deny that low-level radiation causes cancer. Cigarette manufacturers deny a causal link between passive smoking and cancer. Manufacturers of asbestos products take a similar stand about asbestos, as do manufacturers of agricultural pesticides in regard to their products.

A second reason for the continued controversy is that because causal connections between human health and environmental pollution are inherently difficult to establish, the affected industries can hire competent scientists to dispute claims of environmental hazards to human health. In general, three types of evidence can be used to show that an environmental constituent is a health hazard, but none can establish that connection beyond dispute (Luoma).

First, nonhuman animals can be exposed to a suspected health hazard and the effect can be observed. This cannot prove anything conclusively about human exposure because human beings are biochemically different from nonhuman animals. Also, to establish a connection quickly and at minimal cost, nonhuman animals often are exposed to doses much larger than those to which human beings are expected to be exposed. The effect of a small dose on human beings cannot be established conclusively from evidence about the effects of much larger doses on nonhuman animals.

A second method of investigation is to expose human beings over short periods to mild doses of materials suspected of causing serious health problems when exposure is considerably greater or more prolonged. The problem here is that some substances may be so toxic that it would violate human rights to expose people deliberately even to mild doses. Other substances, in contrast, may not have a deleterious effect at low levels of exposure but may be toxic at higher concentrations or over longer periods. In these cases public health hazards may be underestimated or missed entirely.

Third, in epidemiological studies a substance is tested by comparing the rate of disease in one population with that in another in an attempt to correlate differences between the two populations' rates of disease with differences in their rates of exposure. However, it is difficult to establish in that way a connection between a specific suspected toxin and illness or death because under normal conditions people are exposed constantly to many suspected toxins of various strengths for varying periods. It therefore is difficult to isolate the effect of any single substance. Also, the effect of exposure, if there is one, is often weak. In a small population, for example, few additional cancers can be expected to result from exposure to low-level radiation. In addition, the cancer effect is long delayed and spread out in the population over a forty-year period, making it difficult to detect at any specific time (Stewart). Finally, radiation exposure and cancer exist in the human population in any case, and so it is impossible to determine that any given cancer is caused by exposure to low-level radiation or that the low-level radiation in question is related, for example, to a nuclear industry (Stewart).

Basically the same considerations apply when the issue is the effect of exposure to passive smoking, asbestos, or agricultural pesticides. Thus, controversies can continue for decades. Nevertheless, the weight of evidence supports the claim that the exposure of human beings to chemicals and other products and by-products of industrial civilization is often harmful to human health.

The Problem of Toxins in the United States

"Since the 1950s, age-standardized cancer incidence rates in the U.S. have increased by 43.5 percent" (Epstein, 1992, p. 233). Death from cancer has increased at a similar rate. The best attempts to isolate the causes of cancer have resulted in the conclusion that environmental factors account for 60 to 90 percent of cancers. The rest are attributable to inherited tendencies and internal biochemical malfunctions (Epstein, 1987).

Studies have shown cancer effects from doses of radiation that previously were thought to be safe. In one study a distinguishing fact about children who died of cancer before age ten compared with both those who died of other causes and those who survived to age ten is that the cancer victims' mothers received on average twice as many X rays while pregnant (Stewart). Another study showed a strong statistical association between a father's exposure to external radiation while working at a nuclear-waste reprocessing plant before a child was conceived and that child's chance of contracting leukemia (Gardner).

Radiation is not the only risk factor for cancer: Pesticides and other chemicals are implicated as well. A study showed that the mammary adipose tissue of women with breast cancer contained significantly more residues of chemicals associated with pesticides than did the mammary tissue of women with nonmalignant tumors (Falck et al.). Another study revealed that among white male scientists and engineers those who were members of the American Chemical Society had significantly more deaths from leukemia and lymphatic cancer (Arnetz et al.). A study of men from Iowa and Minnesota showed a link between elevated environmental chemical exposures that resulted from living near a factory and two types of cancer: non-Hodgkin's lymphoma and leukemia (Linos et al.). Non-Hodgkin's lymphoma also has been linked to the use of certain pesticides (Weber). Foundry workers in Denmark who were exposed to elevated levels of silica dust, metallic fumes, carbon monoxide, and several organic chemicals had markedly elevated rates of lung cancer (Sherson et al.). Occupational exposure to asbestos is considered responsible for 8,000 to 12,000 deaths each year in the United States (Rauber).

Typically, years intervene between exposure to environmental contaminants and an associated cancer or death. However, in some cases the connection between environmental pollution and human mortality is more direct. The "U.S. Office of Technology Assessment estimates that the mix of sulphates and particulates in ambient air may cause 50,000 premature deaths in the United States each year—about 2 percent of annual mortality" (Postel, 1986, p. 34). Toxic chemicals released into the air in 1988 were estimated by the U.S. Environmental Protection Agency (EPA) to cause "up to 3,000 cases of fatal cancer yearly as well as birth defects, lung disease, nervous system disorders, liver damage, and other health problems" (U.S. General Accounting Office, p. 8). When all types and sources of air pollution are considered, the American Lung Association puts the toll at 120,000 premature deaths per year (French).

There is increasing evidence that indoor air is often a health hazard. Radon in homes is believed to be a leading cause of cancer. The "sick building" syndrome is also a concern; it is the phenomenon of buildings inducing illnesses of various sorts in a large percentage of the people who spend considerable amounts of time in them. For example, chemicals in materials used to build and decorate the Dupage County Judicial and Office Facility in Wheaton, Illinois, were considered responsible for a variety of employee illnesses. As a result, a nearly new building was evacuated temporarily.

Scientists have been concerned particularly about exposure to heavy metals such as lead and mercury. Although exposure to lead has been reduced greatly, pockets of the population still are exposed to lead in peeling household paint, and everyone is exposed to lead in outdoor air pollution and food. The health effects of lead are well documented and include serious and irreversible impairment of children's neurobehavioral development (Brooks et al.). Mercury contamination also has been of particular concern. As with lead, the health effects of mercury are relatively well understood, largely because of several large-scale exposures, including the Minimata Bay disaster, in which a whole Japanese village was poisoned after eating mercury-laced fish. Methylmercury is absorbed readily by fish in polluted aquatic environments. When humans eat contaminated fish, the methylmercury is absorbed readily into the bloodstream and tissues. Mercury can cause tremors, dementia, and congenital neurological deformities (Brooks et al.).

Beginning in the 1990s, concern has intensified about a group of chemicals called persistent organic pollutants (POPs). Those chemicals include the polychlorinated biphenyls (PCBs); pesticides such as DDT, chlordane, aldrin, and heptachlor; and industrial by-products such as dioxins. POPs are fat-soluble and accumulate in the fatty tissues of animals, where they persist for long periods. Research suggests that POPs are "endocrine disruptors": They mimic hormones and may play a significant and largely unacknowledged role in altering reproduction and development. Endocrine disruptors have long concerned wildlife biologists, who believe that declines in avian and amphibian populations are linked to POPs in the environment (Colborn, Dumanoski, and Myers). The way in which these chemicals affect humans is unknown, although some research has connected exposure to POPs with diminished sperm quality and quantity, impaired sexual function, increased testicular cancer, hypospadias, and cryptorchidism (Solomon and Schettler).

Environmental Racism

The risks of contracting environmentally influenced diseases and deaths are not distributed evenly across the population in the United States. Geographically, the people at greatest risk are those who live near sources of industrial pollution such as factories and certain types of mines and those who live near deposits of toxic waste. For example, it seems that a geometrically increasing cancer rate for people in some communities in Cape Cod, Massachusetts, is due to toxic deposits from the nearby Otis Air Force Base (Hallowell). By 1989, 14,401 sites of toxic contamination had been noted in 1,579 military installations around the United States (Renner). When cancer rates are plotted on a map of the nation, the

places that show the highest rates are areas of industrial production such as Chicago, Detroit, northern New Jersey, and the lower Mississippi valley.

There is also a disparate impact on minority communities that is referred to as environmental racism. "Three out of every five African Americans and Hispanics live in a neighborhood with a hazardous waste site, and … race is the most significant variable in differentiating communities with such sites from the communities without them" (Steinhart, p. 18). "Probably the greatest concentration of hazardous-waste sites in the United States is on the predominantly black and Hispanic South Side of Chicago" (Russell, p. 25). With 28 million pounds of toxics poured into that area annually, the U.S. Environmental Protection Agency (EPA) estimates that the risk of cancer is 100 to 1,000 times the normal risk (Lavelle). According to the federal Centers for Disease Control, "lead poisoning endangers the health of nearly 8 million inner-city, largely black and Hispanic children" all over the United States (Russell, p. 24). Rural minority groups suffer disproportionately as well: "2 million tons of radioactive uranium tailings have been dumped on Native American lands; reproductive organ cancer among Navajo teenagers is seventeen times the national average" (Russell, p. 24).

Environmental racism is international as well as domestic. Toxic waste from industrial countries has been deposited in Africa (Jacobson). Some corporations in industrial countries continue to manufacture pesticides that are considered too dangerous for use in their own countries. Those pesticides are sold to farmers in the Third World, resulting in 10,000 to 40,000 poisonings per year (Postel, 1988). The Bhopal accident, in which 2,000 people were poisoned by a chemical leak from a factory in India, highlights the fact that environmental safeguards in the Third World are sometimes inadequate. The company that owns the factory is based in the United States, where it maintains higher standards of safety in its factories.

The Legal Structure

According to traditional Anglo-American jurisprudence, when one person injures another person, the injured party can sue in court to recover damages. The legal rules governing those proceedings constitute the law of torts. This body of law is largely unhelpful, however, when injuries are due to most forms of environmental pollution because it is difficult to prove that a harm such as a case of cancer resulted from a particular emission of radioactivity or a certain dumping of toxic waste. Also, it would be inefficient for each injured party to sue individually, as was done traditionally, when the activity in question is alleged to affect many people, possibly thousands. Finally, tort actions can take place only after harm is done, and it is preferable to use the law to avoid harms when possible. Thus, the major role of government in the area of environmental health lies in the regulatory process.

In 1970 the National Environmental Policy Act was signed into law to "fulfill the responsibilities of each generation as trustee of the environment for succeeding generations." The EPA, which was established soon afterward, required that most federally funded projects be accompanied by an environmental impact statement so that the deleterious effects of those projects could be recognized and possibly ameliorated. Subsequent legislation has given the EPA the authority, for example, to regulate processes that pollute the air and water (the Clean Air Act and the Clean Water Act); locate, authorize, and fund the cleanup of hazardous wastes (the Resource Conservation and Recovery Act, which established the Superfund); and control the use of pesticides (the Federal Insecticide, Fungicide, and Rodenticide Act). States have their own EPAs that perform similar functions.

The U.S. EPA is not the only agency with the responsibility to oversee activities that can affect environmental health. The U.S. Department of Energy (DOE) oversees the disposal of nuclear waste, the U.S. Department of Agriculture (USDA) helps determine consumer exposure to pesticide residues in food, and the U.S. Department of Labor protects the health of workers through the Occupational Safety and Health Administration (OSHA). In addition, most states have administrative agencies with similar responsibilities for intrastate activities.

Because Congress has authorized those agencies and the many subagencies through which they operate to protect the public, courts are reluctant to intervene, making private lawsuits particularly difficult. If an agency is operating within its congressional mandate and arguably is doing its job in a reasonable fashion, the courts usually will protect both the agency and those in compliance with its standards from private lawsuits seeking compensation for environmentally related illnesses. Thus, the protection of environmental health depends much more directly on the actions of those agencies than on the concerns of private citizens and their elected representatives.

Enforcement Problems

As was noted above, the protection of human health from environmental contamination in the United States is largely the responsibility of the EPA and other federal and state

agencies. Unfortunately, the performance of those agencies is sometimes disappointing. The EPA's regulation of pesticides exemplifies the general problem. The EPA regulates pesticides under the Federal Insecticide, Fungicide, and Rodenticide Act. The general public is exposed to pesticides primarily through residues in food and contamination of the groundwater that serves as a major source of drinking water. The EPA recognized in 1988 that "forty-six pesticides … contaminate groundwater solely as a result of normal agricultural use" (Fultz, p. 3). However, a registered chemical can remain in use for up to fifteen years after it is discovered in groundwater before a decision is made about its continued use. An example is atrazine, a pesticide that is in widespread agricultural use (Fultz). For pesticides that already have been found to be toxic, the EPA has not lowered acceptable exposure through residues in food in light of additional exposure through drinking water.

Not all pesticides in widespread use are registered with the EPA, resulting in the continued exposure of the public through food and water to pesticides that have not been tested for their "potential to cause birth defects, cancer, and other chronic health effects" (Fultz, p. 5). Exemption from the registration requirement is given in so-called emergencies for one year at a time, but some exemptions have been granted for more than a decade, during which time people have been exposed to pesticides of unknown toxicity (Guerrero, 1991b). Also, the EPA continues to emphasize the control of point sources of water pollution such as factories and municipal sewer systems instead of nonpoint sources such as agricultural runoff despite evidence that nonpoint sources pose a greater water pollution problem (Guerrero, 1991b). This may be due to the fact that the USDA promotes the use of many pesticides to increase crop yields even though those chemicals constitute health hazards.

Unfortunately, the EPA's inadequate protection of public health from the dangers of pesticides is typical. Similar stories can be told about surface-water pollution, hazardous waste management and cleanup, enforcement of the Clean Air Act, and U.S. Department of Energy (DOE) decisions about the disposal of nuclear waste: "The National Research Council estimated that only 2 percent of at least 60,000 chemicals that are used widely have been comprehensively studied for toxic effects" (Ziem and Davidoff, p. 88).

In addition to poor funding, a general reason for inadequate protection is that agencies tend to establish such close ties to the industries they are charged with regulating that they identify with industry perspectives and needs. An agency's capture by industry results partly from industry offers of future high-paying employment to regulatory personnel who are "reasonable." Another factor may be pressure on an agency by the legislators who are responsible for approving its budget. Those legislators may depend on the regulated industry for campaign contributions (Sanjour).

Conscientious federal employees who try to regulate effectively are relegated to tasks that have little impact. Employees who blow the whistle on an agency's failure to do its job must go before the presidentially appointed Merit System Protection Board, which may be more interested in protecting the president and "the system" than in protecting the whistle-blower (Sanjour).

There is also the appearance of racism in the EPA's enforcement efforts: "Penalties under hazardous waste laws at sites having the greatest white population were about 500 percent higher than penalties at sites with the greatest minority population" (Lavelle, p. S2). This disparity can be accounted for only by race, not by income. There is a similar disparity of 46 percent in penalties concerning nontoxic waste, air pollution, and water pollution. It takes 20 percent longer for toxic waste sites in minority areas to be placed on the priority list for cleanup, and the cleanup in minority areas is more likely than that in white areas to consist only of containment of the waste rather than treatment that removes its toxicity.

Environmental racism also appears to affect government regulation of international trade. For example, pesticides banned in the United States because of their toxicity to human beings can be manufactured and then sold abroad. Some return as residues on imported food.

Decisional Frameworks

How should decisions about environmental health be made? Advocates of free trade and free markets suggest that market mechanisms can protect public health adequately. However, from the perspective of firms competing for customers, environmental protection seldom makes sense. A manufacturer's plastic toys, for example, seldom are more attractive to customers because the water and air used in its manufacturing processes were purified before being released into the environment. Similarly, catalytic converters on automobiles add to cost but do not improve cars in most customers' eyes. Without government mandates requiring all the producers in an industry to protect the environment, the cost of such protection impairs the competitiveness, or reduces the profits, of conscientious firms that act alone. Thus, the free market discourages the protection of environmental health in the absence of government-mandated regulations such as those administered by OSHA and the EPA.

The EPA and other government agencies have been faulted for their failure to oppose the market-driven activities of private enterprise with sufficient vigor. Three kinds of

reforms may be ameliorative. First, agency personnel could be barred for five years from employment, directly or indirectly, by companies that their agency regulates. This would encourage greater independence of agency personnel from the perspectives of regulated companies. Second, campaign finance reform could help diminish the influence of financial interests on the regulatory process. Third, whistleblowers could be given special job and financial protection (Sanjour).

What decisional framework should those agencies employ? Some libertarians, who stress the importance of individual rights, maintain that any environmental pollution that may harm anyone should be disallowed. The government should "enjoin anyone from injecting pollutants into the air, and thereby invading the rights of persons and property. Period" (Rothbard, p. 5). However, this purist approach seems unrealistic because it would disallow, for example, most manufacturing and almost all uses of fossil fuels, including use in automobiles. Polluting the environment in ways that are potentially harmful to human health is too ingrained in industrial ways of life to be eliminated entirely.

Pointing to the benefits of industrialization—air-conditioning in the summer, heating in the winter, rapid transportation, and sophisticated medical interventions—some people maintain that pollution should be allowed until the risks to people outweigh the benefits. According to this view, government agencies such as the EPA should use risk-benefit analysis to determine permissible kinds and levels of pollution (Ruckelshaus).

Critics maintain, however, that risk-benefit analysis favors continued pollution over health-related concerns. First, current levels of pollution often are assumed to be acceptable and are used as precedents for future decisions. Second, whereas the benefits of current pollution practices are assumed, risks must be proved scientifically, a task that is difficult. Third, risk-benefit analysis depends largely on subjective judgments of "experts" whose opinions may reflect employers' interests (Winner).

Some people suggest avoiding subjectivity by using cost-benefit analysis (CBA), in which all the costs and benefits of proposed pollution-controlling regulations are expressed in monetary terms. The alternative with the highest net benefit should be chosen. Costly health hazards thus would be taken into account. The EPA usually allows environmental impact statements to employ CBA, and the Nuclear Regulatory Commission uses CBA regularly.

However, there are many problems with CBA. First, the costs and benefits associated with the length and quality of human life, which are affected by environmental health, cannot be translated reliably into monetary terms. Second, subjectivism remains because there is great uncertainty in projections of health hazards (Shrader-Frechette). Third, by employing money as its standard, CBA takes into account views and desires only insofar as they are expressed in monetary terms. The opportunity for that expression is proportional to the money at people's disposal. Using CBA, then, agencies would give protection to people not equally but in proportion to their wealth or income. In regard to the actions of government agencies CBA denies equal protection of the law. Fourth, using normal economic techniques, CBA discounts the future, making a present cost or benefit larger than an otherwise equivalent but future cost or benefit. This biases public policy toward the short term. If the duty to avoid or minimize harming people is based on human rights, harming future generations is morally equivalent to harming contemporaries. CBA discounts the lives and well-being of future generations (Wenz).

Alternative Frameworks

Instead of CBA, the following are possible rules of thumb. First, the burden of proof should be reversed from that employed in risk-benefit analysis. Before a potentially harmful addition is made to the environment, its safety should be demonstrated. At the beginning of the twenty-first century, for example, potentially carcinogenic pesticides can be used widely for ten to fifteen years before investigations are completed. Products are withdrawn then only if they are demonstrated to harm public health. The burden to demonstrate its safety should be on those who want to expose people to a new chemical.

Second, the people at greatest risk should be given the greatest voice in decisions about creating or using potentially hazardous substances (Shrader-Frechette). For example, corporate officials and owners interested in manufacturing processes that create toxic wastes would retain a significant voice in regulatory decisions if they could and would store the wastes near themselves and their families.

Third, through subsidies the government should encourage sustainable agriculture, integrated pest management, mass transit, energy conservation, and other practices and products that reduce the introduction of health hazards into the environment.

Fourth, when the indirect costs of a product can be calculated reliably, those costs should over time be added as a tax to the consumer price of that product. For example, the price of gasoline should reflect the costs associated with the

deleterious health effects of smog. Only then will consumers be guided by accurate information about how much a product actually costs them. Such information generally improves the results of reliance on market mechanisms.

Fifth, agencies should discourage practices that hide the existence or severity of environmental health problems. Storage of nuclear wastes underground so that the continuing health hazard is not noticed and the war on cancer that lulls people into thinking a cure is near lead the public to underestimate its jeopardy. This should be avoided in part because an informed public is central to addressing problems of pollution. In the absence of an objective formula for balancing alleged benefits against alleged harms to determine the acceptability of pollution, an informed public must be the ultimate judge of government decisions related to environmental health.

ENVIRONMENTAL POLICY AND LAW

• • •

Among the many purposes of environmental law, two stand out: the protection of personal and property rights and the preservation of places. Laws controlling pollution serve primarily the first goal; they constrain the risks people can impose on others. Statutes that pursue the second purpose seek to preserve national forests, landscapes, and landmarks; to protect historical districts; to maintain biodiversity; and to defend the integrity of ecological systems, such as rivers and wetlands.

These two sorts of statutes emerge from two foundational traditions in the political culture of the United States, the first of which draws on the values of property and autonomy; the second, on those of community and diversity. The first tradition, which is associated with libertarianism and individualism, would protect each person from involuntary risks and harms. The second tradition, which is associated with Madisonian republicanism, suggests that Americans may use the representative and participatory processes of democracy to ask and answer moral questions about the goals of a good society. Americans, most of whom are immigrants or descended from immigrants, find in the natural environment a common heritage—a res publica—that unites them as a nation. Environmental laws, then, may regard shared nature as having a cultural shape, form, or value we are responsible to maintain for its own sake and for future generations.

Pollution-control law may be understood in ethical rather than economic terms insofar as it protects the separateness and inviolability of persons rather than satisfies their interests or preferences. Land-use law preserves the ecological and historical character but not necessarily the economic product of landscapes. Environmental law thus responds to intrinsic values, namely, the autonomy of persons and the integrity of places.

This entry provides a brief account of the three stages—aspiration, recrimination, and collaboration—that characterize the historical development of environmental law in the United States since the passage of the National Environmental Policy Act of 1969. It then describes some of the normative and conceptual problems that are most likely to affect the future of environmental policy.

Aspiration: 1980–1990

During the 1970s, when politicians discovered that being in favor of the environment won votes, Congress enacted, among other statutes, the Clean Air Act of 1970, the Occupational Safety and Health Act of 1970 (OSHA), the Endangered Species Act (CAA) of 1972, the Safe Drinking Water Act of 1974, the Toxic Substances Control Act of 1976, and the Resource Conservation and Recovery Act of 1976. These laws were aspirational—one might say, demagogic—because they set lofty but often vague and

unrealistic goals, calling, for example, for *safe* thresholds for pollutants for which no such thresholds exist. The Ocean Dumping Act of 1972 prohibited ocean dumping—but did not say where the wastes should go instead. The Clean Water Act of 1972 required the restoration and maintenance of the "chemical, physical, and biological integrity of the Nation's waters." There is still no agreement on what these words mean.

The rhetorical objectives of laws enacted during the 1970s, which are strong enough to warm the heart of the most ardent environmentalist, soon became fictions as deadlines passed, violations were not monitored or prosecuted, and the agencies fought uphill political and legal battles to make whatever gains they could, given their limited resources. On those rare occasions when the regulatory agencies threatened to enforce a statute to its full extent, Congress could be counted on to weaken it. In 1973, when a court ordered the Environmental Protection Agency (EPA) to bring California into compliance with the Clean Air Act, for example, administrator William Ruckelshaus responded with gasoline rationing, since nothing less draconian would do the job. Congress intervened by extending deadline after deadline; they, too, passed unmet.

Some might regard the aspirational and draconian goals of environmental statutes as cynical: By promising environmentalists the moon, these statutes provided scant direction about how to solve conflicts on earth. OSHA requires the workplace to be as safe from hazards as *feasible,* but the government has regulated only about one hazardous substance per year. The Fish and Wildlife Service avoided drastic effects in applying the Endangered Species Act by failing to list species and by approving inadequate plans to protect those that were listed. This was often as much as was politically possible given the opposition of those who would rather "shoot, shovel, and shut up" than to dedicate their property to zoological ideals. The draconian wording of the statutes at least gave agencies a strong legal foothold when they could muster the political will to act.

The late and unlamented Delaney Clause of the Food, Drug and Cosmetic Act prohibited in prepared food any trace of a pesticide that can be shown to induce cancer when administered in massive doses to laboratory animals. It was rarely enforced. New methods of detection showed that every box, bottle, or can of food contains a trace of some carcinogen, so defined. Rather than close down the food industry, officials used dodges, such as a *de minimis* risk exemption, to skirt the law. Political factors—a congressional or presidential election, for example—did wonders in softening regulations in key districts; industry and other interest groups, moreover, knew how to use campaign contributions and their friends in Congress to chasten agency zeal in applying the law.

Retrospective Liability and Criminalization: 1980–1989

By 1981 environmental regulation had reached an impasse. Congress had announced the good news that the environment would be pollution-free and that the nation would preserve its scenic wonders and biological resources. Regulatory agencies then had to announce the bad news: what it would cost and who would have to pay for it. Many who bore the costs blamed the messenger; EPA and other agencies came under fire for policies that required great outlays to achieve sometimes minor improvements. When President Ronald Reagan announced a program of regulatory rescission and appointed Anne Gorsuch at EPA and James Watt at the Department of the Interior, it seemed that the goals of the 1970s would be abandoned, in view of the ideological commitments and managerial styles of these appointees.

By 1981 however, the constituency of the environmental movement had changed. At first enlisting primarily upper-middle class, well-educated suburbanites, environmentalism had become a populism, including lower-middle-class Americans in the heartland who resented the effects of global markets on their communities. Social-science surveys showed overwhelming support among all economic and social groups for the strictest regulation, regardless of cost. Because of the strength of environmentalism among his own supporters, President Reagan found himself obliged to replace the head of the EPA and the secretary of the interior, and to accept a new barrage of environmental statutes that appealed to a populist not to a technocratic constituency.

During the 1980s, Congress intensified top-down *command-and-control* regulation by enacting, for example, the Comprehensive Environmental Response, Compensation, and Liability Act of 1980, which makes the buyer of a contaminated property liable for the entire cleanup even though it did not contribute to the contamination. Other statutes—such as the Resource Conservation and Recovery Act Amendments of 1984, the Superfund Amendments and Reauthorization Act of 1986, and the Oil Pollution Act of 1990—likewise addressed not just present hazards but also the remediation of past ones. Some of these statutes included criminal penalties or made polluters jointly and severally liable for the entire cost of a cleanup, regardless of fault. Thus, any company whose name appeared on a manifest at a poorly operated waste dump might find itself legally liable to pay the entire cost of a gold-plated remediation.

Laws of this kind take a moralistic or retributivist approach, associated with populist crusades, in regulating pollution. In response, industries backed away from investments entirely, for example, where they were most needed in inner city neighborhoods, or they hired lawyers to avoid or spread liability rather than engineers to clean up or prevent pollution. It took about a dozen years for industry to deal with Superfund in some way other than litigation; eventually, public officials and industry lawyers learned to paper transactions needed to get some decontamination. EPA and state agencies began to allow industries to develop polluted properties—so-called *brownfields*—without incurring open-ended liabilities for perfect cleanups. EPA began to experiment with case-by-case negotiation to turn confrontation into compromise. Half way measures—often enshrined in consent decrees, supplemental environmental provisions, prospective purchaser agreements, habitat conservation plans, negotiated rulemakings, and many other instruments—kept the perfect environment the laws envisioned from becoming an implacable enemy of the good environment that patient case-by-case conflict-resolution could achieve.

The Contractual State

With the Clinton administration, the ethos of environment policy changed again. Large-scale polluters, such as smelters and refineries, had largely been controlled, but small sources, such as automobiles, trucks, lawn mowers, bakeries, cleaners, gas stations, and other modest businesses cumulatively added massively to pollution problems. Global threats, such as climate change, habitat loss, and fisheries depletion, implicated the average consumer, for example, those who drive gas-guzzling cars. Programs to *reinvent regulation* proposed to bring into the public sector innovations—such as information sharing, technology benchmarking, incentives, systems-thinking, and collaborative engagement—that had been introduced successfully in private enterprise.

EPA established several *banking, offset,* and *pollution trading* regimes that allowed firms to avail themselves of the cheapest ways to reduce pollution and gave them incentives to develop more efficient control technologies. Markets for trading pollution allowances, which capped total emissions at reduced levels, lowered lead and, especially, sulfur dioxide emissions, which were halved in a decade. Environmentalists could purchase and thus retire emission *allowances,* which sold at surprisingly low prices. EPA through Project XL engaged corporations in collaborative and negotiated rulemaking. Federal and state agencies also inspired decentralized community and individual action by providing information; for example, EPA's Green Lights program encouraged a transition from energy-intensive incandescent bulbs to far more efficient compact fluorescent ones. Similarly, toxic release inventories, eco-labeling, right-to-know regulations, and environmental certification programs illustrate other ways information can initiate local, decentralized improvements.

With the greater and easier availability of information, individuals and firms have begun to internalize environmental norms. Frustration with agency inaction, moreover, has led citizen and industry groups to try to collaborate to resolve their conflicts. Successful habitat conservation plans—the most famous concerns the desert tortoise—emerged from *civil society,* that is, from negotiation among concerned groups. Environmentalists and ranchers, usually at each other's throats, joined to petition the government to establish a market in tradable grazing rights that environmentalists can retire by buying them from ranchers. Officials have initiated successful stakeholder negotiations as well, for example, to protect visibility in the Grand Canyon, although agency intransigence and turf-mindedness—the Forest Service has opposed stakeholder governance of national forests, as in Quincy, California—can also undermine collaborative agreements.

In trying to decentralize decision making through collaboration, negotiation, information, incentive-formation, and so on, regulatory agencies have gotten ahead of legislation. Since 1990, Congress has enacted no major new environmental regulatory statutes nor significantly amended old ones. Since 1970, only two environmental statutes—the Right-to-Know Act of 1986 and the SO_2 trading program in 1990 CAA Amendments—depart from the standard top-down, command-and-control, one-size-fits-all approach. The trend toward more reflexive, adaptive, and collaborative approaches to conflict-resolution remains tenuous and vulnerable, since it lacks a statutory basis.

Economic Theory and the Environment

In the 1970s, economists described pollution and other environmental concerns as economic problems—external costs of production—that arise because markets fail to internalize in the prices of goods the costs of all the resources they consume. It soon became obvious, however, that public officials were no better able than private actors to gather and process the information needed to set *optimal* levels of pollution. Since the government confronts the same or greater information and bargaining costs as private parties, it is no more able than they to determine what people are willing to pay (or to accept) to gain or allow various

outcomes. The government has confronted prohibitive costs when it has sought to measure the environmental losses caused by an episode of pollution—and defend those measurements.

In the early 1990s, for example, the government spent $30 million to commission experts to assess the damages associated with the discharge of DDT and PCBs into the Los Angeles Harbor. Tens of millions of dollars have funded Contingent Valuation (CV) studies of the non-use value of various environmental goods, such as the losses associated with the EXXON *Valdez* oil spill. EXXON commissioned Nobel laureates and other economists to debunk that study. Economists, like lawyers, take sides; economic estimates and valuations themselves become goods people are willing to pay for. No CV study, however expensive, has ever stood up as credible evidence in litigation.

Chastened by the transaction and information costs that bedevil official efforts to "get the prices right" or second-guess market outcomes, economists have turned to recommending ways that the government can create voluntary arrangements, such as markets in tradable rights and allowances, stakeholder negotiations, and governance committees, as ways to get to consensual and in that sense optimal outcomes. The question "what is the efficient allocation?" has given way to the question "what is the appropriate institution?" for governing resources such as watersheds and forests. When the government agency itself tries to govern, it becomes the object of *rent-seeking,* for example, zero-sum jockeying by opposing interest groups, which hire their own lawyers, economists, toxicologists, ecologists, and other experts. When these interest groups deal directly with each other by trading rights or by collaborating on decisions, they immensely reduce the transaction and information costs that tend otherwise to stymie environmental progress.

A Look Ahead

For thirty years, Congress and the executive branch have engaged in what psychologists call enabling behavior. Like an alcoholic and his or her spouse, Congress and the executive agencies may quarrel, but at a deeper level they have been in league with each other. By letting deadlines pass, accepting *reasonable progress* in lieu of compliance, substituting *reduced risk* for statutory *zero risk* standards, and otherwise failing to enforce legislation, agencies such as EPA spared Congress the unpleasantness of making hard choices and allowed it to parade itself as the defender of nature, personal rights, purity, and so on. Congress in turn gave the agencies autonomy—the ability to work the law as they liked—within the tolerance of the courts.

In the spirit of the civil rights movement, environmentalists enforced landmark legislation by confrontation and litigation, primarily by suing EPA and other agencies for evading draconian statutes, such as the Delaney Clause. In 1992, the Ninth Circuit Court held that the EPA exceeded its statutory authority by allowing a *de minimis* risk standard in conflict with the language of the Delaney Clause. (*Les v. Riley,*1992). The decision implied that food must be absolutely free of chemical additives, including pesticide residues, as the law requires, even if as a result no food could be produced or sold in the United States.

Congress responded by repealing the Delaney Clause and enacting a more flexible policy, the Food Quality Protection Act of 1996, in its place. This result whet the appetite of industry groups who hoped that if environmentalists prevailed in other suits, Congress might be forced to repeal other aspirational statutes. Industry lawyers began to argue that the CAA, for example, taken literally, prohibited all air pollution—and thus nearly all economic activity—or, if, taken in any other way, delegated the entire burden of lawmaking to executive agencies and derivatively to the courts. This would involve an unconstitutional delegation of legislative authority to other branches of government.

When in 1997, EPA tightened the air quality standards for particulate matter and ozone, the D.C. Circuit Court, in *American Trucking Association v. Whitman* (1999), in response to an industry legal challenge, remanded the regulation to EPA on the grounds that neither the statute nor EPA's interpretation of it provided an *intelligible principle* necessary to channel the authority Congress delegated to the executive agencies. In reviewing this decision in 2001, the Supreme Court refused to declare the CAA unconstitutional on the grounds that it delegated the tough tradeoffs—and thus legislative authority—to the agencies. The Court and others recognized, however, that EPA has yet to determine a stopping point for regulation, that is, a point at which emissions are safe enough.

Some commentators argue that EPA should regulate emissions to the *knee of the curve,* referring to a graph in which the x-axis represents pollution reduction and the y-axis represents cost. The idea is that the government should require firms to reduce pollution to the point at which the costs of controlling the *next* unit increase exponentially or go asymptotic. In addition, agencies can encourage new technologies that may push the knee of the curve ever farther out along the pollution-control or the x-axis.

Other commentators argue that the most efficient controls on big sources of pollution are mostly in place, and it is small polluters, indeed, individual households, that hold the key to reducing pollution by becoming more energy-efficient. The reluctance of Americans to replace incandescent with fluorescent bulbs, to drive cars with greater fuel economy, to install better thermostats, windows, insulation, and so on, indicates the extent of the problem. Throughout the 1970s and 1980s, Americans blamed others—particularly large corporations—for their environmental woes, but it is apparent that the behavior of individuals has to change. The motto of the environmental movement has become more and more pertinent since cartoonist Walt Kelly's Pogo coined it: "We have met the enemy, and he is us."

The International Perspective

The other motto, "Think globally; act locally," recognizes that environmental problems have important global dimensions, particularly because carbon dioxide and other *greenhouse* gasses threaten to cause climate change. To some extent the international community has dealt successfully with environmental threats; for example, the Montreal Protocol, an international accord signed in 1987, initiated controls on the production of chemicals that damage stratospheric ozone. And conventions aimed at preserving endangered species and controlling the harvest of common resources—whales, for example—have long exerted influence on the international community.

To an even greater extent, however, international environmental conventions and the institutions—called *regimes*—set up to implement them meet many of the same problems of enforcement that are familiar in domestic contexts. Many of the conventions—such as those that ban pollution in the North Sea—are hortatory or idealistic. Politicians enact these protocols under pressure from the *green* movement, but because of the very great costs involved, they make slow progress in enforcing them. Nongovernmental organizations take the lead in litigating, harassing, and otherwise reminding officials of their responsibilities under the protocols they signed.

In 1997, industrialized nations, including Japan, the United States, and members of the European Union, promised at Kyoto that by 2012 they would cut to significantly less than 1990 levels, and permanently limit their production of, CO_2 and other greenhouse gases. Developing countries such as China, India, Indonesia, and Malaysia, believing that the welfare of their people depends more on the growth of their economies than on the stability of the atmosphere, refused to join the effort to lower emissions. These countries, because of rapid economic and population growth, are likely to surpass the industrialized nations in their greenhouse emissions within about fifteen years, and will by themselves emit more than enough greenhouse gases to destabilize the atmosphere. Partly for this reason, but also because of the costs involved, the U.S. Senate said that it would never ratify the climate treaty unless developing nations commit to *substantial participation.* President George W. Bush later brushed off the Kyoto Treaty entirely.

Environmental organizations have begun to turn their attention to international problems, particularly global climate change. Little has been said, however, about exactly how the United States should lower its emissions—whether by converting from coal-fired to nuclear energy, for example. Ethical debate has centered on a U.S. proposal to allow nations to sell credits for their *excess* reductions to other nations, who would then count them toward meeting their own targets. The United States, for example, might assist Russia to convert inefficient coal-burning electric utilities to cleaner and more efficient gas-fired power plants. The Russians would receive the new technology at little or no cost, and the United States would be able to take credit for the reduction in emissions from the Russian plants. It costs a lot less to achieve a 50 percent reduction from the dirtiest industries in Russia or India than a 10 percent reduction in industries that are already technologically advanced.

Critics have condemned pollution-trading because it "turns pollution into a commodity to be bought and sold," and thereby "removes the moral stigma that is properly associated with it" (Sandel). Yet CO_2, unlike toxic agents or carcinogens, should not be stigmatized. Under a safe global cap—let us say, the levels accepted at Kyoto—CO_2 emissions are not harmful or objectionable. If wealthy countries buy allowances by providing poorer countries with more efficient technologies, moreover, this does not necessarily indicate disrespect or arrogance, but might be looked at as partnership, if wealthy countries do not use less efficient technology at home than they subsidize abroad.

Some commentators have proposed a general requirement that ties CO_2 emissions to economic product, with the idea that wealthy countries can get credit for helping others reach the carbon-efficiency per dollar economic output achieved by the most efficient economies. The ethical impasse that stymies carbon *trading* strategies lies in finding a fair principle on which to distribute initial allowances—namely, whether to *grandfather* present levels or establish per-capita quotas. A global cap on greenhouse gases, in other words, must be translated into an initial set of permits

nations can use or trade. This problem has proven intractable. As economist Tom Schelling has said, "Global emissions trading is an elegant idea, but I cannot seriously envision national representatives sitting down to divide up rights in perpetuity worth a trillion dollars" (Passell).

The greatest threat to the global environment remains war—especially in view of the proliferation of nuclear weapons. Environmental protocols, regimes, and conventions, when successful, bring nations closer together and teach them to cooperate with and to trust each other. Insofar as environmental protection encourages a sustainable peace, it will lay the surest foundation for environmental protection and sustainable development.

EPIDEMICS

• • •

Epidemics may be defined as concentrated outbursts of infectious or noninfectious disease, often with unusually high mortality, affecting relatively large numbers of people within fairly narrow limits of time and space. They probably emerged in human populations with the "Neolithic Revolution," roughly eight to ten thousand years ago, as humans began to domesticate animals, practice agriculture, and settle into towns and villages, with a corresponding increase in the density of population. This entry will cover the history of epidemics with particular reference to their implications for bioethics, beginning with a survey of ancient and medieval times, moving on to responses to epidemics before the nineteenth century, then examining in more detail the impact of cholera and the bacteriological revolution. It will conclude with a discussion of the epidemiological transition and its aftermath, the emergence of new epidemics in the late twentieth century, and the ethical implications of the data surveyed. The focus will be mainly but not exclusively on Europe and North America, where historical source material is richest, and scholarly and scientific studies are most numerous.

Ancient and Medieval Times

Hippocratic texts indicate the presence of tuberculosis, malaria, and influenza in the population of ancient Greece, and the historian Thucydides provides the first full description of a major plague, the precise nature of which remains uncertain, in Athens (430–429 B.C.E.), in his history of the

Peloponnesian War. The increase in trade brought about by the growth of the Roman Empire facilitated the transmission of disease, and there were massive epidemics in the Mediterranean (165–180 C.E. and 211–266 C.E.). The "plague of Justinian" (542–547 C.E.), which was said to have killed ten thousand people per day in Constantinople, is the first recorded appearance of bubonic plague (McNeill). In Europe and Asia, diseases such as measles and smallpox gradually became endemic, affecting virtually all parts of the population on a regular basis, with occasional epidemic outbursts. Periodic epidemics of bubonic plague continued, most seriously in the fourteenth century, when perhaps as much as one-third of Europe's population perished.

When Europeans arrived in the Americas, from 1492 on, they brought many of these diseases to native American populations for the first time, with devastating effects. The importation of African slaves introduced malaria and yellow fever by the seventeenth century (Kiple, 1984). The merging of the disease pools of the Old and New Worlds was completed by what appeared to be the transmission of syphilis to Europe from the Americas at the end of the fifteenth century, though the subject remains disputed by historians, some arguing that it was a recurrence or mutation of a disease that already existed on the Continent (Crosby).

Responses to Epidemics before the Nineteenth Century

The ancient Greeks and Romans commonly, though not universally, believed that epidemics were brought into human communities from outside. Thucydides, for example, described the plague that struck Athens during the Peloponnesian War as having arrived by sea. This belief was the basis of official reactions to epidemics in medieval Europe. Following the closure of the port at Venice to all shipping for thirty days as the plague threatened in 1346, regulations imposed in Marseilles in 1384, and in other ports thereafter, prescribed the biblical period of isolation for a "quarantine" (forty days) outside the harbor for any ship thought to have called previously at a place infected with the plague. In 1423 the Venetians set up a hospital where plague victims were isolated, and by 1485 the city had a sanitary authority armed with wide-ranging powers during epidemics. In some epidemics, as in the Great Plague of London in 1665, victims were compulsorily isolated in their own houses, which were marked with a red cross to warn the healthy not to enter. Compulsory screening was not an issue before the late nineteenth century, however, because diseases were recognized as such only after the onset of obvious symptoms, and the concept of the asymptomatic carrier did not exist. In addition to these measures, the authorities in many medieval towns, working on the theory that epidemics were spread through the contamination of the atmosphere, ordered the fumigation of the streets to try to clear the air. Doctors and priests were expected to attend to the sick; and those who fled, as many did, are strongly criticized in the chronicles of these events.

Popular reactions to epidemics included not only flight from infected areas and evasion of public health measures, but also attacks on already marginalized and stigmatized minorities. As bubonic plague spread in Europe in 1348–1349, for example, rumors that the Jews were poisoning water supplies led to widespread pogroms. Over nine hundred Jews were massacred in the German city of Erfurt alone (Vasold). Such actions reflected a general feeling, reinforced by the church, that plagues were visited upon humankind by a wrathful Deity angered by immorality, irreligion, and the toleration of infidels. A prominent part in these persecutions was played by the flagellants, lay religious orders whose self-flagellating processions were intended to divert divine retribution from the rest of the population. Jews were scapegoated because they were not part of the Christian community. Drawing upon a lengthy tradition of Christian anti-Semitism, which blamed the Jews for the killing of Christ, the people of medieval Europe regarded Jews at such times as little better than the agents of Satan (Delumeau).

State, popular, religious, and medical responses such as these remained essentially constant well into the nineteenth century. The medical understanding of plague continued throughout this period to draw heavily on humoral theories, so that therapy centered on bloodletting and similar treatments designed to restore the humoral balance in the patient's body. They were of limited effectiveness in combating bubonic plague, which was spread by flea-infested rats. The isolation and hospitalization of victims also therefore did little to prevent the spread of plague. Nevertheless, the disease gradually retreated from western Europe, for reasons that are still imperfectly understood. The introduction of more effective quarantines with the emergence of the strong state in the seventeenth and eighteenth centuries was almost certainly one of these reasons, however, and helped prevent the recurrence of epidemics in the seventeenth and eighteenth centuries (Vasold).

State intervention also played a role in reducing the impact of smallpox, the other major killer disease of the age after bubonic plague. Its spread was first reduced by inoculation, before compulsory programs of cowpox vaccination brought about a dramatic reduction in the impact of the

disease in nineteenth-century Europe. Despite the imperfections of these new methods, which sometimes included accidentally spreading the disease, vaccination programs in particular may be regarded as the first major achievement of the "medical policing" favored by eighteenth-century absolutist monarchies such as Prussia. Police methods that paid scant attention to the liberties of the subjects were used to combat the spread of epidemics. They included the use of troops to seal off infected districts, quarantines by land and sea, and the compulsory isolation of individual victims. Most of these measures had little effect, however, either because of lack of medical knowledge or because poor communications and lack of police and military manpower prevented them from being applied comprehensively (Rosen).

The Impact of Cholera

These theories and practices were brought into question above all by the arrival in Europe and North America of Asiatic cholera. The growth of the British Empire, especially in India, improved communications and trade, and facilitated the spread of cholera from its base in the Ganges delta to other parts of Asia and to the Middle East. Reaching Europe by the end of the 1820s, the disease was spread further by unsanitary and overcrowded living conditions in the rapidly growing towns and cities of the new industrial era. At particular moments of political conflict, above all in the European revolutions of 1830 and 1848, the Austro-Prussian War of 1866, and the Franco-Prussian War of 1870–1871, it was carried rapidly across the continent by troop movements and the mass flight of affected civilian populations (Evans, 1988).

Cholera epidemics affected the United States in 1832, 1849, and 1866, on each occasion arriving from Europe in the aftermath of a major conflict. State, popular, and medical responses in 1830–1832 were unchanged from earlier reactions to epidemics. Quarantine regulations were imposed, military cordons established, victims isolated, hospitals prepared. In Prussia, the breaching of such regulations was made punishable by death. But the opposition that such measures aroused among increasingly powerful industrial and trading interests, and the feeling among many liberals that the policing of disease involved unwarranted interference with the liberty of the individual, forced the state to retreat from combating cholera by the time of the next epidemic, in the late 1840s. In addition, medical theories of contagion were brought into disrepute by the failure of quarantine and isolation to stop the spread of the disease in Europe. Until the 1880s, many doctors thought that cholera was caused by a "miasma" or vapor rising from the ground under certain climatic circumstances. It could be prevented by cleaning up the cities so as to prevent the source of infection from getting into the soil (Evans, 1987). This was a contributory factor in the spread of sanitary reform in Europe and the United States during this period. But its importance should not be overestimated. Boards of health established in American cities in the midst of the cholera epidemics of 1832 and 1849 were short-lived and of limited effectiveness, and even in 1866 the more determined official responses had less to do with the impact of cholera than with the changed political climate (Rosenberg).

The fact that cholera affected the poorest sectors of society most profoundly was the result above all of structural factors such as unsanitary and overcrowded living conditions, unhygienic water supplies, and ineffective methods of waste disposal. But state and public responses to epidemics in the nineteenth century, at least in the decades after the initial impact of cholera, were primarily voluntaristic. Religious and secular commentators blamed cholera on the alleged immorality, drunkenness, sexual excess, idleness, and lack of moral fiber of the victims. Fast days were held in eleven New England states in 1832, in the belief that piety would divert God's avenging hand. Once again, the socially marginal groups of industrial society, from vagrants and the unemployed to prostitutes and beggars—or, in the United States in 1866, the newly emancipated slaves and the newly arrived Irish immigrants—were blamed (Rosenberg).

The rise of the medical profession, with well-regulated training and a code of ethics, ensured that doctors were more consistently active in treating victims of epidemics in the nineteenth century than they had been in previous times. Partly as a result, there were popular attacks on the medical profession in Europe during the epidemic of 1830–1832. Angry crowds accused doctors of poisoning the poor in order to be able to reduce the burden of support they imposed on the state or, in Britain, in order to provide fresh bodies for the anatomy schools (Durey). As late as 1892, doctors and state officials were being killed in cholera riots in Russia (Frieden). There were also disturbances in the United States, where a hospital was burned down in Pittsburgh and a quarantine hospital on Staten Island, in New York City, was destroyed by rioters fearing the spread of yellow fever. However, in most of Europe, public disturbances caused by epidemics had largely ceased by the middle of the nineteenth century. Fear of disorder was another reason for the state's withdrawal from policing measures (Evans, 1988). In Europe, too, religious responses to epidemics had become less important by the end of the century as religious observance declined. In 1892, however, as cholera once more threatened America's shores, it fed nativist prejudice and led to the introduction of harsh new restrictions on immigration.

The Bacteriological Revolution

Cholera was only the most dramatic of a number of infectious diseases that took advantage of urbanization, poor hygiene, overcrowding, and improved communications in the nineteenth century (Bardet et al.). Typhus, typhoid, diphtheria, yellow fever, tuberculosis, malaria, and syphilis continued to have a major impact, and even smallpox returned on a large scale during the Franco-Prussian War of 1870–1871. Treatment continued to be ineffective. But the rapid development of microscope technology in the last quarter of the century enabled medical science to discover the causative agents of many infectious diseases in humans and animals. Building on the achievements of Louis Pasteur, Robert Koch identified the tubercle bacillus in 1882 and the cholera bacillus in 1884. These discoveries marked the triumph of bacteriology and completed the swing of medical opinion back from belief in "miasmas" as causes of epidemics toward a contagionist point of view.

From the 1880s, states once more imposed quarantine and isolation, backed by preventive disinfection. The greater effectiveness of state controls, compared with the earlier part of the century, was combined with the more precise focus on eliminating bacterial organisms. Once the role of victims' excretions in contaminating water supplies with the cholera bacillus became known, it was possible to take preventive action by ensuring hygienic water supplies and safe waste disposal. By the outbreak of World War I in 1914, the role of the human body louse in spreading typhus, and that of the mosquito in transmitting malaria and yellow fever, had been identified. Mosquito control programs were launched by the U.S. Army in Cuba following the Spanish-American War of 1898, and subsequently in the Panama Canal Zone, in order to reduce the incidence of yellow fever cases to an acceptable level. Regular delousing reduced typhus among armies on the western front in Europe during World War I. The Japanese army prevented casualties from typhoid and smallpox by a campaign of systematic vaccination during the war with Russia in 1904–1905 (McNeill; Cartwright).

The bacteriological revolution thus inaugurated an age of sharply increased state controls over the spread of disease. Laws were introduced in many countries making the reporting of infectious diseases compulsory. The growth of a comprehensive, state-backed system of medical care, working through medical officers, medical insurance plans, and the like, made comprehensive reporting easier. Hospital building programs in the second half of the nineteenth century facilitated the isolation of victims in hygienic conditions where they could be prevented from spreading the disease. The greater prestige of the medical profession in most industrialized countries by the late nineteenth and early twentieth century ensured that doctors were no longer attacked, and that the necessity of compulsory reporting and isolation was widely accepted by the public. However, a bacteriological understanding of disease causation also involved a narrowing of focus, in which increased emphasis was placed on the compulsory reporting of cases, followed by their isolation, at the expense of broader measures of public health and environmental improvement (Porter).

The Epidemiological Transition

Lower death rates from diseases such as cholera, typhoid, and tuberculosis were only partially the consequence of bacteriologically inspired state preventive measures, and the disease burden from acute infectious disease began to decline rapidly. The provision of clean, properly filtered water supplies and effective sewage systems reflected growing municipal pride and the middle-class desire for cleanliness. It made epidemics such as the outbreak of cholera that killed over eight thousand people in Hamburg, Germany, in little over six weeks in the autumn of 1892 increasingly rare. Just as important were improvements in personal hygiene, which again reflected general social trends as well as the growing "medicalization" of society in western Europe and the United States. Such developments reinforced the stigmatization of poor and oppressed minorities as carriers of infection, since they were now blamed for ignoring official exhortations to maintain high standards of cleanliness, even though their living conditions and personal circumstances frequently made it difficult for them to do so. Particular attention was focused on working-class women, who were held responsible by official and medical opinion for any lack of hygiene in the home (Evans, 1987).

The development of tuberculin by Koch in 1890 made possible the compulsory screening of populations even for asymptomatic tuberculosis. This was increasingly implemented after 1900, in conjunction with the forcible removal of carriers to sanatoria, although this was more effective in isolating people than in curing them. Educational measures also helped reduce the spread of the disease. The development and compulsory administration in many countries of a preventive vaccine against tuberculosis from the 1920s aroused resistance among the medical community, not least because by creating a positive tuberculin reaction in noncarriers, it made it impossible to detect those who truly had the disease, except where symptoms were obvious. These measures had some effect in reducing the impact of the disease. However, although the precise causes of the retreat of tuberculosis remain a matter of controversy among

historians, the long-term decline of the disease from the middle of the nineteenth century was probably more the result of improvements in housing, hygiene, environmental sanitation, and living standards than of direct medical intervention. The introduction of antibiotics such as streptomycin after World War II proved effective in reducing to insignificant levels mortality from a disease that had been the most frequent cause of death or disability among Americans aged fifteen to forty-five (Dubos and Dubos).

Similarly, official responses to syphilis centered, especially in Europe, on the forcible confinement of prostitutes to state-licensed brothels or locked hospital wards, where they were subjected to compulsory medical examination. Before World War I, New York, California, and other states had introduced compulsory reporting of cases of venereal disease, and official concern for the health of U.S. troops led to the jailing of prostitutes. Measures such as these had no discernible effect on infection rates, which rose sharply during the war. They also represented a serious restriction on the civil liberties of an already stigmatized group of women, while the men who were their customers, and equally active in the sexual transmission of disease, were regarded as irresponsible at worst, and were not subjected to similar measures. The development of Salvarsan (arsphenamine) by Paul Ehrlich in 1910 introduced the possibility of an effective treatment for syphilis. But here again there was resistance, both within the medical community and from outside, from those who considered that an increase in sexual promiscuity would be a result. This view became even more widespread following the use of penicillin on a large scale during World War II (Brandt).

Epidemics of the Late Twentieth Century

In the West, epidemic infectious disease was regarded by the second half of the twentieth century as indicating an uncivilized state of mind, and was ascribed above all to nonwhite populations in parts of the world outside Europe and North America. This reflected structural inequalities in the world economy, as the great infections became increasingly concentrated in the poor countries of the Third World. By the middle of the twentieth century, however, rapidly increasing life expectancy was bringing rapid growth of noninfectious cardiac diseases, cancer, and other chronic conditions that posed new epidemic threats to an aging population in the affluent West. Under increasing pressure from the medical profession, the state responded not only with education initiatives but also with punitive measures directed toward habits, such as cigarette smoking, that were thought to make such conditions more likely. The arsenal of sanctions governments employed included punitive taxation on tobacco and the banning of smoking, under threat of fines and imprisonment, in a growing number of public places. Increasingly, institutions in the private sector also adopted these policies. They raised the question of how far state and nonstate institutions could go in forcing people to abandon pleasures that were demonstrably harmful to their own health. At the same time, they contrasted strongly with the reluctance of many states and companies to admit responsibility for cancer epidemics caused by factors such as nuclear weapons testing, the proximity of nuclear power stations to human populations, or the lack of proper precautions in dealing with radioactivity in industrial production.

In the 1980s, the identification of a new epidemic, known as acquired immune deficiency syndrome (AIDS), once more raised the ethical problems faced by state and society, and by the medical profession, in the past. Lack of medical knowledge of the syndrome and the danger of infection from contact with blood or other body fluids, posed the question of whether the medical profession had a duty to treat AIDS sufferers in the absence of any cure. The evidence of the overwhelming majority of past epidemics, for which there was also no known cure, seems to be, however, that medical treatment, even in the Middle Ages, could alleviate suffering under some circumstances, and was therefore a duty of the practitioner. In a condition that could prove rapidly fatal, the ethics of prolonged tests of a drug such as AZT, in which control groups were given placebos, was contested by AIDS sufferers anxious to try anything that might possibly cure the condition, or at least slow its progress.

If this was a relatively novel ethical problem, then the question of compulsory public-health measures was a very old one. Like the sufferers in many previous epidemics, AIDS victims tended to come from already stigmatized social groups: gays, drug abusers and prostitutes, Haitians and Africans. The ability to screen these high-risk groups for the presence of the causative agent, the HIV retrovirus, even at the asymptomatic stage, raised the possibility of compulsory screening measures, quarantine, and isolation. On the other hand, individuals publicly identified as HIV-positive generally found it difficult or impossible to stay employed, to obtain life or health insurance, or to avoid eviction from their homes. In the absence of adequate supportive measures, public-health intervention reinforces existing discrimination against these groups, as in many past epidemics.

An alternative state response has consisted of neglect, on the assumption that AIDS is unlikely to affect the heterosexual, non-drug-abusing, nonpromiscuous majority of the voting public. It is noticeable that, generally, politicians have invested resources in public education and other

preventive measures only when they have believed that the majority population is at risk. These problems have been raised again by the recent resurgence of tuberculosis in Western countries, among the HIV-positive but also among the poor and the homeless. Drug-resistant strains of the disease have become common, and the transient, jobless, and destitute have neither the means nor the stability of life-style to complete the lengthy course of drugs that is necessary to effect a cure. The compulsory isolation of victims and their forcible subjection to a course of treatment is not a satisfactory long-term solution to the problem, since reinfection is likely upon release, unless the social and personal circumstances of the affected groups undergo a dramatic improvement.

Conclusion: Ethical Implications

The history of epidemics suggests that society's responses have usually included scapegoating marginal and already stigmatized groups and the restriction of their civil rights. From the Jews massacred during the Black Death in medieval Europe, through the beggars and vagrants blamed for the spread of cholera in the nineteenth century, to the prostitutes arrested for allegedly infecting troops with syphilis during World War I, and the minorities whose life-styles were widely regarded as responsible for the spread of AIDS in the 1980s and 1990s, such groups have frequently been subjected to social ostracism and official hostility in times of epidemic disease. Frequently, though not invariably, they have been the very people who have suffered most severely from the disease they were accused of spreading. Doctors have sometimes been reluctant to treat them; the state has often responded with punitive measures.

At no time have public-health measures to combat epidemics been politically uncontested. Nineteenth-century feminists, for example, campaigned vigorously against the state's restriction of the civil liberties of prostitutes in the name of disease control. The fact that their male customers were left free to spread sexually transmitted diseases unhampered by the attentions of the state implied an official endorsement of different standards of morality for men and for women, and it was this major structural element of the social value system that the feminists were seeking to change. Without such change, not only was medical intervention ethically indefensible, but there would never be any likelihood of effective control of sexually transmitted diseases. Similarly, many nineteenth-century epidemics, such as cholera or tuberculosis, were spread by poor nutrition, overcrowded housing, and inadequate sanitation. Social reformers therefore regarded major improvements in these areas as more important than direct medical intervention through measures such as compulsory hospitalization.

Epidemics are frequently caused by social and political upheavals. In the past, movements of large masses of troops and civilians across Europe, from the Crusades to the Crimean War, brought epidemics in their wake. In the early 1990s, a major cholera epidemic broke out in Peru as the result of the flight of thousands of peasants from their mountain settlements, driven out by the pitiless armed conflict between the army and the "Shining Path" guerrillas, to the narrow coastal strip, where they lived in makeshift shantytowns with no sanitation. Economic crisis and the dismantling of welfare measures for the homeless, the mentally disturbed, and the destitute in many Western countries in the 1980s contributed to a massive increase in the transient population on the streets of the great cities. Discrimination against AIDS sufferers by landlords and employers has added to this problem. By the early 1990s there were an estimated ninety thousand homeless on the streets of New York City, half of whom were HIV-positive and several thousand of whom were suffering from tuberculosis. Any long-term solution to these epidemics must be more than merely medical, as must any explanation of their occurrence. Public-health measures are thus inevitably political in their implications, since they can be considered and administered only with reference to the wider social and cultural context within which the disease they seek to prevent or control has originated.

ETHICS

I. TASK OF ETHICS

Ethics as a philosophical or theoretical discipline is concerned with tasks that concern ordinary, reflective individuals. Since its origins in classical and preclassical times, it has sought to understand how human beings should act and what kind of life is best for people. When Socrates and Plato dealt with such questions, they presupposed or at the very least hoped that they could be answered in "timeless" fashion, that is, with answers that were not dependent on the culture and circumstances of the answerer, but represented universally valid, rational conclusions.

In fact, however, the history of philosophical or theoretical ethics is intimately related to the ethical views and

practices prevalent in various societies over the millennia. Although philosophers have usually sought to answer ethical questions without regard to (and sometimes in defiance of) some of the standards and traditions prevalent around them, the history of ethics as a philosophical discipline bears interesting connections to what has happened in given philosophers' societies and the world at large. Perhaps the clearest example of this lies in the influence of Christianity on the history of theoretical ethics.

Philosophical/theoretical ethics, of course, has had its own influence on Christianity, for example, Aristotle's influence on the philosophy of Thomas Aquinas and on the views and practices of the church. Nonetheless, to compare the character of the pre-Christian ethics of Socrates, Plato, Aristotle, the Stoics, the Epicureans, and other schools of ancient ethical thought with the kinds of ethics that have flourished in the academy since Christianity became a dominant social force is to recognize that larger social and historical currents play significant roles in the sphere of philosophical ethics.

Socrates, Plato, and Aristotle, for example, do not discuss kindness or compassion, moral guilt, or the virtue of self-denial, or selflessness. Christianity helped to bring these notions to the attention of philosophy and to make philosophers think that issues framed in terms of them were central to their task. By the same token, a late-twentieth-century revival of interest in ancient approaches to ethics may reflect the diminishing force and domination of Christian thinking in the contemporary world.

But if the concepts that ethics focuses on can change so profoundly, one may well wonder whether a single discipline of ethics can be said to persist across the ages, or even whether such a thing as "the task" of philosophical ethics can be said to endure. Socrates, and later Plato, were perhaps the first philosophers to make a self-conscious attempt to answer general ethical questions on the basis of reason and argument rather than convention and tradition. But was the task they accepted really the same as that of contemporary ethics? This issue needs to be addressed before the task of ethics can be described.

Despite the fact that the concepts and problems of physics have varied over the last few centuries, it is still possible to speak of the history of a single discipline called physics. Moreover, we might say that the task of physics has been and remains that of developing physical concepts for the explanation and description of physical phenomena. Something similar can be said about theoretical ethics. Over the millennia, thoughtful people and philosophers have asked what kind of life is best for the individual and how one ought to behave in regard to other individuals and society as a whole. Although different concepts have been proposed to assist in the task of answering these questions, the questions themselves have retained an identity substantial enough to allow one to speak of the task of philosophical ethics without doing an injustice to the history of ethics.

The History of Ethical Theories

There has been a good deal less variation in philosophical concepts between those Plato employed and those we employ than there has been in regard to physical concepts within the field of physics. Concepts in philosophical ethics are the instruments with which philosophers address perennial ethical questions, and the distinctive contribution of any given theoretical approach to ethics resides in how (and how well) it integrates such concepts into an overall ethical view.

The concepts of ethics fall into two main categories. The first category comprises notions having to do with morality, virtue, rationality, and other ideals or standards of conduct and motivation; the second, notions pertaining to human good or well-being and the "good life" generally. Notice that morality is only one part, albeit a major one, of the first category. Claims and ideals concerning how it is rational for us to behave are not necessarily "moral" within our rather narrow modern understanding of that notion. Prudence and far-sightedness, for example, are rational, but their absence is not usually regarded as any kind of moral fault; and since these traits are also usually regarded as virtues, it seems we have room for virtues that are not specifically moral virtues. In addition, questions about human well-being and about what kind of life is best to have are less clearly questions of morality, narrowly conceived, than of ethics regarded as an encompassing philosophical discipline. The two categories mentioned above basically divide the concepts of ethics understood in this broad sense, and all major, substantive ethical theories attempt to say something about how these two classes of concepts relate to one another. Since modern views employ concepts and ask specific questions that are more familiar to contemporary readers, these views will be discussed first.

DEONTOLOGY. Modern deontology treats moral obligations as requirements that bind us to act, in large measure, independent of the effects our actions may have on our own good or well-being, and to a substantial extent, even independent of the effects of our actions on the well-being of others. The categorical imperative of Immanuel Kant (1724–1804), in one of its main formulations, tells us that

we may not use or mistreat other people as a means either to our own happiness or to that of other people, and various forms of moral intuitionism make similar claims (1964). Intuitionists typically differ from Kant in holding that there are several independent, fundamental moral requirements (e.g., to keep promises, not to harm others, to tell the truth). But they agree with Kant that moral obligation is not just a matter of good consequences for an individual agent or for sentient beings generally. Thus even though deontologists such as Kant and, in the twentieth century, W. D. Ross, have definite views about human well-being, they do not think of moral goodness and moral obligation as rooted in facts about human well-being (or the well-being of sentient beings generally); and here a comparison with Judeo-Christian religious thought seems not inappropriate.

The Ten Commandments are not a product of rational philosophy; they have their source in religious tradition and/or divine command. They do, however, represent a kind of answer to the question about how one should behave toward others; that is, they ask the question that philosophical ethics attempts to answer. Moreover, the way the Ten Commandments answer this question is somewhat analogous to the way moral principles are conceived by deontologists such as Kant and the intuitionists.

In religious thinking, the Ten Commandments are not morally binding through some connection to the well-being or happiness of individuals or even the larger community; they are binding because God has commanded them, and deontology seeks to substitute for the idea of a deity, the idea of requirements given by reason itself or of binding obligations perceivable by moral insight. The deontologist typically holds that one's own well-being and that of others are taken into account and given some weight by the set of binding moral requirements, but that these are not the only considerations that affect what we ought to do generally or on particular occasions. For deontologists, the end does not always justify the means, and certain kinds of actions—torture, betrayal, injustice—are wrong for reasons having little to do with good or desirable consequences.

CONSEQUENTIALISM. The contrast here is with so-called consequentialists, for whom all moral obligation and virtue are to be understood in terms of good or desirable consequences. Typically, this has meant framing some conception of human or sentient good or well-being and claiming that all morality is derivative from or understandable in terms such as "good" or "well-being." Thus Jeremy Bentham, Henry Sidgwick (1981), and other utilitarian consequentialists regard pleasure or the satisfaction of desire as the sole, intrinsic human good, and pain or dissatisfaction as the sole, intrinsic evil or ill, and they conceive our moral obligations as grounded entirely in considerations of pleasure and pain. The idea that one should always act to secure the greatest good of the greatest number is simply a way of saying that whether an act is right or wrong depends solely on whether its overall and long-term consequences for human (or sentient) well-being are at least as good as those of any alternative act available to a given agent. And since classical utilitarianism conceives human good or well-being in terms of pleasure or satisfaction, it holds that the rightness of an action always depends on whether it produces, overall and in the long run, as great a net balance of pleasure over pain as could have been produced by performing any of its alternatives.

This utilitarian moral standard is rather demanding, because it says that anything less than the maximization of overall human good or pleasure is wrong, and that means that if I fail to sacrifice my own comfort or career when doing so would allow me to do more overall good for humanity, then I act wrongly. But apart from the fact of how much it demands—there is nothing, after all, in the Ten Commandments or in the obligations defended by deontologists that requires such extreme sacrifice—what is most distinctive about utilitarianism is its claim that moral right and wrong (and moral good and evil) are totally, not merely partially, concerned with producing desirable results. The end, indeed, does justify the means, according to utilitarianism, and thus one might even be justified in killing, say, one innocent person in order to preserve the lives of two others.

Most deontologists would regard this as the most implausible, vulnerable feature of utilitarian and other consequentialist moral conceptions. But the utilitarian can point out that if you do not make human or sentient happiness the touchstone of all morality, but rely instead on certain "given" intuitions about what morally must or must not be done, you have given yourself a formula for preserving all the moral prejudices that have come down to us from the past. We require, Bentham argued, some external standard by which not only the state of individuals and society, but also all our inherited moral beliefs and intuitions can be properly evaluated. Bentham claimed that judging everything in terms of pleasure and pain can enable us to accomplish this goal. Historically, utilitarianism was conceived and used as a reformist moral and political doctrine, and that is one of its main strengths. If overall human happiness is the measure of moral requirement and moral goodness, then aristocratic privilege and the political disenfranchisement of all but the landed and wealthy are clearly open to attack, and Bentham and his "radical" allied did, in fact, make use of utilitarian ideas as a basis for making reforms in the British political and legal system.

But not all the reformist notions and energies lie on the side of consequentialism. The version of Kant's categorical imperative that speaks of never treating people merely as means, but always (also) as ends in themselves, was based on the idea of the fundamental dignity and worth of all human beings. Such a notion is clearly capable of being used—and, in fact, has been used—in reformist fashion to defend political and civil rights.

The debate between deontology and consequentialism has remained fundamentally important in philosophical ethics. Although there are other forms of consequentialism besides utilitarianism and other forms of deontology besides Kantian ethics, the main issue and choice has been widely regarded as lying between utilitarianism and Kant. This may be partly explained by the interest contemporary ethics has shown in understanding ethical and political issues as fundamentally interrelated; for both utilitarianism and Kantianism can claim to be "on the side of the angels" in regard to the large questions of social-political choice and reform that have exercised us in the modern period and may well continue to do so.

In the ancient world, the philosophical interest in ethics was also connected to larger political and social issues; both Plato (ca. 430–347 B.C.E.) and Aristotle sought to embed their ideas about personal morality within a larger picture of how society or the state should operate. Moreover, Plato was a radical and a reformer, though the *Republic* takes a direction precisely opposite to that of both utilitarianism and Kantianism. Plato was deeply distrustful of democratic politics and of the moral and political capacities of most human beings. His *Republic* (1974) advocates the rule of philosophers who have been specially trained to understand the nature of "the Good" over all those who have not attained such mystic/intellectual insight. Nor does Aristotle defend democracy. In somewhat milder form, he prefers the rule of virtuous individuals over those who lack—and lack the basic capacity for—virtue. If the ancient world contains any roots of democratic thinking, they lie in Stoicism, which emphasized the brotherhood of man (which seems to leave women out of account), but also spoke of the divine spark in every individual (including women). (Kant took the idea that all human beings have dignity, rather than mere price, from the Stoic Seneca [4 B.C.E.–C.E. 65].)

VIRTUE ETHICS. All schools of ancient ethics defended one or another form of "virtue ethics." That is, they typically conceived what was admirable about individuals in terms of traits of character, rather than in terms of individual obedience to some set of moral or ethical rules or requirements. Ancient ethics was also predominantly eudaimonistic. *Eudaimonia* is the ancient Greek word for being fortunate or doing well in life, and eudaimonism is the view that our first concern in ethics is with the nature and conditions of human happiness/well-being and in particular our own happiness/well-being. This does not mean that all ancient ethics was egoistic, if by that term one refers to views according to which the moral or rational agent should always aim at his or her own (greatest) good or well-being. Aristotle is a clear example of an ethical thinker whose fundamental orientation is eudaimonistic, but who is far from advocating that people should always aim at their own self-interest.

For Aristotle, the question to begin with in ethics is the question of what is good for human beings. But Aristotle argues that human good or happiness largely consists in being actively virtuous, thus tying what is desirable in life to what is admirable in life in a rather distinctive way. For Aristotle, the virtuous individual will often aim at the good of others and/or at certain noble ideals, rather than seek to advance his or her own well-being, so egoism is no part of Aristotelianism.

But certainly most interpreters have regarded the Epicureans as having a basically egoistic doctrine. Epicureanism resembled utilitarianism in treating pleasure and the absence of pain as the sole conditions of human well-being. Rather than urge us to seek the greatest good of the greatest number, however, the Epicureans argued that virtue consisted in seeking one's own greatest pleasure/absence of pain. (Given certain pessimistic assumptions, the Epicureans thought this was best accomplished by minimizing one's desires and simplifying one's life.)

Although there are some notable modern egoists (e.g., Hobbes, Spinoza, and Nietzsche), most recent moral philosophers have assumed that there are fundamental, rational reasons for being concerned with something other than one's own well-being. Moreover, the eudaimonistic assumption that questions about individual happiness or well-being are the first concern of ethics has, in modern times, given way to a more basic emphasis on questions like, "How ought I to act?" and "What obligations have I?" The Jewish and Christian religious traditions seem to have made some difference here. In both traditions, God's commandments are supposed to have force for one independent of any question of one's own well-being (assuming that one is to obey because God has commanded, and not just because one fears divine punishment). For most Christians, moreover, Jesus sacrificing himself for our redemption places a totally non-egoistic motive at the pinnacle of the Christian vision of morality. So the notions that one should always be concerned with one's own well-being, and that ethics is chiefly about how one is to conceive and attain a good life, are both

profoundly challenged by any moral philosophy that takes Judaism or Christianity, understood in the above fashion, seriously.

Recent Developments

Twentieth-century philosophical ethics bears the imprint of much of the history of the discipline, and many of the more current, prominent approaches to the subject represent developments of historically important views. But earlier in the twentieth century, ethics, at least in Britain and in the United States, veered away from its past in the direction of what has come to be called metaethics. The move toward metaethics and away from traditional ethical theory resulted, in part, from the influence of a school of philosophy called logical positivism. The positivists held up experimentally verifiable science as the paradigm of cognitively meaningful discourse and claimed that any statement that was not empirically confirmable or mathematically demonstrable lacked real content. Since it is difficult to see how moral principles can be experimentally verified or mathematically proved, many positivist ethicists began to think of ethical claims as cognitively meaningless and refused to advance substantive moral views, turning instead to the analysis of ethical terms and ethical claims. Issues about the meaning of moral terms have a long history in philosophical ethics, but the idea that these metaethical tasks were the main task of philosophical ethics gained a prevalence in the early years of the twentieth century that it had never previously had.

In the latter half of the twentieth century, substantive or normative ethics (that is, ethics making real value judgments rather than simply analyzing such judgments) once again came to the fore and tended to displace metaethics as the center of interest in ethics. In particular, there was a resurgence of interest in Kantian ethics and utilitarianism, followed by a renewal of interest in the kind of virtue ethics that dominated the philosophical landscape of ancient philosophy.

The revival and further development of Kantian ethics received its principal impetus from John Rawls and younger philosophers influenced by him. Rawls's principal work, *A Theory of Justice* (1971) represents a sustained attack on utilitarianism and seeks to base its own positive conception of morality and social justice on an understanding of Kant's ethics that bypasses the controversial metaphysical assumptions Kant was thought to have made about absolute human freedom and rationality. Other Kantian ethicists (Christine Korsgaard, Onora O'Neill, and Barbara Herman), however, have sought to be somewhat truer to the historical Kant while developing Kant's doctrines in directions fruitful for contemporary ethical theorizing.

Meanwhile, the utilitarians responded to Rawls's critique with reinvigorated forms of their doctrine, and, in particular, Derek Parfit's Reasons and Persons (1984) seeks to advance the utilitarian tradition of ethical theory within a philosophical perspective that fully takes into account the insights of the Rawlsian approach.

Finally, virtue ethics has been undergoing a considerable revival. In a 1958 article, Elizabeth Anscombe argued that notions like moral obligation are bankrupt without the assumption of God (or someone else) as a lawgiver, whereas concepts of character excellence or virtue and of human flourishing can arise, without such assumptions, from within a properly conceived moral psychology. This challenge was taken up by philosophers interested in exploring the possibility that the notions of good character and motivation and of living well may be primary in ethics, with notions like right, wrong, and obligation taking a secondary or derivative place or perhaps even dropping out altogether. Such virtue ethics does not, however, abandon ethics' traditional task of telling us how to live, since, in fact, ideals of good character and motivation can naturally lead to views about how it is best to treat others and to promote our own character and happiness. Rather, the newer virtue ethics sought to learn from the virtue ethics of the ancient world, especially of Plato, Aristotle, and the Stoics, while making those lessons relevant to a climate of ethical theory that incorporates what has been learned in the long interval since ancient times.

More recently, however, a radical kind of virtue ethics without precedent in the ancient world has developed out of feminist thought and in the wake of Carol Gilligan's groundbreaking *In a Different Voice* (1982). Gilligan argued that men tend to conceive of morality in terms of rights, justice, and autonomy, whereas women more frequently think of morality in terms of caring, responsibility, and interrelation with others. And at about the same time as Gilligan wrote, Nel Noddings in *Caring: A Feminine Approach to Ethics and Moral Education* (1984) articulated and defended the idea of a feminine morality centered on caring.

The ideal of caring Noddings has in mind is particularistic: It is not the universally directed benevolence of the sort utilitarianism sometimes appeals to, but rather caring for certain particular people (e.g., one's friends and family) that she treats as the morally highest and best motivation. Actions then count as good or bad, better or worse, to the extent that they exhibit this kind of caring. Clearly, Nodding's view offers a potential answer to the traditional question of how one should live, but since the answer seems to be based on fundamental assumptions about what sorts of inner motivation are morally good or bad, it is a form of virtue ethics. Of course, her view can be stated in terms of the principle "Be caring and act caringly." But if we focus on

conforming to the principle instead of on the needs of the individuals we care about, we risk falling short of what the principle itself recommends. It is the state or process of sensitive caring, rather than attention to principle, that generates what Noddings would take to be satisfying answers to moral questions and appropriate responses to particular situations.

Enriched by such feminine/feminist possibilities, ethical theory has been actively and fertilely involved with the perennial task(s) of ethics. But because few of the traditional questions have been answered to the satisfaction of all philosophers, one may well wonder whether philosophy will ever be able fully to answer those questions or even whether philosophers have, over the centuries, made real or sufficient progress in dealing with them. But it is also possible to attack the tradition(s) of philosophical ethics in a more radical fashion.

Modern Challenges to Philosophical Ethics

Some modern intellectual and social traditions have questioned the notion that ethics can validly function as a distinct sphere of rational inquiry. One example of such questioning was the widespread view, earlier in the twentieth century, that ethics should confine itself to the metaethical analysis of concepts and epistemological issues (and possibly to the sociological description of the differing ethical mores of different times and places) rather than continue in its traditional role of advocating substantive ethical views. (Metaethics has undergone something of a revival, but largely in a form regarded as compatible with substantive ethical theorizing.)

Historically, various forms of religion and religious philosophy have also posed a challenge to the autonomy and validity of traditional ethics. The claims of faith and religious authority can readily be seen as overriding the kind of rational understanding that typifies traditional philosophical inquiry. Thus, Thomas Aquinas believed strongly in the importance of the ethical issues raised by Aristotle and in Aristotle's rational techniques of argument and analysis; but he also permitted his Christian faith to shape his response to Aristotle and did not fundamentally question the superiority of faith to reason. He believed, however, that reason and philosophy could accommodate and be accommodated to faith and religious authority.

EXISTENTIALISM. But more radical religionists have questioned the importance of reason and have even prided themselves in flying in the face of reason. Religious views that stress our dependent, finite, sinful creatureliness can lead one to view philosophical ethics as a rather limited and even perverse way to understand the problems of the human condition. In modern times this religion-inspired critique of ethics and the philosophical received a distinctive existentialist expression in the writings of Blaise Pascal (1966) and Søren Kierkegaard (1960, 1983).

It is very difficult to give a completely adequate characterization of existentialism as a philosophical movement or tendency of thought. It cuts across the distinction between theism and atheism, and some of the most prominent existentialists have, in fact, been atheists. But the earlier theistic existentialism that one finds in Pascal and, more fully developed, in Kierkegaard is principally concerned with attacking rationalistic Western philosophy and defending a more emotional and individualistic approach to life and thought. Plato and Aristotle, for example, sought rationally to circumscribe the human condition by treating "man" as by his very essence a "rational animal" and prescribing a way of life for human beings that acknowledged and totally incorporated the ideal of being rational. But for Pascal, the heart has reasons that reason cannot know, and Kierkegaard regarded certain kinds of rationally absurd religious faith and love as higher and more important than anything that could be circumscribed and understood in rational, ethical, or philosophical terms.

The atheistic Nietzsche (1844–1900) also attacked philosophical ethics and rational philosophy generally by attempting to deflate their pretensions to being rational. Nietzsche saw human life as characterized by a "will to power," that is, a desire for power over other individuals and for individual achievement, and in *The Genealogy of Morals* (1956) he argued that Judeo–Christian ethics, as well as philosophical views that reflect the influence of such ethics, are based in debilitating and poisonous emotions rather than having their source in rational thought or enlightened desire. What comes naturally to man is, he thought, an aristocratic morality that is comfortable with power and harsh in regard to failure, and the idea that the meek and self-sacrificing represents the highest form of human being he took to be the frustrated and angry response of those who have failed to attain power, but are unwilling to admit even to themselves how they really feel.

Nietzsche clearly expressed an antipathy to the whole tradition of philosophical ethics, and even if he did defend an iconoclastic ethics "of the superman," his writings point the way to an attitude like that of the more recent existentialist Jean-Paul Sartre (1905–1980). In his *Being and Nothingness* (1956), Sartre argued that all ethics is based in error and illusion, and he attempted instead to describe the human condition in nonjudgmental, nonmoral terms. Sartre argued that human beings are radically free in their choice of actions and values, and he claimed that all value judgments, because

they purport to tell us what we really have to do, involve a misunderstanding, which he called "bad faith," of just how free we actually are. At the end of his book, Sartre proposed to write a future book on ethics, but also set out, in compelling fashion, the reasons for thinking that any future ethics is likely to fall into error and illusion about the character of human freedom. Here, as in *Being and Time* of Martin Heidegger (1889–1976) which had a decisive influence on Sartre's existentialism, the existentialist philosopher is essentially critical of the role ethical thinking plays in philosophy and in life generally and says, in effect, that if we face the truth about our own radical freedom, we must stop doing ethics. Ethics may think of itself as a rational enterprise, but for Sartre, it was mainly a form of self-deception.

MARXISM. Existentialism has had a great influence on Western culture, but Marxism has probably had a much greater influence, and Karl Marx's writings (*Capital and the German Ideology*), like those of some of the existentialists, attempt to accustom us to the idea of taking ethics less seriously than practitioners of philosophical ethics have tended to do. According to Marx (1818–1883) (and Friedrich Engels), philosophical ethics and philosophy generally are best understood as expressions of certain class interests, as ideological tools of class warfare, rather than as independently and timelessly valid methods of inquiry into questions that can be settled objectively and rationally.

For example, intellectual, philosophical defenses of property rights can be seen as expressing and asserting bourgeois class interests against a resentful and increasingly powerful proletariat. All philosophy, according to such a view, is merely the expression of underlying economic forces and struggles. A truly liberated view of human history requires us to stop moralizing and start understanding and harnessing the processes of history, using the tools of Marx's own "scientific socialism." While Marx believed that a "really human morality" might emerge under communism, philosophical ethics is seen more as a hindrance than as a means to enlightened understanding of human society.

PSYCHOANALYSIS. In addition, psychoanalysis, as a movement and style of thought, has often been taken to argue against traditional ethics as an objective discipline with a valid intellectual task of its own. The psychoanalytic account of moral conscience threatens to undercut traditional ethical views and traditional views of ethics by making our own ethical intuitions and feelings seem illusory. In a manner partly anticipated by Nietzsche, Sigmund Freud's original formulation of psychoanalytic theory (e.g. in The Interpretation of Dreams and Introductory Lectures on Psychoanalysis) treat conscience and guilt as forms of aggression directed by the individual against himself (Freud). (Freud [1856–1939] tended to focus on the development of conscience in males.) Rather than attack parental figures he feared, the individual psychologically incorporates the morality of these seemingly threatening figures. If conscience is a function of hatred against one or more parental figures, then its true nature is often obscured to those who have conscience. According to classic psychoanalysis, the very factors that make us redirect aggression in such a fashion also make it difficult consciously to acknowledge that conscience has such a source.

If moral thought has this dynamic, then much of moral life and moral philosophy is self-deluded. However, for some more recent psychoanalysts, not all forms of ethical thinking are illusory. Followers of the British psychoanalyst Melanie Klein (1975) have said that various ethical ideals can and do appeal to us and guide our behavior, once "persecutory guilt" of the kind based in aggression redirected against the self is dissolved through normal maturation or through psychotherapy. Moreover, the analyst Erik Erikson (1964) gave a developmental account of basic human virtues that has clear, ethical significance.

In the end, perhaps it should not be surprising that many attempts to undermine ethics eventually reintroduce something like familiar ethical notions and problems. We have to live with one another, and the problems of making life together possible and, if possible, beneficial are problems that will not and cannot go away. Even if a given society and generation has settled on a particular solution to the problems of living together, new historical developments can make these solutions come unstuck, or at least force people to reconsider their appropriateness. And even if different societies and cultures have different moral standards, it is possible to overestimate the differences. For example, however much aggression societies may allow toward outsiders and enemies, no society has a moral code that permits people, at will, to kill members of that society. Moreover, the very fact of moral differences among different societies indicates a need for cooperative and practical ethical thinking that will enable people either to resolve or live with the differences.

APPLIED ETHICS. This is a point where the need for applied ethics most clearly comes into view. Whether it is in medicine, science, biotechnology, business, or the law, people have to come together to solve problems, and ethics or ethical thinking can play a role in generating cooperative solutions. If existentialism, religion, Marxism, and psychoanalysis all in varying degrees question the need for philosophical ethics, the practical problems of contemporary life

seem to indicate some new ways and to highlight some old ways in which philosophical ethics has validity and value.

The explosive development of new knowledge and techniques in medicine and biology has made bioethics one of the central areas of practical, moral concern. And those seeking to solve moral problems in this area naturally appeal to philosophical ethics. To take just one controversial area, the question of euthanasia engages the ideas and energies of different ethical theories in different ways and often with differing results. Thus, the Kantian may focus on issues concerning the autonomy of the dying patient and the right to life, whereas utilitarians will stress issues about the quality of life and the effects of certain decisions on families and society as a whole, and defenders of an ethics of caring will perhaps see less significance in larger social consequences and focus on how a medical decision will affect those most intimately and immediately affected by it.

Applied ethics in our contemporary sense is not new: Socrates' discussion of the duty of obedience to unjust laws in the Crito and Henry David Thoreau's of civil disobedience are only two of countless historical instances of what we would call applied ethics. Today, we think, civilization is more complicated and our problems are more complex. Still, in facing those problems, bioethicists, business ethicists, and other applied ethicists typically look to philosophical ethics, to substantive theories like utilitarianism and virtue ethics and Kantianism, and to the criticisms each makes of the others, for some enlightenment on practical issues.

II. MORAL EPISTEMOLOGY

Moral epistemology is the systematic and critical study of morality as a body of knowledge. It is concerned with such issues as how or whether moral claims can be rationally justified, whether there are objective moral facts, whether moral statements strictly admit of truth or falsity, and whether moral claims are universally valid or relative to historically particular belief systems, conceptual schemes, social practices, or cultures.

The subdiscipline of moral epistemology is hardly a recent arrival on the philosophical scene. Plato's *Republic*,

Aristotle's *Nicomachean Ethics*, Hume's *Treatise on Human Nature*, Kant's *Critique of Practical Reason*, and Hegel's *Phenomenology of Spirit* all grapple with moral-epistemological themes and issues. However, the lion's share of explicit, self-conscious reflection on moral-epistemological problems has taken place in the twentieth century, reflecting Western philosophy's more general preoccupation with the problem of knowledge since the time of Kant. This entry describes and critically evaluates some of the major options in moral epistemology taken during that period.

Intuitionism

When one describes a person as "good," or when one says of an action that it is "the right thing to do" under the circumstances, is one pointing out an objective feature of the person or action, or is one expressing one's own subjective reaction? Is one stating something that could be either true or false? Is one making a claim that could be supported by reasons or evidence, and that would warrant the assent of any rational human being? Or is one merely giving voice to one's own attitudes or feelings? Much of the contemporary debate in moral epistemology turns on the answer to these questions.

Intuitionists, chief among whom were G. E. Moore and W. D. Ross, insist that moral terms such as "good" and "right" name objective properties, refer to real aspects of real things, events, activities, and persons, and claim that we have access to these properties by a form of direct insight or perception. Because of this, moral statements are genuine propositions capable of being assigned a truth value of "true" or "false." To use a technical, philosophical term, morality is "cognitive." Intuitionists, while drawing an analogy between sensory intuition and moral intuition, also generally insist that moral intuition is different in kind from sense perception. While sense perception acquaints us with objective facts, moral intuition acquaints us with equally objective values.

According to G. E. Moore's *Principia Ethica* (1903), "good" is a simple, unanalyzable concept. Like the property concept "yellow," "good" cannot be defined except by pointing out instances of the concept, which enables one to grasp its unitary meaning. Unlike "yellow," which denotes a property intuited by our ordinary sensory apparatus, "good" names a nonnatural property, which, despite the fact that it is not empirically given, is nonetheless just as objective and real as is the property "yellow." W. D. Ross, in *The Right and the Good*, expands Moore's table of simple, objective moral properties to include "duty," or "rightness," and the degrees of rightness that attach to conflicting prima facie duties in different circumstances.

Intuitionists like Moore do not deny that there is moral knowledge; in fact, they affirm it emphatically. But for both Moore and Ross, our knowledge of what is ultimately good or right is not inferred or deduced but immediately given; we do not need to define, rationalize, or justify it. Thus a physician, deciding to remove an irreversibly brain-dead patient from a respirator, might give reasons for her decision by citing the beneficial consequences (e.g., an end to the patient's fruitless suffering) that might be achieved, or by insisting that the duty to preserve life is trumped by the higher duty to preserve a patient's dignity. But as to why these consequences are good, or why these putative duties are duties, the intuitionist physician can rightfully appeal only to her perception of the basic quality of goodness or rightness in them. Look and you too shall see.

The very immediacy of moral knowledge poses a serious problem for the intuitionist, namely, how moral argument and moral disagreement are possible. According to Moore, one either "sees" that something is good or one doesn't, and if one doesn't, there's little to be done except to look again. But what if two or more competent moral agents persistently "see" different values in the same circumstances? Who is "seeing" what is really there, and who is "seeing" a moral illusion? The intuitionist faces the difficulty of accounting for genuine moral disagreement—disagreement not about the empirical, factual issues of how to bring about the greatest good or do one's duty, but the evaluative issue of what sorts of things are genuine, intrinsic goods or actual obligations. This faculty of moral intuition is therefore curious. It is supposed to yield insight into objective properties of things, outcomes, deeds, and institutions, yet it lacks any public criterion against which claims like "X is good" or "Y is the morally right thing to do" might be checked and rationally validated.

Emotivism

A number of thinkers influenced by logical positivism, most notably A. J. Ayer and Charles L. Stevenson, rejected intuitionism and with it the conviction that moral discourse was objective and cognitive. The resulting theory, emotivism, denied that "good" or "right" named any sort of objective, intuitable property. Rather, to say of something that it is "good" or "evil," "right" or "wrong," is to express a subjective attitude or emotional response toward it. For example, the proposition, "You ought not to have lied to that patient," asserts nothing more than "you lied to that patient"; the "ought" merely notes an attitude of disapproval on the part of the speaker. Emotivists emphasize the imperative quality of moral utterance. To say lying is wrong is, in effect, to issue the command, "Do not lie." To place ethical discourse in a

recognizable context, the effort on the part of agents is to influence the behavior of others and to persuade them to adopt different beliefs. If emotivists like Ayer and Stevenson are right about the meaning of moral statements, the demand to account for "moral knowledge" is senseless, since all moral discourse is inherently noncognitive, nonrational, and subjective.

Perhaps this is an acceptable price to pay to make the phenomenon of moral disagreement intelligible. An intuitionist would be vexed by disagreements such as the following:

(1a) Active, involuntary euthanasia is morally acceptable under certain conditions, versus

(1b) Active, involuntary euthanasia is always immoral, under any and all conditions.

Yet what for the intuitionist is an epistemological dilemma, for the emotivist is not a dilemma at all. The proponent of (1a) is "commending" the permissibility of involuntary, active euthanasia under certain conditions rather than asserting a true-or- false proposition; she is expressing a "pro-attitude" toward (1a), and trying to persuade others to do so as well. The proponent of (1b) is doing precisely the same thing, expressing an "anti-attitude." The disagreement is one of subjective attitude and feeling and does not concern anything objective; there is no deep, moral truth under dispute.

But perhaps it might be premature to claim that the ability to make sense of moral disagreement thereby vindicates emotivism. One serious difficulty with emotivism is that it narrows the human significance of moral discourse by flatly denying that whenever one makes a moral claim, one places oneself in the position of having to back up that claim by citing what one takes to be good reasons in its behalf.

Universal Prescriptivism

Universal prescriptivism is a compromise between emotivism and the commonsense conviction that morality is a rational enterprise. Its chief exponent, R. M. Hare, argues in *The Language of Morals* (1952) that moral imperatives carry certain inexorable rational constraints. If I make the moral judgment, "Active, involuntary euthanasia is wrong," I am in effect declaring that one ought not to perform active, involuntary euthanasia on someone, and thus commanding, "Do not perform active, involuntary euthanasia," where the ought command is issued to anyone in the relevant situation, including me, the speaker. So while moral judgments have an imperative or prescriptive component—like Moore, Hare rejects naturalism—they exhibit a universality that binds the speaker's deeds to her claims, and enables the speaker to use reason to draw further moral conclusions on the basis of prescriptions that function as premises in deductive arguments.

In affirming the role of deductive reason in ethics, Hare's universal prescriptivism challenges the emotivist's assumption that only indicative premises are beyond suspicion in valid argumentation. For surely the following argument is a valid deduction:

(2a) I ought not to lie to my patients and thus intentionally mislead them.

(2b) My patient Bill asked me to tell him about his medical condition.

(2c) I ought not to lie to Bill about his condition.

All its premises are meaningful, and since the major premise is prescriptive, the taboo against deducing an "ought" from an "is" is not violated. Furthermore, (2a) itself could be justified by being a valid conclusion drawn from more general prescriptions:

(2d) I ought not to be unjust.

(2e) To lie to one's patients and thus intentionally mislead them is unjust.

(2f) I ought not to lie to my patients and thus intentionally mislead them.

However, there cannot be an infinite hierarchy of such deductions. For the prescriptivist, one's ultimate prescriptive or evaluative premises are chosen rather than deduced: One cannot ground one's moral convictions in premises more basic. The foundations for moral reasoning cannot themselves have a foundation; they reflect one's basic stance or attitude toward persons and things. No "ought" can be derived from an "is." One's moral first principles, being prescriptions, cannot be rooted in indicative soil.

This might lead one to wonder whether universal prescriptivism is more a refinement of emotivism than a genuine advance on it. It seems to push the point where ethical discourse is a matter of attitude and criterionless choice back to the most general evaluation the agent wishes to make. For example, substitute the following premise for (2a) above:

(2a1) I ought not to lie to my patients and thus intentionally mislead them *unless* I have ample reason to judge that doing so will confer some psychological or medical benefit to them.

If a physician were to judge that some such benefit were to be obtained from intentional deception, then the conclusion that one may intentionally deceive a patient will follow, in direct contradiction to (2c) and (2f). Given the initial moral orientation, certain principles for action are validated, but

the original moral orientation cannot itself be validated; it can only be accepted, endorsed, chosen. Since this nonrational, inaugural choice provides the basis for all subsequent moral reasoning, the content of an agent's morality appears to be ultimately arbitrary, even if it is not arbitrary in all its detail.

Hare disagrees. In *Freedom and Reason* (1963) he argues that universal prescriptivism sets limits on the kinds of fundamental moral choices an agent can make. Consider the following:

(3a) Certain people ought to be persecuted because, and only because, their skin is black.

If moral imperatives using "ought" are, as Hare claims, universal prescriptions, then the agent uttering these words is, or ought to be, committing himself to the proposition that if his skin were black he, too, ought to be persecuted. It is clear that few individuals who make such assertions, apart from those Hare dubs "fanatics," would assent to the latter claim. Yet it is entailed by the universal prescription (3a); hence, the morality of any agent who asserts (3a) and refuses to extend it to cover himself is, for that very reason, rationally inadequate.

Of course, there is no possibility of genuine argument with a genuine "fanatic": The fanatic's assertion of ultimate principles or fundamental commitments, however odious or bizarre they may be, can only be met with counterassertion and not counterreasoning. Hare seems willing to accept this lack of logical resources against fanaticism. Nevertheless it seems reasonable to ask universal prescriptivists such as Hare whether, by cutting off rational argument at fundamental principles, they are granting too much to fanatics by ruling out any way in which their convictions can be criticized, rather than their unpleasant characters. The fanatic may be vile and depraved, but by universal prescriptivist standards, he is not necessarily defective in reason.

Naturalism

Intuitionists, emotivists, and prescriptivists all agree that "facts" are distinct from "values"—that an "ought" cannot be deduced from an "is." G. E. Moore coined the term, "the naturalistic fallacy," to describe the frequent attempts on the part of philosophers to define "the good" by deducing it from some matter of fact about human beings and their desires. A number of philosophers have challenged this no-ought-from-an-is doctrine by providing counterexamples to it, in effect denying that the naturalistic fallacy is a fallacy.

Philippa Foot (1959), for example, has cited "rude" and "courageous" as concepts whose evaluative meaning cannot be pried from their descriptive meaning. The criteria for identifying someone as "rude" or "courageous" are factual. If someone fits a given description, one has warrant for saying that he or she is rude or courageous; thus, the proposition "She is rude/courageous" is cognitive. But to describe someone as rude is to evaluate that person negatively. Consider the absurdity of saying: "You're rude, cowardly, and abusive, but that isn't meant as a put-down." So, according to Foot, valid moral arguments can draw evaluative conclusions from factual premises.

Peter Geach (1956) makes an analogous point in his analyses of "good." To say that a thing is good is to say something concerning the kind of thing it is. "Good" does not mean precisely the same thing in the following sentences: "That car is good"; "that watch is a good watch"; and "Mohandas Gandhi was good." To say of each one of these that it is good is to employ criteria determined by the kind of thing being evaluated. But this is to say, again against the emotivist and the prescriptivist, that the criteria that fix the meaning of evaluative terms such as "good" are not ultimately matters of choice, but rather matters of fact. To know a good watch, one needs to know what a watch is and what it is for; to know a good person, one, likewise, must know what a human being is and those ends at which humans aim in their actions.

Finally, John Searle (1964) accuses noncognitivists of harboring an arbitrarily constricted notion of what constitutes a "fact." Human institutions are part of what is the case, and these "institutional facts" can appear in descriptive premises in valid deductive arguments that generate evaluative conclusions. For example, to acknowledge the institution of promising is to grant that under certain circumstances, when one utters the words, "I promise to do X," one places oneself under an obligation to do X, and therefore is obliged to do X, and therefore one ought to do X. Because institutional facts are determined by the rules guiding the aims and actions of participants, one can deduce values from them.

Naturalists sketch a picture of moral language in which moral concepts are understood by deriving them from nonmoral, "naturalistic" ones, upon which moral knowledge rests. A robust naturalism in bioethics, then, would show no qualms about defining "the good" or "the right" in a medical context by appealing to certain key facts about human beings (e.g., their pain, dignity, mortality, etc.) and about the social and institutional setting for these facts.

At this point, however, the prescriptivist can offer a rebuttal that is difficult to answer on the naturalist's own terms without begging an important question. The prescriptivist concedes that moral language necessarily has a

factual or descriptive component, but insists that it also makes ineliminable reference to the agent's desires, aims, and wishes. These can be more or less rational depending on whether their satisfaction interferes with or complements other sets of desires, aims, and wishes, but no desire can be judged rational or irrational per se. These basic desires and attitudes might differ from person to person; there is no escaping the fundamental choice behind all evaluations and prescriptions. So when the naturalist claims to have deduced an "ought" from an "is," either the major premise harbors an implicit prescription (e.g., "One ought to honor institutions like promise-keeping") or the argument is not a strict deduction.

Naturalists might reply that the "natural" premises to which they appeal and that ground moral judgment and description are rooted not in the desires or aims of individuals but in general facts about human nature of which it is the philosopher's job to remind us. For example, Aristotle understood *eudaimonia,* or "human flourishing," to be the good for a human being, because it was a result of acting in accord with one's rational human nature; Thomas Aquinas defined the good in terms of human creatures' reestablishing a right relation to God; and John Stuart Mill's psychological theories stand behind his definition of the good as pleasure seeking and pain avoidance. Aristotle, Thomas Aquinas, and Mill all pursued ethics in the context of what might be called "philosophical anthropology." Yet this simply elevates the naturalist's dispute with the prescriptivist to a higher level of abstraction. The prescriptivist could deny that there is any fact of the matter that might constrain the choice between philosophical anthropologies, while the naturalist could just as adamantly insist upon it. Thus naturalism might provide a coherent, consistent alternative to prescriptivism, but only by accepting philosophical stalemate at a higher level.

Rationalism

One possible avenue around the prescriptivist/naturalist impasse would be to repudiate the naturalistic fallacy, yet insist that moral principles are justified by examining the nature of rationality itself. This sort of moral epistemology owes much to Kant. A number of notable philosophers, inspired by Kant yet eager to avoid his dubious treatment of the self, have endeavored to ground moral knowledge in the reflective exercise of reason by actual human agents.

The most ambitious of these attempts is clearly that of Alan Gewirth, who in *Reason and Morality* tries to prove the fundamental principle of morality by analyzing the bare concept of rational agency. Every rational agent, Gewirth argues, must presuppose certain generic goods—namely, freedom and a degree of well-being—that make the exercise of his or her agency possible. If the agent must claim these generic goods as necessary, he or she must also claim them as rights. But since these goods flow from the generic features of agency, he or she must also concede that all other agents must claim them as rights, and that there is a corresponding obligation to acknowledge and respect them. Hence, the Principle of Generic Consistency (PGC)—"Act in accord with the generic rights of your recipients as well as yourself" (1978, p. 135)—is the fundamental, categorical principle of morality, from which all other concrete moral norms and precepts can be derived, and which can be denied only on pain of logical self-contradiction.

Many of Gewirth's critics (e.g., Nielsen; MacIntyre, 1984; Arrington) have questioned a crucial move in his dialectical "proof" of the PGC: Acknowledging that there exist necessary goods of rational agency need not entail recognizing them as one's rights. If these critics are correct, Gewirth's foundational moral principle is not necessarily true. If it is only contingently true, Gewirth's claim to a proof of the one fundamental principle of morality has not been vindicated.

In contrast to Gewirth's "hard" rationalism, other moral rationalists adopt a "soft" rationalism that proceeds not from unassailable premises about rational agency, but from contingent truths about what all rational agents would, in fact, choose under ideal conditions. For example, John Rawls, in *A Theory of Justice* (1971), maintains that in a hypothetical "original position," where the specific identities, desires, and advantages of rational agents are deliberately obscured behind a perspective of impartiality—a "veil of ignorance"—rational agreement would be secured regarding two specific principles of justice, equal liberty and equal distribution of goods, except in those cases where an unequal distribution of goods would work to the benefit of the worst-off social group.

"Soft" rationalism proceeds from assumptions about the rational choices individuals would make in imagined, empirical situations; thus it lends itself well to concrete application in such fields as legal, business, and medical ethics. For example, Robert M. Veatch, in *A Theory of Medical Ethics* (1981), argues that the responsibilities of medical professionals are set in an implicit "triple contract" involving those professionals, their patients, and society at large; specifically, medical rights and obligations are fixed by determining what sorts of agreements would be rational for all three interested parties to agree upon.

There are serious difficulties with these "soft" forms of moral rationalism. Rawls's "original position" suggests that

individuals could and should be able to abstract themselves from their specific, contingent identities when formulating and justifying the principles of justice. But, as Michael Sandel (1982) and Charles Taylor (1985) have argued, this project faces formidable epistemological difficulties. It presupposes that "the self" is prior to its ends, that one's identity as a pure, rational chooser is separable from and more basic than one's identity as, say, an American, a Christian, a physician, and so on—and that it can and must draw upon rational resources that are neutral with respect to the ends and desires connected with these identities. Yet it is questionable whether such an "unencumbered" self would have any rational resources upon which to draw or any concrete intentions upon which to act; whether, indeed, the contracting chooser in the "original position" could ever be more than a philosophical fiction. Thus it seems as if moral rationalism—if it is to remain on epistemologically solid ground—must compromise its purity by admitting that the contingencies of time, place, and personal identity do make at least some difference in determining which choices and which sets of moral beliefs will be accepted as rational.

Realism and Antirealism

Another way to get around the prescriptivist/naturalist standoff would be to insist with the naturalist that there are objective moral truths, but to question whether such truths can be deduced from more basic facts concerning human nature or human institutions. On this "realist" account of moral knowledge (so called because it affirms objective moral realities independent of the knowing subject), moral discourse is less a matter of reason than of careful perception and insight, of developing the capacity to discriminate moral facts and to describe them accurately and adequately. To the extent that moral knowledge rests on "seeing" moral properties, moral realism suggests Moore's intuitionism. Yet, unlike Moore, moral realists claim no special faculty of moral intuition, insist that moral properties are observable in precisely the same way as are empirical properties, and hold that moral judgments and observations are fallible and revisable.

This renewed form of moral realism has been advanced by a number of British philosophers (Platts; McDowell, 1979; Lovibond) influenced by Donald Davidson's theory of meaning and Ludwig Wittgenstein's critique of reductionism in the philosophy of language. From Davidson they have borrowed the idea that to know what any sentence means is to be able to specify the conditions under which it is true. From Wittgenstein they have taken the conviction that there is no way to establish a ground for language that is independent of and cognitively superior to actual language in use. Taken together, these Davidsonian and Wittgensteinian commonplaces work to deflate all forms of noncognitivism.

The noncognitivist needs to rely on a contrast between two kinds of utterances—those that carry truth values and those that do not—and thus insists on two kinds of "meaning" and two kinds of discourse. One kind of discourse can accurately represent facts (usually assumed to be science), and the other does not represent facts, but expresses attitudes and imposes those attitudes on a world plastic enough to accept them (art, poetry, morality). But since determining the meaning of any linguistic statement is inseparable from determining whether that which it asserts is true or false, the noncognitivist cannot plausibly draw the required contrast between first-rate, fact-picturing discourse and second-rate, value-projecting discourse. To know what any expression means is to know what would make it true, and this ability neither demands nor supports any assumptions about the superior cognitive reliability of any one form of discourse (scientific) over any other (commonsense, literary, or moral).

The moral realist argues that there are moral facts just as there are scientific facts, and does not expect moral facts to be reducible to or deducible from any other kind of fact. Moral properties are "supervenient" upon nonmoral properties. One discerns a moral property by enumerating a number of nonmoral properties standing in relation to each other, from which the moral property "emerges" without being strictly entailed by them. "Supervenience" becomes clearer when one turns from examining "thin," abstract moral concepts ("good," "right," "duty") to "thick" moral concepts (concrete, specific concepts, like "courage," "loyalty," or "mercifulness"). To know, for example, that a physician's treatment of an end-stage cancer patient with larger than usual doses of painkillers was merciful involves knowing a great number of facts concerning cancer, pain, the special needs of the terminally ill in general and of this patient in particular, and so on. While one does not infer the moral property of being merciful from these nonmoral facts, the property is a function of them; one perceives the moral fact that this act is merciful in and through perceiving the aforementioned nonmoral facts.

"Seeing" the moral facts in the associated nonmoral facts is a complex skill, demanding discipline, practice, and attentiveness to matters of minute detail. For the moral realist, becoming a morally competent bioethicist is largely a matter of acquiring and honing a certain sensibility, akin to that of understanding a work of art or literature, whereby one comes to notice the moral goods and obligations in the context of medical practice, and to disclose and explicate them in descriptive speech.

A number of moral epistemologists (e.g., Mackie) have complained that the realists' account of supervenience is incoherent. If the supervenient moral properties of a person change (for example, if someone ceases to be courageous or just), it is necessary that other, nonmoral properties also have changed (fleeing from every danger; ceasing to give others their due). Yet if that person possesses all the nonmoral dispositions associated with a moral property (steadfastness in the face of danger; a consistent willingness to keep promises), it cannot be inferred that he or she necessarily possesses the associated moral properties (the person might not be courageous or just, "despite appearances"). Supervenience is supposedly a logical relation between properties, yet because it cannot be interpreted as a form of inference, it becomes an inexplicable fact.

John Mackie subscribes to a form of moral antirealism or "projectivism" that allows for cognitive expressions in moral discourse—that is, the truth or falsity of moral beliefs, the validity or invalidity of moral arguments—yet understands them in an equivocal sense, as a disguised, second-level reflection upon first-level moral judgments and attitudes. The moral idiom forces us to speak as if there were moral facts, but such "facts" are ultimately projections of our attitudes. To insist that moral judgments are more than expressions of attitude would be to reintroduce supervenience, with all its difficulties. Moral antirealists would not exactly deny, then, that moral knowledge is a result of coming to "see things" and describe them in a certain way; they would, however, deny that such descriptions bear more than an instrumental function. The physician who "sees" that a particular act toward a patient is merciful is indeed "seeing" something, but that something is a function of the physician's subjective attitude projected outward toward the patient.

This may not be cause for genuine worry on the realist's part. He or she could, of course, stand firm and endorse the reality of objective moral facts—the instantiation of "thick," descriptive moral properties such as "courage," "patience," and "mercifulness"—in the face of the logically peculiar notion of supervenience. Perhaps supervenience is an inexplicable logical and epistemological fact. So what? Supervenience is a feature of ordinary moral discursive practice, one that morally competent speakers can handle without much trouble. The difficulties that antirealist moral epistemologists claim to have uncovered are more a matter of their a priori prejudices (perhaps their epistemological "scientism") than their discovery of a defect in moral language and moral practice.

The realist, like Wittgenstein, confidently affirms that ordinary moral language is in good working order as it is. The antirealist, of course, can reply that such "folk" moral philosophy is untidy, plagued with logical ambiguities and desperately in need of philosophical reinterpretation. Thus the clashes between moral realists and moral antirealists recapitulate the earlier standoff between prescriptivists and naturalists. What is at issue is not whether values can be derived from facts, but whether it even makes sense to speak of emergent "moral facts" alongside nonmoral ones.

Against Epistemology

Virtually all the various schools of moral epistemology considered seem to employ an ahistorical approach to moral discourse, argument, and judgment. Both prescriptivists and naturalists confidently speak of "*the* language of morals," presupposing that "morality" has a singular essence lurking under all the various "moralities" of human history. Their dispute only concerns what this "essence" might be. Rationalists, realists, and antirealists also claim their particular moral epistemologies for morality per se, as opposed to the morality characteristic of a particular time, place, or community; these epistemologies are seen as perennial options for anyone who wishes to think about ethics.

The assumption that "epistemology" studies the invariant universal structures of human knowledge, entitling it to "legislate" over all knowledge claims, has been the target of sustained philosophical attack in the latter half of the twentieth century by Ludwig Wittgenstein, Martin Heidegger, and John Dewey, among others. Richard Rorty's landmark *Philosophy and the Mirror of Nature* (1979) was one of the first works to point out the affinities between the projects of Wittgenstein, Heidegger, and Dewey. Rorty showed that all three undermined the pretense of "epistemologically oriented philosophy" to have attained a timeless, ahistorical, necessary vantage point in its judgments about knowledge by pointing out, in different ways, how knowledge claims are situated and justified in shared practical and social contexts and are unintelligible apart from such contexts. From Rorty's perspective, the different approaches of moral epistemologists are less important than their common goal of discovering the foundations of moral reason and showing how these foundations might (or might not) be "justified" to any rational person. But Rorty insists that the epistemological assumptions undergirding their "common goals" are baseless. Among those assumptions are the idea that there are moral truths available to human rationality as such, or that "morality," like "knowledge" and "being," is a concept with a unique, stable core meaning. Rorty's Wittgensteinian, Heideggerian, and Deweyan case against foundationalist philosophy thus makes a new, antifoundationalist and self-consciously historical approach to moral knowledge all the more appealing.

Relativism and the Feminist Critique of Objectivity

Antifoundationalism in moral philosophy has taken a number of different forms. One of them, relativism, has once again emerged as a serious option in moral epistemology. The doctrine associated with the ancient Sophists—that objectivity, truth, and knowledge are matters of adhering to sociocultural convention rather than of attaining insight into nature—has been revived and expressed in more sophisticated ways by Gilbert Harman (1975), Bernard Williams (1985), Joseph Margolis (1991), and David Wong (1984). Wong, for example, maintains that the concept of "an adequate moral system" is relative to particular places and times: There is no single, universally valid moral system available, even as an unattainable ideal. Within each extant system, there are resources available for evaluating and criticizing rival systems binding on all who share its standpoint. Wong is neither a subjectivist nor a noncognitivist. There is, however, no standpoint outside all such systems from which judgment could be passed upon each of them indifferently. For Wong, the collapse of epistemological foundationalism, and the acknowledgment that our "moral systems" are not the deliverances of pure, universal human reason but are products of historical contingencies, supports a form of relativism that is less concerned about specific judgments of right or wrong than with the assessment of moral systems or cultures on the widest scale.

Many critics of contemporary relativism have argued that it retains most of the self-referential inconsistencies that plagued its earlier incarnations. Can the relativist maintain that the relativistic thesis is "true" or "reasonable" without begging the question? (See Putnam.) Other critics argue that the historical contingency of moral beliefs and their lack of necessary epistemic foundations does not imply relativism, since it does not preclude the possibility of one moral system being more rationally adequate than its competitors (see Stout).

Yet this response elicits a further question: Whose conception of "rationality" is being employed when someone judges a moral system superior or inferior? Several important feminist philosophers have responded to this question by noting that, generally, the "rationality" employed and championed by moral philosophers has been "rationality" as understood and defined by men, who are ideologically biased by their place in a patriarchal social system and who tend to exclude the experiences and judgments of women (Tong; Code; Tuana). The idea that reason and objectivity could be "gendered" concepts has led some feminists to conclude that men and women evince different kinds of moral knowing, and to champion a feminine "ethic of care" as against a masculine "ethic of principles" (Gilligan), just as it has led others to reject those very "feminine virtues" as yet another aspect of women's oppression by men (Bartky; Puka). Whatever the ultimate outcome of these debates, contemporary feminism has done much to reinforce the antifoundationalist and historicist critique of "objectivity" and "rationality" as universal, unproblematic features of human thought and discourse. But does that critique undermine the idea of "moral knowledge" as such?

Historicism, Virtue, and Tradition

One systematic moral philosopher who disagrees with that sentiment, and who has used the insights of historicism and antifoundationalism in rethinking and recovering a workable notion of "moral knowledge," is Alasdair MacIntyre. *After Virtue* (1984) begins by noting both the interminable and arbitrary character of contemporary moral arguments and the vehemence with which they are conducted, and asks what might account for the powerlessness of contemporary moral philosophy to resolve moral conflict and secure agreement. MacIntyre attempts to answer this question by pursuing a historical inquiry into the succession of moral theories and the social contexts in which they arose. MacIntyre maintains that the intractability of moral disagreement is one aspect of the "emotivist culture" of late modernity that provides no solid basis for making shared, rational moral judgments and thus renders the idea of genuine moral knowledge unintelligible.

Most modern moral theory and practice has dispensed with the Aristotelian idea of a human *telos,* an "end" proper to human beings as such. Modern social and political orders have ceased to define their mission as that of articulating a shared vision of the good life and communally pursuing it, since it is assumed that there is no good-defining end to seek. Then what can moderns claim to "know" when they make ethical assertions, decisions, and judgments? MacIntyre dubs the standard modern response to this question "the Enlightenment project": the task of finding the universal rules or standards that guide conduct yet swing free from any substantive conception of a good life, and are justifiable by appealing to rationality.

All attempts to fulfill the ambitions of the Enlightenment project have failed, according to MacIntyre, by their own standards of success. Kantians, Utilitarians, Humeans, Intuitionists, and so on, all presuppose that there is something universally known or grasped (the Categorical Imperative, the principle of utility, the sentiment of benevolence, the self-validating property of goodness or rightness) that provides an adequate ground for moral judgment and action. Upon closer inspection, however, both the prescriptive force and the specific content of such moral foundations seem arbitrary and local rather than necessary and universal.

If this is so, the epistemological universalism of the Enlightenment project functions as a mask, concealing the manipulative, will-driven ambitions of its disciples under guise of the objectivity of universal principle. Friedrich Nietzsche thus stands as both the fruition and the ruin of the Enlightenment project. His achievement is to have revealed that behind the rhetoric of objective, universal rational foundations, the morality of the modern West is yet another arbitrary upsurge of "will to power," and its impending collapse is testament to its own timid denial of this hard truth.

While MacIntyre insists that Nietzsche is certainly right about modern moral theory and practice, he has not thereby shown that all morality falls victim to the same disease. If the history of moral beliefs and moral theories can reveal the bankruptcy of the Enlightenment project and the moral nihilism of Nietzsche's "genealogical" critique of morality, it can also show how the moral philosophies they displaced can succeed where they themselves failed. MacIntyre contends that contemporary Aristotelians can draw upon epistemological resources that both Enlightenment rationalists and Nietzschean skeptics lack.

First, Aristotelians begin thinking about morality with a systematic conception of the virtues, a set of character traits that enable human agents to perfect their natures and thus realize, however imperfectly, their ultimate end. Duties and obligations—what one ought to do—begin to make sense only against the background of belief about what one ought to be. Since virtue is intrinsically connected to a conception of well-being or human flourishing shared by members of a moral community, one can establish a sound, rational motive for being moral, without reducing what one ought to prefer or desire, in light of one's true end, to what one empirically happens to prefer or desire.

Second, by understanding moral behavior as action that proceeds from a character perfected by these virtues, one eliminates the need for thinking of morality as exclusively, or even primarily, a matter of conscientious rule-following. Hence one evades the difficulty afflicting most forms of moral rationalism, that of specifying substantial moral principles, rather than empty generalities, to putatively compel the rational assent of anyone whosoever. For Aristotelians, as MacIntyre understands them, there is no moral knowledge apart from moral education and training, education not so much in assimilating precepts and norms, but in acquiring the skilled moral wisdom (*phronesis*) to express the proper responses and sentiments in the proper way at the proper times.

Finally, Aristotelianism, for MacIntyre, can make sense of the ways in which traditions of rational inquiry and communal practice can sustain a conception of the virtues while subjecting it to both internal scrutiny and external challenge. Most moral epistemologists make the false assumption that morality names a universal phenomenon rooted in universal human reason. If MacIntyre is right, there is no morality except as rooted in particular communities with their own particular traditions concerning the nature of the virtues and their role in promoting human well-being. This might seem to lend comfort to those moral and political conservatives who take reason and tradition to be polar opposites, and who denigrate the former and deify the latter. Yet only by participating in the common life and practices of a tradition can we come to recognize moral reasons as reasons. By dialectically examining and testing these reasons against those of rival traditions of thought and practice, we can confirm or deny their adequacy and provisionally justify our confidence in them. Traditions are the primary bearers of moral reasons; the internal evolution of traditions and the conflicts between alternative traditions indicates the way in which moral knowledge is embodied in time and history, and how moral knowers can yet transcend historical limitations.

Conclusion

The virtue-centered historicism exemplified by MacIntyre might seem, at first, to be yet another item on the menu of moral epistemologies, yet another intellectual position for ethicists to choose and then defend. But it would be a mistake to view it in this way. Moral epistemology, as a historicist like MacIntyre conceives of it, differs from moral epistemology as most moral epistemologists have conceived of it. MacIntyre denies the ability to transcend all traditional allegiances and to spell out the conditions for moral knowledge in general and as such. As MacIntyre suggests, the moral system it would be rational to adopt depends on who one is and how one understands oneself; there is no moral system that is rational without qualification (1988). This is certainly not to suggest a radical moral relativism, since one's initial loyalties, convictions, and self-understandings are precisely what are to be tested by inquiry and comparative criticism. One must begin inquiring somewhere, however, and the only available starting points are within the assumptions and ways of life of the specific traditions one happens to inhabit.

Thus, for historicists like MacIntyre, Rorty, Stanley Hauerwas, and Jeffrey Stout, moral epistemology can no more escape the gravitational pull of human practice and human history than can any other form of inquiry. Since they cannot be detached from the changing, finite traditions that give them rational legitimacy, it may be more accurate to speak of moral epistemologies in the plural rather than a singular moral epistemology.

The implications of historicism for bioethics are, if anything, even more profound. Since claims to moral knowledge are always made within specific traditions of thought and practice, the claims made by bioethicists about informed consent, active and passive euthanasia, paternalism and autonomy will inevitably reflect these particular traditions and will preclude appeal to any neutral ground transcending these traditions to bioethics as such. "Bioethics as such," like "rationality as such," is a post-Enlightenment fiction. Each moral tradition—whether Christian, Jewish, Islamic, or secular—will provide resources for bioethical reflection, but the individual bioethicist cannot escape reflecting and theorizing as a member of his or her tradition, as opposed to being a disengaged, impersonal spectator on "universal values." From the vantage point of historicism, bioethical inquiry and debate need to be reconfigured as conflict among and reconciliation between these traditions, which give moral thought and action their lease on life.

III. NORMATIVE ETHICAL THEORIES

The concept of normative ethics was invented early in the twentieth century to stand in contrast to the concept of metaethics. In ethical theories prior to the twentieth century, it is impossible to discern any sharp distinction between what have come to be called metaethics and normative ethics. In the first half of the twentieth century, however, this distinction began to structure ethics as an intellectual discipline and it continues to be influential at the end of the twentieth century even though crucial theoretical supports for it have disappeared.

Normative ethics was regarded as that branch of ethical inquiry that considered general ethical questions whose answers had some relatively direct bearing on practice. The answers had to be general rather than particular in order to distinguish normative ethics from casuistry; they had to have a bearing on practice in order to distinguish normative ethics from metaethics. Casuistry was understood in its classical sense as the study of particular cases, while metaethics was understood originally as the inquiry into the semantics of ethical language.

G. E. Moore's classic proposal for the structure of ethics distinguished three key questions: (1) What particular things are good? (2) What kinds of things are good? and (3) What is the meaning of "good"? The first question is the central question of casuistry, while the second question falls within normative ethics, and the third, within metaethics (although Moore used neither the term "metaethics" or "normative ethics" in his early work). Normative ethics as a field of inquiry, then, is positioned somewhat precariously between the detail of casuistry and the abstractness of metaethics.

The character of normative ethics was also strongly influenced in the first half of the twentieth century by the

almost universal acceptance of the principle of moral neutrality. This principle, accepted by virtually all mainstream Anglo-American moral philosophers from the 1930s to the 1960s, asserted that the results of metaethical investigations were logically independent of normative ethics. When coupled with the original understanding of metaethics as an account of the meaning of key ethical terms, it implied that such semantic investigations were logically irrelevant to inquiries about how to live. Under the influence of this principle, normative ethics was largely abandoned by Anglo-American moral philosophers in favor of a single-minded pursuit of metaethical inquiry. And since the metaethical views most in favor during this period were various forms of noncognitivism (e.g., emotivism and prescriptivism), it was regularly asserted that normative ethics should be relegated to preachers, novelists, and other nonphilosophers. The widely accepted noncognitivist views held that there was no cognitive content to normative ethical judgments since these judgments were primarily expressions of attitudes (as emotivists held) or primarily expressions of prescriptions (as prescriptivists held). But if normative judgments had no cognitive content—if, that is, they were primarily the expression of noncognitive attitudes or imperatives—then it was unclear why moral philosophers should be concerned with examining them. Normative ethics was regarded as largely a matter of exhortation and was removed from the standard repertoire of strictly philosophical concerns.

This sharp distinction between metaethical and normative inquiry, however, together with the relegation of normative ethics to nonphilosophical inquiry, was too unstable to last. Philosophers increasingly recognized that the principle of moral neutrality was not a theoretically neutral presupposition of ethical inquiry but rather drew a considerable amount of its support from the prevailing noncognitivist view. When these noncognitivist views were severely challenged in the late 1950s and 1960s (by, among others, Philippa Foot, Kurt Baier, Stephen Toulmin, and Alan Gewirth), the sharp distinction between metaethics and normative ethics was blunted; this opened the way to a resurgence of interest in normative ethics, expressed by new attempts to reformulate and to defend classical ethical views. Although a complete historical explanation of the remarkably sudden return of philosophers in the 1960s and 1970s to the classical questions of normative theory will no doubt be extremely complex, the decline of noncognitivism and the concomitant rejection of a sharp distinction between normative ethics and metaethics surely contributed to it. Classical Kantian theory was developed in a creative and persuasive manner by John Rawls and his student, Thomas Nagel, along with Alan Donagan, Alan Gewirth, and others. Utilitarianism received new attention from, among others, Richard Hare and his students Derek Parfit and Peter Singer. The classical Aristotelian/Thomist view was reformulated and defended by Elizabeth Anscombe, Peter Geach, Alasdair MacIntyre, and like-minded moral philosophers.

What was revived under the label "normative ethics," however, was not identical to what had previously been neglected by moral philosophers as normative ethics. The watershed in ethical theory in the 1960s changed not only the interests of moral philosophers but also changed their conception of their discipline. The task of metaethics was expanded from the narrow one of clarifying the semantics of ethical terms to a much broader investigation of the whole range of metaphysical, epistemological, and semantic questions associated with ethical inquiry. Metaethics came to be concerned not only with questions about the meaning of ethical terms and judgments, but also with metaphysical questions about the nature of ethical properties and epistemological questions about how claims to ethical knowledge are to be appraised. Normative ethics in turn came to be understood as that pole of ethical theory that stood closest to practice. Whereas previously the distinction that most clearly structured ethical inquiry was the distinction between metaethics and normative ethics, the crucial distinction increasingly came to be that between ethical theory and applied ethics.

Ethical theory was distinguished from applied ethics by being both more general and more abstract, and also by being less driven by a concern that its results would have some immediate consequences for action or policy. Within ethical theory, however, elements coexisted that, according to earlier views, would have been sharply distinguished as metaethical and normative. Ethical theory inquired into the epistemological and metaphysical features of ethics as well as into the most general truths about how we should live. Also, the new conception of ethical theory held that these two kinds of inquiry were continuous; it was not possible to pursue either kind without attending to its implications for the other. Ethical theory had become a seamless web with areas of greater or less practical relevance, roughly corresponding to those areas earlier distinguished as the normative and the metaethical.

One consequence of these complex historical developments is that it has become much more difficult to give a precise characterization of normative ethics than it would have been at an earlier time. Nevertheless, certain common assumptions about the nature of normative ethics, as well as a widely shared taxonomy of the varieties of normative theory, have persisted through these developments in the concept of normative ethics. The common assumptions include the claim that the central task of normative ethics is to define and to defend an adequate theory for guiding

conduct. The received taxonomy divides normative theories into three basic types: virtue theories, *deontological* theories, and *consequentialist* theories. The following section will examine these three types of normative theory with the aim of exploring their distinctive features.

Types of Normative Theory

The basis for distinguishing the three types of normative theory lies in three universal features of human actions. This recourse to the features of actions should not be surprising, since the aim of normative theory is to guide action. Every human action involves (1) an agent who performs (2) some action that has (3) particular consequences. These three features may be set out as follows:

P	——→	+ + + + + + +
Agent	Action	Consequences

If Jones tells a lie to Smith that causes Smith to miss his train, then Jones is the agent, his telling a lie is the action, and Smith's missing the train is one of the consequences of the action. Difficulties arise, of course, in many cases in determining whether someone is an agent in a particular case (e.g., if Jones is insane when he shoots the president, is he really the agent of any action?); or the nature of the particular action performed (e.g., if Jones is cutting down a tree, believing reasonably that he is the only one in the forest, but Smith wanders by and the tree falls on him, causing his death, does a killing take place or merely a death?); or what the consequences of a particular action may be (e.g., if Jones tells Smith "Take the stuff," but Smith understands him to say "Take the snuff," with the consequence that he takes the snuff and due to a hitherto undiscovered allergy becomes ill, is his illness a consequence of Jones's action in saying "Take the stuff"?). These are difficult questions, of course, and they have been much discussed in contemporary action theory in philosophy. In the typical case of human action, however, agent, action, and consequences can be identified, and the typical case provides the basis for the widely shared taxonomy of normative theories.

Ethical or broadly evaluative judgments can also be classified using a taxonomy drawing on these features of human action. Some ethical judgments are primarily evaluations of agents, such as "Jones is a compassionate doctor" or "Smith is a conscientious nurse." In these cases the object evaluated is a particular person, and he or she is evaluated as a possible or actual agent of an action. Some other ethical judgments are primarily about actions in the narrow sense, such as "Jones has a duty to tell the patient the truth about the diagnosis" or "The direct killing of the innocent is always wrong." In these cases, the primary object of ethical evaluation is an action—the thing done or to be done. This action may be characterized either as required ("X must be done") or as permitted ("X would be right to do") or as forbidden ("A would be wrong to do"). More concrete characterizations of actions are also possible, such as "X was a vicious action" or "X was a heroic action." In all of the cases, however, the action is the primary object of evaluation.

A third class of ethical judgments is primarily about states of affairs or objects that are neither agents nor actions, such as "Health is more important than money" or "Human suffering is a terrible thing." Ethical judgments like these do not, directly at least, evaluate either agents or actions. However, the objects evaluated in them, may be, and frequently are, the possible consequences of actions. Thus, this last class of judgments can also be matched to one of the three basic features of human action.

Normative theories may have any of three basic structures, and the differences among these structures are determined by which of the three kinds of practical judgments is taken as basic by a particular theory. *Virtue* theories take judgments of agents or persons as most basic; *deontological* theories take judgments of actions as most basic; and *consequentialist* theories take judgments of the possible consequences of an action as more basic. The sense in which a theory takes a judgment of a certain kind as most basic will become clear in the discussion of each type of theory.

VIRTUE THEORIES. Normative theories that regard judgments of agents or of character as most basic are called virtue theories because of the central role played in them by the notion of a virtue. In the context of these theories, a virtue is understood as a state of a thing "in virtue of which" it performs well or appropriately. In this broad understanding of virtue not only human beings possess virtues but also certain inanimate objects—a virtue of a knife, for example, will be a sharp blade. Indeed, anything that can be said to have a function or role attached to it because of the kind of thing it is may be said to possess virtues, at least potentially.

A virtue theory takes judgments of character or of agents as basic in that it regards the fundamental task of normative theory as depicting an ideal of human character. The ethical task of each person, correspondingly, is to become a person who has certain dispositions to respond in a characteristic way to situations in the world. Differences among persons may be of quite different kinds. Some people are shorter or fatter than others, some more or less intelligent, some better or worse at particular tasks, and some more courageous, just, or honest than others. These differences can be classified in various ways: physical versus mental differences, differences in ability versus differences in performance, and so on. Those features of human beings on which virtue theories concentrate in depicting the ideal

human being are states of character. Such theories typically issue in a list of virtues for human beings. These virtues are states of character that human beings must possess if they are to be successful as human beings.

Typically, a virtue theory has three goals:

1. to develop and to defend some conception of the ideal person
2. to develop and to defend some list of virtues necessary for being a person of that type
3. to defend some view of how persons can come to possess the appropriate virtues.

Virtually all ancient moral philosophers developed normative ethical theories of this sort. The ethical theories of Plato and Aristotle, in particular, provide models of this kind of normative ethical theory. As a consequence, the particular disputes that occurred among ancient philosophers centered on questions that one would expect to arise within a virtue perspective. What are human virtues? How are they acquired? Are they essentially states of knowledge? Can one know that a certain trait of character is a virtue without possessing it? Is it possible to have one, or a few, of the virtues without possessing all of them? Are all human virtues of the same type or are there fundamentally different kinds? Are human virtues a matter of nature or of convention? And, most important of all, what is the correct list of moral virtues? Much of the discussion of ethics in ancient Greece centered on a particular short list of virtues—justice, temperance, courage, and wisdom—that came to be called the *cardinal virtues.* After the introduction of Christianity into Europe, these four virtues were joined by faith, hope, and charity—the so-called *Christian virtues*—to form the seven virtues; these, together with the seven deadly vices, dominated medieval thinking about ethics.

One can also see how questions of human character are basic according to virtue theories by seeing how questions about (1) which actions one ought to perform and (2) which consequences one ought to bring about are subordinated to questions of human character. For a virtue theory the question "Which actions ought one to perform?" receives the response "Those actions that would be performed by a perfectly virtuous agent." Similarly, those states of affairs one is required to bring about in the world as a consequence of one's actions are those states of affairs valued by a perfectly virtuous person. Of course, particular actions may also be required by one's particular virtues. For example, someone who possesses the virtue of honesty may be required by the virtue itself to tell the truth in certain cases. Or someone may be required to pursue certain consequences by certain virtues. For example, an agent who has the virtue of benevolence may be required to pursue the happiness or well-being of others. But these requirements are derivative from the virtues, and the fundamental ethical question thus remains a question about the correct set of virtues for human beings.

DEONTOLOGICAL THEORIES. Deontological normative theories take moral judgments of action as basic, and they regard the fundamental ethical task for persons as one of doing the right thing—or, perhaps more commonly, of avoiding doing the wrong thing. While virtue theories guide action by producing a picture of ideal human character and a list of virtues constitutive of that character, deontological theories characteristically guide action with a set of moral principles or moral rules. These rules may refer to particular circumstances and have the following form:

> Actions of type T are never (always) to be performed in circumstance C.

Or, they may be absolute in that they forbid certain actions in all circumstances and have the following form:

> Actions of type T′ are never to be performed.

The essential task of a deontological theory, then, is twofold:

1. to formulate and to defend a particular set of moral rules
2. to develop and to defend some method of determining what to do when the relevant moral rules come into conflict.

One must qualify, however, the claim that deontological theories make rules fundamental in ethics. What is fundamental, in fact, are actions themselves and their moral properties. This emphasis on actions can take either of two forms: A normative theory may guide action by requiring agents to perform certain kinds of action that can be specified by a rule or other general action guide. Alternatively, one might regard normative theories as requiring particular actions that in their "particularity" elude specification by a rule. This difference has led some moral philosophers to distinguish two forms of deontological normative theories: *rule deontological theories,* which guide action in the first manner, and *act deontological theories,* which guide action in the second. Virtually all influential deontological theories, however, have taken a rule form and, for this reason, this discussion will continue to emphasize the centrality of rules.

Just as a virtue theory subordinates judgments of actions and consequences in a characteristic way, a deontological theory subordinates judgments of character and consequence. The state of character ethically most important in a deontological view is *conscientiousness*—that state of character that disposes persons to follow rules punctiliously, whatever the temptations may be to make an exception in a

particular case. Conscientiousness does not have value in itself, but it has value derivatively because it is the most important state of character for ensuring that persons follow rules and, hence, that they do what is right. In a similar way, the consequences of actions that deontologists are most concerned with are the consequences of particular rule-followings. Not all of an agent's practical life, however, need be reduced to rule-following. An agent may have certain personal ideals or particular projects that exist apart from moral rules. These personal ideals or personal projects may be pursued, according to the deontologist, but their pursuit is permitted only if it does not violate the moral rules. Moral rules define the limits of practical pursuits and projects. They are the moral framework within which nonmoral matters can go on. And this is the sense in which moral rules with their emphasis on judgments of actions are basic, according to the deontological view.

Just as virtue theory has its historical roots in the moral philosophy of ancient Greece, deontological theories have affinities with legalistic modes of thought characteristic of Judaic and later Roman thought. The Decalogue (Ten Commandments), although it functions in a religious context, provides a model of a set of rules of conduct that are basic in much the same way rules function in a deontological theory. One is required to follow the rules in the Decalogue because they are the commandments of God, and reasons can be given why it is appropriate to do what God tells one to do. When a deontological theory is deployed in a secular context, however, this reason for rule-following is necessarily absent. Nor can deontologists require that rules be followed because doing so is necessary to become persons of a certain sort or because doing so is necessary to bring about certain consequences. If they took the first route, their view would become a *virtue* theory; if they took the second route it would become a *consequentialist* theory. For a view to be genuinely deontological, it must claim that an agent's fundamental ethical task is to perform certain actions and that the value of this task cannot be dependent on the value of either virtues or consequences.

The most profound attempt to defend this view was anticipated in ancient moral philosophy by the Stoics and was developed in its most persuasive form by the modern German philosopher Immanuel Kant. The Stoics claimed that moral rules are expressions in the human realm of laws of nature and that rational creatures are required to follow these rules because, as creatures, they are parts of nature and, as such, obligated to bring their action in line with natural forces. Human beings differ from other objects of nature by possessing both freedom and reason. Since they are free, they may act against nature; since they have reason, however, they can understand natural laws and choose to bring their action in line with such forces. Kant's view agrees with the Stoic view in broad outline, but he develops the notions of freedom and reason far beyond the Stoic view. Kant's ultimate answer to questions about how we discover the correct set of moral rules is that only by following the dictates of reason can we be genuinely free.

CONSEQUENTIALIST THEORIES. Consequentialist normative theories take judgments of the value of the consequences of actions as most basic. According to these theories, one's crucial ethical task is to act so that one will bring about as much as possible of whatever the theory designates as most valuable. If a particular consequentialist theory designates, for example, that pleasure is the only thing valuable in itself, then one should act so as to bring about as much pleasure as possible. The goals of a consequentialist theory itself are threefold:

1. to specify and to defend some thing or list of things that are good in themselves
2. to provide some technique for measuring and comparing quantities of these intrinsically good things
3. to defend some practical policy for those cases where one is unable to determine which of a number of alternative actions will maximize the good thing or things.

Like deontological theories, consequentialist theories can be divided into act and rule varieties. *Act consequentialism* requires agents to perform the particular action that in a particular situation is most likely to maximize good consequences. *Rule consequentialism* requires agents to follow those moral rules the observance of which will maximize good consequences. The difference between these two forms of consequentialism, however, is not as straightforward as it may at first seem. It is particularly difficult to precisely characterize rule consequentialism. Is the agent supposed to follow those rules that, if followed by everyone, would maximize good consequences, or rather those rules that will maximize goodness, regardless of how other agents act? There are a number of similar difficulties in characterizing rule consequentialism, and these difficulties have led some moral philosophers to deny that there is a genuine distinction here at all. They have argued, indeed, that when any form of rule consequentialism is rigorously characterized it will be found to degenerate into a form of act consequentialism.

For consequentialists, the distinction between instrumentally good things and *intrinsically* good things is also of special importance. Instrumentally good things are good only insofar as they play some role in bringing about intrinsically good things. If, in a particular case, something

that is ordinarily instrumentally good does not stand in the appropriate relation to an intrinsically good object, then its goodness evaporates. Its goodness is merely dependent. Intrinsically good things, on the contrary, are good not because of any relation in which they may stand to other things. Their goodness is independent because it is constituted by the kind of thing the good thing is. Thus, a particular consequentialist theory may hold that only pleasure is intrinsically good, but that other things, including types of action and states of character, are instrumentally good. The virtue of honesty, for example, might be regarded as instrumentally good by such a theory since honesty is likely to contribute to maximizing human happiness. Even if honesty is typically instrumentally good, however, situations may arise in which one could maximize pleasure by acting deviously rather than honestly. In such cases, a consequentialist theory (complications about rule versions of the theory aside) would hold that one should perform the devious action. According to this view, there is nothing about honesty in itself that is good.

Consequentialist theories find their fullest expression in modern thought, especially in the thought of the British utilitarians Jeremy Bentham, John Stuart Mill, and Henry Sidgwick. Drawing on earlier work in the British empiricist tradition, the classic utilitarians claimed that the only intrinsically good thing is human happiness, which they understood as constituted by pleasure and the absence of pain. The utilitarian maxim, "Act always in such a way as to promote the greatest happiness to the greatest number," has been the paradigmatic consequentialist moral principle and has inspired many more recent consequentialists.

There was much disagreement among classical utilitarians, however, about the details of their view. Can pleasures be distinguished qualitatively as well as quantitatively? What role should rules and virtues play within the practical thought of a utilitarian? How can the flavor of the absolute prohibitions associated with justice and the inviolability of the person be preserved within a utilitarian framework? These questions, along with other similar ones, were answered differently by different utilitarians. They were at one, however, in aspiring to formulate and defend a particular version of consequentialism.

The distinction above between the instrumentally and intrinsically good makes it possible to specify more clearly what a consequentialist theory is and to overcome certain difficulties of definition that may creep in. If a consequentialist theory is characterized as one that specifies some object, state of affairs, or property that should be maximized, one might ask whether the object or state of affairs referred to in this definition might be either a state of character or the performance of certain actions. If so, then the distinctions between a consequentialist theory, on the one hand, and a deontological theory or a virtue theory, on the other, seems to be in jeopardy. If the intrinsically valuable things specified by a consequentialist theory can include actions or states of character, then virtue theories and deontological theories would seem to be mere species of consequentialism, distinguished from other forms of consequentialism by the type of thing they specify as intrinsically valuable. Virtue theories would be consequentialist theories that specify states of character as intrinsically valuable; deontological theories would be consequentialist theories that specify the performance of certain actions as valuable. If deontological and virtue theories are merely varieties of consequentialism, however, there are not three basic structures but rather one basic structure with a number of varieties.

One might deal with this difficulty by defining a consequentialist theory as one that specifies what is intrinsically good but includes neither states of affairs nor actions, but this seems arbitrary. In addition, although this solution no longer allows that deontological theories and virtue theories are varieties of consequentialism, it does not make it possible to understand how these three types of theory exhibit different structures. One can see that there are different structures here, however, by looking more closely at the differences among these theories. Suppose that a particular consequentialist theory specifies certain virtues as the only intrinsically valuable things. Suppose, more specifically, that a particular consequentialist theory, C, specifies that the virtue of justice is the only intrinsically valuable thing. One can also suppose that a virtue theory, V, specifies the good for human beings such that it is constituted solely by the virtue of justice. Are these two theories practically equivalent? If virtue theories are a mere variety of consequentialism, they should be. If they are not, then virtue theories are not a mere variety of consequentialist theory.

One can see that these two theories are not practically equivalent by considering the practical requirements each imposes on an agent. C requires that an agent act in such a way that he or she will maximize the number of just persons. Since consequentialist theories require that agents maximize whatever is intrinsically valuable, and since the only intrinsically valuable thing according to C is the virtue of justice, agents are required by this theory to maximize justice. V, however, need not have this consequence. What V requires of an agent is that he or she develop those virtues that are constitutive of being a good human being. V requires, then, merely that an agent develop justice. There is nothing in V itself that requires an agent to try to bring about justness in others. A virtue theory more complicated than V may include a virtue—perhaps benevolence—that requires agents to promote the well-being of others as well as themselves.

But this requirement to maximize the number of people who possess virtues is not a requirement derived from the nature of a virtue theory itself. It can be derived only from some particular virtue that may—or may not—be a component of a particular virtue theory.

One can arrive at this same point by considering an agent who finds herself in a situation where she can maximize the number of just persons only by becoming herself unjust. In order to make others just, she must become unjust. One example of such a case might be a politician who believes that the best way to make the citizens of her country just is to acquire political power and to exercise it in ways that only she can succeed in doing. Also, suppose she knows that only by renouncing justice herself, by being prepared to act unjustly, can she acquire political power. Thus it is only by becoming unjust that she can most efficiently make others just.

What do C and V have to say to this agent? It is clear that C would approve the renunciation of justice on her part if that would maximize the number of persons who possess justice. The loss of this particular agent's own justice to the sum of justice in the world is more than offset by the gain in the number of persons who are just. The sacrifice is worth it. But what would V require? It is equally clear that V does not require the agent to sacrifice her own justice. Virtue theories hold that an agent's own character plays a special role in his or her practical thinking that it does not play in a consequentialist theory. A virtue theory gives agents reasons to act because it is supposed that each person wants to be a flourishing and fulfilled human being. An agent's own life and character then will have a certain primacy according to a virtue theory. Virtues are not just intrinsically valuable things that should be inculcated in as many agents as possible. They are states of character that each agent must acquire in order to succeed as a human being. Thus, V will not necessarily require that this agent become unjust even if this would maximize the amount of justice in the world.

Similar conclusions follow with regard to a comparison between consequentialist theories and deontological theories. Consider a particular consequentialist teleological theory, C', that specifies that the only intrinsically valuable things are acts of truth-telling, and a particular deontological theory, D, that specifies that the only moral rule is one that enjoins truth-telling in all cases. Are these two theories practically equivalent? Again it is useful to consider a case in which maximizing a particular good requires the renunciation of it by an agent. Suppose that an agent finds himself in a situation in which he can most efficiently produce the maximum ratio of truth-tellings to lyings by himself telling a lie. Perhaps he has discovered that, by telling others that whenever they tell a lie their life is shortened by three weeks, he can most efficiently promote truth-telling. But he also knows that this is a lie. What should he do?

It seems clear that C' would require him to act in whatever way will maximize the number of truth-tellings, and, if this requires him to lie, so be it. Although his lie may be intrinsically bad, its badness will be more than outweighed by the intrinsically good states of affairs it brings about. The person who accepts D, however, believes that there is a moral rule enjoining everyone always to tell the truth. This rule gives him a reason to act, because he is committed to doing the right thing. He is not committed primarily to bringing about as many right or dutiful actions as possible; rather, he is committed to doing the right thing. Just as a virtue theory holds that an agent stands in a more intimate relation to his own character than he does to the characters of other persons, a deontological theory holds that an agent stands in a more intimate relation to his own actions than he does to the actions of others. The action of an agent who follows a moral rule will have a different moral significance for a deontologist than the action of an agent who brings it about that someone else follows a moral rule. For a deontologist, it is not as important that there be rule-followings as that he or she follow moral rules. D need not then require, or even permit, that the agent tell a lie if this is necessary to maximize truth-telling, and hence C' and D, like C and V, are not practically equivalent. If they are not practically equivalent, however, then deontological normative theories, like virtue theories, are not mere varieties of consequentialism.

Deeper Differences among Normative Theories

This comparison of virtue, deontological, and consequentialist normative theories suggests that the differences among them are deeper than might at first appear. Indeed it suggests that while they certainly differ with regard to which of the three kinds of practical judgments they take as most basic, there are other, and more fundamental, differences among them. To accept one of these normative theories is to accept a particular attitude toward the relation of an agent to his or her character and actions. If one adopts a virtue theory, one's own character comes to have an especially important place in one's practical thinking. It is of the first importance that one become a person of a certain sort. This view need not imply, as it may seem to, that one is committed to an egoistic or selfish life. One may be guided by a virtue theory to pursue a life dominated by generosity and concern for others. One may, indeed, strive to become completely selfless in the sense of always putting the needs of others ahead of one's own needs. But even if this is one's goal, it is also true that one's

own character forms the primary focus of one's practical life. The apparent combination here of concern for self and concern for others may appear paradoxical, but it is surely not incoherent. Some of the greatest moral heroes—for example, Gandhi, Jesus, and Albert Schweitzer—seem to have combined these two concerns in their lives.

In a similar way, if one adopts a deontological theory, one's own actions come to play an especially important role in one's practical thinking. It makes a difference to one that one's actions are wrong. It is more important practically to an agent that he or she has told a lie than that a lie has been told. In cases where one's telling a single lie will prevent three others from telling lies, one will not decide what to do by simple arithmetic. Of course, a deontologist will not expect that others will have the same concern for her lie as she will have for it. She may recognize that for someone else, his telling a lie will have a different practical significance for him than *her* telling a lie will have for him. And just as she may not be prepared to tell one lie to prevent him from telling two, she will not expect him to tell one lie to prevent her from telling two. Indeed, she will recognize that from his point of view, his telling one lie is worse in an important sense than her telling two, just as from her point of view her telling one lie is worse than his telling two.

The special significance given to one's actions by a deontological theory need not imply that a deontologist is egoistic or, in the ordinary sense of the term, self-centered. In this way the deontologist is in a situation similar to that of the virtue theorist. The particular moral rules that one is required to follow may give the needs and interests of others parity with one's own, or, more likely, they may require one to put others ahead of oneself. What they cannot require is that one take up a particular attitude toward the rules themselves. The rules cannot, as it were, define their own condition of application—nor can they specify how they relate to one's faculty of practical decision making at the deepest level.

To a consequentialist, giving this special significance to one's character or one's actions may seem confused and possibly morally corrupt. Of course, consequentialists may be concerned with questions of character, but character cannot be their central normative focus. According to consequentialism, what is of primary ethical importance is that the amount of the intrinsically valuable be maximized. Determining the most effective means for maximization involves straightforward questions of efficiency. These questions may be neither simple nor easily answered, but structurally they are straightforward: Which of the possible courses of action will most likely maximize the amount of goodness in the world? In canvassing the possible means to this end, the consequentialist requires an agent to throw his own character and actions into the same category with other possible means. The kind of character one should develop depends upon the kind of character that will contribute most to the relevant goal. The actions one should perform depend similarly on consequentialist goals. For a consequentialist, one must put a certain distance between oneself—considered as the agent who must make practical choices—and one's own character and actions. One's character and actions have the same role in one's practical thinking as would any other possible means—one's wealth, for example, or influence—that are in a more usual sense external. More important, one's own character and actions have no more special role in practical thinking than do the character and actions of others. All are regarded as possible means to maximize intrinsically good things, and one's own actions and character may have special significance only insofar as they may be more easily—because more directly—manipulated by oneself.

One might think, however, that one feature of the agent's character cannot be treated as a mere means, even by a consequentialist. For any consequentialist theory, it will surely be important that persons have those states of character that dispose them to pursue or to favor intrinsically good things. It might be argued that this state of character cannot be treated by the theory as a mere means. But this argument underestimates the resources within consequentialism for distancing an agent from his or her character. Suppose an agent holds a consequentialist normative theory, C'', according to which the only intrinsically good things are states of human pleasure. Suppose also that this agent has a character such that he is disposed always to act in ways he believes will maximize human pleasure. This argument suggests that this agent will not be prepared to sacrifice for the goal of maximal pleasure his own disposition to pursue this goal. But why should this be the case? One might think that a case could never arise in which an agent could contribute most to maximizing pleasure by changing his character to that of someone unconcerned with maximizing pleasure. But this view is surely wrong. Suppose the agent discovers an empirical law according to which human pleasure is maximized only if agents are disposed not to pursue human pleasure but to pursue knowledge. But if this is true—and it is surely possibly true—the agent should act to change as many persons' characters as possible from pleasure-seeking to knowledge-seeking characters. Nor is there any reason why, on consequentialist grounds, this agent should make an exception in his or her own case. So even those features of human character that lead an agent to pursue the maximization of intrinsically good things are not given a special place by consequentialists. Every feature of

the character of an agent may be regarded as a possible means to the maximization of the relevant goal.

This feature of consequentialist theories was first emphasized by Henry Sidgwick, the greatest of modern utilitarians. Sidgwick was convinced that if the utilitarian goal of human happiness was to be maximized, then it was necessary that most persons not be utilitarians. Indeed, he thought that what was probably required was that most persons hold deontological views and have their character shaped in accordance with such views. He proposed then, for utilitarian reasons, that utilitarianism be propagated as an esoteric view, and that only a few of the most able and intelligent members of society have their characters shaped in accord with it. These bearers of the esoteric view, in turn, would mold the characters of those less able and enlightened in accord with a deontological perspective. Had Sidgwick's enlightened few become convinced that maximal human happiness required that they, too, acquire "deontological characters," simple consistency would have required them to change their own characters appropriately. In this way, consequentialism might require that agents strive to bring about a world in which no one, not even oneself, has the kind of character that would dispose one to strive at the most basic practical level for consequentialist goods.

Justifying Normative Theories

The question of how, if at all, one can rationally choose among these three normative theories is a question taken up under the topic of moral epistemology. It is important to note here, however, that these normative theories emerge in Western thought as components in comprehensive philosophical theories developed by Plato, Aristotle, Aquinas, Kant, Mill, and other major philosophers. They are embedded in rich and complex worldviews in ways that make it difficult to discuss them in isolation from their theoretical and historical settings.

The tendency within contemporary ethical theory is to discuss the merits of these views in purely ethical terms and to ignore to a large extent their larger theoretical settings. Thus, consequentialism is frequently attacked because it is alleged to countenance the judicial punishment of the innocent if that is required for achieving some good end. In arguments like this one, the alleged ethical implications of a normative theory are appealed to in order to evaluate the theory. Similarly, deontologists may be criticized for holding that certain actions are morally forbidden even if performing them in a particular case might prevent an enormous tragedy. It is now a matter of record that these arguments have been unsuccessful in producing agreement within normative ethics. Nevertheless, the same slightly tired arguments continue to be made.

The lesson from the history of these views would seem to be, however, that if any of them is to be adequately defended, or successfully criticized, its theoretical setting must be taken into account. Each of these theories has complex relations with particular philosophical accounts of rationality, explanation, nature, intention, the law, the passions, and other topics of central philosophical interest. A more adequate account of them, if possible here, would have to take these theoretical entanglements into account. Certainly any serious attempt to choose rationally among them would have to locate them in this larger theoretical setting.

Normative Ethics and Practice

The raison d'être for normative ethics, as we have seen, is to guide action, and the theories explored above have been developed with such guidance in mind. There is general disagreement, however, about exactly how these normative theories are to relate to the resolution of particular normative problems. It is not easy to demonstrate how the debate between consequentialists and deontologists is related to more concrete disagreements about physician-assisted suicide or recombinant DNA research. Part of the difficulty arises from the fact that each of the three normative theories embodies a particular conception of how it relates to concrete normative problems. There is no theory-independent criterion of how normative theories are to guide action, since each theory embodies a view about its own application. In this way normative theories double back on themselves with regard to their action-guiding function.

An illustration of this doubling-back phenomenon is found in current debates about the relation of virtue theories to practice. Virtue theories are frequently criticized because they do not yield concrete action guides in the way that consequentialist and deontological theories appear to do. The moral advice to "Be just" lacks the action-guiding bite of either a moral rule that requires an agent to perform certain actions or a consequentialist conception that specifies some good to be maximized. But this objection fails to take account of the distinctive way in which virtue theories purport to guide action. A central claim of virtue theories is that the action-guiding function of a normative theory is not to resolve concrete puzzles about action. Edmond Pincoffs, a leading contemporary virtue theorist, coined the useful term "quandary ethics" precisely to designate what virtue theories are against: a conception of normative ethics as guiding action by giving a particular solution to quandaries about action. If one supposes that the only way in which a normative theory can guide action is by resolving particular

moral quandaries, then one is unlikely to take virtue theories seriously.

Virtue theories offer, however, an alternative account of the action-guiding function of normative theories. They claim that an adequate normative theory will prescribe something like a training program to make agents ethically "fit." This program may not specify exactly how one is to act in particular cases, because these decisions are best left to the prudential decisions of a "morally fit" agent in the concrete decison-making situation. Thus, virtue theories double back on themselves and specify how they are to relate to practice. Both deontological and consequentialist theories also contain such self-referential accounts of their own application.

An important implication of this doubling-back phenomenon is that one cannot assess the adequacy of normative theories by invoking a well-defined criterion for "successful" action-guiding without begging the question. To have such a well-defined criterion is already to have taken a position on some of the fundamental questions in normative ethics.

This difficulty is actually even more serious than this first point suggests. It is not just that each of the three normative theories embodies a well-defined criterion of how normative theory should relate to practice. Also, there are a number of different models of how general ethical thinking should relate to concrete practice. Some of these models have loose affinities with some of the normative theories, but there is not a fixed or necessary connection between them. Indeed, the conflicts among the normative theories cut across, in complex ways, the conflicts among these models for relating normative theory to practice. A representative collection of these models would include: (1) deductivism, (2) dialectical models, (3) principlism, (4) casuistical models, and (5) situation ethics. These models have been for the most part badly defined in the current literature, and the differences among them and their relations to traditional normative theories tend to be matters of dispute.

DEDUCTIVISM. The deductivist model regards the action-guiding function of ethical theory to be the development of highly abstract and general first principles that, together with some factual description of a particular morally problematic situation, will entail concrete action guides. According to this model, moral principles developed and defended within normative ethical theory will play the role of premises in deductive arguments for ethical judgments about particular cases. This model of application is particularly attractive to some deontologists and consequentialists. It is related to more general accounts of justification in contemporary epistemology that suggest that all justification must come from some set of foundational claims in the area in question. It also makes large demands on the justificatory resources of a normative theory, since all of the justification for the principles must come from the theory itself. There is no "bottom up" justification from particular moral beliefs to general principles, as will be found in some of the other models.

DIALECTICAL MODELS. Partly because of worries about the foundationalist character of deductivism, some moral theorists understand the relation between normative theory and practice in a dialectical way. Instead of supposing that justification is exclusively "top down," they suppose that there is dialectical interplay between the principles in a normative theory and particular moral judgments. Normative principles may be modified if they fail to fit our deeply held particular moral beliefs, just as our particular beliefs may be modified in order to fit principles. Whether agents modify principles or particular judgments will depend upon their degree of commitment to each and to the other beliefs they might hold. Just as the deductivist model has affinities with foundationalist theories in epistemology, the dialectical model is inspired by coherentist epistemological theories, which suggest that justification in general is to be understood as a function of how large sets of propositions "hang together" or cohere. The most influential form of the dialectical model is John Rawls's "method of reflective equilibrium," which he uses to support his deontological normative theory.

PRINCIPLISM. Some philosophers have wanted to downplay the importance of normative theory for resolving concrete ethical problems. They emphasize, for example, that consequentialist and deontological normative theories in most cases mandate the same actions, and that it is only in exceptional cases that differences seem to emerge. And they add that the exceptional cases are likely to be so difficult to resolve that both consequentialists and deontologists disagree among themselves about what normative theory requires. They conclude that general ethical reflection should focus on what they call "middle-level" principles, that is, not the most general principles in any normative theory but those that are likely to be acceptable to adherents of different normative theories. They hope that agreement may be easier to achieve in practical matters if the premises for practical arguments are not sought at the deepest level of normative theory. This model has been especially influential in bioethics and has been developed and defended by Tom Beauchamp and James Childress (1989). The middle-level principles they propose are labeled autonomy, beneficence, nonmaleficence, and justice. Their claim is that these principles, when suitably refined, are likely to be acceptable to both rule consequentialists and deontologists.

CASUISTICAL MODEL. Some philosophers have understood genuinely practical and action-guiding thinking in a way that makes it even more remote from the disputes among the classical normative theories. They propose that the appropriate model for practical reflection is found in the case-based approach popular in late medieval and early modern moral thought. According to this approach, ethical reflection should focus on certain paradigm cases of morally good action or morally bad action. Arguments from these paradigm cases to more problematic cases may be made by exploring similarities and differences between the two. This approach rejects attempts to formulate the goodness or badness of paradigm cases in abstract and general principles, and emphasizes analogical as opposed to deductive reasoning. Albert Jonsen and Stephen Toulmin (1988) have been the leading advocates of this model in recent normative ethics.

SITUATION ETHICS. Some might suggest that situation ethics is not so much a model for practical thinking as a rejection of any model. It claims that one should approach the resolution of particular moral problems by eschewing all general action guides in favor of concentrated attention to the details of the particular situation. In some of its versions it may look a bit like the casuistical model; but in its most radical formulations it would mandate that even paradigm cases should play no central role in particular reflection because they could deflect the agent's attention from the particular features of the case under consideration. Among contemporary thinkers, Joseph Fletcher has been the most prominent advocate of this view, although his early commitment to situation ethics developed later into a more general commitment to consequentialism. In his formulation of situation ethics, he suggests that reflection on particular cases should be guided by the general principle, "Do the loving thing!" However, he is insistent that this principle does not play the role of a premise in any deductive practical argument.

These five models represent different ways of thinking about how ethical reflection might be brought to bear on particular moral problems. They range from deductivism, in which successful ethical reflection requires premises drawn from an adequate normative theory, to situation ethics, which eschews any dependence on normative theory. The other three theories occupy the middle ground between these two extremes. In contemporary ethics there is no consensus on which of these models is most adequate. Each has its defenders and its critics, and there is a lively discussion in the contemporary literature about their respective merits.

When this disagreement about the correct approach to concrete ethical reflection is added to the disagreement among classical normative theories, it is easy to see why contemporary applied ethics involves conflicts of such depth and complexity. One is confronted not only with competing normative theories, but also with competing conceptions of how such theories would relate to concrete ethical problems. These two different levels of disagreement indeed tend to reinforce one another, since particular disagreements at each level tend to be tied to particular disagreements at the other.

Normative Theories and Bioethics

The revival of normative ethics in the 1960s was associated with a general renewed interest, across Western culture, in applied ethics and especially in bioethics. Rational reflection on the difficult ethical issues associated with the expanded technological resources of the biological sciences demanded a theoretical structure of some richness, and the classical normative theories provided that structure.

The conflicts between deontological and consequentialist theories have been particularly salient in discussions within bioethics. Indeed, some general discussions of bioethics and many popular textbooks treat these two options as if they are the only possible theoretical perspectives. Part of the explanation for this is surely that so many of the ethical problems in medical practice, as well as in the biological sciences more generally, involve questions about whether actions that are generally regarded as morally problematic can be justified in cases where they appear to promise great benefits. Examples of this kind of conflict are plentiful in contemporary bioethics: Can information obtained by a physician in a doctor-patient encounter be revealed to a third party without the patient's consent, if doing so will prevent some great harm? Can physicians lie to their patients in cases where doing so will increase the effectiveness of therapy and decrease the chances of severe depression? Can physicians override the religious objections of patients to certain therapies when it is clear that these therapies will provide important benefits to the patients?

Moral difficulties like these have been at the center of contemporary discussions in bioethics from its inception. They lend themselves to an analysis that regards them as embodying a general conflict between the thought that some actions (e.g., revealing confidential information, lying, or paternalistic interference) are simply not to be done and the thought that one should be prepared to do whatever is necessary so that things go as well as they can. This conflict in turn seems very close to the fundamental issues at stake between the deontologist and the consequentialist.

Until recent years, virtue theories have been conspicuously absent from most discussions of bioethics. The renewed interest in these approaches is associated with their revival within moral philosophy generally. But there are also features of contemporary bioethics that explain the attention

they receive. First, a kind of impasse has developed between consequentialist and deontological approaches to some bioethical problems, and bioethicists have turned to virtue theories with the hope that they can avoid this impasse. Second, there is a new interest in questions about the character of the various agents (e.g., physicians, nurses, researchers, and technicians) who work in settings where bioethical issues arise. This interest in character is partially a reflection of impatience with "quandary ethics." It also, however, grows out of the search for new models of moral education. Molding and shaping character has seemed to many a more attractive goal for moral education than the goal of inculcating rules. Shaping character indeed seems especially important in bioethics, where change is endemic and rules become outdated quickly.

Finally, virtue theories seem to be attracting more attention within bioethics because of the strong analogies between the notion of health and overall biological fitness, on the one hand, and, on the other, the more general notion of human flourishing that lies at the heart of virtue theories. For those who think that bioethical issues are best approached by getting clear on the goals of the biomedical sciences, this analogy is likely to lead them to take virtue theories seriously.

In spite of the recent revival of virtue ethics both within bioethics and within moral philosophy more generally, however, the dominant argumentative strategies in bioethics continue to be drawn from the deontological and consequentialist traditions. Nevertheless, each of the three traditions is now represented in the contemporary bioethical discussion by competent and enthusiastic advocates, and it seems certain that the central problems within bioethics will continue to be discussed in terms contributed by these normative traditions.

IV. SOCIAL AND POLITICAL THEORIES

Every social and political theory is entangled with ethics. The great political philosopher Jean-Jacques Rousseau proclaimed that the person who would separate politics from ethics will fail to understand both. Despite the efforts of practitioners of "value-free social science," the concepts and categories with which political theorists work—order, freedom, authority, legitimacy, justice—are part and parcel of competing ethical frameworks. It is very difficult to talk about justice without talking about fairness. What is fair is an ethical question that cannot be adjudicated without some reference to what is good for human beings or what kind of good human beings may strive to attain. Terms that circulate within ordinary discourse, such as "fairness" and "freedom," are also central themes within social and political thinking. The implication for bioethics is straightforward. No matter how strenuously the bioethicist may hope to isolate his or her perspective from metaphysical, ontological, epistemological, and civic imperatives, social and political theory frames and penetrates all bioethical considerations.

The human sciences cannot be value-free. In Charles Taylor's words, "they are moral sciences in a more radical sense than the eighteenth century understood" (p. 51). There are, according to Taylor, inescapable epistemological arguments for what might be called an interpretive approach to the human sciences, for human beings are self-defining animals. These self-definitions, in turn, take place within a context that shapes our understanding of self and other as well as our appreciation of human possibilities and the need for constraint. We are caught in conceptual webs. It is the task of social and political theory to make more explicit the nature of the frameworks within which we think and act, and hence, the context within which bioethical imperatives make themselves felt, whether as advances in human freedom, triumphs of human control, or dangerous new forms of oppression. Based on an interpretive approach to political theory, this entry will demonstrate why political theory must be normative and will go on to rehearse contemporary debates in social and political theory using the public/private distinction and the women's movement as illustrative examples.

Why Social and Political Theory Must be Normative

Terms of ordinary discourse serve as a conceptual prism through which we view different human relationships, activities, and forms of life. Most of the time we take such terms for granted. We are all shaped by ways of life that are built upon basic notions and rules. Political theorists concern themselves with the ways in which a society's constitutive understandings either nourish or deplete human capacities for purposive activity. It is, therefore, one task of the political theorist to examine critically the resources of ordinary language, revealing latent meanings, nuances, and shades of interpretation others may have missed or ignored. When we examine our basic assumptions, we enhance our ability to sift out the most important issues (Elshtain, 1981).

Society's understanding of the terms "public" and "private," for example, are always defined and understood in relationship to each other. One version of private means "not open to the public," and public, by contrast, is "of or pertaining to the whole, done or made in behalf of the community as a whole." In part these contrasts derive from the Latin origin of "public," *pubes,* the age of maturity when signs of puberty begin to appear: Then and only then does the child enter, or become qualified for, public activity. Similarly, *publicus* is that which belongs to, or pertains to, "the public," the people. But there is another meaning: public as open to scrutiny; private as that not subjected to the persistent gaze of publicity. The protection of privacy is necessary, or so defenders of constitutional democracy have long insisted, in order to prevent government from becoming all-intrusive, as well as to preserve the possibility of

different sorts of relationships—both mother and citizen, friend and official.

Our involvement in one of a number of competing ethical or normative perspectives is inescapable. It is influenced by what we take to be the appropriate relationship between public and private life, for this also defines our understanding of what politics should or should not attempt to define, regulate, or even control. There is widespread disagreement over the respective meaning of public and private within societies. Brian Fay sees the public and the private as part of a cluster of "basic notions" that serve to structure and give coherence to all known ways of life. The boundaries between the public and the private help to create a moral environment for individuals, singly and in groups; to dictate norms of appropriate or worthy action; and to establish barriers to action, particularly in areas such as the taking of human life, regulation of sexual relations, promulgation of familial duties and obligations, and the arena of political responsibility. Public and private are embedded within a dense web of meanings and intimations and are linked to other basic notions: nature and culture, male and female, and each society's "understanding of the meaning and role of work; its views of nature; … its concepts of agency; its ideas about authority, the community, the family; its notion of sex; its beliefs about God and death and so on" (p. 78). The content, meaning, and range of public and private vary within each society and turn on whether the virtues of political life or the values of private life are rich and vital or have been drained, singly or together, of their normative significance.

The social and political theorist recognizes that no idea or concept is an island unto itself. Basic notions comprise a society's intersubjectively shared realm. "Intersubjectivity" is a rather elusive term referring to shared ideas, symbols, and concepts that reverberate within a society and help to constitute a way of life. The philosopher Ludwig Wittgenstein claims that when we first "begin to believe anything, what we believe is not a single proposition, it is a whole system of propositions. (Light dawns gradually over the whole.)" (p. 21e). Similarly, when we use a concept, particularly one of the bedrock notions integral to a way of life, we do not do so as a discrete piece of "linguistic behavior" but with reference to other concepts, contrasts, and terms of comparison.

As with the concepts of public and private, there are no neatly defined and universally accepted limits on the boundaries of politics. Politics, too, is essentially contested. An essentially contested concept is internally complex or makes reference to several dimensions, which are, in turn, linked to other concepts. Such a concept is also open-textured, in that the rules of its application are relatively flexible, and it is appraisive or normative. For example, one political theorist might claim that a given social situation is unjust. Another might argue that to label the situation unjust only inflames matters, because he or she believes that certain underlying cherished social institutions and relations should not be tampered with or eliminated in the interest of attaining a political or ideological goal. In another example, the feminist political theorist who believes that being born female in and of itself constitutes an injustice on the "biological" level may want to eliminate all sex differences and a public/private distinction as well, for she will see in distinctions themselves a ploy to oppress women (Firestone). Other feminist thinkers may find this view reprehensible, as it deepens rather than challenges societal devaluation of female bodies and a woman's central role in reproduction. This latter group sees injustice in inequalities that are socially and politically, not biologically, constituted. The point is not to eliminate a public/private distinction but to push for parity in male and female participation in both realms.

Boundary shifts in our understanding of "the political" and hence, of what is public and what is private, have taken place throughout the history of Western life and thought. Minimally, a political perspective requires that some activity called politics be differentiated from other activities. If all conceptual boundaries are blurred and all distinctions between public and private are eliminated, no politics can, by definition, exist (Elshtain, 1981). The relatively open-textured quality of politics means that innovative and revolutionary thinkers are often those who declare politics to exist where politics was not thought to exist before. Should their reclassifications remain over time, the meaning of politics—indeed of human life itself—may be transformed. Altered social conditions may also provoke a reassessment of old, and a recognition of new, "political" realities. Sheldon Wolin observes, "The concepts and categories of a political philosophy may be likened to a net that is cast out to capture political phenomena, which are then drawn in and sorted in a way that seems meaningful and relevant to the particular thinker" (p. 21). Thus each social and political theorist must be clear about what rules he or she is employing to sort the catch and to what ends and purposes.

Bioethical Issues in the Concepts of Public and Private

In the history of Western political thought, public and private imperatives, concepts, and symbols have been ordered in a number of ways, including the demand that the private world be integrated fully within the public arena; the insistence that the public realm be "privatized," with politics controlled by the standards, ideals, and purposes emerging from a particular vision of the private sphere; or, finally, a

continued differentiation or bifurcation between the two spheres. Bioethics is deeply implicated in each of these broad, general theoretical tendencies that often touch on the private and the public, as in a case, for example, where a couple decides to conceive a child through artificial insemination by donor (AID). What happens to a society's view of the family and intergenerational ties if more couples resort to artificial insemination? What is the effect on the psychosocial development of donor children? What are the responsibilities, if any, of the donor father beyond the point of sperm donation for a fee? Do contractual agreements suffice to "cover" not just the legal but also the ethical implications of such agreements? Does society have a legitimate interest in such "private" choices, given the potential social consequences of private arrangements? Should such procedures be covered by health insurance, whether public or private?

Questions such as these pitch us into the world of social and political theory and the ways particular ideals are deeded to us. Thus, the social-contract liberal endorses a different cluster of human goods than the virtue theorist or the communitarian. Political and social theory yield ethical debates about these competing ideals of human existence. Moral rules—and whether they are to be endorsed or overridden—are inescapable in debating human existence and the human imperative to create meaning. "Public" and "private" and the relations of politics to each exist as loci of human activity, moral reflections, social and historic relations, the creation of meaning, and the construction of identity.

The ways in which our understanding of public, private, and politics plays itself out at present is dauntingly complex. Contemporary society is marked by moral conflicts. These conflicts have deep historical roots and are reflected in our institutions, practices, laws, norms, and values. For example, the continuing abortion debate in the United States taps strongly held, powerfully experienced moral and political imperatives. These imperatives are linked to concerns and images evoking what sort of people we are and what we aspire to be. The abortion debate will not "go away" because it is a debate about matters of life and death, freedom and obligation, and rights and duties.

Perhaps the intractability of many of the debates surrounding bioethics can best be understood as flowing from a central recognition that language itself has become a preoccupation for theorists and ethicists because of our growing concern for establishing norms, limits, and meanings in the absence of a shared ethical consensus. A persistent theme of contemporary social and political theory is that language helps to constitute social reality and frames available forms of action. We are all participants in a language community and hence share in a project of theoretical and moral self-understanding, definition, and redefinition. Our values, embedded in language, are not icing on the cake of social reasoning but are instead part of a densely articulated web of social, historical, and cultural meanings, traditions, rules, beliefs, norms, actions, and visions. A way of life, constituted in and through language, is a complex whole. One cannot separate attitudes toward surrogacy contracts, in vitro fertilization (IVF), use of fetal tissue for medical experimentation, sex selection as a basis for abortion, or genetic engineering to eliminate forms of genetically inherited "imperfection," from other features of a culture. These bioethical dilemmas do not take place in isolation but emerge from within a culture and thus engage in the wider contests over meaning that culture generates.

Contemporary Debates in Social and Political Theory

Current debate in social and political theory has focused on the question of whether to buttress or to challenge the liberal consensus that came to prevail in modern Western industrial societies. These broad, competing schools of thought are known as liberalism, civic republicanism, and communitarianism. A social movement informed by one or more of these traditions will exhibit conflicting tendencies and posit incompatible claims.

Liberalism comes in many different forms. Some liberal thinkers stress the individual and his or her rights, often downplaying notions of duty or obligation to a wider social whole. They assume, optimistically, that each individual's pursuit of self-interest will result in "good" for the society as a whole. Those whose analyses begin with the free-standing individual as the point of reference and the "good" of that individual as their normative ideal are often called individualists. In the nineteenth century, this standard of individualism was most cogently articulated by John Stuart Mill in his classic work, *On Liberty* (1859).

By contrast, communitarians begin not with the autonomous individual but with a social context out of which individuals emerge. They argue that the pursuit of individual self-interest is more likely to yield a fragmented society than a "good" and fair one. Communitarians insist that rights, while vital, are not the individual's alone. Instead, individual rights necessarily flow from rights recognized by others within a community of a particular sort in which responsibilities are also cherished, nourished, and required of individuals (Bellah et al.).

FEMINISM. The contemporary women's movement and the way in which it reflects, deepens, and extends features of

these traditions illustrate the range of social and political debate. There is no single ethics or moral theory of feminism. Liberalism, with its vibrant individualist strand, has been attractive to feminist thinkers. The language of rights is a potent weapon against traditional obligations, particularly those of family duty or any social status declared "natural" on the basis of ascriptive characteristics. To be free and equal to men became a central aim of feminist reform. The political strategy that followed was one of inclusion. Since women, as well as men, are rational beings, it followed that women as well as men are bearers of inalienable rights. It followed further that there was no valid ground for discrimination against women as women. Leading proponents of women's suffrage in Britain and the United States undermined arguments that justified legal inequality on the basis of sex differences. Such feminists, including the leading American suffragists Susan B. Anthony and Elizabeth Cady Stanton, claimed that denying a group of persons basic rights on the grounds of difference could not be justified unless it could be shown that the difference was relevant to the distinction being made. Whatever differences might exist between the sexes, none, in this view, justified legal inequality and the denial of the rights and privileges of citizenship.

Few early feminists pushed this version of liberal individualist universalism to its most radical conclusion of arguing that there were no bases for exclusion of adult human beings from legal equality and citizenship. Nineteenth-century proponents of women's suffrage were also heirs to a civic-republican tradition that stressed the need for social order and shared values, emphasized civic education, and pressed the importance of having a propertied stake in society. Demands for the inclusion of women often did not extend to all women. Some women, and men, would be excluded by criteria of literacy, property ownership, disability or, in the United States, race. Thus liberal feminism often incorporated the civic-republican insistence on citizenship as a robust, civically demanding, and limited privilege rather than a legalistic and universalistic standing.

At times, feminist theory turned liberal egalitarianism on its head by arguing in favor of women's civic equality on grounds of difference, an argument that might be called neo-Aristotelianism. Ronald Beiner writes,

> The basic conception of neo-Aristotelianism is that moral reason consists not in a set of moral principles, apprehended and defined through procedures of detached rationality, but in the concrete embodiment of certain human capacities in a moral subject who knows those capacities to be constitutive of a consummately desirable life. (p. 75)

Thus greater female political participation was promoted in terms of women's moral supremacy or characteristic forms of virtue. These appeals arose from and spoke to women's social location as mothers, using motherhood as a claim to citizenship, public identity, and civic virtue (Kraditor). To individualist, rights-based feminists, however, the emphasis on maternal virtue as a form of civic virtue was a trap, for they were, and are, convinced that only liberalism, with its more individualistic construal of the human subject, permits women's equality and standing.

The diverse history of feminism forms the basis for current feminist discourse and debate. These debates are rife with ethical imperatives and moral implications. Varieties of liberal, socialist, Marxist, and utopian feminism abound. Sexuality and sexual identity have become highly charged arenas of political redefinition. Some feminists see women as universal victims, some as a transhistorical sex class, others as oppressed "nature." A minority want separation from "male-dominated" society. Others want full integration into that society, hence its transformation toward liberal equality. Others insist that the feminist agenda will not be completed until "women's virtues," correctly understood, triumph. Feminism, too, is an essentially contested concept.

Divisions among feminists over such volatile matters as AIDS, IVF, surrogate embryo transfer, surrogate motherhood, sex selection—the entire menu of real or potential techniques for manipulating, controlling, and altering human reproduction—are strikingly manifest. One broad general tendency in feminist theory might be called noninterventionist. Noninterventionists see reproductive technologies as a strengthening of arrogant human control over nature and thus over women as part of the "nature" that is to be controlled. Alternatively, the prointerventionist stance foresees technological elimination of males and females themselves. Prointerventionists celebrate developments that promise control over nature.

The prointerventionists, who welcome and applaud any and all techniques that further sever biological reproduction from the social identity of maternity, are heavily indebted to a stance best called ultraliberalism. This theory is driven by a vision of the self that exists apart from any social order. This view of the self, in turn, is tied to one version of rights theory that considers human beings as self-sufficient, promoting a view of society that sees itself organized around contractual agreements between individuals.

THE SOCIAL-CONTRACT MODEL. The contract model has its historical roots in seventeenth-century social-contract theory, and it incorporates a view of society constituted by individuals for the fulfillment of individual ends, with social goods as aggregates of private goods. Critics claim that this

vision of self and society ignores aspects of community life, such as reciprocal obligation and mutual interdependence, thereby eroding the bases of authority in family and polity alike.

The pervasiveness of the individualist position is further evident in the prointerventionist stance on bioethical innovations in the area of reproduction. In this view, new reproductive technologies present no problem as long as they can be wrested from male control (Donchin). Women, having been oppressed by "nature," can overthrow those shackles by seizing the "freedom" offered by technologies that promise deliverance from biological "tyranny." Strong prointerventionists go so far as to envisage forms of biological engineering that would make possible the following: "One woman could inseminate another, so that men and nonparturitive women could lactate and so that fertilized ova could be transplanted into women's or even into men's bodies" (Jaggar, p. 132). The standard of evaluation concerning these technologies is self-sufficiency and control, paving the way for invasive techniques that break women's links to biology, birth, and nurturance, the vestiges of our animal origins and patriarchal control.

The prointerventionist position owes a great deal to Simone de Beauvoir's feminist classic, *The Second Sex*. Beauvoir argues that the woman's body does not "make sense" because women are "the victim of the species." The female, simply by being born female, suffers an alienation grounded in her biological capacity to bear a child. Women are invaded by the fetus, which Beauvoir describes as a "tenant" and a parasite upon the mother. Men, by contrast, are imbued with a sense of virile domination that extends to reproductive life. The life of the male is "transcended" in the sperm. Beauvoir's negative appraisal of the female body extends even to the claim that a woman's breasts are "mammary glands" that "play no role in woman's individual economy: they can be excised at any time of life" (p. 24). If to this general repudiation of female embodiment one adds strong individualism, the prointerventionist stand becomes clearer.

Opposed to the radical prointerventionist stance is the noninterventionist voice associated with feminism in a less individualist, more communitarian frame. The noninterventionists ponder the nature of the many choices the new reproductive technology offers. They wonder whether amniocentesis is really a free choice or merely a coercive procedure with only one "correct" outcome: to abort if the fetus is defective. They speculate whether new reproductive technologies are an imposition upon women who see themselves as failures if they cannot become pregnant. Furthermore, noninterventionists reassess the values identified with mothering and encourage the growth and triumph of values they consider to be strongly, if not exclusively, female. They insist that technological progress is never neutral, stressing that "progress" requiring the invasion and manipulation of women's bodies must always be scrutinized critically and may need to be rejected.

Strong noninterventionists claim that women want nothing to do with new reproductive technologies. In the words of one, "The so-called new technology does not bring us and our children any kind of qualitative or quantitative improvement in our lives, it solves none of our basic problems, it will advance even more the exploitation and humiliation of women; therefore we do not need it" (Mies, p. 559). As with the prointerventionist posture, there are noninterventionists who maintain a critical stance but do not condemn all reproductive technologies outright. Moderate prointerventionists support some but not all of the technological possibilities presented by contemporary reproductive science.

These differences played themselves out in the quandaries confronted by feminists with the Baby M surrogacy-motherhood case, a situation in which biological motherhood and social parenting were severed—as feminists, especially strong individualist feminists, had long claimed they could or should be (*Baby M, In re,* 1988). It was also a case in which everyone presumably freely agreed to a contract. Baby M was born to Mary Beth Whitehead, who had contracted with a couple, the Sterns, to be artificially inseminated with Mr. Stern's sperm. She was to relinquish the baby on birth for $10,000. Ultimately, she could not give the baby up and refused the money. The Sterns sued on breach of contract grounds.

Although liberal feminism emphasizes contractarian imperatives, many liberal feminists, including such popular leaders of the women's movement as the liberal Betty Friedan, saw in the initial denial of any claim by Mary Beth Whitehead, the natural mother, to her child, "an utter denial of the personhood of women—the complete dehumanization of women. It is an important human rights case. To put it at the level of contract law is to dehumanize women and the human bond between mother and child" (Barron). Friedan implies an ethical limitation to freedom of choice and contract.

Clearly, feminist debates concerning reproductive technology and surrogacy inexorably lead feminists back into discussions of men, women, children, families, and the wider community. Once again we see that bioethical capabilities and possibilities cannot be severed from wider cultural and social surroundings, including our understanding of the human person and his or her private and public needs, identities, and commitments. One broad frame, the social

contract, has been noted; it either assumes or promotes the image of the self-sufficient self and goods as the properties of individuals.

THE SOCIAL-COMPACT MODEL. A second model of social theory, that of the social compact, or social covenant, offers a more rooted and historical picture of human beings than that of the social contract. Compact, or covenant, theory does not recognize primacy of rights and individual choice as the self-evident starting point. The compact self is a historical being who acknowledges that he or she has a "variety of debts, inheritance, rightful expectations, and obligations" and that these "constitute the given of my life, the moral starting point" (MacIntyre). Modern uprootedness is construed as a problem in the social compact. To be cut off from a wider community as well as from the past, as required by strong individualist modes, is to deform present relationships. The argument here is not that the compact self is totally defined by particular ties and identities, but that without a beginning that recognizes our essential sociality, there is no beginning at all.

The world endorsed in the social-compact model is in tension with the dominant individualist mindset. For this reason, individualists sometimes claim that communitarians, who endorse a social-compact idea, express little more than nostalgia for a simpler past. But the compact defenders argue, in turn, that the past presents itself as the living embodiment of vital traditional conflicts. The social compact makes room for rebellion against one's particular place as one way to forge an identity with reference to that place. But there is little space in the compact frame for social revolt to take a form that excises all social ties and relations if the individual "freely chooses" to do so, a possibility the contractarian must admit. It follows that the familial base of the social compact is opaque to the standpoint of contract theory, given its individualist foundation. This difference about the family, the social institution that first introduces the child into the world, is the focus of political theory debates that bear important implications for bioethics.

The Family as a Theoretical Battleground

Given their individualist starting point, contractarians tend to devalue women's traditional roles and identities as mothers and familial beings. Proponents of the social-compact model, by contrast, understand women's contributions as wives, mothers, and social benefactors as vital to the creation and sustenance of life itself and, beyond that, of any possibility for a "good life." The compact theorist argues that community requires that an important segment or significant number of its members be devoted to the task of caring for the young, the vulnerable, and the elderly. Historically, the work of care has been seen by ethicists, political theorists, and political leaders, including many prominent women, as the mission of women. They worry that in a world of individualism, an ethic of care will be repudiated or replaced by modes of intervention less tied to concrete knowledge and concern of those being cared for (Ruddick; Tronto). They also advocate a reevaluation of families that gives conceptual weight to the "private realm" by showing that this sphere is central to social and political life. They insist that our understanding of justice must include a notion of what it means to be a caring society and to honor the work of care.

The compact theorist regrets the lack of a descriptive vocabulary that aptly and richly conveys what we mean when we talk about families and what makes caring commitments different from contractual agreements. The intergenerational family, for example, necessarily constitutes human beings in a particular web of relationships in a given time and place. Stanley Hauerwas, for example, claims that, "Set out in the world with no family, without a story of and for the self, we will simply be captured by the reigning ideologies of the day." We do not choose our relatives—they are given—and as a result, Hauerwas continues, we know what it means to have a history. Yet we continue to require a language to "help us articulate the experience of the family and the loyalty it represents.… Such a language must clearly denote our character as historical beings and how our moral lives are based in particular loyalties and relations. If we are to learn to care for others, we must first learn to care for those we find ourselves joined to by accident of birth."

Political theorists have grappled with the issue of the family's relationship to the larger society from the beginning: Where does the family fit in relation to the polity? In his work *Republic,* Plato eliminates the family for his ideal city. The ruler-philosophers he calls Guardians must take "the dispositions of human beings as though they were a tablet … which, in the first place, they would wipe clean." Women must be held "in common." A powerful, all-encompassing bond between individuals and the state must be achieved such that all social and political conflict disappears, and the state comes to resemble a "single person," a fused, organic entity. All private loyalties and purposes must be eliminated.

Plato constructs a meritocracy that requires that all considerations of sex, race, age, class, family ties, tradition, and history be stripped away in order to fit people into their appropriate social slots, performing only that function to which each is suited. Children below the ruler class can be shunted upward or downward at the will of the Guardians,

for they are so much raw material to be turned into instruments of social "good." A system of eugenics is devised for the Guardians. Children are removed from mothers at birth and placed in a child ghetto, tended to by those best suited for the job. No private loyalties of any kind are allowed to emerge: Homes and sexual attachments, devotion to friends, and dedication to individual or group aims militate against single-minded devotion to the city. Particular ties are a great evil. Only those that bind the individual to the state are good.

No doubt the modern reader finds this rather extreme. Many contemporary theorists contend that Plato constructed his utopia in an ironic mode. Whether Plato meant it or not, his vision is instructive, for it helps us to think about the relation of the family to wider civic loyalties and obligations. Plato aspired to "rational self-sufficiency." He would make the lives of human beings immune to the fragility of messy existence. The idea of self-sufficiency was one of mastery in which the male citizen was imbued with a "mythology of autochthony that persistently, and paradoxically, suppressed the biological role of the female and therefore the family in the continuity of the city" (Nussbaum).

Moral conflicts, for Plato, suggest irrationalism. If one cannot be loyal both to families and to the city, loyalty to one must be made to conform to the other. For Plato, then, "Our ordinary humanity is a source of confusion rather than of insight … [and] the philosopher alone judges the right criterion or from the appropriate standpoint" (Nussbaum). Hence the plan of *Republic,* which aims to purify and to control human relations and emotions. Later strong rationalists and individualists take a similar tack: They hold that all relationships that are not totally voluntary, rationalistic, and contractual are irrational and suspect. Because the family is the ultimate example of embedded particularity, ideal justice and order will be attained only when "the slate has been wiped clean" and human beings are no longer limited by familial obligations.

Yet a genuinely pluralist civic order would seem to require diversity on the level of families as well as other institutions which, in turn, promote and give rise to many stories and visions of virtue. This suggests the following questions for social and political theory: In what ways is the family issue also a civic issue with weighty public consequences? What is the relationship between democratic theory and practice and intergenerational family ties and commitments? Do we have a stake in sustaining some models of adults in relation to children compared to others? What do families, composed of parents and children, do that no other social institution can? How does current political rhetoric support family obligations and relations?

Equality among citizens was assumed from the beginning by liberals and democrats; indeed, the citizen was, by definition, equal to any other citizen. Not everyone, of course, could be a citizen. At different times and to different ends and purposes, women, slaves, and the propertyless were excluded. But these exclusions were slowly dropped. Whether the purview of some or all adults in a given society, liberal and democratic citizenship required the creation of persons with qualities of mind and spirit necessary for civic participation. This creation of citizens was seen as neither simple nor automatic by early liberal theorists, leading many to insist upon a structure of education in "the sentiments." This education should usher into a moral autonomy that stresses self-chosen obligations, thereby casting further suspicion upon all relations, practices, and loyalties deemed unchosen, involuntary, or natural.

Within such accounts of civic authority, the family emerged as a problem. For one does not enter a family through free consent; one is born into the world unwilled and unchosen by oneself, beginning life as a helpless and dependent infant. Before reaching "the age of consent," one is a child, not a citizen. This vexed liberal and democratic theorists, some of whom believed, at least abstractly, that the completion of the democratic ideal required bringing all of social life under the sway of a single democratic authority principle.

COMMUNITARIAN VERSUS INDIVIDUALIST VIEWS OF FAMILY: MILL AND TOCQUEVILLE. In his tract *The Subjection of Women,* John Stuart Mill argued that his contemporaries, male and female alike, were tainted by the atavisms of family life with its illegitimate, or unchosen, male authority, and its illegitimate, or manipulative and irrational, female quests for private power (1970). He believed that the family can become a school in the virtues of freedom only when parents live together without power on one side and obedience on the other. Power, for Mill, is repugnant: True liberty must reign in all spheres. But what about the children? Mill's children emerge as blank slates on which parents must encode the lessons of obedience and the responsibilities of freedom. Stripped of undemocratic authority and privilege, the parental union serves as a model of democratic probity (Krouse).

Mill's paean to liberal individualism is an interesting contrast to Alexis de Tocqueville's observations of family life in nineteenth-century America, a society already showing the effects of the extension of democratic norms and the breakdown of patriarchal and Puritan norms and practices. Fathers in Tocqueville's America were at once stern and forgiving, strong and flexible. They listened to their children

and humored them. They educated as well as demanded obedience, promulgating a new ethic of child rearing. Like the new democratic father, the American political leader did not demand that citizens bow or stand transfixed in awe. The leader was owed respect and, if he urged a course of action upon his fellow citizens following proper consultation and procedural requirements, they had a patriotic duty to follow.

Tocqueville's discerning eye perceived changing public and private relationships in a liberal, democratic society. Although great care was taken "to trace two clearly distinct lines of action for the two sexes," women, in their domestic sphere, "nowhere occupied a loftier position of honor and importance," Tocqueville claimed. The mother's familial role was enhanced in her civic vocation as the chief inculcator of democratic values in her offspring. Commenting in a civic-republican vein, Tocqueville notes, "No free communities ever existed without morals and, as I observed …, morals are the work of women."

Clearly, Tocqueville rests in the social-covenant or communitarian camp; Mill, in the social-contract or individualist domain. In contrast to Mill, Tocqueville insisted that the father's authority in a liberal society was neither absolute nor arbitrary. In contrast to the patriarchal authoritarian family where the parent not only has a "natural right" but acquires a "political right" to command his children, in a democratic family the right and authority of parents is a natural right alone. This natural authority presents no problem for democratic practices as Tocqueville construed democracy, in contrast to Mill. Indeed, the fact that the "right to command" is natural, not political, signifies its special and temporary nature: Once the child is self-governing, the right dissolves. In this way, natural, legitimate paternal authority and maternal moral education reinforce a political order that values flexibility, freedom, and the absence of absolute rule, but requires order and stability as well.

Popular columnists and "child experts" in Tocqueville's America emphasized kindness and love as the preferred technique of child nurture. Obedience was still seen as necessary—to parents, elders, God, government, and the conscience. But the child was no longer construed as a depraved, sin-ridden, stiff-necked creature who needed harsh, unyielding instruction and reproof. A more benign view of the child's nature emerged as notions of infant depravity faded. The problem of discipline grew more, rather than less, complex. Parents were enjoined to get obedience without corporal punishment and rigid methods, using affection, issuing their commands in gentle but firm voices, insisting quietly on their authority lest contempt and chaos reign in the domestic sphere (Elshtain, 1990).

FAMILY AUTHORITY AND THE STATE. In Tocqueville's image of the democratic family, children were seen both as ends and as means to a well-ordered family and polity. A widespread moral consensus reigned in the America of that era, a kind of Protestant civic religion. When this consensus began to erode under the force of rapid social change (and there are analogues to the American story in all modern democracies), certainties surrounding familial life and authority as a secure locus for the creation of democratic citizens were shaken as well. Tocqueville suggested that familial authority, though apparently at odds with the governing presumptions of democratic authority, is nonetheless part of the constitutive background required for the survival and flourishing of democracy.

Family relations, so this politico-ethical argument goes, could not exist without family authority. These relations and responsibilities, in turn, remain the best way to create human beings with a developed capacity to give ethical allegiance to the principles of democratic society. Because democratic citizenship relies on the self-limiting freedom of responsible adults, a mode of child rearing that builds on basic trust, loyalty, and a sense of commitment is necessary. Family authority structures the relationship between adult providers, nurturers, educators, and disciplinarians, and dependent children, who slowly acquire capacities for independence. Modern parental authority is shared by mother and father.

What makes family authority distinctive is its sense of stewardship: the recognition that parents undertake continuing obligations and responsibilities. Certainly in the modern West, given the long period of childhood and adolescence we honor and recognize, parenting is an ongoing task. The authority of the parent is special, limited, and particular. Parental authority, like any form of authority, may be abused, but unless it exists, the activity of parenting itself is impossible. The authority of parents is implicated in moral education required for the creation of a democratic political morality. The intense loyalties, obligations, and moral imperatives nurtured in families may clash with the requirements of public authority, for example, when young men refuse to serve in a war they claim is unjust because war runs counter to the religious beliefs of their families. This, too, is vital for democracy. Keeping alive a potential locus for revolt, for particularity, for difference, sustains democracy in the long run. It is no coincidence, this argument concludes, that all twentieth-century totalitarian orders aimed to destroy the family as a locus of identity and meaning apart from the state. Totalitarian politics strives to require that individuals identify only with the state rather than with specific others, including family and friends.

Family authority within a democratic, pluralistic order, however, does not exist in a direct homologous relation to the principles of civil society. To establish an identity between public and private lives and purposes would weaken, not strengthen, democratic life overall. For children need particular, intense relations with specific adult others in order to learn to make choices as adults. The child confronted prematurely with the "right to choose" is likely to be less capable of choosing later on. To become a being capable of posing alternatives, one requires a sure and certain place from which to start. In Mary Midgley's words: "Children … have to live *now* in a particular culture; they must take some attitude to the nearest things right away." The social form best suited to provide children with a trusting, determinate sense of place and ultimately a "self" is a family in which parents provide ongoing care, protection, and concern.

The stance of the democratic political and social theorist toward family authority resists easy characterization. It involves a rejection of any ideal of political and familial life that absorbs all social relations under a single authority principle. Families are not democratic polities. The family helps to hold intact the respective goods and ends of exclusive relations and arrangements. Any further erosion of that ethical life embodied in the family bodes ill for democracy. For this reason, theorists representing the communitarian or social-covenant perspective are often among the most severe critics of contemporary consumerism, violence in streets and the media, the decline of public education, the rise in numbers of children being raised without fathers, and so on. They insist, against their critics, that a defense of the family—by which they mean a normative ideal of mothers and fathers in relation to children and to a wider community—can help to sustain a variety of ethical and social commitments, including providing a strong example of adults working together to create a home. Because democracy itself turns on a generalized notion of the fraternal bond between citizens (male and female), it is vital for children to have early experiences of trust and mutuality. The child who emerges from such a family is more likely to be capable of acting in the world as a complex moral being, one part of, yet somewhat detached from, the immediacy of his or her own concerns and desires.

Toward an Ethical Polity

All political and social theorists, whatever their particular philosophic frameworks and normative commitments, agree that social and political theories always embody some ideal of a preferred way of life. Although a handful of postmodern or deconstructive contemporary theorists disdain all normative standards, most social and political thinkers insist that no way of life can persist without a widely shared cluster of basic notions. Those who locate ethical concerns at the heart of their theories hope for a world in which private and public lives bearing their own intrinsic purpose are allowed to flourish. A richly complex private sphere requires freedom from some all-encompassing public imperative for survival. But in order for the private sphere to flourish, the public world itself must nurture and sustain a set of ethical imperatives, including a commitment to preserve, protect, and defend human beings in their capacities as private persons, and to allow men and women alike to partake in the good of the public sphere with participatory equality (Elshtain, 1981). Such an ideal seeks to keep alive rather than to eliminate tension between diverse spheres and competing ideals and purposes. There is always a danger that a too strong and overweening polity will overwhelm the individual, as well as a peril that life in a polity confronted with a continuing crisis of legitimacy may decivilize both those who oppose it and those who would defend it.

The prevailing image of the person in an ethical polity is that of a human being with a capacity for self-reflection. Such persons can tolerate the tension between public and private imperatives. They can distinguish between those conditions, events, or states of affairs that are part of a shared human condition—grief, loss through death, natural disasters, and decay of the flesh—and those humanly made injustices that can be remedied. Above all, human beings within the ethical polity never presume that ambivalence and conflict will one day end, for they have come to understand that ambivalence and conflict are the wellspring of a life lived reflectively. A clear notion of what ideals and obligations are required to animate an authentic public life, an ethical polity, must be adumbrated: authority, freedom, public law, civic virtue, the ideal of the citizen, all those beliefs, habits, and qualities that are integral to a political order.

Much of the richest theorizing of democratic civil society since 1980 has come from citizens of countries who were subjected for forty years or more to authoritarian, even totalitarian regimes. They pose alternatives both to collectivism and to individualism by urging that the associations of civil society be recognized as subjects in their own right. They call for a genuinely pluralist law to recognize and sustain this associative principle as a way to overcome excessive privatization, on the one hand, and overweening state control, on the other. Solidarity theorist Adam Michnik insists that democracy

> entails a vision of tolerance, and understanding of the importance of cultural traditions, and the realization that cherished human values can conflict with each other.… The essence of democracy

> as I understand it is freedom—the freedom which belongs to citizens endowed with a conscience. So understood, freedom implies pluralism, which is essential because conflict is a constant factor within a democratic social order. (p. 198)

Michnik insists that the genuine democrat always struggles with his or her own tradition, eschewing the hopelessly heroic and individualist notion of going it alone. Michnik positions himself against contemporary tendencies to see any defense of tradition as necessarily "conservative"; indeed, he criticizes all rigidly ideological thinking that severs every political and ethical concern between right and left, proclaiming that "a world devoid of tradition would be nonsensical and anarchic. The human world should be constructed from a permanent conflict between conservatism and contestation; if either is absent from a society, pluralism is destroyed" (p. 199).

A second vital political-ethical voice is that of Vaclav Havel, a playwright, dissident, political theorist, and, in the years following the "tender revolution" of 1989, the president of a then-united Czechoslovakia. In his essay, "Politics and Conscience," he writes:

> We must trust the voice of our conscience more than that of all abstract speculations and not invent other responsibilities than the one to which the voice calls us. We must not be ashamed that we are capable of love, friendship, solidarity, sympathy and tolerance, but just the opposite: we must see these fundamental dimensions of our humanity free from their "private" exile and accept them as the only genuine starting point of meaningful human community. (pp. 153–154)

To this end, he favors what he calls "anti-political politics," defined not as the technology of power and manipulation, of cybernetic rule over humans or as the art of the useful, but politics as one of the ways of seeking and achieving meaningful lives, of protecting them and serving them. "I favor politics as practical morality, as service to the truth, as essentially human and humanly measured care for our fellow humans. It is, I presume, an approach which, in this world, is extremely impractical and difficult to apply in daily life. Still, I know no better alternative" (p. 155). This is the voice of an ethical polity. Were this voice to prevail, the way in which our ethical dilemmas are adjudicated, including those emerging from bioethics, would be rich and complex enough to enable us to see the public and civic consequences of our private choices, even as it would guard against severe intrusion into intimate life from the outside.

Ethical dilemmas are inescapably political and political questions are unavoidably ethical. Bioethical matters can never be insulated from politics, nor should they be. But the way in which such matters are addressed will very much turn on the social or political theories to which the ethicist, the medical practitioner, the patient or consumer, and the wider, interested community are indebted.

V. RELIGION AND MORALITY

In the minds of many people, religion and morality are closely connected. Even in secular discussions of ethics, law, and medicine, the presumption remains strong that religious beliefs are an important source of moral guidance, and that religious authorities have a significant influence in shaping attitudes toward biomedical research, new technologies, and medical interventions at the beginning and end of life. Both those who hold religious beliefs and those who do not expect that such beliefs will make a significant difference in the moral lives of their adherents.

When this commonplace assumption about the connection between religion and morality is subjected to examination, however, problems emerge. Although moral virtues and behaviors characteristic of Christian love or Buddhist compassion may be clearly associated with a specific religion, the human possibilities they describe are often familiar and admired, even among those who do not share the religious beliefs. Persons outside of a community of faith may display its characteristic virtues, and those who reject a particular religion may realize its moral ideals better than most of its adherents. For example, Christian writers often turn to Gandhi as the modern model of the love that Jesus preached, while Gandhi valued the life of Jesus as an example of the harmlessness he sought to encourage. This recognition of specific moral virtues in persons outside the community of belief in which those virtues are defined and taught is so common today as to be unremarkable, but it challenges the assumption that specific moral beliefs and practices can be tied to specific religious commitments.

The assumption that religion and morality are somehow related thus gives way to questions about exactly what forms this relationship may take and how it is understood. What claims are persons making when they relate a moral judgment to a religious belief, and how are we to understand the similar judgments that others make on nonreligious grounds? How will these different moral and religious orientations relate to the findings of the biomedical sciences? How should the providers of medical services relate to the diversity of these religious and moral orientations in a complex, pluralistic society?

Types of Relationships

A first step toward answering these questions is to identify the variety of relationships between religion and morality that are found in the world's moral and religious traditions (Little and Twiss). In general, religion is an authoritative source of moral norms and a primary motivation for conformity to moral requirements. Significant variations on this general idea do, however, exist. Is religion the only source of the moral norms, or may those norms, or some of them, be discovered or created in other ways? Is the authoritative source the will of a divine lawgiver, or an intrinsic goodness in the nature of things themselves? Is the motive for moral action a religious love of the good for its own sake, or the hope for an ultimate compensation for the hardships that moral behavior sometimes requires?

Answers to these questions differ, both among different religious traditions and among different schools of thought within a single tradition. The major monotheistic traditions—Judaism, Christianity, and Islam—often represent key moral norms as direct commands of God. In the religions that originated in India—Hinduism, Jainism, and Buddhism—by contrast, the central concept is *karma,* a cosmic moral order that fixes inescapable consequences for any action (Green). Protestant Christianity has often stressed the word of God, the direct divine command that is independent of any human knowledge or wisdom, while Roman Catholic moral theology has relied more on the concept of "natural law," a moral order established by God, but knowable by human reason and apparent in the workings of the natural order (Gustafson).

While it would be possible to explore the relationships between religion and morality by surveying major religious traditions individually, that approach would quickly become a volume unto itself, and it would still do scant justice to the nuances and variety within each tradition. For present purposes, we must limit consideration to a typology of relationships that can be observed in a number of traditions, especially as these traditions come into contact with one another and with the forces of modern technological change. Examples of each type can be identified in a variety of religious traditions, but readers who seek a comprehensive understanding of morality in, for instance, Buddhism or Islam will need to consult other sources, some of which are identified in the bibliography for this entry.

The wide variety of possible relationships between religion and morality may be organized in three prominent types that have received most serious attention from modern scholars: (1) cosmic unity, in which moral obligations derive from a natural or metaphysical order that is understood in religious terms; (2) logical independence, in which moral norms, despite their historical connections to religion, do not depend directly on religion for their validity, and in which religious values must be sharply distinguished from judgments of moral worth; and (3) cultural interdependence, in which neither religion nor morality can be understood apart from the communities in which they have developed and in which their practices have become intertwined.

This typology is derived from modern Western scholarship and reflects particularly the development of religion in modern, secular societies. Each of the types, however, has roots in earlier developments in Western theology and philosophy, and most have parallels in other, non-Western religious and cultural communities. While the emphasis in what follows will be on the modern West, much will be relevant to modern and modernizing cultures in other parts of the world, and analogies to the relationship between religion and morality in other cultural settings may illuminate both those settings and the West's.

COSMIC UNITY. Many cultures have conceived moral and natural orders as an undifferentiated unity. The rewards and punishments associated with moral action are as much a part of reality as the forces of wind and water or the patterns of growth and development observed in plants and animals. To put the matter another way, both the observable patterns of nature and the system of moral requirements are part of a larger order that encompasses all reality, seen and unseen. This unity, expressed both in myths and poetry and in speculative metaphysics, comes into question as science and philosophy develop, but it remains a powerful influence, even in modern, secular societies.

Sometimes, the power that requires moral conduct is thought of in impersonal terms, as a force to be reckoned with by humans and by more powerful beings as well. Early Greek philosophers and poets understood justice (*diké*) in these terms. Justice keeps gods and humans from exceeding their limits, and those who ignore justice risk disaster for the whole community (Adkins). In ancient China, *dao* was a

pervasive force that both regulated the order of natural events and set the standard for human conduct (Girardot). Similar concepts appear in other traditions.

In the Hebrew scriptures, the ultimate power is a personal God who is not subject to higher forces, but who addresses human beings in terms of moral commandments (Deut. 5:1–21). This God is also the creator of the natural forces with which humans must reckon. A somewhat later strand of the tradition represents wisdom (*hokmah*) as the pervasive, unifying power by which God both shapes the material world and directs the conduct of good persons (Prov. 8:1–31).

These early conceptions of a moral order inherent in the order of things often gave way to an understanding of laws and obligations as purely human creations, having power only so far as they are enforced. The development of these skeptical ideas often coincided with the breakdown of traditional social patterns, or with the discovery of other peoples and cultures who lived by quite different rules. Both Greek and Roman philosophers, however, retained the notion that some requirements are not conventional, but natural. However much Greece and Persia otherwise may have differed, some moral requirements remained the same in both places (Aristotle).

This idea provided theologians with the basis for a concept of "natural law," through which God's commandments could be known by all rational persons. Thus, the same minimal requirements of morality apply to everyone, whether or not they share the same ideas about God. Both Judaism and Islam developed philosophical systems that transmitted the Hellenistic notion of natural law to the Christian West, and for a brief time in the Middle Ages, teachers in all three traditions could debate the relationship between God's will and the created order in a shared philosophical framework (Jacobs). In medieval Christian theology, natural law related all rational beings to God. Natural law was seen to be the way a finite, rational being participates in the eternal law by which God orders the universe.

The ever-present possibility of elevating a particular aspect of nature to the level of equality with God led, however, to widespread suspicion of natural law ideas among moral and religious reformers. The main line of development in Jewish ethics centered on observance of a code of law based on scripture and rabbinic interpretation, rather than on a rationalist moral philosophy (Lichtenstein). In Islam, the philosophical movement evolved in a more mystical direction, focused on the identity of the human spirit with the spiritual character of all reality, rather than on the moral requirements of a natural order (Rahman). In Western Christianity, the Protestant Reformation challenged all forms of religious legalism, including the precepts of natural law.

During the seventeenth century, however, a new group of legal and political theorists seized upon the concept of natural law as the key to understanding the relationships between nations as well as persons. While the religious significance of the natural law was not necessarily rejected, it was the universality of the obligation, not its divine origin, that attracted these jurists to the idea. In both legal and theological treatments of natural law, however, these highly articulated systems of moral thought share with the earliest myths of cosmic unity the notion that some moral requirements are inescapable because they are part of the structure of reality itself. Since World War II, renewed interest in theories of natural law as a starting point for an international recognition of basic human rights testifies to the continuing significance of this way of relating moral requirements to religious beliefs about the origin and end of the world in which the moral life is lived (Maritain).

The idea of a comprehensive order that encompasses both moral and religious requirements thus appears both in the most ancient religious traditions and in modern Western theories of natural law. Although reformers in many theistic traditions have sought to restore religious morality to a direct dependence on the will of God, the underlying idea that what God wills is also supported by the natural order that God has created never entirely disappears, even when the human ability to know God's will through the natural order is contested.

LOGICAL INDEPENDENCE. The fact that religion and morality are closely related in the history of Western thought does not, of itself, establish that their connection is important for contemporary moral decisions. The historical relationships might be viewed as accidental or contingent, subject to change without altering the basic requirements of morality. The links between religion and morality might even be points of confusion that obscure important features of both religious and moral truths. For some thinkers, then, it is important to establish the distinction between religious and moral evaluations, even though these may be commonly confused in practice, or integrally related in some more comprehensive system of ideas. Failure to make the distinction between religion and morality runs the risk of subordinating both to prevailing cultural practices, which may themselves be morally questionable.

By the eighteenth century, European philosophers had begun to advance theories about the historical development of religion that were not based on the history presented in the Bible. Religion could thus be given a "natural history," as

opposed to the sacred history revealed in scripture. David Hume's "The Natural History of Religion" postulated a primitive connection between fear of the awesome power of natural forces and dread of punishment for moral transgressions. Such fear may continue to serve as a useful inducement to moral conformity, but it leads only to confusion if the source of the moral imperatives is sought in a supernatural power. Against those who worried that a distinction between religion and morality would lead to a decline in moral standards, Hume argued that a sound logical connection between moral requirements and the public good was the only secure basis for morality. A utilitarian calculation of the line of conduct that will produce the largest social benefits is the final source of moral norms, and respect for that public good is the only secure ground of moral motivation.

In addition to the possibility that the connection between religion and morality is simply a residue of primitive superstitions, philosophers noted another point that seemed not only to distinguish religion from morality, but also to give a logical priority to morality. Religious traditions frequently praise a divine center and origin of moral goodness, or point to the lives of exemplary religious figures as examples to be followed. To recognize that goodness seems, however, to require a moral judgment that precedes the religious assent. We can only praise God or emulate the saints for moral goodness if we have an idea of what is morally good, by which we measure even these supreme examples. "Even the Holy One of the gospel," wrote Immanuel Kant, "must first be compared with our ideal of moral perfection before we can recognize him as such" (p. 76).

Clearly, whether one begins with Hume's "natural history" of religion or Kant's rational foundation for moral judgments, morality and religion cannot be simply identical. The Christian natural law tradition used reason to discern God's will in the order of the created world. In Kant and Hume, reason formulates its requirements independently, on the basis of social utility or of logical necessity. The resulting standard of morality is then applied to religion, which may or may not measure up.

This separation of moral requirements from religious belief does not, however, imply that religion has no connection to morality. Many who accepted a rational morality, the requirements of which did not depend on faith, continued to value religion as a motive for the moral life. Love of a God who is perfect in goodness, and reverence for saints who have upheld the requirements of morality in the face of severe temptations, provide powerful motives for people to live up to moral expectations in more ordinary circumstances. Indeed, Kant argued that some conception of God is ultimately required to make sense of the sacrifices that all moral action requires of us. The logical independence of morality from religion does not require that religion be abandoned, but it does require that moral actions be undertaken precisely because we are convinced that they are morally right, and not because we believe that God commands us to do them.

These philosophical developments coincided with important historical changes in European religious life. By the end of the seventeenth century, the normative requirement of religious conformity was rapidly being replaced by practices of religious toleration and, eventually, by a civic commitment to religious freedom. The logical separation of religion from morality became a sociological necessity as well, if citizens who were no longer united in their religious beliefs were to acknowledge moral obligations to one another. In the United States, especially, the idea developed that a variety of quite different religious beliefs could support a common moral consensus (Frost). Because morality and religion are independent, diversity of religious beliefs need not lead to moral conflict, and moral order does not require religious agreement.

In other cases, where the break with traditional forms of religious and social life was sharper, or where the conflict between religious groups was more intense, public moral expectations were reformulated in nonreligious terms. Where cooperation between religion and government proved difficult, or where the moral consensus between different religious groups was obviously lacking, the concept of a "secular state" provided the necessary basis for social unity. A secular state not only refuses to privilege one or another religious perspective among its people, it resolutely excludes religious considerations from the formation of policy and regulations. Religion and religious morality become private considerations, subject to regulation for the public good.

This understanding first emerges clearly in the French Revolution, but the idea of a secular state has also provided hope for civil unity for many twentieth-century leaders in countries deeply divided by religious strife or torn by controversy over modernizations that undermine traditional forms of religious life. In the United States, where the prevailing model has been the religious consensus on moral expectations, elements of the secular state concept have nonetheless been invoked to curb sectarian religious practices that differ sharply from those of the majority, or to exclude religious arguments from controversial questions of policy. Judicial limitation of a parent's power to withhold medical care from children on religious grounds and political arguments that Roman Catholic opposition to abortion violates the constitutional separation of church and state are two instances in which the apparent lack of religious consensus has prompted arguments for policies of a secular state.

The logical separation of morality from religion, then, provides an important intellectual starting point for the ordering of societies divided by religious differences or seeking to modernize in the face of opposition by traditional religious groups. The distinction between religion and morality does not, by itself, prescribe a role for religion in public life. Religion may be one element in a powerful moral consensus that differs from the religious morality of a traditional society, or it may be virtually excluded from influence by a secular state that defines public morality in terms of a utilitarian calculation of the public good.

CULTURAL INTERDEPENDENCE. Although the logical separation of morality from religion is a premise for much of Western European and North American thought in ethics, law, politics, and even theology, its relevance to other points in history and other parts of the world is less clear. The modern Western distinction between religion and morality is missing from many highly developed religious and cultural systems, which assign duties to persons on the basis of their position in society without obvious distinctions between what modern Westerners differentiate into moral requirements, common courtesy, religious obligations, and patriotic duties.

This is most clear in the traditional societies of India, China, and Japan. Hinduism recognizes few duties that correspond to the universal moral obligations of modern Western ethics. Specific persons owe duties to specific others, based on the place each occupies in a social, moral, and religious hierarchy, so that traditional Hinduism can hardly exist outside of the social system in which it originates. In China, a Confucian system of philosophical morality was tied to the details of the education and duties of an elite corps of governing intellectuals, while in Japan, the traditional religion of the people centered on the cults of specific ancestors and the spirits of specific places. Hinduism and, to a certain extent, Confucianism demonstrated in the nineteenth century that they could be reinterpreted in more universal philosophical terms, but the reconstruction of State Shinto in Japan during the same time period suggests that the unitary system of religion, state, and morals can also be adapted to the demands of modernizing societies (Hardacre).

While the interdependence of religion and culture is most clearly seen in these highly developed national traditions, the missionary religions that have moved across large parts of the world also illustrate this interdependence, precisely in their adaptability to very different cultural settings. Christianity presents very different appearances in Moscow and in Dallas. Buddhism in Tokyo is distinctively Japanese, as it is distinctively Thai in Bangkok. The same might be said for Islam in Cairo and in Kuala Lumpur. Nor are these variations simply the result of a constant teaching consciously applied to different situations. Religious traditions develop by interacting with the economic life and productive systems by which their adherents meet their material needs, as well as by the inner logic of their spiritual teachings. The modern sociological study of religion rests on this awareness of the nonreligious forces that operate on religious communities and the unintended consequences that religious beliefs have in the world of economic life (Weber).

Those who view religion from this perspective identify important changes that religions undergo in modern, technological societies. The institutions of religion no longer occupy the central positions of power and authority they once held. Wider knowledge of the world and more exposure to other cultures lead to an awareness of other religions beside one's own. These changes mark what sociologists call secularization, but the interactions of religion and culture are no less real in that context than they were when religion had a more dominant position.

Secularization may reduce the power of religions institutions and leaders, but it does not produce a neutral culture free of religious influences. A "secular" society is shaped in part by the historical interactions between the religion and culture that have shaped the particular place in which the society now exists. A modern economy influenced by a Confucian past differs significantly from one that has developed out of European Protestantism. The process of secularization, therefore, does not provide a neutral, universal standpoint from which to settle questions of morality and policy.

Since the 1970s, social scientists, philosophers, and theologians have widely accepted this contextualization of their work and have sought to explore its implications for their systematic thought (Stout). What was believed to be universal and rational is now widely seen to be particular. Notions of objectivity, tables of individual rights and duties—even, perhaps, the idea of rationality itself—are shaped by particular cultural starting points.

Where supposed neutrality and rational authority have been used to suppress religious conflict, the continuing influence of religion on culture sometimes results in violent rejection of the secular state and its institutions. Fundamentalist movements throughout the Islamic world and among Hindus in India reject modern secular culture as an alien Western imposition and reassert an identity of religion, morality, and culture. In the United States and elsewhere, renewed interest in the religions of indigenous peoples includes a rediscovery of their distinctive understandings of

health and healing, which link religion, morality, and medicine in ways unfamiliar to modern medical science (Sullivan).

The implications of this reassertion of the cultural integrity of religion and morality are, however, variously construed by authors reflecting on modern pluralistic societies. One view suggests that the loss of community and the rise of social disorder is a direct result of the attempt to exclude from public discussion the religious values that are the only available foundation for morality. The social achievements that people in the United States most prize, including their individual rights and political freedoms, are simply the fruit of the Christian moral traditions that gave rise to them. If we hope to continue to enjoy them, we must restore those moral traditions in which they originate to a central role in shaping the life of society (Neuhaus).

Another point of view suggests, by contrast, that the public life of a pluralistic society can no longer provide a forum for genuine moral convictions, which always have a particular religious basis. If we seek to develop persons of moral character, we must do it within religious communities that have a distinctive identity. It may then be possible to translate some of these religious values into public policy through political action, but it will not be possible to offer a public argument for the values at stake. They can only be understood in a community where the way of life in which they originate is cherished and enacted (Hauerwas).

An understanding of the cultural interdependence of religion and morality thus calls into question both the cosmic order that sustains religion's requirements everywhere and the universal, rational morality that is characteristic of modern understandings of the independence of morality from religion. In this emphasis on cultural specificity that is sometimes called "postmodern," everything depends on the relationship between religion and morality in a particular place and time. Those who hold this view agree on the importance of the interaction of morality and religion. They differ over whether this interaction should take the form of cultural hegemony by a particular religious tradition, in order to provide the necessary foundation for public order, or should be practiced in small communities of shared faith, who venture into politics and public policy only for limited purposes and confine their virtues to their separated life.

Implications for Bioethics

Perhaps the most striking result of this survey is the diversity of relationships between religion and morality that are held in different religious traditions and, indeed, within the same religious tradition, in different historical and cultural settings. In a pluralistic society, where researchers often work in global networks and medical-care providers deal with patients and families from many communities, many different understandings of morality and religion will impinge on their work, raising new issues in bioethics.

Questions of patient autonomy and appropriate respect for the human subjects of biomedical research become even more difficult when the parties have not only different religious beliefs about the nature of the human being, but also different understandings of how these beliefs appropriately relate to moral decisions that doctor and patient, researcher and subject, primary parties and review committees must make together. Conflicts may arise, for example, when medical personnel appeal for decisions on clinical or scientific grounds to patients and families whose beliefs do not admit nonreligious reasons for decisive personal choices. It is important in the first instance simply to be aware of this diversity of moral and religious perspectives and alert to their relevance to professional choices. Even specialists who are well trained in bioethics often uncritically accept the viewpoint that morality is logically independent of religion, because that is the position of the moral philosophy that has provided much of the theoretical framework for contemporary bioethics. Without awareness of the other possibilities this entry has surveyed, significant moral issues may be overlooked until they become the subject of public controversy or undermine the relationship of trust between medical-care providers and patients.

Investigations of the cultural interdependence of religion and morality may make us aware of serious moral claims. What a patient believes about ritual purity or about the fate of the soul after death deserves more than just respectful interest. It may determine what it means to treat that patient as a free person with an inherent dignity. In any case, the cultural specificity of all moral and religious perspectives should also alert us to the limitations of the claims of biomedical science.

Cultural interdependence opens up possibilities for serious conflicts between cultural perspectives in medical and scientific institutions. Often, research and clinical personnel do not share the commitments of universities or hospitals that have religious sponsorship. An ethical commitment to scientific objectivity or clinical autonomy, which is easy to sustain when religion and morality are believed to be logically distinct, may come into conflict with the view that sustaining a distinctive religious culture within the institution is the only way to sustain it as a moral community. Alternatively, religious views that stress the importance of distinctive moral communities may withdraw from the more complex, pluralistic world of the medical center or research institute, thus eliminating a possibly important mediating influence between the narrowly focused aims of

medical practice and the values of ordinary Jews, Catholics, Muslims, or Baptists who happen for the moment to be patients in a medical facility.

The increasing cultural complexity of biomedical science and its institutions prompts the search for a core of morality that would provide the basis for policy decisions, without requiring unanimity on the religious reasons for those moral requirements. Logical independence of this common morality from particular religious commitments seems to be required, whether the morality is to be founded on a universal moral logic or, less ambitiously, on the necessary requirements of medical practice. Although the idea of a completely neutral, secular medical ethics may no longer be plausible, a standard of "secular arguments" for policy choices seems to some observers to solve the problem of moral and religious difference. By insisting that arguments for or against specific policy choices must be made for reasons accessible to all parties in the debate, we eliminate public choices based on specific religious convictions. Arguments for or against a program of acquired immunodeficiency syndrome (AIDS) education and prevention on ground of its effect on community health are acceptable. Arguments for or against it on grounds that it conforms to the requirements of a specific religious teaching are not.

While the standard of "secular arguments" or "publicly accessible reasons" is appealing, it presupposes a very large area of public moral consensus. Although some such consensus does exist, its scope is unclear, and there is no guarantee that it is actually broad enough to resolve the difficult bioethical issues that divide society today. In short, it may be that a strictly defined "secular argument" will be insufficient to yield a determinate solution to the problems, that some appeal to the religious convictions or other private views of the participants will be necessary if we are to settle the questions at all (Greenawalt).

Efforts to define an independent system of morality, in which bioethical issues could be resolved without reference to the diversity of religious moral positions, are thus subject to a variety of problems. The issues range from attacks on the supposed neutrality and objectivity of secular scientific inquiry, to the criticism that if it should achieve this neutrality, it would be unable to provide determinate solutions to policy questions that have been posed to medicine and science.

Another possibility, however, is to accept the unity of religious and moral discourse and ask whether biomedical science and clinical practice might participate in it. Physicians and other providers of medical services have ideas about human flourishing based on long experience with patients and clients. Scientific research may confirm or disprove widespread convictions about the best means to achieve and sustain a good life, and it may provide new evidence of causal links between choices and outcomes. Discussion of the human good typically takes quite different forms from the highly structured discourse of the biomedical sciences, but those sciences clearly do have a contribution to make to it.

Beliefs that hold that there is a cosmic unity of religion and morality, a single reality in which religious and moral truths make sense together, offer the clearest opportunities for biomedical participation. This openness is most apparent in contemporary formulations of natural law theory, which explicitly make use of biomedical knowledge as part of the determination of what is natural and what the conditions for human flourishing are. Even where religious traditions have not developed systematic statements, however, their narratives and rituals make implicit claims about the constraints that the world imposes on human life, and about what human beings must do to live well within those limits (Lovin and Reynolds).

Where these myths, narratives, hymns, and rites are taken to be rivals to a scientific account of reality, there will inevitably be conflicts between the biomedical sciences the religious ideas about morality. But religious discourse is never simply an objective account of the way things are. It is always also an orientation of human life within that world of facts, and the physician's or the medical researcher's account of those facts may have a place in that orientation. Such an understanding neither separates religion from morality, nor links them both to a specific cultural system, but regards morality as an orientation of human life within a reality that is susceptible both to scientific examination and to the imaginative and liberating comprehension that religion offers.

Those who seek to join a discussion of the human good in which both religious wisdom and scientific discovery have a place must acknowledge that there are other views, religious and scientific, that will reject that collaboration. A moral realism that links religion, science, and morality may provide the best framework for biomedical researchers and clinicians to explain the ethical implications of their work in terms that many religious traditions can accept.

ETHICS COMMITTEES AND ETHICS CONSULTATION

• • •

The dominant mechanism for dealing with clinical ethics problems in healthcare at the beginning of the twenty-first century is the ethics committee. Present in various capacities since the 1960s, ethics committees in their contemporary form emerged in the late 1970s and 1980s in response to the growing need for a formal means to address ethical issues in clinical settings (Fost and Cranford). Early ethics committees were typically staffed by physicians and convened on an *ad hoc* basis. Indeed, in the period immediately following *In re Quinlan* (1976), ethics committees functioned largely as prognosis committees for difficult end-of-life cases in acute care settings. A 1983 study indicated that only about 1 percent of all U.S. hospitals had ethics committees, a figure that is consistent with this very limited function (Youngner, Jackson, Coulton, et al.). As awareness of the value-laden nature of clinical decision making grew, so did the role and number of ethics committees. Just four years later, a 1987 study suggested the presence of ethics committees in over 60 percent of U.S. hospitals (Fleetwood, Arnold, and Baron). In 1998–1999, the University of Pennsylvania Ethics Committee Research Group (ECRG) conducted the most comprehensive study of ethics committees to date and found that approximately 93 percent of U.S. hospitals have ethics committees (McGee, Caplan, Sanogle, et al.). Around the same time, an Agency for Healthcare Research and Quality (AHRQ) study of ethics consultation in U.S. hospitals, a standard function of ethics committees today, found ethics consultation services in all U.S. hospitals with 400 beds or more, all federal hospitals, and all hospitals that are members of the Council of Teaching Hospitals (Fox). Though there has been no systematic study of the presence of ethics committees outside of hospital settings, it should be noted that ethics committees are present in many other healthcare settings, such as long term care, hospice, and even home care.

Contemporary ethics committees are usually standing committees with multidisciplinary representation, including medicine, nursing, social work, law, pastoral care, healthcare administration, and various specialty areas (McGee, et al.). The primary functions of contemporary ethics committees are ethics education, policy formation and review, and ethics consultation, in decreasing order of time commitment (McGee, et al.).

Education

In re Quinlan gave impetus to the development of early ethics committees. Since, as mentioned above, these committees were largely staffed by physicians and primarily concerned with prognosis issues in end-of-life situations, the educational needs of ethics committee members were rather narrowly focused. Encouraged, among others, by a President's Commission (1983), professional societies such as the American Medical Association (1985), and accrediting bodies such as the Joint Commission on the Accreditation of Healthcare Organizations (JCAHO, 1992), ethics committees evolved to become the primary mechanism through which clinical ethics issues are formally addressed. Educational efforts of a thriving ethics committee should include self education, education of health professionals and staff, and community outreach. Of these, self education is critical as it is an important precondition of both sound policy formation and review and ethics consultation. Consistent with this, the 1999 ECRG study indicated "self education" as the single activity to which ethics committees devoted the highest percentage of time (McGee, et al.).

Though physicians and nurses make up the largest majority of ethics committee membership, most ethics committees are multidisciplinary with members from social work, pastoral care, legal, and administration, among others (McGee, et al.). This broad spectrum of health professionals brings valuable experience and perspective in dealing with clinical ethical issues, which are inevitably complex and multilayered. The vast majority of ethics committee members, however, have no formal education or training in clinical ethics; thus self education is an important ethics committee activity (Fox; McGee, et al.). Indeed, in the 1999 ECRG study mentioned above, half of all ethics committee chairs reported "feeling inadequately prepared to address" the issues they face (McGee, et al.). This is not surprising, given that ethics committees face an array of complex clinical ethics issues, including informed consent and refusal of treatment, decision capacity or competence, confidentiality and privacy, minors and decision making, and a host of issues related to end of life decision making. To deal with these and other clinical ethics issues, ethics committees need to have a sustained self-education program.

Ethics committees have used a variety of means to meet this need. Ethics committees at academic medical centers, for example, often have members who are bioethics faculty at their respective centers or departments who are able to offer (or arrange for) ethics education for the committee. Some ethics committees that are part of large integrated systems may have access to system-supported centers or departments of clinical ethics that themselves offer ethics education for committee members. A notable example of this is the Veterans Health Administration (VHA), which has established a National Center for Ethics in Health Care, in part to assist in meeting the educational needs of ethics committee members throughout the VHA network (Glover and Nelson). Ethics committees without access to these types of resources might identify one or two members willing to do formal education and training in clinical ethics through the completion of a clinical bioethics degree, fellowship, or certificate program. Other ethics committees avail themselves of sustained continuing ethics education offered through regional ethics networks such as the University of Pittsburgh's Consortium Ethics Program (Pinkus), the Midwest Ethics Committee Network of the Medical College of Wisconsin (Kuczewski), or the West Virginia Network of Ethics Committees (Moss). These efforts foster partnerships to bring the bioethics resources often present in primarily academic settings to serve the broader healthcare community (Glover and Nelson).

Policy Formation and Review

A second important function of ethics committees is policy formation and review. The type and number of policies that are formulated or reviewed by the ethics committee will vary depending on the nature of the institution, and the authority and responsibility of the ethics committee. For example, a medical-staff-level ethics committee at a major academic medical center may have input on a large number of ethics-related policies. In addition to any policy governing the ethics committee itself, these might include policies governing informed consent, end-of-life decisions (e.g., advance directive and life-sustaining treatment policies), brain death, organ donation and transplant, disclosure of medical mistakes, and so forth. Indeed, the policy formation and review function of ethics committees has developed to the point where a number of "model policy" manuals are available as resources for ethics committees that may be struggling to establish themselves (Aspen Health and Administration Development Group). In addition to these more traditional

ethics policy areas, ethics committees are increasingly being asked to give input on organizational ethics issues, especially when these issues may have an impact on patient care (Schyve, Emanuel, Winslade, et al.). The JCAHO ethics standards, for example, extend to organizational ethics issues (e.g., marketing, billing, financial incentives for clinicians, and so forth) and explicitly acknowledge the interdependence of patient rights and organizational ethics (see JCAHO, 2002).

Ethics Consultation

Ethics consultation, perhaps the best known and most discussed function of ethics committees, commands only about 20 percent of ethics committee effort, with the average number of consults ranging from twelve to twenty-three per year (McGee, et al.). Though variously defined, ethics consultation is "… a service provided by an individual or a group to help patients, families, surrogates, healthcare providers, or other involved parties address uncertainty or conflict regarding value-laden issues that emerge in healthcare" (American Society for Bioethics and Humanities, p. 3). Clinical ethics consultation focuses on ethical issues that arise in specific clinical cases and on policy consultation regarding patient care issues. As noted above, partly due to the rise of managed care in the United States, the 1990s brought a growing awareness of the important relationship between clinical and organizational ethics, thereby raising the visibility of organizational ethics consultation. The mid- to late-1990s also saw the first national level effort in the United States to set voluntary standards for ethics consultation when the American Society for Bioethics and Humanities (ASBH) released its report *Core Competencies for Health Care Ethics Consultation.* The report was the result of a two year effort by a national task force on standards for bioethics consultation which functioned as a consensus panel.

The prevalence of ethics consultation is hard to gauge. Ellen Fox's AHRQ supported study of ethics consultation in U.S. hospitals found that approximately 81percent of all U.S. hospitals have an ethics consultation service of some kind; ethics consultation services were found to be present in 100 percent of hospitals with 400 beds or more, federal hospitals, or hospitals that are members of the Council of Teaching (Fox). The same study estimated that each year in U.S. hospitals, approximately 35,000 individuals are involved in performing over 15,000 ethics consultations. The predominant model for ethics consultation is a small team approach (68%), as opposed to a full committee (23%) or an individual consultant (9%). Of those doing ethics consultation, 36 percent are physicians, 30 percent are nurses, 11 percent are social workers, 10 percent are chaplains, and 10 are administrators, while less than 1 percent are philosophers or theologians. Only 5 percent of those doing ethics consultation were reported to have completed a fellowship or degree program in bioethics or to have had any formal education or training for ethics consultation other than direct supervision (Fox).

From its inception in the late 1960s and early 1970s through the present, ethics consultation has raised a number of controversial questions (LaPuma and Schiedermayer; Singer, Pellegrino, and Siegler; Fletcher, Quist, and Jonsen). Some of these questions are directly attributable, no doubt, to the fact that ethics consultation emerged in part to address highly-charged and conflicted issues such as withholding or withdrawing life-sustaining treatment (see also *In re Quinlin*). Other questions, however, are endemic to the practice of ethics consultation. These include both practical and theoretical questions such as: What types of issues are involved in ethics consultation? Is ethics consultation best done by individuals, teams or committees? What is an appropriate approach to ethics consultation? What types of skills and knowledge are important for doing ethics consultation? Should those doing ethics consultation be required to be certified or accredited in some way? How might ethics consultation be evaluated?

In order to see the controversial and complex nature of these questions, it will be helpful to consider a case that is fairly representative of the types of cases that are brought to ethics consultation services, the Case of Mr. Jones:

> Mr. Jones, an 82 year old man, came to the ER with a gangrenous leg. He had fallen in his apartment and was unable to contact family or friends. Mr. Jones was discovered by his niece, his closest living relative, two days later. Mr. Jones, who was otherwise healthy, needed to have his leg amputated in order to save his life (without amputation he was likely to die from septicemia). Mr. Jones adamantly refused amputation and expressed a deep desire to die "in one piece." Mr. Jones' niece was devastated by his refusal of amputation and wanted the healthcare team to save her uncle's life. Mr. Jones' niece felt responsible for his condition since she was supposed to check-in on him everyday, but she had missed a day due to illness. Members of the healthcare team were split over whether Mr. Jones' refusal of treatment should be honored. The attending physician believed that the team had a moral obligation to go ahead with amputation since it was a "straightforward, relatively low risk, procedure that could save Mr. Jones' life." He argued that the procedure was

> "ordinary," not "extraordinary," and therefore obligatory. He emphatically stated "I became a doctor to save life, not to watch people die because they are afraid!" Other members of the healthcare team, especially several nurses, thought Mr. Jones' wishes should be respected. Some worried, however, that Mr. Jones might be depressed and was trying to kill himself by refusing amputation. An ethics consultation was called to resolve the conflict. (Aulisio, 1999, p. 211)

TYPES OF ISSUES. Clinical ethics consultation typically involves any of a range of clinical ethics issues, including informed consent, decision capacity, surrogate decision making, confidentiality and privacy, and a variety of issues surrounding end of life care (ASBH). The best current data suggests that a number of different types of cases are brought to ethics consultation and that these cases themselves may involve a variety of issues. For example, the ECRG study by McGee, et al. lists research trials, new technologies, patient autonomy and competency, cost containment, distribution of goods, improving communications, clinician competency, and end-of-life decision making as among the most common issues raised in ethics consultation. Among these, the largest percentage by far fall into three categories: patient autonomy and competence (38%±25%); improving communications (35%±26%); and end of life (7%±21%).

The case of Mr. Jones, however, illustrates well how a single case can (and often does) raise multiple issues, and the problem of categorizing cases. The case surely raises questions about patient autonomy and competence, as some members of the healthcare team fear that Mr. Jones may be depressed and "trying to kill himself" by refusing amputation. The case also raises questions about end-of-life decision making: Should Mr. Jones, even if competent and well informed, be allowed to refuse a life saving intervention? What is an appropriate role for family members or loved ones in end-of-life (or other) decisions? When are health professionals obliged to accede to patient wishes? Are health professionals ever permitted to override patient wishes or refuse to participate in certain patient decisions? Lastly, the case might just as easily be categorized as an "improving communications" case. Mr. Jones, for example, may simply not understand that he will die without the amputation due to septicemia, because he is confused by technical medical terminology or because he mistook probabilistic language as uncertainty on the part of his doctors.

In addition to the multiple issues that might be raised in a single case, the actual practice of ethics consultation differs from mere case analysis in important ways. As the 1998 ASBH report states, "The actual cases that give rise to these questions frequently also have complex interpersonal and affective features, such as guilt over a loved one's sickness or impending death, disagreement among healthcare providers, possible conflicts of interest, or distrust of the medical system. Increasingly, ethical issues regarding clinical care are raised or complicated by organizational factors" (ASBH, p. 3).

Even from a distance, one can discern these features in the case of Mr. Jones. His niece's feeling of guilt is a powerful factor in the case, as are divisions among members of the healthcare team. These factors are compounded by the time pressures of a real case, i.e., that a decision must be made and soon.

INDIVIDUALS, TEAMS, OR COMMITTEES. Though nearly always conducted under the auspices of an ethics committee, ethics consultation may be done by individual consultants, small groups or teams, or a full ethics committee. Which of these models is best is a matter of some controversy (Rushton, Youngner, and Skeel). Consultation by ethics committee was the dominant model following the *Quinlan* case and the rise of ethics committees in general. If ethics consultations are rare and called only in crisis situations, consultation by a full committee may be practical; however, the more active the consult service the more cumbersome full committee consults will be. Full committee consults also tend to be more formal and adversarial (Rushton, et al.). In contrast, consultation by an individual ethics consultant, though possibly present in a few U.S. healthcare institutions as early as the late 1960s or early 1970s, grew in popularity through the early 1990s at least in part as an alternative to full committee consults. Criticized by some as anti-democratic, the individual consultant model, though efficient, is impractical for many institutions because of the knowledge, skill and time demands it places on one person (Rushton, et al.). A small ethics consult team that functions as an extension of the ethics committee is probably the best model for most institutions. Not surprisingly, in U.S. hospitals today, as noted above, the predominant model for ethics consultation is a small team (Fox).

APPROACHES TO ETHICS CONSULTATION. A number of different approaches to ethics consultation can be found in the literature (Agich; ASBH; Rubin and Zoloth-Dorfman; Zaner). These range from those focused primarily on conflict resolution through facilitation or negotiation, to those that emphasize consensus building, to more directive approaches aimed at guiding participants to the morally "right" solution. One of the challenges for proponents of ethics consultation over the years has been to carve out a role for it

that is consistent with societal values. In the United States, this means creating a model of ethics consultation that is consistent with the defining characteristic of a liberal society: that no particular set of substantive moral values should be politically privileged. For example, in the case of Mr. Jones, all involved parties have a right to their moral views and those moral views are widely divergent. Indeed, it is arguably the convergence of these features with the complex and value-laden nature of medical decision making that creates the need for ethics consultation in contemporary clinical settings (Aulisio, 2003).

In the case of Mr. Jones, the intersection of these factors leads to a value conflict that raises a question regarding the role of ethics consultation. Whether or not it is "right" to amputate Mr. Jones's leg depends, in part, on the individual set of values through which the decision is assessed. Mr. Jones's niece and the attending physician think that the morally right course is to amputate Mr. Jones's leg, but for different reasons. Mr. Jones, because he values "dying whole," considers the morally right course to be one that allows him to keep his bodily integrity, even if it ultimately leads to his death. According to the case vignette, "an ethics consultation was called to resolve the conflict," but how should the conflict be resolved? The ethics consultants themselves will bring their own moral values to the case. Should they help resolve the case based on whether their moral values are more in line with those of the doctor, nurse, niece, or patient? Do they get to play the role of the moral sage, adjudicating on who is morally right—that is, who has the correct values? What is the role of ethics consultation in such a case?

The most strident critics of ethics consultation have made much of this problem, claiming that ethics consultation is at odds with democratic values (Ross; Scofield). Democratic values alone, however, would leave ethics consultation susceptible to a tyranny of the majority, in which the morally appropriate course might be determined, for example, by a vote. The deeper question is whether there is an appropriate role for ethics consultation that is consistent with the rights of individuals to live by their values (that is, consistent with a liberal society) (May). The 1998 ASBH report recognized the importance of societal context in informing a proper role for ethics consultation when it stated that:

> … societal values frame the context in which ethics consultation occurs and, therefore, shape the appropriate role for ethics consultation in contemporary healthcare settings. Individuals, for example, do not give up the right to live by their own moral values when they become patients or take up the practice of healthcare. These rights set boundaries that must be respected in ethics consultation, and they often suggest who has decision-making authority in different types of cases. Discussions of these boundaries, not surprisingly, comprise a large portion of the bioethics literature (e.g., explorations of informed consent, autonomy, confidentiality, privacy, resource allocation, and conscientious objection). Indeed, helping to identify the implications of these rights and who has decision-making authority in particular cases is an important role for healthcare ethics consultation in our society (p. 4).

Though a full characterization of any approach to ethics consultation is well beyond the scope of this entry, it should be noted that the ASBH report does go on to endorse what it terms an "ethics facilitation" approach to ethics consultation that is intended to be consistent with the societal context described above. "Ethics facilitation," according to the report, aims at "identifying and analyzing the nature of the value uncertainty" that underlies the request for consultation and "facilitating the building of consensus" among involved parties (pp. 6–7). This approach is contrasted with what the report terms "pure facilitation" and "authoritarian" approaches to ethics consultation, which risk running afoul of appropriate boundaries for ethics consultation and displacing those with legitimate decision-making authority. The "ethics facilitation" approach aims at consensus building but in deference to the decision-making authority of involved parties. Indeed, when a consensus cannot be reached, the report recommends that

> … the proper course of action can sometimes be determined by answering the question "Who should be allowed to make the decision?" Societal values often indicate who should be allowed to make the decision in the absence of consensus. As several of the cases above underscore, the right of a competent and well informed patient to refuse treatment typically establishes decision-making authority even if some family members or healthcare providers disagree with the decision. Similarly, the right of conscientious objection typically gives a healthcare provider the authority to refuse to participate in a procedure that would seriously violate his or her conscience even if a patient and/or family wants the provider to participate (p. 8).

It is important to note that, at a general level, the ethics facilitation approach as characterized in the ASBH report is far more concerned with who has the right to decide than with who is right, and with building a consensus that respects legitimate decision-making authority. In the case of

Mr. Jones, this would require establishing whether he is competent and well informed. If so, his moral and political right to accept or refuse treatment is firm and, thus, any consensus will have to respect his decision-making authority (this does not preclude compromises or even a change of heart on his part). It is also important to highlight the general nature of the ethics facilitation approach and its potential compatibility with many different consult models and methodologies. Attempts to offer normative characterizations of ethics consultation, with their attendant methodological questions, will undoubtedly continue to receive attention in the coming years.

SKILLS AND KNOWLEDGE. Just as there is some disagreement about broad approaches to ethics consultation and more particular methodological issues regarding how ethics consultations should be done, there is also some disagreement about the skills and knowledge required to do ethics consultations. Some emphasize the importance of a strong clinical background such as medicine or nursing, while others emphasizes the importance of formal education and training in ethics, or, more commonly, bioethics (LaPuma and Schiedermayer; Baylis). Despite the disagreements in emphasis, there are some broad areas of agreement regarding core skills and knowledge for ethics consultation. The ASBH Task Force tried to capture these in its 1998 report, *Core Competencies for Ethics Consultation.*

The 1998 ASBH report articulated the broad skill areas as including interpersonal, process, and ethical assessment. Ethical assessment skills are those involved in identifying and analyzing the ethical issues that arise in specific clinical cases. This might include the ability to distinguish the ethical from other (e.g., legal, medical, psychiatric) dimensions of the case, identify relevant values, clarify key concepts, and justify a range of morally acceptable options given the contextual features of the case. Certain types of process skills, such as the ability to facilitate meetings and build consensus, are likewise central to helping to resolve ethical conflicts in actual cases. Finally, certain types of interpersonal skills are critical to nearly every aspect of ethics consultation. For example, the ability to listen well and to communicate interest, respect, support, and empathy to involved parties will be important throughout the consult process.

With respect to important knowledge areas for those doing ethics consultation, the 1998 ASBH report emphasized the importance of advanced knowledge in three areas as they relate to ethics consultation: moral reasoning and ethical theory; bioethical issues and concepts; and local healthcare institution's relevant policies. The report identified six additional areas in which those doing ethics consultation should have basic knowledge: clinical context, relevant health law; knowledge of local healthcare institution, beliefs and perspectives of patient and staff population, relevant codes of ethics and professional conduct, and guidelines of accrediting organizations.

It is important to underscore that the skill and knowledge can be distributed across a small team or even a full committee, depending on the model for ethics consultation employed. As noted above, over 90 percent of U.S. hospitals employ a team or committee approach, while less than 10 percent employ an individual consultant. The "core competency" recommendations are fair less onerous when considered against this backdrop. Individual ethics consultants, however, may need to supplement their professional backgrounds in order to satisfy these recommendations. This is discussed in the ASBH report and elsewhere (Baylis).

Conclusion

There are, of course, a plethora of other issues that must be addressed as ethics committees and ethics consultation continue to evolve and develop. These include questions concerning how their activities might be evaluated, legal liability for committees and consultants, and the ever-present question of whether committees or consultants should be certified or accredited in some form. Some of the data considered above, however, suggest a more immediate and pressing concern. Recall that contemporary ethics committees are usually standing committees with multidisciplinary representation, including medicine, nursing, social work, law, pastoral care, healthcare administration, and various specialty areas, and that half of all ethics committee chairs reported "feeling inadequately prepared to address" the issues they face (McGee, et al.). Even more concerning, recall that only 5 percent of those doing ethics consultation were reported to have completed a fellowship or degree program in bioethics, or to have had any formal education or training for ethics consultation other than direct supervision (Fox). Perhaps the single biggest challenge in the immediate future, then, will be helping to ensure that ethics committee members and ethics consultants have adequate education and training to carry out the important work that is entrusted to them.

EUGENICS

I. HISTORICAL ASPECTS

The word "eugenics" was coined in 1883 by the English scientist Francis Galton, a cousin of Charles Darwin and a pioneer in the mathematical treatment of biological inheritance. Galton took the word from a Greek root meaning "good in birth" or "noble in heredity." He intended the term to denote the "science" of improving human stock by giving the "more suitable races or strains of blood a better chance of prevailing speedily over the less suitable" (Kevles, p. ix).

The idea of eugenics dated back at least to Plato, and discussion of actually achieving human biological melioration had been boosted by the Enlightenment. In Galton's day, the science of genetics had not yet emerged: Gregor Mendel's 1865 paper, the foundation of that discipline, was not only unappreciated but also generally unnoticed by the scientific community. Nevertheless, Darwin's theory of evolution taught that species did change as a result of natural selection, and it was well known that through artificial selection farmers and flower fanciers could obtain permanent breeds of animals and plants strong in particular characters. Galton thus supposed that the human race could be similarly improved—that through eugenics, human beings could take charge of their own evolution.

The idea of human biological improvement was slow to gather public support, but after the turn of the twentieth century, eugenics movements emerged in many countries. Eugenicists everywhere shared Galton's understanding that people might be improved in two complementary ways—to use Galton's language, by getting rid of the "undesirables" and by multiplying the "desirables" (Kevles, p. 3). They spoke of "positive" and "negative" eugenics. Positive eugenics aimed to foster greater representation in a society of people whom eugenicists considered socially valuable. Negative eugenics sought to encourage the socially unworthy to breed less or, better yet, not at all.

How positive or negative ends were to be achieved depended heavily on which theory of human biology people brought to the eugenics movement. Many eugenicists, particularly in the United States, Britain, and Germany, believed that human beings were determined almost entirely by their germ plasm, which was passed from one generation to the next and overwhelmed environmental influences in shaping human development. Their belief was reinforced by the rediscovery, in 1900, of Mendel's theory that the biological makeup of organisms was determined by certain "factors," which were later identified with genes and were held to account for a wide array of human traits, both physical and behavioral, "good" as well as "bad."

In the first third of the twentieth century, eugenics drew the support of a number of leading biologists, not only in the United States and western Europe but also in the Soviet Union, Latin America, and elsewhere. Many of these biologists came to the creed from the practice of evolutionary biology, which they extrapolated to the Galtonian idea of taking charge of human evolution. One of the most influential was Charles B. Davenport, the head of the Station for Experimental Evolution, a part of the Carnegie Institution of Washington and located at Cold Spring Harbor, New York, where Davenport established the Eugenics Record Office. Other eugenic enthusiasts included, in the United States, the biologists Raymond Pearl, Herbert S. Jennings, Edwin Grant Conklin, William E. Castle, Edward M. East, and Herman Muller; in Britain, F. A. E. Crew, Ronald A. Fisher, and J. B. S. Haldane; and in Germany, Fritz Lenz, who held the chair of racial hygiene in Munich, and Otmar von Verschuer.

Some eugenicists, notably in France, assumed that biological organisms, including human beings, were formed primarily by their environments, physical as well as cultural. Like the early-nineteenth-century biologist Jean Baptiste Lamarck, they contended that environmental influences might even reconfigure hereditary material. Environmentalists were mainly interested in positive eugenics, contending that more attention to factors such as nutrition, medical care, education, and clean play would, by improving the young, better the human race. Some urged that the improvement should begin when children were in the womb, through sound prenatal care. The pregnant mother should avoid toxic substances, such as alcohol. She might even expose herself, for the sake of her fetus, to cultural enrichment, such as fine plays and concerts.

Individuals with good genes were assumed to be easily recognizable from their intelligence and character. Those with bad genes had to be ferreted out. For the purpose of identifying such genes, in the early twentieth century eugenics gave rise to the fist programs of research in human heredity, which were pursued in both state-supported and private laboratories established to develop eugenically useful

knowledge. The Eugenics Record Office at Cold Spring Harbor was typical of these institutions; so were the Galton Laboratory for National Eugenics at University College (London), whose first director was the statistician and population biologist Karl Pearson, and the Kaiser Wilhelm Institute for Anthropology, Human Heredity, and Eugenics in Berlin, which was directed by the anthropologist Eugen Fischer. Staff at or affiliated with these laboratories gathered information bearing on human heredity by examining medical records or conducting extended family studies. Often they relied on field workers to construct trait pedigrees in selected populations—say, the residents of a rural community—on the basis of interviews and the examination of genealogical records. An important feature of German eugenic science was the study of twins.

However, social prejudices as well as dreams pervaded eugenic research, just as they did all of eugenics. Eugenic studies claimed to reveal that criminality, prostitution, and mental deficiency (which was commonly termed "feeblemindedness") were the products of bad genes. They concluded that socially desirable traits were associated with the "races" of northern Europe, especially the Nordic "race," and that undesirable ones were identified with those of eastern and southern Europe.

Eugenics entailed as many meanings as did terms such as "social adequacy" and "character." Indeed, eugenics mirrored a broad range of social attitudes, many of them centered on the role in society of women, since they were indispensable to the bearing of children. On the one hand, positive eugenicists of all stripes argued against the use of birth control or entrance into the work force of middle-class women, on grounds that any decline in their devotion to reproductive duties would lead to "race suicide." On the other hand, social radicals appealed to eugenics to justify the sexual emancipation of women. They contended that if contraception were freely available, women could pursue sexual pleasure with whomever they wished, without regard to whether a male partner was eugenically promising as a father. If and when a woman decided to become pregnant, then her choice of the father could focus on the production of a high-quality child. Sex for pleasure would thus be divorced from sex for eugenic reproduction.

In practice, little was done for positive eugenics, though eugenic claims did figure in the advent of family-allowance policies in Britain and Germany during the 1930s, and positive eugenic themes were certainly implied in the "Fitter Family" competitions that were a standard feature of eugenic programs held at state fairs in America during the 1920s. In the interest of negative eugenics, germ-plasm determinists insisted that "socially inadequate" people should be discouraged or prevented from reproducing themselves by urging or compelling them to undergo sterilization. They also argued for laws restricting marriage and immigration to their countries, in order to keep out genetically undesirable people.

In the United States, eugenicists helped obtain passage of the Immigration Act of 1924, which sharply reduced eastern and southern European immigration to the United States. By the late 1920s, some two dozen American states had enacted eugenic sterilization laws. The laws were declared constitutional in the 1927 U.S. Supreme Court decision of *Buck v. Bell,* in which Justice Oliver Wendell Holmes delivered the opinion that three generations of imbeciles are enough. The leading state in this endeavor was California, which as of 1933 had subjected more people to eugenic sterilization than had all other states of the union combined (Kevles).

At the time, a number of biologists, sociologists, anthropologists, and others increasingly criticized eugenic doctrines, contending that social deviancy is primarily the product of a disadvantageous social environment—notably, for example, of poverty and illiteracy—rather than of genes, and that apparent racial differences were not biological but cultural, the product of ethnicity rather than of germ plasm. In 1930, in the papal encyclical *Casti connubii,* the Roman Catholic church officially opposed eugenics, along with birth control. By the 1930s, a coalition of critics had helped bring a halt in most countries to the attempts of eugenicists to gain significant social and political influence. An exception to this tendency was Germany, where eugenics reached its apogee of power during the Nazi regime. Hundreds of thousands of people were sterilized for negative eugenic reasons and scientific authority joined with social hatred to send millions of the "racially unfit" to the gas chambers. Verschuer trained doctors for the SS in the intricacies of racial hygiene, and he analyzed data and specimens obtained in the concentration camps. In the years after World War II, eugenics became a dirty word.

In the 1930s, attempts to sanitize eugenics had been made by various British and American biologists. They wanted to maintain Galton's idea of human biological improvement while rejecting the social prejudice that had pervaded the conception. They realized that sound eugenics would have to rest on a solid science of human genetics, one that scrupulously rejected social bias and weighed the respective roles of biology and environment, of nature and nurture, in the making of the human animal. They succeeded in laying the foundation for such a science of human genetics, and that field made great strides in the following decades.

The advances in human genetics boosted the new field of genetic counseling, which provided prospective parents with advice about what their risk might be of bearing a child with a genetic disorder. In the 1950s, the early years of such counseling, some geneticists had sought to turn the practice to eugenic advantage—to reduce the incidence of genetic disease in the population, and by extension to reduce the frequency of deleterious genes in what population geneticists were coming to call the human gene pool. To that end, some claimed that it was the counselor's duty not simply to inform a couple about the possible genetic outcome of their union but also to instruct them whether to bear children at all. By the end of the 1950s, however, the informal standards of practice in genetic counseling were strongly against eugenically oriented advice—that is, advice aimed at the welfare of the gene pool rather than of the family. The standards had it that no counselor had the right to tell a couple not to have a child, even for the sake of the couple's welfare.

At first, genetic counseling could draw only on family histories and could tell parents nothing more than the odds that they might conceive a child with a recessive or dominant disease or abnormality. Since the 1960s, as the result of amniocentesis and advances in human biochemical and chromosomal genetics, genetic counseling has become coupled to technical analyses that can identify whether a prospective parent actually carries a deleterious gene and can determine prenatally whether a fetus truly suffers from a selection of genetic and chromosomal diseases or disorders. If the fetus is found to be at such a disadvantage, the parents have the option to abort—at least in countries where abortion is legal, which in 1993 included the United States, Great Britain, and France.

Reproductive selection on a genetic basis—by screening of parents, abortion of fetuses, or both—has found support among liberal religious groups, secular ethicists, and many feminists. They regard it as enlarging women's freedom to control their lives and as contributing to family well-being. However, reproductive selection has been contested by the Roman Catholic church and fundamentalist Protestants, mainly because of their opposition to abortion for any reason. Some feminists have interpreted such selection as yet another among several recent innovations in reproductive technology—for example, in vitro fertilization—that threaten to reduce women to mere reproductive machines in a patriarchal social order. Others have pointed to the heavy emotional and familial burdens placed upon women by prenatal diagnosis that reveals a fetus with a genetic disease or disorder. Genetic selection also has raised apprehensions among some members of minority groups and among disabled persons that it will lead to a revival of negative eugenics that may affect them disproportionately. Handicapped people and their advocates have attacked the attitude that a newly conceived child with a genetic affliction merits abortion, calling it a stigmatization of the living who have the ailment and the expression of a eugenics mentality (Stanworth; Rothman, 1986, 1989; Duster; Cowan).

The Human Genome Project

These fears have been exacerbated by the Human Genome Project, the multinational effort, begun in the late 1980s, to obtain the sequence of all the DNA in the human genome. Once the complete sequence is obtained, it will in principle be easy to identify individuals with deleterious genes of a physical (or presumptively antisocial) type, and the state may intervene in reproductive behavior so as to discourage the transmission of these genes in the population. Such a policy could work special injury upon certain minority groups—for example, people of African origin, since the recessive gene for sickle-cell anemia occurs among them with comparatively high frequency. It could also threaten the disabled, since the only "therapy" currently available for most genetic or chromosomal diseases or disorders is abortion, and since identifying such fetuses as candidates for the procedure stigmatizes people who have been born with the handicap. In 1988, China's Gansu Province adopted a eugenic law that would—so the authorities said—improve population quality by banning the marriages of mentally retarded people unless they first submit to sterilization. Such laws have been adopted in other provinces and in 1991 were endorsed by Prime Minister Li Peng.

Negative eugenic intentions appeared to lie behind a July 1988 proposal from the European Commission for the creation of a human genome project in the European Community. Called a health measure, the proposal was entitled "Predictive Medicine: Human Genome Analysis." Its rationale rested on a simple syllogism—that many diseases result from interactions of genes and environment; that it would be impossible to remove all the environmental culprits from society; and that, hence, individuals could be better defended against disease by identifying their genetic predispositions to fall ill. According to the summary of the proposal: "Predictive Medicine seeks to protect individuals from the kinds of illnesses to which they are genetically most vulnerable and, where appropriate, to prevent the transmission of the genetic susceptibilities to the next generation." In the view of the European Commission, the genome proposal would make Europe more competitive—indirectly, by helping to slow the rate of increase in health expenditures; directly, by strengthening its scientific and technological base (Commission of the European Community).

Economics may well prove to be a powerful incentive to a new negative eugenics. In the United States, the more that healthcare becomes a public responsibility, paid for through the tax system, and the more expensive this care becomes, the greater the possibility that taxpayers will rebel against paying for the care of those whose genetic makeup dooms them to severe disease or disability. Even in countries with national health systems, public officials might feel pressure to encourage, or even to compel, people not to bring genetically affected children into the world—not for the sake of the gene pool but in the interest of keeping public health costs down.

However, a number of factors are likely to offset a broad-based revival of negative eugenics. Eugenics profits from authoritarianism—indeed, almost requires it. The institutions of political democracy may not have been robust enough to resist altogether the violations of civil liberties characteristic of the early eugenics movement, but they did contest them effectively in many places. The British government refused to pass eugenic sterilization laws. So did many American states; and where they were enacted, they were often unenforced. Awareness of the barbarities and cruelties of state-sponsored eugenics in the past has tended to set most geneticists and the public at large against such programs. Moreover, persons with handicaps or diseases are politically empowered, as are minority groups, to a degree that they were not in the early twentieth century. They may not be sufficiently empowered to counter all quasi-eugenic threats to themselves, but they are politically positioned, with allies in the media, the medical profession, and elsewhere, including the Roman Catholic church, to block or at least to hinder eugenic proposals that might affect them.

The European Commission's proposal for a human genome project provoked the emergence of an antieugenic coalition in the European Parliament that was led by Benedikt Härlin, a member of the West German Green Party. The Greens had helped impose severe restrictions on biotechnology in West Germany and raised objections to human genome research on grounds that it might lead to a recrudescence of Nazi biological policies. Guided by Härlin, the European Parliament's Committee on Energy, Research and Technology raised a red flag against the genome project as an enterprise in preventive medicine. It reminded the European Community that in the past, eugenic ideas had led to "horrific consequences" and declared that "clear pointers to eugenic tendencies and goals" inhered in the intention of protecting people from contracting and transmitting genetic diseases or conditions. The application of human genetic information for such purposes would almost always involve decisions—fundamentally eugenic ones— about what are "normal and abnormal, acceptable and unacceptable, viable and non-viable forms of the genetic make-up of individual human beings before and after birth." The Härlin Report also warned that the new biological and reproductive technologies could make for a "modern test tube eugenics," a eugenics all the more insidious because it could disguise more easily than its cruder ancestors "an even more radical and totalitarian form of 'biopolitics'" (European Parliament, Committee on Energy, Research, and Technology, pp. 23–28).

The Härlin Report urged thirty-eight amendments to the European Commission's proposal, including the complete excision of the phrase "predictive medicine" from the text. As a result of the report, which won support not only from German Greens but also from conservatives on both sides of the English Channel, including German Catholics, the European Commission produced a modified proposal that accepted the thrust of the amendments and even the language of a number of them. The new proposal called for a three-year program of human genome analysis as such, without regard to predictive medicine, and committed the European Community in a variety of ways—most notably, by prohibiting human germ line research and genetic intervention with human embryos—to avoid eugenic practices, prevent ethical missteps, and protect individual rights and privacy. It also promised to keep the European Parliament and the public fully informed via annual reports on the moral and legal basis of human genome research. Formally adopted in June 1990, the European Community's human genome program will cost 15 million ECU (about $17 million) over three years, with some one million ECU devoted to ethical studies (Kevles and Hood).

In the United States, apprehensions of the ethical dangers in the Human Genome Project found expression in the Congress across the political spectrum—from liberals who had long been concerned about governmental intrusion into private genetic matters to conservatives who worried that the Human Genome Project might foster increased practice of prenatal diagnosis and abortion. Among the Americans most sensitive to the eugenic hazards and the ethical challenges inherent in the project were a number of its leading scientific enthusiasts, particularly James D. Watson, the first head of the National Center for Human Genome Research, who considered it both appropriate and imperative that the American genome program stimulate study and debate about its social, ethical, and legal implications. In 1988, Watson announced that such activities would be eligible for roughly 3 percent of the National Center's budget. He told a 1989 scientific conference on the genome: "We have to be aware of the really terrible past of eugenics, where incomplete knowledge was used in a very

cavalier and rather awful way, both here in the United States and in Germany. We have to reassure people that their own DNA is private and that no one else can get at it" (Kevles and Hood, pp. 34–35).

Human Genetics in a Market Economy

Despite the specter of eugenics that some see in the Human Genome Project, many observers hold that its near-term ethical challenges lie neither in private forays into human genetic improvement nor in some state-mandated program of eugenics. They lie in the grit of what the project will produce in abundance: genetic information. These challenges center on the control, diffusion, and use of that information within the context of a market economy.

The advance of human genetics and biotechnology has created the capacity for a kind of individual eugenics—families deciding what kinds of children they wish to have. At the moment, the kinds they can choose are those without certain disabilities or diseases, such as Down syndrome or Tay-Sachs disease. Although most parents would now probably prefer just a healthy baby, in the future they might be tempted by the opportunity—for example, via genetic analysis of embryos—to have improved babies, children who are likely to be more intelligent or more athletic or better-looking (whatever such terms might mean). People may well pursue such possibilities, given the interest that some parents have shown in choosing the sex of their child or that others have shown in the administration of growth hormone to offspring they think will grow up too short. In sum, a kind of private eugenics could arise from consumer demand.

Many commentators have noted that the torrent of new human genetic information will undoubtedly pose challenges to social fairness and equity. They have emphasized that employers may seek to deny jobs to applicants with a susceptibility—or an alleged susceptibility—to disorders such as manic depression or illnesses arising from features of the workplace. For example, around 1970, it came to be feared that people with sickle-cell trait—that is, who possess one of the recessive genes for the disease—might suffer the sickling of their red-blood cells in the reduced-oxygen environment of high altitudes. Such people were unjustly prohibited from entering the Air Force Academy, were restricted to ground jobs by several major commercial air carriers, and often were charged higher premiums by insurance companies. Life and medical insurance companies may well wish to know the genomic signatures of their clients, their profile of risk for disease and death. Even national health systems might choose to ration the provision of care on the basis of genetic propensity for disease, especially to families at risk for bearing diseased children (U.S. Congress, Office of Technology Assessment; Kevles).

In response to these threatening prospects, many analysts have contended that individual genomic information should be protected as strictly private. However, legal and insurance analysts have pointed out that insurance, and insurance premiums, depend on assessments of risk. If a client has a high genetic medical risk that is not reflected in the premium charged, then that person receives a high payout at low cost to himself or herself but at high cost to the company. The problem would be compounded if the person knows the risk—while the company does not—and purchases a large amount of insurance. In either case, the company would have to pass its increased costs to other policyholders, which is to say that high-risk policyholders would be taxing low-risk ones. Thus, insisting on a right to privacy in genetic information could well lead—at least under the largely private system of insurance that now prevails in the United States—to inequitable consequences.

American legislatures have already begun to focus on the genuine social, ethical, and policy issues that the Human Genome Project raises, particularly those concerning the use of private human genetic information. In the fall of 1991, a U.S. House of Representatives subcommittee held hearings on the challenge that such information posed to insurability. About the same time, the California state legislature passed a bill banning employers, health service agencies and disability insurers from withholding jobs or protection simply because a person is a carrier of a single gene associated with disability. Although California Governor Pete Wilson vetoed the bill, it was a harbinger of the type of public policy initiatives that the genome project no doubt will increasingly call forth. The Human Genome Project, like most of human and medical genetics, is less likely to foster a drive for a new eugenics than it is to pose vexing challenges to public policy and private practices for the control and use of human genetic information.

II. ETHICAL ISSUES

To what extent are there continuities, parallels, and trajectories between past eugenic ideas and practices, and current and pending developments with genetic testing and screening, prospective gene therapies, and the increasing utilization of sperm banks and egg donations? To begin to answer

these questions, it is imperative to distinguish between state-sanctioned eugenic programs on the one hand, and private, individualized, *personal* decisions that are socially patterned, on the other. In the former case eugenic goals are usually explicitly articulated, and thus easy to identify, examine, and oppose or support. In the latter the eugenic implications are often unarticulated and subterranean—only exposed by a review of statistical patterns of what are otherwise perceived as individual choices. In matters of public policy and market choices, emphasis upon individual intent can camouflage the collective eugenic force of personal decision-making.

One heuristically useful attempt to distinguish between different kinds of contemporary eugenic forms can be found in Philip Kitcher's *The Lives to Come* (1996). Kitcher makes a distinction between *laissez-faire eugenics,* a hands-off approach that presumes that everyone will make their own *individual choices*—and a *utopian eugenics,* where as a matter of public policy there is an attempt to make available to all sectors of a society the information and technology to make those choices. While no public policy can ever deliver such information and technology evenly across all sectors, this provides an analytic device for assessing the degree of success of such an attempted distribution. The major difficulty surfaces with an empirical problem generated by the molecular genetic revolution itself, the fracture of the public health consensus of what constitutes *the public good.* Allen Buchanan and his associates, in *From Chance to Choice* (2000), argue that an assessment of the consequences for the general public good are vital to a discussion of the treatment/enhancement distinction. Before 1960 it was possible to achieve consensus that the public good was well-served by an elimination or mitigation of such diseases as smallpox, cholera, tuberculosis, yellow fever, typhoid, and sexually transmitted diseases. However, with the discovery that genetic disorders are located in risk populations that do not place the general population at risk, a new set of issues and new kinds of eugenic concerns have been generated regarding who has control over genetic screening and testing.

While it is true that individuals make choices, they do so in a social and economic context that can be demonstrably coercive. While relatively obvious when looking at other societies, it is less understood when examining one's own—substantially obscured because individual choice is deeply embedded in the taken-for-granted assumptions about decision-making. For example, long before the advent of prenatal detection technologies, preference for a male child in India and China was so great that a notable fraction of the population practiced infanticide of newborn females. While sex selection does not qualify as a eugenic strategy (unless the purpose is to prevent a gender-linked disorder), the practice in India and China does illustrate how and why a focus on individual choice can obscure the dramatically collective aspect of socially patterned individual choices.

Once technologies for prenatal determination of sex became available, the quest for *disclosure* of the sex of the fetus took a momentous turn for public policy in India. In 1971 India passed the Medical Termination of Pregnancy Act, which stipulates that a woman can be given an abortion only if there is a life-threatening situation, or grave injury to her physical or mental health. Amniocentesis use began in India in 1974, but there were early reports that the test was being used less to detect birth defects than to determine the sex of the fetus. In August 1994 the Indian Parliament passed a new law that stiffened the penalties for screening the fetus to determine the sex. However, there was a large loophole in the law that made it practically unenforceable—and the practice has continued at such a high rate that in 1994 *New York Times* reported that Haryana, a populous northern state, had an astonishingly low sex ratio of 874 females to every 1,000 males.

Individual Decision and Unexamined Group Patterns

It should be clear from the above examples of sex selection preferences in India that what appear to be individual familial choices may often be better understood as empirical social patterns reflective of the social and cultural hegemony. For example, in early 1994, *Nature* published "China's Misconception of Eugenics," an article that portrayed the Chinese government's policy of trying to prohibit couples with certain diseases from procreating as having a distinctively distasteful eugenic quality. While the article was forthright in denouncing the use of state power as the vehicle for discouraging procreation, it implied that a personalistic and individualistic decision to interrupt a pregnancy. Health Minister for China, Chen Minzhang, announced the plan to enforce a new law that would not only prohibit screening of the fetus for sex determination, but also ban marriages for people "diagnosed with diseases that may totally or partially deprive the victim of the ability to live independently, that are highly possible to recur in generations to come and that are medically considered inappropriate for reproduction"—as reported in the *New York Times* on November 14, 1993 in an article titled "China to Ban Sex-Screening of Fetuses."

The logical and empirical extension of the technology can be made explicit: Once it is possible to determine in time for the termination of a pregnancy whether the fetus has a condition that is regarded as a defect, who is entitled to make the decision about carrying to full term, or aborting? As noted, this should not be seen as a simple binary matter of

voluntarism versus state power. There is considerable evidence to support the observation that what are characterized as personal or individual decisions in Western societies are upon closer inspection (just as with sex selection in India) actually very remarkably socially patterned.

In an influential treatise on reproductive choice titled *Children of Choice,* John Robertson acknowledged that social and economic constraints such as access to employment, housing and child care might play a role in the decision to have a child. However, the overarching theme, to which he returns again and again, is that reproduction "is first and foremost an individual interest" (p. 22). Because this is not reducible to an either/or formulation, it should be clearer why a continuum is a better analytic device for arraying an understanding of strategies and options—from individual choice to embedded but powerful social pressures (stigma and ridicule)—and from economic pressures (fear of loss of health insurance, or even of inability to obtain such insurance), and only then to the coercive power of the state to penalize.

When framed as individual choice, debate about a reproductive choice is set into the arena of individual rights: to have a child or not, then to have a male or female child, to have a child with Down Syndrome, cleft palate, or to choose to produce a clone. Such discussions of individual rights are typically de-contextualized from systemic concerns such as affordability. But amniocentesis is a relatively expensive procedure for the poor. The state often provides assistance to women seeking amniocentesis. In the 1980s California's Department of Maternal and Child Health noted with alarm that primarily wealthier women were getting state support for amniocentesis. Mindful of the state's eugenic history, officials embarked upon a program to try to get poorer women to accept the service. However, because the poor tend to have their children at an early age, this has become moot as a visible issue in the eugenics debate.

Continuity and Persistence of Eugenic Thought and Goals

During a time of rapid social change in which there are disruptions of the established order and the attendant challenges to authority and tradition, there is a special appeal of genetic explanations and eugenic solutions to the most privileged strata of society. The power of the state to control its population can be awesome, and thus when the state puts forward eugenic programs in a post-holocaust world, critics are well prepared to react with revulsion. The government of Singapore came under fire during the 1990s for its program to reward middle-class and wealthy families for having more children, while actively discouraging the poor from having large families. Far less attention has been given to the fact that 30,000 babies have been produced by sperm banks and egg donations in the United Kingdom alone, from people who are literally choosing what they consider to be *better human stock* (Maranto; Hill).

The industrial revolution and rapid urbanization wreaked havoc with traditional life and traditional social roles in both nineteenth-century Europe and the United States. Extended kinship systems that had been valued as an economic advantage on farmlands were often inverted and became economic liabilities when those families were forced off the land and moved to the teeming cities. Unemployment, homelessness, mental illness and a host of other social problems seemed to especially victimize the poor, whose visibility if not sheer numbers dominated the public sphere of urban life.

Cholera, yellow fever, typhoid, and tuberculosis were the scourge of city dwellers, and once again, the poor were the most likely victims. But as Sylvia Tesh noted in *Hidden Arguments* (1988), the poor were also the most likely to be blamed for causing the problems, typically characterized as living in unclean conditions. Hygiene came first as both an explanation for the better fortunes of the privileged and middle classes, and later—as a challenge to the poor.

As the wealthier families began to have fewer children, and to have the resources to hire the poor as servants to help them *clean up*—some observers began to notice what they thought was a disturbing pattern. The more well-to-do members of society were procreating less, while the poor were still having very large families. The dark Malthusian prediction about a population explosion took a particularly elitist turn. If people are to learn anything from the past, it is imperative to have a more complete understanding of the appeal and popularity of eugenics and why it was compelling to the full range of thinkers of all political persuasions at the beginning of the twentieth century. Very much like its sister concept *hygiene*—there was a strong association between cleanliness and order, progress and eugenics.

Just as hygiene was seen as the normal value of cleanliness to which all should aspire, eugenics was widely accepted and actively promoted by the major public figures of the period. University presidents, medical doctors, judges, academic scholars, writers, intellectuals, political figures on both the left and right of the political spectrum—all espoused the idea that the betterment of humankind would result from the practices and techniques that would prevent the procreation of *imbeciles* and *mental retards* and *criminals* and *prostitutes* and *homosexuals* and *alcoholics* and *gamblers.*

Contemporary Echoes of a Eugenic Past: The Genetic Screen

Genetic screening is one of the outgrowths of health screening for a number of public health problems, most notably tuberculosis. But unlike tuberculosis, genetic disorders tend to cluster in populations in which there have been centuries of in-breeding, because of cultural endogamy rules (who can marry whom), and/or because of long-term geographical residence of a population in which there has not been much physical mobility. In both circumstances, genes that cause diseases cluster in these populations, making those who are part of those populations at greater risk. Examples include cystic fibrosis, a disease affecting the lung's ability to accumulate liquids, primarily affecting persons of North-European descent; beta-thalassemia, a blood disease affecting persons living in the Mediterranean area; and sickle-cell anemia, a blood disorder primarily affecting persons with ancestors from West Africa, and in some areas of the Mediterranean.

In the last two decades of the twentieth century, many states began to offer postnatal genetic screening of all newborns. If the screen detects a high level of a particular chemical (alpha-feta protein) on the first go-round, the woman is offered a second test to determine if the fetus is likely to have anencephaly, which can produce a serious neural tube defect. In the most literal sense, to *screen* something means to prevent that something from getting past the screen. Thus, whether explicitly or implicitly, the institutionalization of genetic screening programs contains a strong residue of the old image of *cleaning* or *purifying* the gene pool. The social aspect of the eugenic implication is disguised by its being offered to individual women, or individual families. Thus the specter of state-sponsored screening of a particular group is diffused and obscured. However, as noted above, since genetic diseases tend to cluster in certain ethnic and racial groupings, individual decision-making (imposed or presumed) cannot mitigate the fact of systematically different outcomes for different groups.

Getting rid of *bad babies* with *genetic defects* is only half of the eugenic equation. There is also the idea of a positive eugenics, in which there is the active recruitment of some to procreate and selectively breed to increase some human trait or characteristic that is considered positive. Singapore actively encourages and rewards its wealthy and middle-class citizens to have more children. That is the group-approach to positive eugenics. On the individual level, contemporary residues of eugenic thinking can be seen in the emergence and increasing use of sperm banks with sperm donated by medical students, athletes, and Nobel laureates; the much higher cost of ova from young women from exclusive private colleges; and the exorbitant pricing of the ova from supermodels, which are offered on a website. Given a choice, there is evidence that some people will try to add a bit of height to their offspring with a growth hormone. Each of these developments indicates a lingering of a eugenic past.

Population/Group Taxonomy and the Relevance to Debates on Germ Line Intervention

The current discussions and debates about whether we should engage or support research that might alter the germ line rarely address the systematically eugenic potential that is a possible outcome. Germline is the term used to describe genetic changes that would influence inheritance across the generations, and is distinguished from genetic interventions that alter only the particular person undergoing gene therapy. Because bioethicists do not tend to formulate ethical concerns along dimensions of group stratification or access to political power on the part of *groups of individuals,* the discussion about the ethics of germ line intervention for group differentiation and social stratification is rare. An increased understanding of human genetics will enable the sorting of groups at higher and lower risk for certain diseases even more systematically than what was noted above.

If technology permitted entry into the germ line to eliminate either cystic fibrosis or sickle-cell anemia in an individual, that individual (or parent or guardian acting in behalf of that individual) might well make the individual choice. But a different order of ethical concern surfaces if one thinks about this more at the social and political level and less at the individual level. Zuni Indians are more likely to have cystic fibrosis than are persons of European ancestry, albeit a different mutation for cystic fibrosis than *Caucasians.* Yet the genetic test for cystic fibrosis is aimed at the Delta F508, the mutation most likely to be found in those of North-European ancestry. Quite simply, this is because genetic disease research is most likely to be aimed at those diseases that have the most politically powerful constituencies and/or for which there is a strong profit motive in the biotechnology industry. With more research dollars going into the Delta F508, than into the mutation which appears more frequently among the Zuni, individual Caucasians may come to believe that they are making an individual decision about altering the familial germ line. Stepping back to another level of analysis, social, political, and economic engines are driving molecular biology down certain research corridors of a particular group's genetic disorder and not others, and these have little to do with individual choice at the user end.

Parallel Massive Social Displacements: Late-Ninteenth and Late-Twentieth Centuries

Just as the twin shifts from agrarian to industrial and rural to urban dominated the shifting social demography of the late-nineteenth century in Europe and the United States, so the shift from industrial to service (or tertiary) and from urban to suburban dominated shifting social demography of the late-twentieth century. The United States has been in the vanguard of this development, and the massive economic displacement of African-American urban youth is the context for a renewed conception of biological thinking about social issues. At the beginning of the twenty-first century, the United States is heading down a subtly parallel road entertaining the connection between genes and social outcomes. This is being played out on a stage with converging preoccupations and tangled webs that interlace youth unemployment, crime and violence, race, and genetic explanations.

There is direct link between de-industrialization, youth unemployment, and ethnic or racial or immigrant minority status in the United States. In 1954 black and white youth unemployment rates in the United States were equal, with blacks actually having a slightly higher rate of employment in the age group from 16 to 19. By 1982 the black unemployment rate had nearly quadrupled in this age group, while the white rate had increased only marginally (Kasarda). Just as unemployment rates among African-American youth were skyrocketing during these three decades, so were their incarceration rates. This provides the context in which to review and interpret the clear pattern of the recent historical evolution of general prison incarceration rates by race. In the last half of the twentieth century, the incarceration rate of African Americans in relation to whites has gone up in a striking manner. In 1933 blacks were incarcerated at a rate approximately three times that of whites. By 1970 it was six times; and in 1995 it was seven times that of whites.

Genetic studies of criminality have a heavy dependency on incarcerated populations. Thus, for example, one of the more controversial issues in the *genetics* of crime is whether males with the extra Y chromosome, or XYY males, are more likely to be found in prisons than are XY males. The first major study suggesting a genetic link came from Edinburgh, Scotland. In 1965 Patricia Jacobs and her colleagues reported that while all of the 197 males in this account of prison hospital inmates were described as *dangerously violent,* seven had the XYY karotype. These seven males constituted about 3.5 per cent of the total. But since it was estimated that only about 1.3 per cent of all males has the XYY chromosomal make-up, the authors posited that the extra Y significantly increased one's chances of being incarcerated. Ever since a controversy has raged as to the meaning of these findings and the methodology that produced them. The claim for a genetic link to crime is based entirely upon studies of incarcerated populations.

Yet, incarceration rates are a function of a full range of criminal justice decisions, a fact which research has long shown to be a function of social, economic and political factors (Cole; Mauer; Miller; Currie). At the beginning of the twenty-first century, forensic sciences are attempting to use DNA markers to identify *ethnic affiliation estimations* of suspects in criminal investigations (Lowe et al.; Shriver et al.). Just as health and hygiene were the vanguard for the late-nineteenth century screen for the *unfit,* so the genetic screen was first a health screen. However, the shift in use and focus to forensic science has already begun. The national DNA database, CODIS (acronym for COmbined DNA Identification System) contained, as of January 2000, genetic profiles of 210,000 convicts. It is coordinated by the Federal Bureau of Investigation (FBI), and all fifty states contribute to the databank.

The states are the primary venues for the prosecution of violations of the criminal law, and their autonomy has generated considerable variation in the use of DNA databanks and storage. Even as late as the mid-1980s, most states were only collecting DNA samples from sexual offenders. The times have changed quite rapidly.There has been active change in the inter-linking of state databases, and states are uploading an average of 3,000 offender profiles every month. Computer technology is increasingly efficient and extraordinarily fast, and it requires only 500 microseconds to search a database of 100,000 profiles.

As the United States increases the numbers of profiles in the national database, there will be researchers proposing to provide genetic profiles of specific offender populations. Twenty states authorize the use of databanks for research on forensic techniques. Based on the statutory language in several of those states, this could easily mean assaying genes or loci that contain predictive information (Kimmelman). The program of research for CODIS is increasing exponentially on an annual basis, and this data base is sitting there waiting to be tapped by researchers looking for *violence genes*—as evidenced by the spate of national interest over the monoamine oxidase A (MAOA) gene. In the latter part of 2002, Caspi and his associates published an article in *Science* that cemented the relationship between behavioral and molecular genetics. The authors claimed to have produced findings that a functional polymorphism in the MAOA gene affects the impact of early childhood maltreatment on the development of antisocial and violent behavior. The policy implications of the research were strongly suggested in the conclusions, and re-ignite an old debate about the prospects and dangers of early identification of children who are

thought to be at risk for violent or antisocial behavior. As in the earlier forms of eugenics, early identification always carries with it the appendage of both treatment and prevention.

Conclusion

Eugenic thought, practice, and advocacy are best understood as existing along a continuum with degrees of activity. It is therefore misleading and obscuring the complexity of the range of reproductive options to suggest that either a society does or does not have eugenic practices. Most significantly the social setting in which eugenics flourishes or declines is as important as the knowledge base in genetics and biology. The oft cited post-World War II defeat of eugenic thought is actually therefore better framed as its mitigation, its submersion, muting, or transmogrification. These changes came about more because of the defeat of the Nazis, and less because of advances in scientific knowledge of the genetics of race. As early as the 1930s, German and U.S. scientists had conclusive evidence that the ABO blood system did not track along racial or ethnic lines, but this knowledge did not inhibit some of the most vicious racist eugenic practices ever promulgated and perpetrated.

The social and economic setting in the technologically developed part of the world since the mid-1980s is propitious for a strong resurgence of eugenic thinking and advocacy, similar in degree to the social transformations of early-twentieth century Europe and the United States. The decline of the welfare state, the increasing gap between rich and poor, and the erosion of safety nets for the poorest members of a society have set the stage. This is accompanied by transnational migrations of laborers in the increasingly global labor markets of major post-industrial nations. The entry and consignment of these workers to the bottom quartile of the economic order, with the highest rates of poverty, disease, and recorded crime and violence will fuel the re-insurgence of attempts to explain their behavior. The new forms of eugenic insurgency will be disguised, muted, and made more palpable as: (a) the neutral requirements of forensic techniques of ethnic estimation; (b) the convergence of molecular and behavioral genetics in explanations of violent and antisocial behavior; and (c) the over-arching framework of individual choice regarding reproductive options, whether to prevent the birth of a child with a genetic defect, or in the use of new technologies to enhance the prospect of the fetus for competitive advantage.

EUGENICS AND RELIGIOUS LAW

• • •

I. JUDAISM

The laws against incest and consanguinity in the Old Testament would seem to have a rationale in eugenics, although this is never specified in the biblical text. The traditional commentators, too, advert only to the natural repugnance against incest. In the Talmudic discussion as well as in the legal codes, the subject is treated as a sexual offense, involving a breach of morality rather than a eugenic error. (The Talmud is the repository of rabbinic exposition of biblical law and teaching, spanning more than five centuries. The legal codes are based on the Talmud and on subsequent development of the law, such as in Responsa, formal opinions rendered by rabbinic authorities in response to new case-law inquiries.)

Even bastardy is a moral rather than a eugenic category. The *mamzer* (in Jewish law, the product of an adulterous or incestuous liaison, not of a relationship between two persons who are not married to one another) is not legally ill-born; his or her status is compromised only legally and socially, rendered so in punitive or deterrent judgment against parents not free to have entered the relationship. But no difference obtains between the *mamzer* born of adultery—even a technical adultery, such as when the document of divorce for the mother's previous marriage was impugned—and the *mamzer* born of incest. Hence, no eugenic motive can be assigned here.

A man "maimed in his privy parts" bears the same legal disabilities as the *mamzer.* Thus, a man of "crushed testicles or severed member" is excluded from "the congregation of the Lord" (Deut. 23:2). This verse is interpreted to mean only that he may not enter into conjugal union with an Israelite woman. Thus, the castrated male is under the ban because the act of castration is forbidden. But one "maimed in his privy parts" as a result of a birth defect or disease, as opposed to one castrated by his own or another's deliberate

assault, is free of this disability. The legal situations were thus analogized: "Just as the *mamzer* is the result of human misdeeds, so only the castrated one who is such as a result of human misdeeds is to be banned." Since that distinction is made in both cases, and since the banned *mamzer* and the castrated are permitted to marry, for example, another *mamzer* or a proselyte, it must be concluded that moral outrage and punitive judgment rather than eugenic considerations are operative.

Eugenics, in the sense of choosing a marriage partner with the well-being of progeny in mind, is more clearly present in Talmudic counsel and legislation. A man is counseled to choose a wife prudently, and guidance is offered in doing so in accordance with the intellectual and moral virtues of the prospective bride. And since, we are told, a son, for example, normally takes after his mother's brothers, a man should regard the maternal uncles in making his decision (Bava Batra, 110a). A hidden physical blemish in a spouse is grounds for invalidating a marriage, unless the other spouse can be presumed to have known of it in advance.

Heredity as a eugenic principle takes its legal model from rulings with respect to circumcision. A male infant whose two brothers died possibly as a result of this operation may not be circumcised. He is deemed to have inherited the illness (probably hemophilia) that proved fatal to his two brothers. The Talmud goes on to say that an infant whose two maternal cousins showed that weakness may not be circumcised either. That is, statistical evidence yielded by two sons from the same mother can also be reflected in two sisters of that mother (Yevamot, 64b). Coming from Talmudic times (before 500 C.E.), this is a remarkably early recognition that hemophilia is transmitted through maternal lineage—in itself a significant eugenic discovery.

The statistical evidence or the presumption of adverse hereditary factors in a third family member, when those factors are seen to exist in two others, thus becomes the basis of Talmudic laws of eugenics. With modern laboratory means to determine the presence of these factors, the principle of course operates even sooner, without waiting for statistical evidence in two members. The Talmud rules that one may not marry into a family of epileptics or lepers (Yevamot, 64b) or—by extension—a family in which tuberculosis or any similar disease appears in multiple members. This may be the first eugenic edict in any social or religious system.

The pure "heredity" underlying this recommendation is not unanimously agreed upon. While one view in the Talmud attributes the transmission of characteristics in the pre-Mendelian age to heredity, another view sees it as "bad luck." In a Responsum where the questioner considered abortion because the mother was epileptic, the rabbi responded that the latter of the two views stated above may be the right one, and that fear of bad luck is an inadequate warrant for abortion (Feldman, 1968).

In an earlier context, the Mishnah (the foundation layer of the Talmud) speaks of the faculties that a father bequeaths to his son: "looks, strength, riches, and length of years" (Eduyot, II, 9). Here, too, the commentaries align themselves on both sides: one sees the bequeathing of faculties as a natural hereditary process, the other sees them as divine reward for the father's virtues.

Two other Talmudic ideas with eugenic motifs are reflected in current practice. In the interests of fulfilling the injunction to "love one's wife as much as himself and honor her more than himself," a man is advised to seek his sister's daughter as a bride; his care for her will be the more tender due to his affection for his own sister. Yet in the thirteenth century, Rabbi Judah the Pious left a testamentary charge to his children and grandchildren that became a source of guidance to others on the level of precedent for subsequent Jewish law. In this famous testament, he advises against marriage with a niece because it may have adverse genetic results. Modern rabbinic authorities dismiss such fears as unjustified unless they are medically warranted.

A second point is a Talmudic notion that eugenic factors operate in intercourse during pregnancy. Conjugal relations, we are told, should be avoided during the first trimester as "injurious to the embryo"; but they are encouraged during the final trimester as desirable for both mother and fetus, for then the child is born "well-formed and of strong vitality" (Niddah, 31a). A medieval Jewish authority makes the matter a point of pride in comparative culture: the Talmud recommends coitus during the final trimester, whereas the Greek and Arab scholars say it is harmful. Do not listen to them, he says (Responsa Bar Sheshet, no. 447). Nonetheless, the Talmud prohibits the marriage of a pregnant or nursing widow or divorcee. In the case of a pregnant woman, the second husband, it is suggested, may be less considerate of a fetus fathered by another man and may inadvertently damage it through abdominal pressure during intercourse (Yevamot, 36a). In the nursing situation, the new father may fail to take the necessary steps to supplement the diet of his stepchild (it is assumed that a pregnancy diminishes the mother's milk). And a pregnant woman who feels an urgent physical or psychological need for food during the Yom Kippur fast is to be fed for the sake of her fetus's welfare as well as her own (Yoma, 82a).

More a matter of preaching than of law is the notion that defective children can be the result of immoral or

inconsiderate modes of intercourse—an idea expounded but ultimately rejected by the Talmud (Nedarim, 20a). Yet in more modern times, the Hasidim (pietistic Jewish groups with a mystical orientation) maintain that spiritual consequences of the act are indeed possible; that if a man has pure and lofty thoughts during or preparatory to cohabitation, he can succeed in transmitting to the child of either sex an especially lofty soul. Hence dynastic succession of leadership, presuming the inheritance of that loftier soul, as opposed to democratic selection, obtains among Hasidic groups.

A study of biblical and Talmudic sources written by Max Grunwald in 1930, cited by Immanuel Jakobovits, discerns a broad eugenic motif. Grunwald writes that Judaism

> quite consciously strives for the promotion of the quantity of progeny by the compulsion of matrimony, the insistence on early marriage, the sexual purity of the marital partners and the harmony of their ages and characters, the dissolubility of unhappy unions, the regulation of conjugal intercourse, the high esteem of maternity, the stress on parental responsibility, the protection of the embryo, etc. To be sure, there can be no question here of a compulsory public control over the health conditions of the marriage candidates, but that would positively be in line with the principles of Jewish eugenics: the pursuit after the most numerous and physically, mentally, and morally sound natural increase of the people, without thinking of an exclusive race protection. (p. 154)

Although abortion is warranted primarily for maternal rather than fetal indications, screening of would-be parents for actual or potential defective genes, such as in Tay-Sachs disease, would, like premarital blood tests, be much in keeping with the Jewish traditional eugenic concern. Such genetic screening is, in fact, facilitated by a unique computerized system under the auspices of the New York-based Dor Yesharim (Generation of Upright [Descendants], from Psalms 112:2). Young men and women diagnosed as Tay-Sachs carriers are identified by code number. When marriage is contemplated, the couple is alerted to the fact that both are carriers, with one chance in four of a homozygous fetus, so that marriage plans may be reconsidered. Besides Tay-Sachs, which is fatal to the child by about age five, nonfatal disabilities have been added to Dor Yesharim's data base.

Although surrogate parenting and artificial insemination create social and family problems, the conceptional procedures that make them possible are in and of themselves acceptable when natural means are ineffective. In vitro fertilization, to assist in a conception that might otherwise be thwarted by blocked fallopian tubes or by sperm inadequacy, has been accorded full moral and legal sanction. Genetic engineering that alters the germ line has been ruled out by Jewish ethicists, but gene therapy, removing or correcting defective genes, would be a proper extension of the mandate to heal. The newly announced technology for cloning embryos has been greeted with more caution than hope—hope for improved procreational prospects for couples otherwise limited to one or no progeny, but caution against creating multiple embryos deprived of their distinctiveness as individuals. Safeguards are called for against the dangers of genetic mutation, or of political or profit-motive "baby farming" that could result from abuse of broader eugenic techniques.

II. CHRISTIANITY

The following is a revision and update of the first edition entry "Eugenics and Religious Law: Christian Religious Laws" by the same author. Portions of the first edition entry appear in the revised version.

Christian religious laws historically comprehend a large spectrum of rules to guide individual conduct and social relationships among the baptized. The laws most likely to have eugenic significance are the canons prohibiting the marriage of relatives. These regulations also form the basis for the modern civil law prohibitions against the marriage of relatives in both the Continental legal systems and the Anglo-Saxon statutory scheme. Though the principal justification given for such prohibitions in Christian law has been ethical and social, there is substantial evidence that they also may reflect considerations classified as eugenic in contemporary scientific research.

The ecclesiastical regulations that forbid marriage between persons closely related by consanguinity are among the most ancient canons of the Christian tradition. Penalties attached to the violation of religious exogamic laws have varied historically in their severity, as, indeed, have the ways of measuring the degrees of kinship and defining within which degrees the crime of incest shall be punished. But the core of the tradition of canon law remains constant and reflects an extreme reluctance to accept the marriages of close relatives as humanly or religiously feasible.

For Roman Catholics all marriages within the direct line of blood relationship, that is, between an ancestor and a descendant by parentage, and within the collateral line to the fourth degree, that is, to third cousins, are forbidden (*Code of Canon Law,* 1983, canon 1091). The definition of marriages within four degrees of relationship as incestuous dates to the Fourth Lateran Council in 1215 (c. 50). In the Greek Orthodox tradition, marriage in the direct line and in the collateral line to the sixth or seventh degree by the Roman method of computation is prohibited in canon 54 of the Synod in Trullo, 691/692 (Hefele). All Oriental Christians forbid marriages in the direct line; Armenians, Jacobites, and Copts prohibit it in the collateral line to the fourth degree, Melkites to the sixth degree, Serbs and Chaldeans to the third degree, and Ethiopians without distinction. Among Protestant reformers the restrictions of the medieval canon law were accepted by some, such as Phillip Melanchthon and Martin Chemnitz (Kemnitz); only the Old Testament regulations of Leviticus 18:6–18 by others, such as Martin Bucer and, perhaps, Martin Luther; and only the closest ties of direct parental relationship by still others, such as John Wycliffe. In the Anglican community, The Book of Common Prayer contains a table drawn up by Archbishop Matthew Parker based on Leviticus in naming relatives incapable of marriage (Wheatly). Most Protestant churches today follow the prohibitions of civil law regarding incest and kinship marriage (Acte for Kynges Succession; Acte for Succession of Imperyall Crowne; Concerning Precontracte and Degrees).

The sources of and commentaries upon the Christian laws record debate about the extent of the prohibition, the possibility of dispensation within certain close degrees of kinship, and the related question of the divine or natural law origin of the laws (e.g., Burchard of Worms, *Decretum,* bk. 7, "De Incesto"; Burchard of Worms, *Collection in 74 titulis* 65.281–284). They reveal, however, only the most sketchy discussion of the foundations of the regulations themselves.

The classical reasons given for the prohibition of consanguineous marriages are ethical and social. The first reason was called the *respectus parentelae,* namely, that such marriages would undermine the respect due to parents and consequently to all those who are closely related (Aquinas, 1948, *Summa theologiae* II–II, 154, 9). Second, they constitute a moral danger to family life arising from the possibility of early moral corruption of the young dwelling within the same household in which marriage could be allowed (ibid.; Sánchez 1605, 7.52.12, 7.53). Third, the prohibition of consanguineous marriages prevents the disruption of the family by sexual competition and forces the multiplication of friendships and the spread of charity (Augustine). These three reasons seem to have been sufficient to justify the laws, so that most scholars did not go beyond them to seek a further justification. Adhémar Esmein, for example, said the laws arose out of an instinctive repulsion for incest and were not reflective of any known adverse physical consequences. Some modern authors speculate that the reason for strict enforcement of prohibitions against incestuous marriages was to force the breakup of landed family estates (Duby).

It is only in comparatively modern times that an explicitly eugenic reason for the prohibition has received scientific attention. Writing in 1673, Samuel Dugard noted: "There is a *judgment* which is said often to accompany these Marriages, and that is *Want of Children* and a *Barrennesse*" (p. 53). "The Children are weak, it may be; grow crooked, or, what is worse, do not prove well; presently, Sir, it shall be said what better could be expected? an unlawfull Wedlock must have an unprosperous successe" (p. 51). Ambrosius J. Stapf's *Theologia moralis* in 1827 alluded to this possibility (p. 359). A fuller treatment is found in Dominic Le Noir's 1873 edition of St. Alphonsus's *Theologia moralis.* Edward Westermarck in 1889 and Eduard Laurent in 1895 spoke at length of a physiological justification of the canons to prevent indiscriminate inbreeding and the risk of a high incidence of deleterious genetic effects. Franz Wernz, in 1928 (n. 352 [70]), writing from a comprehensive knowledge of the canonical tradition, said the ancient writers also knew of the undesirable effects of excessive inbreeding. He noted reasons derived from contemporary medical science in the writings of Gratian (early twelfth century) (C.xx "Anglis permittitur, ut in quarta vel in quinta generatione cognibitur,"

c. 20, c. 35, q. 2), Pope Innocent III (1161–1216) (Schroeder), and Thomas Aquinas (*Commentum in libros IV Sententiarum,* dist. 40 and 41, q. 1, art. 4). Since the late nineteenth century nearly all commentators on the canonical rules speak of eugenic objections to marriages of blood relatives.

It is possible to find in the ancient ecclesiastical commentators an awareness of a eugenic foundation to the prohibition expressed in primitive and undifferentiated modes of speech. For example, a persistent belief was kept alive among theologians and canonists that children of incestuous relationships will die or will be greatly debilitated, or that the familial line will be cursed with sterility. Benedict the Levite (850?) wrote of these marriages: "From these are usually born the blind, the deaf, hunchbacks, the mentally defective, and others afflicted with loathsome infirmities" (*Capitularum collectio*). Furthermore, in the explanations of the name of the impediment (i.e., the impediment of consanguinity), if one traces their origins through medieval glossography to the *Etymologies* of Isidore of Seville (560?–636), there appears an awareness of a physiological factor in the blood bond of close relatives that must be weakened before marriage can be contracted safely.

The antecedents of the Christian canons in the Mosaic law (Lev. 18:6–18) and the Roman law (Burge) were taken as expressions of natural law by the canonists and were continued in the barbarian codes (*Pactum legis salicae* 13.11; *Leges visigothae* 4.1.1–7; *Codex Euriciani* 2). In his *Ecclesiastical History* (I, 27), where the Venerable Bede (673–735) notes these laws, he records a quotation from a letter of Pope Gregory I to Augustine of Canterbury, written in 601 (*Responsa Gregorii*). The reason given by Gregory for forbidding marriages of close relatives is, "We have learned from experience that from such a marriage offspring cannot grow up." This letter and this reason not only are later picked up and cited by Gratian ("Anglis permittatur," c. 2, c. 35, q. 5) and Thomas Aquinas (*Summa theologiae suppl.* 54, 3), but may be found in virtually all the canonical collections of the early Middle Ages. Though comment on this passage is rare, comment was, perhaps, unnecessary. The passage from Gregory seems clearly to say that experience teaches that children from forbidden consanguineous marriages are affected or unable to grow up. There is thought to be a physiological consequence to incest. In the light of this it seems probable that the labored argumentation over the question of how close the relationship must be for marriage to be forbidden by natural law must have been conducted in some awareness of a popular belief in the biological consequences of such unions. The fear of genetic anomalies or biological debilitation from indiscriminate inbreeding may not be perfectly articulated. It is difficult to imagine, however, that warning of some physiological dangers to offspring may not have been intended in the frequent citation of Pope Gregory to sustain the severity of the prohibition.

Tomás Sánchez (1605), who wrote the greatest of the canonical commentaries on marriage, says that the most suasive ground for forbidding incestuous unions is that there is a sharing of the blood among close relatives and that the physical image of a progenitor (*imago, complexio, effigies, mores, virtus paterna*) passes to offspring, so that the blood must be weakened through successive generations before marriage should be contracted (7.50; 7.51.1–2). Thus, preventing marriages of close relatives to protect the offspring by allowing several generations to pass before procreation can be called a measure of eugenic foresight, however simple the scientific awareness to support it may have been.

In summary, a eugenic foundation to Christian religious laws forbidding the marriage of close relatives is clearly articulated and commented upon by modern scholars from the late eighteenth and nineteenth centuries. Evidence of this kind of awareness may be discovered earlier in the canonical sources, however, going back at least to the seventh century. It would seem consistent with the eugenic connotation of those laws rooted in antiquity, together with a Christian sense of responsibility for offspring that partly motivated them, to consider further eugenic restrictions on marriage in Christian communities today, in light of contemporary knowledge of genetics.

III. ISLAM

The idea of eugenics is not well developed in the Islamic world. Both Islamic law and tradition generally condemn abortion, which is permitted only if the mother's life is endangered, so there is no genetic counseling that would lead to abortion. Both religious law and tradition do include references to a man's choosing an appropriate wife, but these concerns have been interpreted as moral and social, rather than eugenic.

Islamic religious-moral law, the Shari'a, deals with questions concerning laws of incest and consanguinity from the perspective of moral and social relationships rather than eugenic concerns. The general counsel of the Qur'an and the Prophetic traditions regarding marriage is promulgated in the laws that require a Muslim to marry within the community of believers. A Muslim is better than a non-Muslim as a spouse. "A woman may be married for four reasons: for her property, her status, her beauty, and her religion; so try to get one who is religious" (Muslim, tradition 3457). There is no law to suggest choosing a marriage partner with the intention of improving the progeny through the control of hereditary factors. With slight variations among the Sunni and Shiite schools, the law specifies that a woman may not marry a man who is not equal to her. The earliest ruling to require equality in matters of piety and freedom from physical defects detrimental to marriage is found among the Malikis (see al-Juzayri, for variations among the four schools of Sunni law).

In the Qur'an the main source for marriage law is book 4, verse 23. This prohibits marriage between persons closely related by blood, but this ban reflects ethical and social, rather than eugenic, considerations. Thus in Muslim jurisprudence a man and a woman may be forbidden to marry either because of blood relationship (e.g., a man may not marry his mother or either of his grandmothers, etc.) or relationships established through marriage (e.g., he may not marry the mother or grandmothers of his wife, etc.). Moreover, there are women whom a man may marry singly, but not be married to at the same time (e.g., two sisters, a woman and the sister of her mother or father). This latter prohibition seems to be more for psychological than for eugenic reasons.

Evidence that the Qur'an (or Shari'a) considers nurture, or the environment, to have impact on a child perhaps comparable to that of nature, or genetic inheritance, comes from the Book of Marriage, which prohibits marriage not only between a man and the woman who gave birth to him but also between a man and the foster mother who breastfed him at least a certain number of times.

The ruling seems to indicate similar consequences for foster relations established through suckling: "What is unlawful because of blood relations, is also unlawful because of corresponding foster suckling relations" (al-Bukhari, tradition 46; al-E'Amili, 7/281, tradition 2). In establishing unmarriageability, a foster mother who suckles an infant is regarded exactly as the infant's real mother.

There is further evidence of the Islamic tradition's lack of interest in eugenics. Islam abolished one of the four types of marriages among Arabs, the one described in Arab tradition in terms that may reflect eugenic concerns. The tradition says:

> The second type [of marriage] was that a man would say to his wife after she had become clean from her period, "Send for so-and-so [whose nobility is well established] and have sexual relations with him." Her husband would then keep away from her and would not touch her at all till her pregnancy became evident from that man with whom she was sleeping. After the pregnancy was established her husband would sleep with her if he wished. However, he allowed his wife to sleep with that person being desirous of the nobility of the

> child (*najabat al-walad*). Such marriage was called "marriage seeking advancement" (*nikah al-istibda*). (al-Bukhari, 1986, sec. 37)

Islam, which insisted that faith in God was the main source of all human nobility, was uninterested in this practice, traditional in the Arab tribal culture, for the improvement of the human race through the control of hereditary factors.

Other traditions counsel the believers to choose a partner for breeding (*al-nutaf*) "bravery among the people of Khurasan" [in Iran], sexual potency among the Berber [in North Africa], and "generosity and envy among the Arabs" (al-ʿAmili, 7/29, tradition #6). The Islamic traditions (hadith literature) do reflect explicit knowledge of eugenics in choosing a marriage partner. The source of these eugenic considerations seems to be the Irano-Semitic culture, in which such interests were commonplace. Although these traditions were never used as authoritative precedents for legislation in the Shari'a, they express the popular piety connected with marital relations. For example, the Prophet is quoted saying, "Anyone wishing to follow my tradition should know that among my traditions is marriage. Seek children [through it].... Protect your children from the milk of the prostitute and the insane among women, because milk makes inroads [in the character of a child]" (al-ʿAmili, 1969, 7/4, tradition 6). Moreover, in the case of a person drinking wine, the Prophet regarded it permissible to annul the marriage contract, especially, if the person was alcoholic (literally, "sick" with alcohol) (al-ʿAmili). There also existed a warning against marrying fatuous individuals because their offspring would be a loss. However, it was acceptable to marry them for sexual reasons, as long as one did not seek children through such a union. These traditions reveal the concern about hereditary factors in the progeny.

Other traditions encourage marriages within one's own collateral line, to first cousins. The Prophet, who belonged to the Hashimite clan, at one time looked at the children of ʿAli and Ja'far, two brothers and his paternal cousins by relation, and said, "Our daughters for our sons, and our sons for our daughters" (al-ʿAmili, 7/49, tradition 7). This encouragement is contradicted by other traditions that recommend exogamous marriage and even intermarriage between Arab and non-Arab, and between a free person and a slave. There does not seem to be any awareness in these early traditions of deleterious genetic effects from excessive inbreeding. However, since 1970 there has been a growing debate among traditional Muslim jurists over the authenticity of the tradition that encourages endogamy indiscriminately. Certain injurious hereditary conditions have been detected in the fourth and fifth generations of some tribes in Muslim societies where endogamy is the norm.

Muslim traditions also speak about the negative impact on the fetus of "improper" modes of intercourse rejected by the Qur'an. Yet it was believed that special prayer when one intends to have intercourse with his wife keeps the devil away from what God has ordained to be created. The pure state of the parents' minds and bodies can be transmitted to the child through the invocation of the Divine Name before intercourse. In light of belief in the divine purpose and decree in the creation of offspring ("It is God who brought you forth from your mothers' wombs," Qur'an 16:78), either born with birth defects or normal, there does not seem to be any indication to support genetic diagnosis or screening that would justify abortion, which Islam permits primarily to safeguard the mother's health.

IV. HINDUISM AND BUDDHISM

Because reproduction is one of the most important concerns of human life, most religions concern themselves with the regulation of sexual activity, marriage, and production of children. Hinduism and Buddhism also guide their followers in these matters, but in ways very different both from each other and from Western religions.

Eugenics might be defined as controlling human reproduction to modify or benefit the species. Prior to the present innovation of genetic engineering, eugenics meant restrictions on who could reproduce and with which partner. The recent development of methods of altering the human genome has opened a new area of ethical discussion: the propriety of voluntarily altering the human genome. Eugenics has also been used to excuse genocide, but this aspect will not be discussed here since nothing in Hinduism or Buddhism allows rationalization of genocide.

Although Hinduism and Buddhism have highly developed ethical philosophies, neither religion produces set positions on such contemporary matters as eugenics, nor is it likely that they will, given the nature and organization of the two religions. In both religions, ethics are developed by the individual or the social community; there is no official body that produces ethical statements. Hence there are no official Hindu or Buddhist positions on issues that were not envisioned when their scriptures were composed over 2,000 years ago. However, both religions have ethical ideas or methods that can be applied to modern problems.

Hinduism has its beginnings in the two millennia before the Common Era; the historical Buddha, Shakyamuni, died about 500 B.C.E. In those remote times there were no concepts akin to those of modern genetics and hence there could be no ethical discussions of genetic manipulation. Rather than a single scripture analogous to the Judeo-Christian Bible or the Koran, Hinduism and Buddhism have vast collections of diverse canonical texts that have appeared over millennia. Hinduism does have several authoritative legal texts, the most important of which, *The Laws of Manu,* was composed from about 200 B.C.E. to 200 C.E. These texts codify religious law (*dharma*) but are not regarded as the only legal or ethical authority. Buddhist texts are concerned with spiritual development and give only very general precepts for regulation of lay life. However, it is possible to develop Hindu or Buddhist positions on eugenics.

Hinduism and Buddhism both arose in India and share many common beliefs, such as the doctrine of *karma* (discussed below), yet the differences between the two religions must not be underestimated. Generally speaking, Hinduism is a legalistic religion and pays great attention to regulating life in the world. Buddhism sees worldly life as secondary in importance; attainment of release from suffering in this or subsequent existences is its central concern.

Reproduction in Hindu Religious Law

Although Hinduism recognizes a final stage of life in which the individual is released from domestic and social obligations in order to be able to pursue enlightenment (*moksha*), in the earlier, householder stage, detailed rules define acceptable behavior. Among the most important are those that regulate reproduction. The intent of these rules is to maintain the hereditary caste distinctions. Here Hinduism's outlook is very similar to that of nineteenth- and early twentieth-century Western eugenics, which proposed controlling reproduction to prevent what were considered undesirable unions. Although the specific rules for regulating marriage and reproduction were different from those proposed by Western eugenics, the spirit is the same: to protect the human species from degeneration due to unsuitable matches. Hinduism does not define suitability for marriage according to scientific understanding of genetics, but by caste membership, which is hereditary, and by physical traits, which are correlated with astrology. Traditionally, prospective brides were inspected undressed and an elaborate system of body divination existed for interpreting body markings, particularly on erogenous areas. Manu states, "A man should not marry a girl who is a redhead or has an extra limb or is sickly or has not body hair or … is too sallow … He should marry a woman who does not lack any part of her body … whose body hair and hair on the head is fine …" (Manu, p. 44). There are also rules for selecting the sex of children (males are conceived on even-numbered nights) and in all cases, the social class of husband and wife must match.

These procedures amount to methods of selecting marriage partners according to biological suitability, although the biological traits selected for concern may not seem very appropriate today. Marriage is discouraged if partners are not biologically and astrologically suited. In India, marriages have been and still are arranged by parents on the basis of social, economic, and reproductive suitability. Romantic interest is at best a very secondary consideration. The entire basis of marriage in Hinduism is eugenic, but the factors felt to predispose favorably to suitable offspring are quite different from modern Western ones. Marriage in Hinduism exists to ensure offspring and perpetuate family distinction and caste separation. These laws were intended to regulate reproduction rather than sexuality. Sexual liaison outside of marriage and across caste, though not approved of, was not considered wrong so long as no offspring resulted.

Hinduism does not contemplate elimination of inferior castes, but simply limitation of physical contact between them and higher ones. The higher castes must preserve their purity, but all castes are necessary and have their place in the cosmos (Danielou). This contrasts with the extreme, modern racism, in which one group, which considers itself superior, aims at the elimination of others. There is no idea of altering the genetic or social situation of humanity as a

whole. On the contrary, marriage rules attempt to maintain the status quo. Their rationale is not to improve the human species but to prevent its degeneration.

In general, Hinduism has not been opposed to attempts to control reproduction. Female infanticide has been extensively practiced in India. An innovation is the use of ultrasound machines by entrepreneurs; at village marketplaces a pregnant woman can find out whether she is carrying a boy or girl, with abortion elected in the instance of the latter. A similar practice exists in China. Although the practice of female infanticide can be explained in economic terms (a girl's parents must provide a dowry if she is to be married), it represents a practice of controlling reproductive outcome for family or social goals. Infanticide has not been viewed with the same opprobrium as in the West, although it is certainly not fair to imply that the Hindu religion condones such acts.

The Indian concept of karma, which is fundamental to all its philosophical and religious systems, has some similarities to modern genetics. It is a law of moral cause and effect. The literal meaning of karma is action, and the theory holds that one's present state is the result of personal and collective actions in this and previous lives. Actions, like genes, have effects that persist across lifetimes. Much of each individual's present circumstances are the result of previous actions carried across generations. Karma and scientific genetics seek to account for the human experience that the past tends to repeat itself in the present. Both offer an explanation of how an individual comes to have certain traits.

Buddhism and Human Reproduction

Buddhism, which abolishes the caste system, has no concern with the suitability of marriages. Indeed, its monastic nature has made Buddhism generally uninterested in family life and reproduction. Throughout Buddhist history, clergy were forbidden to solemnize marriages; this was seen as inappropriate involvement in worldly affairs. (Wedding ceremonies officiated by Buddhist monks are a recent innovation.) Nor does Buddhism have an elaborate ethical code for regulation of lay behavior. Throughout most of its 2,500-year history, Buddhism has been monastic; lay life was not considered conducive for progress toward enlightenment. However, the sangha, the order of monks and nuns, did try to inculcate simple moral understanding in the laity.

In the Theravada form of Buddhism, which most closely resembles early Buddhism, the laity is taught the Five Precepts, which call on the Buddhist to avoid (1) unnecessary killing, (2) taking what is not given, (3) sexual misconduct, (4) harmful speech, and (5) use of intoxicants. Although Buddhist teachers will offer their particular interpretations of these principles, detailed rules are not given in any canonical text. Sexual misconduct, for example, is rarely defined and there is no position on contraception. Nor are there specific rules on suitability of marriage or sexual partners. The first precept might be interpreted as discouraging abortion; however, termination of pregnancy is not absolutely forbidden, though it is considered highly undesirable. Buddhism would see the ideal situation as one in which the partners are mindful of the consequences of their actions and avoid a situation in which abortion is a consideration. If carried out, abortion should use a method that minimizes any suffering. (For Buddhist analyses of the abortion issue see Taniguchi, 1987, and Redmond, 1991.) In Japan, where abortion is used as a method of family planning, Buddhist monks are involved in practices that women use to atone for abortion.

In contrast to the religious law of Judaism, Christianity, and Islam, the Buddhist precepts are very general, expressing morality in spirit rather than letter. Nothing in the five lay precepts can be construed to oppose genetic manipulation, provided that it is not harmful. Buddhism does not try to regulate lay behavior by detailed codes of laws, but rather by teaching *sati,* "mindfulness" and *ahimsa,* "harmlessness." The ultimate value in Buddhism is not living in accordance with a code of religious laws but being aware of the effects of one's actions so as to minimize harm. In general, a Buddhist would be concerned that genetic knowledge not be used in a way that causes suffering, but would not be opposed in principle to the acquisition or application of such knowledge. Buddhism places its highest value on knowledge, which it sees as the sole vehicle for enlightenment and release from suffering. Ignorance, not sin or disobedience, is the case of a human's unhappy state. Hence, Buddhism may be seen as favoring the acquisition and use of genetic knowledge, provided that it is applied in ways that help, rather than harm, living beings. Changing the genetic code so as to eliminate a disease in the offspring would be quite acceptable so long as it was carried out skillfully, that is, not harmfully. Partner selection for genetic or ethnic reasons is not supported by Buddhism, which abolished the Hindu caste system. However, such selection would not be ethically improper if it did not cause suffering to those involved.

Cosmology and Eugenics

There are two commonly held contemporary Western positions about eugenics that Hinduism and Buddhism see rather differently from most Western ethicists. One position is that since the world and everything in it, including human

beings, are held to be created by God according to a divine plan, then altering the human genome is altering the very basis of God's creation, which is impermissible. Thus the Vatican's statement on reproductive technology holds that "no biologist or doctor can reasonably claim, by virtue of his scientific competence, to be able to decide on people's origin or destiny" (Vatican, Congregation for the Doctrine of the Faith, 1992, p. 84). A similar but secular argument holds that we should not alter nature. Although altering nature may not be inherently wrong, pragmatically such alterations are much more likely to do harm than good. The only safe course is stringently to restrict novel technologies such as genetic engineering.

Neither Hinduism nor Buddhism conceives of a creator God whose divine plan might be altered by genetic manipulation. (Although Brahma is considered the creator in Hinduism, the metaphysics of creation are quite different. Creation occurs from moment to moment and not according to a perfect plan.) Far from seeing the world as divine or perfect, both religions regard the world as inevitably a place of suffering. The fundamental virtue in both Hinduism and Buddhism is practicing *ahimsa,* or harmlessness, which means to avoid making living beings suffer. For example, the environment should not be harmed because living creatures are dependent on it. Since the universe was not created by divine plan, altering it is not considered a repudiation of God. In this context genetic manipulation is perfectly acceptable.

As to the second argument, that humans cannot handle their power over the genome, neither Hinduism nor Buddhism can be held to have a clear position on this. Evil is the result, respectively, of delusion, *moha,* or ignorance, *avidya.* Ethical ignorance is simply an aspect of more general spiritual ignorance, which clouds perception of the true nature of existence. However, Buddhism and Hinduism conceive of ethical ignorance somewhat differently. In Hinduism, it is necessary to be aware of the complex laws, or dharma, regulating human behavior. In Buddhism, ignorance is lack of awareness of the law of cause and effect, for example, of knowing how one's actions will affect oneself and others (Taniguchi, 1994). Mindfulness shows that an action harmful to another will cause suffering just as it would if done to oneself. A unique moral insight of Buddhism is that ethical behavior requires factual knowledge (Redmond, 1989)—for example, what effects behavior will have on others—as well as knowledge of ethical precepts. The way to this knowledge is through self-cultivation such as meditation, study of religious texts, and, especially, the influence of a teacher. Ethical behavior results from personal moral development rather than detailed moral legislation.

Karma and Eugenics

The concept of karma can be interpreted, or sometimes misinterpreted, so that it appears to oppose eugenics. Karma holds that misfortunes in this life are due to harmful actions in a former life (although there are also social sources of unfavorable karma). By this interpretation, if a child is born with a genetic disorder, then the misfortune is due to previous voluntary actions that harmed others and hence is deserved. Furthermore, this karma must be worked off; the suffering must be endured to expiate the previous wrongdoing. If the suffering is prevented, it will simply occur later. Thus, if a fetus with Down syndrome is aborted, the same individual will simply be reincarnated later with a similar affliction.

The idea that suffering should not be relieved, because karmically deserved, is widespread in India and Buddhist countries and is sometimes articulated by Buddhist teachers in the West. It is a misunderstanding of the Buddha's teaching, which was concerned to explain the way of release from suffering. Although Buddhism teaches compassion, some Buddhists, in common with some followers of other religions, find interpretations that rationalize evasion of the ethical obligation to be kind to others. It is not consistent with Buddhist teachings on compassion to refrain from relieving another's suffering on the grounds that it is due to the operation of karma.

Buddhism, although not opposed to eugenics if it is skillfully applied, does not require it. In contrast to Hinduism, it does not establish rules regarding reproductive behavior. Some contemporary Buddhists believe that each individual has his or her tasks in life and that, although these might be different for someone with a birth defect, others should not assume that such a life is therefore less worthy. This has affinities with the idea that we should not interfere with nature because we may not fully understand the effects of what we do.

Hinduism, then, requires a form of eugenics, and Buddhism is essentially neutral on eugenics as such, but would be greatly concerned to ensure that eugenic practice decreased suffering rather than increasing it. Neither religion sees eugenics as in itself improper, but both concern themselves with how it is carried out. However, Hinduism and Buddhism produce no set positions, and individual Hindus and Buddhists may have views different from those summarized here.

EXPERT TESTIMONY

• • •

Courts frequently look to the testimony of expert medical witnesses to assist them in the search for legal truth. In addition to Egyptian and Biblical references to forensic medicine, physicians in Greece and Rome functioned as expert witnesses. A physician testifying at the inquest into Julius Caesar's death stated that he found twenty-three stab wounds on the corpse but only one wound, a wound in the throat, that could have caused death. The Institutes of Justinian (529–533 C.E.) and the codices of Charles V, the Lex Bambergensis (1507), also made provisions for expert medical testimony (Landé; Clements and Ciccone). In the United States, physicians are called on to testify as expert witnesses in a variety of civil and criminal matters. The civil issues range from workers' compensation to child custody, from physical and emotional damages to malpractice. The issues in criminal cases range from cause of death to competence to stand trial, from deoxyribonucleic acid (DNA) typing to the insanity defense. This entry traces how a physician becomes involved as a medical expert witness, what the requirements of the role are, and the ethical issues that may arise.

Courts of law distinguish between fact witnesses and expert witnesses. Fact witnesses may be required to testify if they have some direct knowledge about the issue before the court, but may not express opinions. Expert witnesses have knowledge that goes beyond that of the ordinary citizen and agree to undertake the role of expert witness and are permitted to express opinions.

The difference between a "fact" and an "opinion" is the degree of concreteness of the description, or the difference in the "nearness or remoteness of inference" (McCormick, p. 26). The courts and the public receive expert testimony with both admiration and suspicion. There is appreciation for the clarity provided, but fear that experts may control the legal outcome. This fear may be accentuated in a democratic society that mistrusts those with special knowledge. In 1986, the American Medical Association (AMA) took the position that "as a citizen and as a professional with special training and experience, the physician has an ethical obligation to assist in the administration of justice" (Council on Ethical and Judicial Affairs of the AMA, p. 138). The participation of the medical expert may be justified on the basis that a meaningful concept of justice requires empirical data on the function of the human organism in health and disease—data that the medical expert can provide (Ciccone and Clements).

The Expert-Witness Role

Expert-witness testimony in an adversarial legal system may lead to a battle of the experts, a battle that may be avoided if the court appoints an expert approved by both sides of a legal action. There are different models for the expert-witness role. In the first model, the court-appointed or "impartial expert" witness model, the expert witness is still subjected to cross-examination, yet has the implied endorsement of the court—the court would not hire an unqualified expert. However, the view that such an expert witness is neutral is a fallacy (American Academy of Orthopedic Surgeons) because the expert is necessarily an advocate for his or her opinion. In the second, the objective "expert-model," the expert is hired by or appointed to one party, but the expert's role is limited to a comprehensive examination of the evidence and formulation of an opinion, if possible. In the third, the "consultant" model, the expert functions as a consultant to the attorney. The expert provides an accurate

statement of the examination conducted, the findings of the examination, and the opinion and reasoning used to arrive at the opinion, and provides assistance with trial strategy and cross-examination (Appelbaum). The ethical hazard of this model is that the expert may identify with the attorney's position and become an advocate.

In each model, the medical expert is expected to provide a clinical evaluation and a review of the applicable data in light of the legal question posed and in the spirit of honesty and striving for objectivity—the expert's ethical and professional obligation. This includes a thorough, fair, and impartial review and should not exclude any relevant information in order to create a view favoring either the plaintiff or the defendant (American Academy of Psychiatry and the Law). The treating physician, whom the court may compel to testify as a fact witness regarding contact with a patient, is frequently sought to provide expert-witness testimony. The legal system assumes that the treating doctor is more credible than a nontreating doctor. The treating physician has a specific therapeutic focus—the patient's health—that may not allow service as an expert witness. The treating physician may encounter a conflict of interest (e.g., maintaining the patient's confidentiality versus providing the court with information).

When taking on the functions and obligations of the expert-medical-witness role, the treating physician may, out of loyalty to the patient's best interests, act as an advocate for the patient. This distorts the obligation of the expert witness. On the other hand, if the treating doctor's expert testimony does not have the effect of adequately supporting the patient's position, the doctor-patient relationship may deteriorate as a result. Hence, the role of physician as advocate for the patient may be inconsistent with the role of physician as expert witness and pose the ethical issue of conflict of role obligation. This conflict should be avoided. When this is not possible, self-awareness of the possible conflict and awareness by the court of the conflict may minimize its effects.

The Ethics of Being a Medical Expert Witness

Medical professionals who undertake the role of expert witness are generally expected to have an unrestricted license to practice medicine, to be knowledgeable and experienced in the area in which they are functioning as a medical expert, and to have knowledge of the legal system. At the initial contact by the court or an attorney, the expert clarifies the question being asked and explores the relevant information about the case. The discussion of the question also permits the expert to be explicit about limitations of the evaluation he or she can offer. The expert witness must know the law that is relevant to the forensic question in the jurisdiction in which the expert may testify. The court or the attorney can provide the applicable statutes. Professional values require such obligations. In addition, legal consequences involving criminal and civil verdicts with ensuing penalties require this standard of obligation.

Medical experts can expect cooperation from the court or attorney in obtaining all the relevant legal, social, and medical documents. Medical experts should obtain consultations from others when there are important areas outside of the expert's knowledge. The medical expert must also be aware that the attorney may have a hidden agenda—understanding the hidden agenda may influence the expert's decision to accept or refuse the case. For example, when the evidence is not strong, is the prosecuting attorney's raising the question of competence to stand trial (CST) a way to keep the individual from being released? Is the defense attorney's request for an evaluation of CST a way to prolong the legal process so that prosecution witnesses may become difficult to locate, thereby weakening the district attorney's case? These are ethical questions the legal system must address, but medical experts who work with the legal system have a clinical obligation to avoid abuse of their role.

The individual who agrees to function as an expert witness is entitled to an expert witness fee, the terms of which should be clear and explicit at the time that the work is started. It is unethical for expert witnesses to make their fees contingent on the outcome of trials. In fact, there are advantages to the expert working with a retainer fee, against which the work of the forensic expert may be charged: (1) it diminishes whatever influence the examiner's concern for payment has on the quality of the work, and (2) if asked on cross-examination if the experts are being paid for their opinions, the experts are able to respond that in fact they were paid on a retainer basis for their time. Such arrangements avoid the ethical problem of experts being seen as "hired guns."

The informed consent of the individual to undergo a forensic medical evaluation should be obtained whenever possible. This includes a description of the purpose of the evaluation, the limits to confidentiality that may exist, and to whom a report will be made. The doctor-patient relationship includes, as one of its ethical requirements, the qualified obligation that the physician maintain confidentiality. The examinations conducted by the medical expert witness are usually outside the scope of the doctor-patient relationship; however, the bioethical obligations remain, and the physician must be aware of the bioethical obligation not to harm the individual unnecessarily by gratuitous disclosure of information. The disclosure of information must conform with the requirements of the law and the explanation made

to the individual examined. In a legal context, the medical expert is bound not by rules of medical confidentiality, but by the rules of confidentiality that the legal circumstances require. It is expected that the medical expert witness will be aware of and abide by the specific rules of confidentiality applicable to work with the legal system. Informing the examinee may not be sufficient protection because the physician can create a relationship in which the examinee forgets the warning (Diamond). There are circumstances in medical-legal evaluations where consent is not required. The individual is then informed that the evaluation is legally required. However, if the individual chooses not to participate, the refusal will be included in any report or testimony.

Admission of Expert Testimony

The role of the expert witness is based on education, training, and experience that gives the expert knowledge in a particular discipline. The United States Supreme Court in *Daubert* v. *Merrell Dow Pharmaceuticals* (1993) described the limits of expert scientific testimony and endorsed the *Federal Rules of Evidence* (United States) that had broadened the admissibility of scientific testimony to include theories that were not widely held. The *Daubert* decision rejected the restrictive standard that permitted the judge to exclude expert testimony that the judge found was not "sufficiently established to have gained general acceptance in the particular field to which it belongs" (*Frye* v. *United States*, 1923). However, the U.S. Supreme Court also put limits on "the admissibility of purportedly scientific evidence" by requiring the trial judge to determine whether the reasoning or methodology underlying the testimony is scientifically valid and whether that reasoning or methodology properly can be applied to the facts in issue (*Daubert* v. *Merrell Dow Pharmaceuticals*, p. 2796). This gatekeeping function of the judge on expert scientific testimony may lead to judges who appoint their own experts to examine the experts put forward by opposing parties in the litigation.

Ethics and Medical Expert Testimony

The medical expert may be required to testify in perhaps one of ten cases that the expert is called upon to evaluate. It is this public role that causes the most discomfort and is the most sensationalized of all the expert's functions. The medical expert witness usually engages in this work as a part of a larger clinical practice. While some experts have given up clinical work, this is rare. Medical experts who have not actively engaged in their discipline or who have given it up may find their credibility questioned in court. Medical experts have the ethical obligation to inform the court or attorney hiring them of the status of their clinical practice. Prior to entering the courtroom, experts assist the attorney as well as they can "but only within the requirement of medical ethics" (Stone, p. 27). Each of the three models carries the ethical obligation that the expert be honest and, even when assisting an attorney, not become an advocate. The medical expert who is called to testify should require full and complete preparation from the attorney. Preparation for testimony, which almost always includes at least one pretrial conference between attorney and expert, is essential to adequate work in the courtroom.

In court, medical expert witnesses are not advocates for either side in the litigation, but may advocate their opinion. The most effective role of the expert witness is that of teacher—that is, one who elucidates the nature of the evaluations and the reasoning used to arrive at his or her opinions. The expert should present credentials without exaggeration. The expert should be prepared to present specific perspectives or bias and identify value components that are always present in interpretations of the data. If the issue before the court presents an ethical dilemma for the expert, whether as a result of personal belief or from concerns about societal harm that his or her opinion may cause, the expert has the obligation to avoid involvement in such cases. The requirement of truthfulness on the part of the medical expert witness requires that relevant information not be kept secret (Rappeport). In addition, there are limitations that occur in medical examinations, and these limitations of reviewed materials (e.g., completeness of the examination or knowledge of that area of medicine) may require the expert to qualify an opinion or, at times, to decline to provide an opinion to a particular question.

The attorney who retained the medical expert will call and question the expert with direct examination. This usually begins with eliciting the expert's credentials; the questions present the expert's education, training, experience, and other information that chronicle the achievements of the expert to the court. Using the *Daubert* directives, the judge may rule to exclude the expert. Medical-expert witnesses are expected to present their testimony—avoiding jargon—with sufficient clarity so that those lacking expertise can understand the findings and follow the reasoning. The attorney who has retained the expert can be expected to emphasize his or her ability and the brilliance of the conclusions. The cross-examining attorney, both in speech and gesture, will often attempt to convey to the court that the expert witness lacks credibility and that his or her conclusions are worthless.

The expert may be presented a hypothetical question, which is a conflation of assumptions and proven facts into an organized account of a situation. The hypothetical question calls for expert witnesses to assume the information in the

question to be fact. Then experts are asked if they have an opinion derived from those facts and, if they do, to state that opinion. The hypothetical question is used because there is a dispute about the facts, and the hypothetical question allows the court to hear the expert's opinion without deciding if the facts in evidence are true.

The expert witness has rights in the courtroom and may ask the judge to clarify when material that is asked for is privileged. The expert witness may ask for clarification of a question or refuse to answer questions the expert does not understand. Experts may and should say that they do not have a response to the question, if in fact they do not have one. Experts, when asked a yes or no question, can ask the judge whether the answer can be qualified. If on cross-examination this is not permitted, on subsequent redirect examination the attorney who retained the expert may ask for further clarification. The expert has a right to complete an answer and should protest if interrupted. Expert witnesses, as contrasted with fact witnesses, may refresh their recollections using written notes and records.

The courtroom, the most visible portion of the adversarial system with its "battle of the experts," is viewed by some critics as a three-ring circus. Even when expert witnesses agree substantially, small differences may be exaggerated by an attorney and held up as proof that the entire discipline has nothing to offer the courts. If expert witnesses are expected to provide absolute certainty, the witnesses will inevitably be clowns in the courtroom. However, the opinion of the expert witness, as with a medical diagnosis, is a probability statement and as such, is the best conclusion given the analysis of the data. This conclusion may certainly be open to question. Although the credibility of the expert witness is important, the courtroom belongs to the attorneys. The weight given to the testimony of the expert is markedly influenced by the courtroom skill of the attorneys involved. Do the faults of the legal system outweigh its benefits and is there an alternative, superior system for arriving at legal verdicts? This is a question better considered in an analysis of the adversarial system.

At a trial, the ultimate issue is the question about which the jury or judge must arrive at a verdict (e.g., did the defendant's negligence cause the injury to the plaintiff?). It has been suggested that the medical expert respond only to questions about the medical condition and avoid responding to the ultimate issue, which some have called either a leap in logic (American Psychiatric Association [APA] Statement on the Insanity Defense) or the application of medical reality to a legal procedure. It is contended that the ultimate issue is an issue of social and moral policy and, therefore, is beyond the province of scientific inquiry. While there are circumstances when the information does not permit the medical expert to arrive at an opinion, the fact that the question has been framed in a legal context may make it appropriate for the expert to express an opinion. This opinion need not usurp the role of the trier of fact.

Conclusion

Much of society's ambivalence toward expert witnesses is derived from society's unrealistic hopes and fears of expert witnesses. The hope that the expert will have secret skills, which provide special access to absolute truth, imbues the expert role with unrealistic authority and certainty. This expectation of expert witnesses is not consistent with the reality of scientific expertise that allows for probable conclusions. The fear that the expert will take over the legal process and subvert justice is also exaggerated. The legal system has rules of procedure that limit the influence of the expert witness. Functioning within the boundaries of science and governed by ethical guidelines, experts are not oracles whose conclusions are not open to question, but witnesses who can provide the legal system with useful information.

F

FAMILY AND FAMILY MEDICINE

• • •

Families have played a most important role in the history of medicine, tending the sick when doctors were unavailable or unavailing. Medicine and the family, the two ancient and in some respects rival systems of care for the very vulnerable, are each in part shaped by the other and rely upon the other for certain kinds of help. When illness or injury exhausts a family's capacity for care, the family looks to professional medicine for the necessary facilities and expertise; in turn, technological advances in medicine have driven the healthcare system to depend on families for what can be enormous sacrifices of time, money, caring labor, and even spare body parts on behalf of its patients. Recent developments in medicine have not only expanded the options for forming families—for example, through in vitro fertilization and contract pregnancy—but they have also had an impact on familial demographics: artificial means of birth control have helped reduce family size, while improvements in healthcare have extended longevity, though they have not eradicated the ills of old age.

Yet the most profound impact of contemporary medicine on the family may not be so much a function of new technologies as of new social practices. A characteristic of the social arrangement of healthcare in the twentieth century was the professionalization of care and the concomitant migration of care provision from home to hospital. If trends in the 1990s hold true, however, the twenty-first century may see a reversal of that process, with greater amounts of care—requiring greater skill, and more intensive investment of time, energy, and emotion—moving back into family contexts.

Bioethics has a rather checkered record of engagement with moral issues that arise where families and medicine meet. While new reproductive technologies have been the focus of bioethical attention from the start, the proper role of family interests in healthcare decision making has been addressed only by relatively few workers in the area, and bioethics has, as of yet, taken little notice of the moral questions involved in the "hospital to home" shift. The lack of attention to issues apart from those suggested by reproductive technologies is curious, both because of the practical exigencies involved (family members, for example, are and will continue to be much more influential than formal advance directives in making healthcare choices for the incompetent), and because the conceptual and moral questions involved in understanding the special character of these intimate associations are very challenging. What constitutes a family? How do various forms of family relationship translate into moral duties and prerogatives? What does "justice" mean in such contexts, and how should justice within families relate to broader concerns about justice in the allocation of healthcare resources in society?

With the turn of the twenty-first century, however, bioethicists have shown a greater willingness to take up these questions, and to consider in particular that the role of family members in the care of ill relatives may be morally more complex than simply that of serving as conduits of information about the treatment preferences of patients too ill to express them on their own. The pioneering work of scholars such as John Hardwig has helped to instigate broader bioethical reflection on how healthcare choices can affect the well being of other family members, and has pressed in particular the question whether the impact of

patient care on families gives them a legitimate stake in the treatment decision-making process. While the notion that the interests of families should be considered along with patient interests in choosing among treatment options remains highly controversial among bioethicists, there is some evidence that healthcare providers are more receptive to this idea than are theorists. A 2003 study by Hardart and Truog reports that many physicians regard the interests of family members as pertinent to healthcare decision making, even in the absence of specific patient acknowledgement of those interests. A sizable minority went further, regarding family interests as of equal significance to those of patients. If these results are representative, then bioethicists will have a strong incentive to consider the role of families more carefully then they have yet done, and to address in particular the burdens on families that do not emerge primarily from clinical decision making, but rather from policies on the part of hospitals and insurers that send patients home "quicker and sicker."

There is other evidence that healthcare providers have been more sympathetic than bioethicists to the role that families play in the lives of so many patients. *Family medicine* or *family practice* is a distinct primary care specialty within medicine, but there is no comparably entrenched specialty within bioethics and little bioethical attention has been paid to family medicine's particular focus and problems. In addition to its treatment of the family from perspectives pertinent to bioethics, then, this entry also contains a brief discussion of the ethical dimensions of family medicine.

Families: Myth and History

The development of a mature "bioethics of the family" is significantly complicated by controversies concerning the nature and importance of this much-vaunted, much-maligned social institution. The dramatic shifts in the demographics of American families have rendered them suspect, as have public debates that underscore the family's role in sustaining practices hostile to women's interests and that identify families or *family values* as a particular focus of conservative political perspectives. Families have come to seem so fragile, their configurations so arbitrary compared with what they once were, and their value so contested, that offering them a special role in bioethical deliberation may seem a dubious enterprise.

Yet neither hostility nor sentimentality does justice to the moral character of these complex and puzzling entities. Nor is the notion that families are particularly unstable in today's world altogether accurate. American families have always been somewhat fragile and subject to rapid reconfigurations. African- and European-American families in the Chesapeake colonies of Virginia and Maryland, to take only one instance, were so vulnerable to malaria and other fatal illnesses that it was not at all unusual for an adult, whether slave or free, to bury three or even four spouses, or for half-orphaned children to be reared by relatives other than the surviving parent. In the matrilineal Iroquois societies of that same period, divorce was quite common. It is true that middle-class families gained a certain solidity when they underwent a shift around 1800 to a sentimental, child-centered model of domestic life, but this was achieved through an arguably unjust gendered division of labor, in which the middle-class father was increasingly absent from home and the mother's work was narrowed principally to unpaid domestic tasks. For many poor young nineteenth-century mothers—whether black, Latina, Irish, or east European—this arrangement was not an option, and the long hours spent working outside the home left the care of their children a somewhat haphazard business. Death in childbed and other premature deaths once threatened the family's integrity as much as the divorce rate, which has risen by a steady 3 percent in every decade since the Civil War, does now. In short, there is good reason to think that stress, turmoil, and identity crises have long been a feature of American families.

The "Culture of Divorce"

The long history of family fragility notwithstanding, however, sophisticated scholarship now identifies divorce as a source of instability particularly threatening to children's well being. Sociological and ethnographic studies appearing since the mid-1990s suggest that the fate of the "family of origin" is of systematic and enduring importance to many central features of children's lives, and that the damage ensuing from divorce has a strong tendency to reach well into adulthood, at least in contemporary American culture. Judith S. Wallerstein, Julia M. Lewis, and Sandra Blakeslee argue in *The Unexpected Legacy of Divorce* (2000) that divorce impairs children's ability to consolidate their identities as mature adults and to form their own enduring intimate relations, in a way that is apparently different and seemingly graver than other forms of familial disruption and reconfiguration. Some of this damage would seem to be a function of features that often attend divorce: the subsequent inability of parents to provide reliable, timely, and well-directed care, the tendency of noncustodial parents—particularly fathers—to attenuate or even abandon their connections to their children, economic losses leading to a reduced ability of custodial parents to spend time with children, and so forth. Some damage, however, apparently is attributable to divorce itself. Even when parents divorce

relatively amicably, maintain continual and substantial engagement in their children's lives, do not require their children to "take care of them" emotionally in inappropriate ways, and are able to support their children's fiscal and emotional needs without interruption, children undergo losses in their expectations and abilities concerning the maintenance of their own long-term intimate relationships, and seem to suffer a measurable delay in their movement into adulthood. These decrements seem to be of a different and more severe character than the harms that affect children who have grown up in families where the parents were continually unhappy but did not divorce.

While many questions remain to be answered—for example, why these harms seem to be more pernicious in the United States than in, say, Scandinavia; and whether divorces in which care is taken to protect the children are worse on the whole than other ways in which families have come unglued throughout history—recent social scientific studies make it difficult to regard divorce as a feature of contemporary life that children can simply get over.

These results may have implications for bioethics as well as for healthcare practice and policy. Is the process of transferring ever more intensive forms of care from hospital to home made more morally suspect by the possibility that children with divorce in their pasts will be less willing to provide such attention with the consistency and quality required for good health outcomes? Is the role of family members as presumptive proxy decision makers cast under a cloud? Is the apparent willingness of many physicians and at least some bioethicists to recognize family interests as relevant to medical choices rendered more problematic by these data? And, given the emotionally complex, internally contested, and structurally protean character of people's affiliative and kinship patterns, what counts as a family anymore, anyway?

Defining *Family*

A measure both of the importance of families to our lives and of our ambivalence about them is that any discussion of the topic quickly elicits a demand for an explicit statement of what is meant by *family.* The most useful such account is perhaps a normative one, which identifies features of special moral significance in the clear paradigm cases. Those features can then be used to determine what counts as a family in the less clear cases. Ludwig Wittgenstein's notion of family resemblances may be pressed into service here: any social configuration that incorporates at least most of the morally significant features of, say, marital and parent-child relationships can be thought of as a family for purposes pertinent to healthcare. These features include longstanding, committed relationships; blood ties; emotional intimacy; shared histories; and shared projects that produce solidarity among family members. Other crucial features identify functions: families forge the selves of their youngest members and help maintain the selves of adults. Further, familial relationships go beyond the contractual and the voluntary; in them people incur responsibilities not of their own choosing.

Relationships within families will take on greater or lesser bioethical significance, depending on the familial question under consideration. If treatment decisions for a badly damaged neonate are at issue, *family* means the mother and father; if the issue at hand is pedigree testing for a genetic disorder, *family* means blood kinship; if the issue is determining the appropriate caregiver for a person with progressive dementia, *family* may mean spouse or child.

Family and the Law

Discussions in family law echo the question of how we are to define families. While there was for many years no basis in common law for family members to make treatment decisions for incompetent adults, for example, a number of court decisions in the 1980s as well as various legislative actions gave families explicit decisional authority in twenty states. By the turn of the century, thirty-five states plus the District of Columbia recognized the authority of family members to make many significant healthcare decisions, should their relatives become incompetent, without having an explicit advance directive. This legal trend makes it all the more necessary to know just who is entitled to count as family. A strictly biological definition does not capture what seems socially significant about single parenting, adoptive parenting, step-parenting, or contract pregnancy. The legal notion of marriage skips over *kith*—long-standing, committed relationships resembling kinship that might give, say, a neighbor or housemate moral authority to speak on behalf of a patient who is too ill to make treatment decisions. The law also fails to recognize gay and lesbian relationships, though these are often more significant than blood ties to the people within them. On the other hand, functionalist definitions of families require courts to determine whether a particular relationship closely enough approximates an accepted norm of *family* to count as one. This involves inquiry into such areas as sexual activity, management of finances, and degree of exclusivity and commitment—a profound intrusion into personal privacy.

When one compares the body of family law against the body of law dealing with, for example, commercial transactions, family law seems distinctly underdeveloped and lacking in detail. The reason for this, Lee Teitelbaum argues in

"Intergenerational Responsibility and Family Obligation: On Sharing," is that families, incorporating "diffuse, particularistic, and collective values and relations," tend to reflect a wide-ranging set of circumstances and goals, while law is better suited to consider individuals as abstracted from these particulars in public settings that can be assimilated into a formal, rational scheme (Teitelbaum, p. 789). There is a further problem. In "Bioethics and the Family," Carl Schneider points out that in the last few decades family law has increasingly eschewed moral discourse. The temptation is understandable: the problems within families are complex and often "reduce to unresolvable disputes over unverifiable beliefs" (Schneider, p. 822). But by avoiding the language of morality, family law has stripped itself of conceptual notions that might help resolve such bioethical perplexities as contract pregnancy and the family's role in decision making for incapacitated patients.

Challenges to an Ethics of Strangers

Bioethics, however, need not lie down with the law. Because it can achieve a high degree of particularity, it is better suited than the law to use a working definition of families that identifies morally relevant features and notes family resemblances (so to speak) among various small-scale human groups that include some such features. Roughly speaking, two approaches have been used to incorporate what is morally valuable about families into bioethics.

The first approach assumes the moral framework characteristic of the Enlightenment, with its stress on the impartial and the universalizable. Within this tradition, Nancy Rhoden has criticized the suspicion of the motives and interests of family members that has opened family decisions concerning nontreatment of incapacitated relatives to court review. Arguing in "Litigating Life and Death" (1988) that because family members "are in the best position to reproduce the preferences of an incompetent patient," Rhoden concludes that the burden of proof should be on the physician rather than the family to convince a court of law that an unwise decision has been made. Using the same moral framework but setting it in service of a more radical departure from current practice, Hardwig (1990) has attacked the exclusionary bias of the doctor-patient relationship, insisting that the interests of all those with a stake in a medical decision, not just the patient's, be honored impartially.

At the same time, the so-called personal turn in ethics explored by Bernard Williams, Lawrence Blum, Jeffrey Blustein, Margaret Urban Walker, and others has challenged the orthodox assumption that ethics has primarily to do with right conduct among strangers—an ethics that favors no one and whose dictates are universalizable. The personal turn might be said to have begun with Williams's germinal observation in "Persons, Character, and Morality" (1981) that impartialist dictates, if followed scrupulously, leave insufficient room for moral agents to pursue their own individual interests, desires, and projects—all the substance, in fact, that gives life its meaning, yet such meaning is what motivates one to go on. The task of Williams and others has been to construct moral accounts that honor the particular and the personal, but do so in a nonarbitrary way. Feminist ethical theory has devoted much attention to this task (see Hanen and Nielsen; Kittay and Meyers; Mahowald; Nussbaum; Walker).

In bioethics, one can see the direct impact of the personal turn in the writings of Ferdinand Schoeman. He has argued that a Kantian ethics for strangers, which insists that medical decisions for an incompetent person can be made only in accordance with what is in that person's best interests, provides an inadequate basis for understanding the parent-child relationship. That relationship, because it is intimate, permits parents to compromise the child's interests so as to promote the family's goals and purposes. Parents could, for example, permit a child to donate bone marrow to save a sibling's life, even though donating the marrow is not in the child's medical interests. In Schoeman's view, then, the family is seen as an entity with an integrity of its own that is greater than the sum total of the interests of its members (Schoeman, 1980, 1985).

Rhoden's attempt to vindicate the decisional authority of families and Hardwig's challenge to the patient-centered focus of conventional bioethics use the relatively straightforward strategy of applying impartialist standards to a context—the doctor-patient relationship—where they have not been applied before. Both writers are concerned with decision making, and more particularly with the locus of the decision. By contrast, the personal turn in bioethics, which is concerned with a more fine-grained understanding of the structures of interpersonal relationships and their importance for human action, is less well developed. But attention to the personal suggests certain moral features of family life that might be used to construct an ethics of the family.

Some Elements of an Ethics of the Family

Social critics from Plato through Shulamith Firestone have argued that the distinctive features of the family constitute moral liabilities, and that families ought to be altered or abolished. In *A Theory of Justice* (1971), John Rawls notes quite explicitly that the family is always a problem for egalitarian social theory. A more sympathetic approach

would portray those features as morally valuable, but whatever one's basic stance toward families, they do possess features that require moral attention and analysis.

One rather marked characteristic of families is their tendency to favor their own over outsiders. A central question is whether this sort of bias can be adequately understood inside a universalizable, impersonal framework. For example, can the favoritism parents show their children be justified insofar, and only insofar, as it increases the overall utility? James Rachels has argued for a position he calls "partial bias," which allows the expression of particular regard for children (and presumably for one's intimates in general) in those cases where their needs are in conflict with similarly serious needs of others, but not otherwise. This approach, he suggests, allows the special goods of intimacy to flourish within the context of appropriate regard for the needs of all, impartially considered. It is, however, questionable whether a truly disinterested regard for the needs of others, in a world where resources are massively maldistributed, would leave any appreciable room for special regard for the needs of one's own, particularly for people living in affluence. But even if some measure of special attention to loved ones could be made consistent with general impartialist norms, unless family members favor their own to at least a slightly greater degree than impartialist considerations mandate, it would seem they express only an ersatz partiality, not true loyalty, love, or commitment. To feel the force of this point, consider the intuitive response to a father who, when his only daughter thanks him affectionately for taking her to a baseball game, tells her, "Oh, I would have had to do the same for any child of mine."

Rather than attempt, as Rachels does, to assimilate personal loyalty into an impartialist framework, a promising strategy might be to put less emphasis on individual integrity and the separateness of individuals, and attend a little more to the connections among individuals. A careful attention to these interconnections offers a basis for just dealings with others that takes account of the difference between strangers and intimates.

A second notable feature of families is that not all of its relationships fit comfortably under what has come to be modern ethics' most favored image of relationship: the contract. Children notoriously "didn't ask to be born," and no one chooses one's blood relations. This fact has important implications for any theory that bases duties solely on consent; indeed, families are perhaps the most plausible counterexample to such theories. It is sometimes claimed that parental duties toward children arise from the parents' having tacitly consented to the child's existence, first, by agreeing to have sexual intercourse and second, by choosing not to abort the fetus. But this analysis entails that where intercourse was forced or good-faith efforts at contraception failed, and where abortion is for ethical, logistical, or economic reasons not an option, the parents are off the moral hook. Many will be reluctant to pay this dearly to retain the contract as the model of obligation. Ordinarily, responsibilities can arise from causal as well as contractual relationships. A proximate causal role in putting another in danger, for example, obligates one to stand ready to provide aid. This thought leads Hilde Lindemann Nelson and James Lindemann Nelson to suggest, in their 1995 work *The Patient in the Family,* that parental responsibility may stem from the fact that parents caused the child's existence and not from their having contracted for the child. In fact it can be maintained that intimate living as such creates expectations and other vulnerabilities, which, as Robert E. Goodin has argued, carry with them certain prima facie noncontractual duties (Goodin). Such an analysis would embrace family members other than parents in a web of moral but nonconsensual relationship.

A third feature of the ethics that typifies families is a less individualistic image of persons than is customary in impersonal ethics. Actions are often assessed in terms of their impact on the family overall, and there is a certain amount of collective responsibility for family members' well-being. A family of immigrants might, for example, devote its resources to settling other relatives in the new country, an enterprise that requires individual family members to subsume their own projects and goals to the familial one. While the communitarian feature of family ethics has often lent itself to abuse as repeated sacrifices are demanded of certain family members (particularly women) in service of an agenda set by its dominant members, it is also true that a family cannot function if its members are altogether unwilling to pull in common. An ethics of the family, in contrast to standard ethical theories, will concern itself with interests that are essentially held in common, as well as with individual interests.

A fourth distinguishing feature of what might emerge as an ethics of the family is that it is particularistic. Leo Tolstoy notwithstanding, happy families are not all alike. There are myriad differences among and within them—as there are, for that matter, among unhappy ones. Because familial relationships are not only intimate but also of long standing, family members can come to know each other in rich, particular detail and from a highly specific standpoint. This means that the principles governing their behavior toward one another can be fine-tuned to a pitch of precision that is impossible in other contexts such as law, where individual differences are perforce flattened out. What Iris Murdoch has called loving attention and Martha Nussbaum calls fine awareness would likely play an important role in any ethics

of intimacy, whether among friends or within families. Attention to the particulars is what allows people involved in intimate relationships to focus on who they are together. This self-awareness, guided by general moral ideas such as justice, permits intimates to arrive at ethical decisions that are highly sensitive to circumstances and persons; the ethical work can be done "close up." Further, as these ethical deliberations become a part of the history of the relationship, their results can be used to guide future decisions that will be just as sensitive to the particulars.

Implications for Medicine

The primary health specialty of family medicine, or family practice, distinguishes itself by focusing on the healthcare needs of people from cradle to grave, and by explicitly acknowledging the ways in which illness or traumas that individuals confront resonate through the families of which they are a part. More than any other medical specialty, family practitioners have espoused the view that "the patient is the family," and they are typically trained to understand various family systems theories to gain a systematic perspective on how families can both suffer from, and contribute to, the ailments with which patients present. These skills and this orientation naturally lend themselves to dealing with ethical issues that involve patients and their families. While family practice physicians do not as a group dissent from the orthodox medical ethics doctrine that the interests of the patient always trump any inconsistent interests that individual relatives or the family as a whole might have, their interest in the family as an integral part of understanding both illness and caring can contribute to more nuanced and thoughtful ways of appreciating and ameliorating tensions between patient and family interests, as well as ways of supporting family contributions to the care of their relatives.

When a patient is incompetent to decide about his or her own medical treatment, or when competence is intermittent, physicians turn to the family for help, since families are presumed to know best what the patient would want and also to care about the patient's interests. Families are instructed to make their decision on the basis of what the patient would want—the "substituted judgment" standard established in the 1976 *In re Quinlan* case. If the patient was never competent, the family is expected to decide on the basis of what is best for her or him—the "best interests" standard. Tightly focused on the patient, either standard is open to challenge.

Linda L. Emanuel and Ezekiel J. Emanuel observe that the substituted judgment standard has been challenged on both theoretical and empirical grounds. An important theoretical objection is that reconstructing what a patient would want in highly specific circumstances from a general knowledge of the person's values requires a tremendous imaginative effort that may be beyond most people, while the empirical objections are that patients do not in fact discuss their preferences with family members, that family members are not good at assessing a patient's quality of life, and that proxies' selections are not much better than random chance in predicting patients' preferences for life-sustaining interventions. As Patricia White points out, people often do not know what they themselves would want if seriously ill.

The best interests standard is open to the objection that it cannot be seen as a patient's exercise, by proxy, of his or her right to refuse or consent to treatment, but instead gives the family power to exercise its own authority over the incompetent patient—something our society is reluctant to do because of the fear of abuse. While there are certainly instances of familial abuse of patients, one might question whether we ought to base social policy on the assumption that abuse is the possibility most to be feared. Yet if this objection to the best interests standard is unpersuasive, there is another that may be more convincing: the standard is not suitable to families because they are not, typically, a group of people each simply seeking to maximize his or her own self-interest. There is a collective character to family life that is not easily accommodated by the notion of individual best interests, and so the best interests standard is a code of conscience that from the family's point of view is distinctly second best. In fact, the standard is invoked primarily in adversarial situations where the family's solidarity has broken down, as in child custody disputes.

An ethics of the family might suggest that what family members owe each other is not the best, understood abstractly. If it were, parents would have a duty to find better parents for their children than they are themselves. Rather, what is owed is the good that inheres in this particular set of relationships. If this is right, then at the sickbed it is less important that a brother, lover, or daughter-in-law should correctly decide what is best for an incompetent patient than that the decision be made by this particular person, the one who stands as close to the patient as possible and so serves the patient as an extended self. Here, as well as where the patient is competent, decision making that recognizes morally salient features of family life might set the needs and desires of the patient into careful balance against the family's resources for care, bringing a nuanced understanding of all the relevant particulars to bear on the decision.

What, if anything, do adult children owe their frail elderly parents? Theories affirming a duty of reciprocity argue that parents gave their children life and cared for them when they needed care; in return, children owe their parents care when they are in need. The difficulty with such theories

(held by Aristotle and Aquinas, and more recently by the Victorian jurist William Blackstone) is that they do not seem to recognize that parents have a duty to provide their children a decent minimum of goods and services. If parents are merely discharging their own obligations, it is hard to see why the child need respond with anything more than thanks. Following this line of reasoning, neither Jane English nor Norman Daniels can defend a duty of adult children to care for their parents. The child, not having contracted for the parental sacrifices made on his or her behalf, has no duty to reciprocate, since sacrifices that have not been requested require no return. A third view, shared by Blustein and Joel Feinberg, distinguishes between duties of indebtedness and duties of gratitude, and concludes that duties of gratitude are owed even for those actions that are included in the parents' own duties (Blustein, 1982; Feinberg). To discharge this duty of gratitude, children must help their parents when help is needed. And a fourth theory, developed by Nelson and Nelson (1992; 1995), bases a duty to parents in the parents' own moral duties, holding that the parental duty consists in part in encumbering the child with a loving relationship that in the child's maturity will be mutual. Once that mutuality is achieved, the mature relationship in turn generates the duty to care for parents in need.

Whatever the source of duties to frail elderly parents, the content of those duties is not easy to ascertain. If postindustrial societies do not set limits on the amount of increasingly costly medical care they offer the old as they leave this life, they may impoverish the young. Within a family, this dilemma might be played out in terms of nursing-home care for a grandparent versus a child's college fund. In "Moral Particularity" (1987), Walker has described such a decision as an opportunity for defining oneself morally, ratifying or breaking from a past course of action as one sets the course of one's future. Families, too, might be capable of strong moral self-definition of this kind.

Medical solutions to infertility are genetic solutions; there is an attempt to establish a genetic tie between the child and at least one parent. In a *genetic* contract pregnancy (in which the birth mother's egg is used to produce a child for people who have paid her to have the baby on their behalf), the importance of the maternal genes is played down, but the paternal genes—those of the contracting father—are considered crucial. In the far less common arrangement whereby the birth mother is hired to carry to term an embryo formed in vitro by the contracting couple's egg and sperm (this is called gestational contract pregnancy), the maternal genes regain their standard social meaning; the woman who is genetically linked to the child is regarded as its mother. By contrast, in artificial insemination by donor, the paternal genes are seen to carry no social responsibility for the child. The model for all this is one of consumer choice, in which the infertile parties are at liberty to decide for themselves what weight to give genetic ties.

This model raises important questions about the moral significance of being a parent. If those who contribute genetically to a child can be said to cause that particular child to exist, and if an ethics of the family adopts a causal rather than a contractual model of responsibility, then the child's genetic parents would seem to have a prima facie obligation to remain in the child's life in an ongoing way. Even if they delegate much of their responsibility for rearing the child, it does not follow that they may put themselves totally out of power to keep the child from harm. Thus lesbian or gay couples, for example, might have a duty to foster a loving bond between the child and the biological parent of the opposite gender.

Medicine invites a consumer-choice approach not only in the matter of genetic ties but also in the matter of genetic screening. While it is reasonable to protect one's family by trying to avoid giving birth to a child with a serious genetic defect, the choices made possible by genetic screening can be a burden as well as a benefit. An important mechanism for drawing new members into the family—the pregnant woman's continual process of making friends with her fetus—is distorted and interrupted by amniocentesis, endoscopy, chorionic villus sampling, ultrasound, alpha-fetoprotein assays. Such screening, along with the new possibility of fetal surgery, prompts the question, not when the fetus becomes a person, but how and when the fetus joins the family. As Stanley Hauerwas and William Ruddick ask, when is a fetus a child? (Hauerwas; W. Ruddick, 1989). At what point in the process of family creation ought the pregnant woman to make specific sacrifices on the fetus's behalf, and to what extent should these sacrifices be socially imposed?

A major function of the family is the care of its sick and vulnerable members. Because the United States has not acknowledged a basic responsibility to provide a minimum of healthcare for all its citizens, and because healthcare institutions are greatly concerned to minimize their own costs, the burden of providing that care has fallen disproportionately on families—and within families, on women. The difficulty in achieving gender justice with respect to healthcare is not conceptual but political: how can we reconfigure our society—and our families—to eliminate the bias that sees unpaid care as a natural task for women?

A further allocation issue concerns the range of the family's care. To whom is it owed, and when is it discretionary? What about adult siblings? Cousins? Grandparents? A child's partner? Need and the person's role in the family's

history are both relevant considerations, as are the family's resources. If, after all, familial caregiving is exhausted, no further care will be forthcoming. What limits may the family set on the care it owes to its own? What limits may the family set on individual members' sacrifices? More particularly, in light of the fact that women assume a greatly disproportionate amount of the burden of care, what steps should be taken both within families and in the larger society to achieve gender justice? An ethics of the family might offer guidance through the concept of familial integrity, understood as the particular way in which a given family strives to sustain a fruitful tension between intimacy and autonomy, and the way it engages in its characteristic projects and activities. Family integrity cannot, perhaps, be preserved at any price, but it is important to recognize that families as well as individuals can be destroyed unless justice forbids it.

Implementing an Ethics of the Family

Just as medical care is ethically inadequate when the focus is on the organ to be treated rather than on the person in whom the organ resides, so it is likely to be inadequate when no notice is taken of the families in which patients reside. An ethics that treats people as if they were unconnected and self-centered is not up to the task of promoting either justice or human flourishing. Primary care physicians—not only practitioners of family medicine but also pediatricians and internists—are often adept at seeing beyond the patient to the nest of relationships within which that patient lives. They, like nurses and social workers, although hampered by institutional pressures that push families into the background, tend to be attuned to these relationships even when they cannot give a formal moral account of them. That account has been slow in coming; the values of families remain much more diffuse and implicit than the well-articulated values of medicine. But the relationship between the two systems of care is beginning to receive systematic exploration.

As discussions continue regarding what that relationship should be in the twenty-first century, it may be concluded that taking families seriously requires major institutional changes. Hospitals might need to be restructured so that patients are not so estranged from their families; hospital ethics committees might have to take on a mediator's role for disputes among family members concerning patient care; the moral significance of families might have to be better reflected in case law; the conditions under which care is delivered will certainly have to be more hospitable to an ongoing relationship between patients and those who care for them; there will have to be a greater acknowledgment that families—the original providers of primary care—are as essential a source of healthcare as medicine is. The practical difficulties in implementing an ethics of the family as it relates to healthcare, while daunting, are surely counterbalanced by the importance of the enterprise to the larger task of bioethics: thinking well and carefully about the concrete human realities—our differences, our similarities, our particularities, our intimacies—that have a direct bearing on health, whether within a medical or a familial setting.

FEMINISM

• • •

As a social and political movement with a long, intermittent history, feminism has repeatedly come into being, generated change, and subsided into oblivion. As an eclectic body of theory, feminism entered the academy in the early 1970s as a part of the women's studies movement, where its contribution to scholarship in the arts, social sciences, and humanities has perhaps been particularly significant. Despite the variety of its political positions, social commitments, and theoretical vantage points, feminism's common concern is with the social pattern, widespread across cultures and history, whereby power and entitlements are distributed asymmetrically to favor men over women. This asymmetry has been given many names, including the subjugation of women, sexism, male dominance, patriarchy, systemic misogyny, phallocracy, and the oppression of women. A number of feminist theorists simply call it gender, and that usage will be adopted here.

The concept of gender rests on the assumption that there are two sexes, male and female. The cultural meanings assigned to those sexes through complex social processes establish a power relation in which masculinity predominates over femininity, and the things associated with masculinity predominate over their feminine counterparts. The term *gender* refers to this power relation, which operates through society's institutions and practices by conferring the control of resources and the right to social goods on men while relegating women to subordinate positions in service of men's interests and concerns. But because gender always works in a complicated interconnection with other abusive power systems such as race, ethnicity, sexual orientation, class, age, and disability, some women enjoy more power than some men. By the same token, these other power systems produce greater amounts of privilege for some women than for others.

One of the characteristic features of gendered power relations is androcentrism: the (usually unstated) view that man is the point of reference for what is normal for humans. According to the logic of androcentrism, if man is the yardstick or measure for being human, then women, not being men, must be defective humans. Furthermore, because androcentrism presumes that men are the point around which everything else revolves, the feminist insistence that women too are full–fledged human beings is just as much about men as everything else is—it is a threat to masculinity, or an attempt to usurp men's rightful place in the natural order of things.

Racism and discrimination against gays and lesbians employ the same sort of logic: the white race and heterosexuality are the norm for human beings, so anything other than the norm must be defective—not just statistically but morally abnormal. From this it follows that the demand to de–center the dominant group (or, to use another spatial metaphor, to dismantle the hierarchy that puts the dominant group on top) must be seen as a threat to the group—a threat to "the Southern way of life" or to "the family as we know it." Looking at the demand in this way keeps the focus on the dominant group, so that it, rather than unjust treatment of the subgroup, remains the center of attention.

Criticism and Construction

As a political movement, feminism has sought to undermine or overthrow the social mechanisms through which gender operates to oppress women. Because gender identity cannot

be understood or even perceived outside its complicated interaction with other abusive power systems, feminists resist those as well. A feminist politics is not only a politics of resistance, however. It is also a politics of construction. It seeks to build a more just society—one that is as good for all kinds of women as it is for all kinds of men. So, for example, "first-wave" U.S. feminists such as Elizabeth Cady Stanton, Sojourner Truth, and Lucretia Mott worked for the right of women to own property, not to be enslaved, and to vote.

As a field of scholarship, feminism likewise pursues two goals. The first is criticism. Feminists have uncovered and opposed gender bias in the humanities, social sciences, natural sciences, the arts, and professions such as law and medicine. Sandra Harding, for example, has criticized the view, widely shared by scientists themselves, that science is value–free. She argues that scientific knowledge is produced largely by men who command significant amounts of social prestige, and that the perspective of these men is necessarily colored by assumptions and values arising from the kinds of activities in which they engage. As science leaves this perspective unexamined, it assumes an objectivity that it does not in fact possess.

What Donna Haraway has dubbed the "god trick"—the ideal of a perspectiveless and timeless view from nowhere that purports to secure objectivity—strikes many feminists as both politically suspect and impossible to achieve. Feminist epistemologists such as Lorraine Code and Helen Longino argue that greater objectivity is attained by taking careful and rigorous account of knowers' social locations than by ignoring the effects of power on what kinds of knowledge is legitimated, whose knowledge is considered authoritative, and which knowers are ignored or excluded as a result.

As well as questioning sexist understandings of objectivity, feminists have criticized the gender bias that inheres in other key theoretical concepts and indeed in mainstream theories themselves. But like political feminism, academic feminism does more than criticize—it also constructs. Feminist economists, for example, have not rested content with condemning the masculine bias inherent in the individualism and competition of much economic theory; they have constructed economic models that begin from the fact of human dependency and connection. Feminist historians have not only pointed to the gender gaps created by their profession's focus on military campaigns and other male–dominated activity in the public sphere, but have used women's diaries, letters, and other writings to construct histories of women and of domestic life. Feminist constructions in philosophy include a shift from mainstream epistemology's preoccupation with necessary and sufficient conditions for knowledge, to the theoretical importance of the social location of the knower. Equally significant has been the construction of feminist moral theory, particularly the ethics of care and feminist responsibility ethics.

Feminist Epistemology

While on its face there seems to be something paradoxical about feminist criticisms of reason, given that the forms of argumentation on which these criticisms depend are themselves a part of what is under attack, the burgeoning literature on this topic may be understood, not as a repudiation of reason *tout court,* but as a dissatisfaction with a particular picture of reason. This picture, which underlies much of contemporary nonfeminist ethics as well as other areas of mainstream philosophy, is that of a pure, universal reason, abstracted from historical and social contexts, operating dispassionately and objectively to produce true propositions. Feminists fault this picture as much for what it excludes as for what it portrays.

For one thing, the picture excludes the emotions, rather than acknowledging that feelings such as empathy, resentment, or anger play a useful role in reasoning—especially moral reasoning. The picture in particular excludes what people care about, rather than acknowledging that what they care about can itself be a reason for thinking or acting the way they do. It excludes trust, rather than acknowledging that trust is what keeps one's reasoning from becoming paranoid. And it excludes narrative or figurative modes of reasoning, rather than acknowledging that people often use stories and images to make sense of the world.

One important strategy for feminist epistemologists, then, has been to identify the tension between the explicit content of philosophical arguments, which appears gender–neutral, and the models, metaphors, and imagery underlying these arguments, which covertly favor the experiences and preoccupations of privileged men. A second important strategy has been to question the tradition that divorces reason from other human attributes. Many feminists have emphasized the role of the emotions in rational reflection, while others have emphasized the point that human reasoners are embodied, and that the social constructions surrounding differences in embodiment count among the conditions that make knowledge possible. Still others have emphasized the essentially social nature of human existence, arguing that knowledge is not "in the head" of solitary reasoners, but rather is produced and imparted in communities of knowers, and that abusive power systems operate in these communities to discredit unjustifiably certain kinds of reasoning while authorizing others.

Borrowing from Marxist analysis, in the 1980s feminist standpoint theorists such as Nancy Hartsock and Patricia Hill Collins drew an analogy between women in gendered

societies and workers in capitalist societies. They contended that just as the false presuppositions that sustain the ideology of capitalism are most visible from the hard–won perspective of the worker who has participated in consciousness–raising and political engagement, so too the false presuppositions that sustain the ideology of gender are best seen from the standpoint of those who have had to acquire detailed, self–reflective knowledge of the gender system simply in order to be able to function within it. Feminist standpoint theorists are less interested in claiming a single, unified standpoint that is representative of all women, however, than in taking seriously the knowledge that informs women's practices—whether domestic, emotional, intellectual, or professional.

Ethics of Care

One such practice is that of giving care. In the United States, but also in many other societies, women do far more unpaid, hands–on caregiving than men—they change the diapers, wash the dishes, clean the bathrooms, take the dog to the vet, feed and dress the children, take care of sick or disabled family members, and provide long–term care for elderly relatives. Even when married women have full–time jobs, they still almost invariably do the vast majority of the housework, childcare, and elder care. Nearly 75 percent of unpaid elder care is done by women, and after a divorce or in cases where the parents never married, 75 percent of dependent children live with and are cared for by their mothers rather than their fathers—a figure that approaches 100 percent when the children are infants or toddlers. Paid caregivers are mostly women, as well. Almost 96 percent of professional nurses are women, and the percentage of women providing daycare for children is close to 99 percent. In Canada, women do 80 percent of all caregiving, both paid and unpaid.

The Harvard psychologist Carol Gilligan, taking seriously the idea that women's experience of caregiving produces its own kind of moral reasoning, questioned whether the scale of moral maturity developed by her colleague, Lawrence Kohlberg, was as universally applicable as he supposed. At the first stage of Kohlberg's scale, morality is conceived of as a system of punishment and obedience. At Stage Two, it is motivated by personal reward. At Stage Three, it is taken to be a matter of helping and pleasing other people. At Stage Four it is understood as a set of rules for maintaining the social order. Those who reach Stage Five can sum up those social rules in a principle such as "the greatest good for the greatest number," while those at Stage Six are able to think of morality in terms of self–chosen universal principles of justice. Not everyone, claimed Kohlberg, reaches the more advanced stages of moral maturity.

Gilligan, noting that men consistently scored higher on the Kohlberg scale than women, questioned the reliability of the scale rather than accept its implication that women tend to be less morally mature than men. She claimed that many of the girls and women in her own developmental studies simply reasoned about moral matters "in a different voice." Instead of talking about rights and rules, they were using the language of relationships and connection. Rather than reasoning abstractly, their thinking was contextual and concrete. She called this a "care" orientation toward morality, and opposed it to the "justice" orientation displayed at stages Four, Five, and Six on Kohlberg's scale. Gilligan was careful not to say that the "different voice" is the voice of all women across cultures and through time, any more than the voice of justice is the voice of all men. She did, however, argue that gender shapes the experience of men and women differently, and that gendered experience—particularly the experience of living in a society that expects girls and women to perform vast amounts of caring labor—produces "different modes of moral understanding."

Nel Noddings, Virginia Held, Sara Ruddick, Joan Tronto, and Eva Kittay are among the most prominent of the feminist theorists who have used Gilligan's moral psychology to construct an ethics of care. They have examined caregiving for the moral understandings internal to the practice, offering accounts of not only what it is to care well, but also of the social and political framework in which this practice takes place. While care theorists have by no means created a unified account, it is nevertheless possible to identify three characteristic features of the ethics on which most, but not all, care theorists agree:

1. a caring relationship;
2. engagement with another's will; and
3. particularism.

Caring well both requires and is an expression of a caring relationship. The caregiver must care about the person she cares for, not only to keep the caregiving from becoming impersonal, cold, or self–serving, but because caring is a value in itself. To care in this sense is to feel concern for one's charge (Kittay's term for the person receiving the care). But while caring engages the emotions, the word does not refer solely to a cluster of feelings. As Held points out, it is also a moral term. It is a good thing to care about others; a bad thing not to care. Because it is a moral term, it can be used to guide how and when to act on one's feelings, as well as to evaluate specific instances of caregiving.

On the view of a number of care ethicists, the caring relationship requires engagement with another's will—the caregiver must treat her charge not simply as an object of her care, but as someone with wants, intentions, and desires of

his own. Noddings calls on caregivers to practice what she calls engrossment, which consists of such close attention to the feelings, needs, ideas, or wants of their charges that the caregivers' own will is displaced. Other care ethicists emphasize the importance of self–knowledge, lest the caregiver confuse her own will with the will of her charge.

Caring well also requires the caregiver to pay attention to the particulars of a caring relationship rather than being guided by abstractly formulated rules or principles. It is by being closely attentive to this particular person, who needs this particular kind of care, in these specific circumstances, rather than by reflecting on general moral precepts, that morally admirable care is given. This is not to say that caregivers ought never to engage in abstract thinking. But the point is to remain within the caring relationship, which requires attention to the person for whom one cares rather than attention to moral abstractions.

A number of feminist ethicists have argued (repeatedly) that each of the three central features of the ethics of care reinforces the stereotype of the self–effacing wife and mother, prescribing courses of action and ways of thinking that are bad for women. In particular, the critics have identified three dangers. First, if the caregiver cares about the person she cares for, her feelings will not permit her to leave her charge's needs unmet, which poses the danger of exploitation. Second, the caregiver might become so engrossed in the needs and wants of her charge that she gives up her own sense of right and wrong, thereby losing her integrity. And third, if the caregiver attends closely to the particular needs and circumstances of her charge, her field of vision cannot accommodate the broader concerns of social justice.

Kittay's solution to the problem of exploitation is to call for financial, economic, and logistical support for caregivers. She argues that if one begins from the fact of human dependency instead of from the assumption that "all men are created equal," then caring for those who need it can be seen as one of the requirements of justice—as can support for those who provide this care. Diemut Bubeck has a different solution. Her idea, modeled on military service, is that men and women alike could spend some period of their lives in a "caring service" whose mission would be to provide respite care for unpaid dependency workers.

As for the problem of integrity, one solution is to build self–care into the ethics of care so that it does not become an ethics of self–erasure. However, if the caregiver's only motive for taking care of herself is that she can then better care for her charge, she stands in danger of losing herself altogether. Cheshire Calhoun's 1995 account of integrity provides a different solution. She argues that integrity is not only the personal virtue of holding fast to the moral values that are central to one's self–conception, but also a social virtue, exercised by reliably standing for one's own best moral judgments to other people. If integrity involves being the kind of person others can depend on, it cannot be threatened by caring well. Indeed, for the caregiver to do what she knows to be wrong would count as defective care, because it would mean that her charge could not rely on her.

In response to the claim that the ethics of care is too focused on the personal and the particular to attend to issues of social justice, Tronto proposes to redraw the boundary that political theorists and others have marked between morality and politics. As caregiving is a practice embedded in social life, she claims, it has to be understood in a political context and not just a moral one. A politics of care that complements the ethics of care would, in Tronto's view, recognize and support the caring labor on which every society depends. Such a politics would shift the goals of social policy from preserving autonomy to fostering interdependence; from promoting interests to meeting needs. It would value citizens even when they cannot fend for themselves.

Responsibility Ethics

The ethics of care is based on a morally crucial relationship between people that has too often been ignored or dismissed by nonfeminist ethicists, but relationships other than those involving care are also morally important, and they too give rise to responsibilities. Nor are relationships the only source of the moral demands made on people. For these reasons, several feminist ethicists have gone beyond care to develop an ethics of responsibility.

Margaret Urban Walker is less interested in the abstract questions that philosophers have traditionally raised about the conditions under which someone is morally responsible (Was he free to act otherwise? Did she form the proper intention?) than in examining how practices of responsibility operate within actual moral communities. People hold one another to their promises, excuse them, demand an explanation, give them a standing ovation, let them stew in their own juice, award them the Nobel Prize, and sentence them to death by lethal injection. In these and other ways responsibility is assigned, accepted, taken, deflected, redirected, and renegotiated.

How one is expected to participate in society's practices of responsibility depends just as much on one's gender, class, age, ethnicity, and race as it does on one's own achievements. Who gets to do what to whom is largely determined by the social power that is distributed according to these demographics, as is the matter of who must account to

whom. And just as social position influences whether and to what extent one may take, assign, or avoid responsibility, so too it plays a role in determining who may set or change the rules that govern when, how, and by whom this may be done.

As Walker points out, however, the system is rigged. The social forces that allow some people to take responsibility for the things that are pleasant or rewarding, while imposing on other people the kinds of responsibility that keep them from attaining many of the good things in life, are the same forces that hide the fact that this is going on. Some of these forces naturalize the uneven distribution of responsibility, concealing the coercion that sustains the arrangement by representing it as natural—as when women are said to have a maternal instinct that qualifies them to care for children while men do not. Other forces normalize the unfairness, focusing so much attention on the norms or standards for fulfilling a particular responsibility that the question of why a particular kind of person must assume the responsibility is completely hidden from view. Incessantly barraging women with the norms for looking attractive, for example, is a wonderful way of concealing the unfairness of requiring them to take far more responsibility for their appearance than men.

Practices of responsibility look forward as well as backward. In *The Unnatural Lottery,* Claudia Card points out that people who have suffered from unfair distributions of responsibility can do more than make backward–looking assignments of blame for past wrongs. A woman who has been raped, for example, can adopt a forward–looking stance that allows her to take responsibility for what happened to her—not in the sense of blaming herself, but in the sense of refusing to be a victim. She can be responsible for rebuilding her life at the same time as she holds her attacker responsible for his deed.

Normally, adults are expected to know the moral rules and to be aware of the standards by which other people judge them. That is part of what it means to be a morally competent person. But in "Responsibility and Reproach," Calhoun observes that morally competent people can lose their competence in abnormal moral contexts, such as the one that feminists take themselves to inhabit. If, for instance, the normal moral context allows men to deflect responsibility for changing their babies' diapers, then even a well–meaning man is unlikely to see the sexism behind his assumption that when he does change a diaper, he is doing something nice rather than doing merely what he ought. As he is behaving irreproachably according to the standards of the moral context he inhabits, it hardly seems fair to blame him. One could, after all, excuse him for the same reason one excuses young children's wrongdoing—that he is not responsible for his attitude because he has not yet learned the moral rules that govern the abnormal moral context feminists occupy. But Calhoun thinks he should be held responsible anyway. When feminists reproach people who engage in sexist behavior, she argues, they teach them that what they are doing is wrong, motivate them to change their behavior, and show them respect rather than treating them like children. This is one way in which feminists can take responsibility (in Card's sense) for sexism.

The ethics of care and responsibility ethics display some common themes. Both reject the idea that persons are essentially self–sufficient and unconnected, insisting instead that selves are always nested in webs of relationship. Both emphasize the differences among people rather than making abstract generalizations about human nature. Both use gender as a central category of analysis. Both use the language of responsibilities rather than rights or duties. And both begin from careful examinations of actual, real–time personal interactions. This on–the–ground quality is highly characteristic of feminist ethics—it is a way of avoiding the mistake of theorizing from too limited a set of examples.

Feminist Bioethics

In Canada and the United States, the bioethics movement and second–wave feminism both began in the late 1960s, but the two discourses had little to say to one another for the better part of two decades. It was not until 1989 that the U.S. journal of feminist philosophy, *Hypatia,* published two special issues devoted to feminism and medical ethics. The few essays by feminists published up to that time in the premier U.S. journal in bioethics, the *Hastings Center Report,* dealt solely with ethical issues surrounding women's reproductive systems.

All that has changed. The 1990s saw a steady stream of conferences, monographs, anthologies, and essays in learned journals that examine bioethical issues through a feminist lens. Susan Sherwin's *No Longer Patient: Feminist Ethics & Health Care* appeared in 1992, as did *Feminist Perspectives in Medical Ethics,* edited by Helen Bequaert Holmes and Laura M. Purdy. The International Network on Feminist Approaches to Bioethics, begun in 1993 by Holmes and Anne Donchin, has some 300 members worldwide and has sponsored several conferences on feminist bioethics, in conjunction with the International Association of Bioethics. In 1995, the prestigious Kennedy Institute of Ethics devoted its Advanced Bioethics Course to feminist perspectives on bioethics, and the plenary lectures of that course were then published in a special issue of the *Kennedy Institute of Ethics Journal.* In 1996, the *Journal of Clinical Ethics* published special sections in each of its four issues on feminism and

bioethics. That same year saw the publication of an anthology edited by Susan M. Wolf, *Feminism and Bioethics: Beyond Reproduction.* In 1998, the *Journal of Medicine and Philosophy* devoted an entire issue to the feminist ethic of care. Anne Donchin and Laura M. Purdy's anthology, *Embodying Bioethics: Feminist Advances,* appeared in 1999. In 2001, the journal *Bioethics* published an issue devoted to feminist bioethics. Textbooks and readers in bioethics routinely include essays written by feminists.

Feminist bioethics largely consists of criticism directed at practices surrounding the care of women's bodies, and in particular, the parts of women's bodies that mark them as different from men. There has been an ongoing focus on women's reproductive practices, in the form of arguments in defense of abortion, debates about the wisdom of various methods of assisted reproduction, arguments against sustaining postmortem pregnancies, ethical analyses of various sorts of maternal–fetal conflicts, concern about HIV testing of newborns and pregnant women, pleas for better prenatal care for pregnant women, debates about the use and abuse of the birth control implant Norplant, arguments for and against amniocentesis and other genetic testing of fetuses, and discussions about hormone replacement therapy for postmenopausal women. And when feminist bioethicists have moved "beyond reproduction," as Susan M. Wolf puts it, they have tended to criticize practices of healthcare for women—weighing in, for example, on the debates over the medical management of breast cancer, arguing that tying healthcare insurance to employment disadvantages elderly women, or protesting the injustice of a healthcare delivery system that devotes a disproportionate amount of high–tech care, such as arterial angioplasty and organ transplantation, to men. While this criticism can be seen as a political and moral protest against the sexism that permeates the healthcare system, it has been argued that the preoccupation with women's bodies, and especially women's reproductive health, tends to reinforce the androcentric view that men are normal but women, being abnormal, require special accommodations both within healthcare and within bioethics.

Not all of feminist bioethical criticism focuses on women's (reproductive) health. Mary Mahowald has, for example, used standpoint theory to criticize healthcare providers who systematically discount their patients' knowledge about their illness and treatment. Virginia Warren has pointed out that medicine's preoccupation with crisis issues diverts attention from what may be called housekeeping issues, which are perceived as women's work and are on that account not valued. Susan M. Wolf has argued that gendered differences in medical treatment, suicidal behavior, healthcare insurance, and social expectations about self–sacrifice offer a reason to suppose that legalizing physician–assisted suicide would further oppress women. A number of feminists have criticized the cost–cutting measures resulting in shorter hospital stays that unfairly exploit the gendered division of labor within families, where, compared to men, women do vastly disproportionate amounts of caregiving, even if this means that they are restricted to part–time employment or give up their jobs altogether.

Feminist bioethicists' constructions have consisted mainly of reconceptualizing problems in areas of healthcare practice and policy ranging from postmenopausal motherhood to home healthcare, and then offering solutions based on those reconceptualizations. With the major exception of the work of some feminist bioethicists on the ethic of care, however, constructions in theory have been almost nonexistent. Much more could be done both to expand the ethic of care so that it furnishes conceptual tools for social and political analysis, and to use the practice of medicine itself to enrich ethical theory. That so little of this work has been done is not surprising, not only because feminist bioethics is a very young discourse but also because bioethics in general has failed to produce much distinctive theory, contenting itself with the pragmatic strategy of agreeing on middle–level ethical principles where it can, and scavenging from the standing political and moral theories when it must. Feminist bioethicists, however, do not have the luxury of that sort of pragmatism, because it is the business of feminism to be deeply suspicious of the standing political and moral theories, on the grounds that they are shot through with gender bias and so cannot be regarded as trustworthy. Many feminists argue that their task is to construct new theory rather than to refine theories that leave everything exactly as it was.

Why ought feminists theorize about ethical issues arising from biomedical practice? Why, that is, should there be a feminist bioethics at all? One answer is that medicine ought to be of particular concern to feminists because it is one of the hegemonic discourses of our time, commanding enormous amounts of social prestige and authority. Because it is so powerful that no other discourse except, possibly, that of international capitalism competes with it, it interacts with gender at many levels and in many different ways. Feminists continue to criticize that interaction, but they also wish to learn from it. By studying how power, in the guise of gender, circulates through the healthcare system, they contribute to the body of normative theory that might guide this socially valuable institution in the direction of greater justice.

FERTILITY CONTROL

• • •

I. MEDICAL ASPECTS

The ability of individuals to regulate their own childbearing represents one of the great medical advances of the twentieth century. As a result of demographic trends, which indicate an earlier onset of sexual activity and smaller family size, a woman may spend as long as thirty-five years purposefully avoiding pregnancy. An array of contraceptive methods is necessary to provide individuals with options that are most appropriate to their lifestyle, motivation, desire for effectiveness and convenience, and acceptance of medical risk. Two fundamental trends have affected contraceptive practice since 1960: the development of safe, continuous, and highly effective hormonal contraception, and more recently, an increased awareness of the role of barrier contraceptives for the dual purposes of pregnancy prevention and protection against sexually transmitted infections.

Currently available contraceptive methods include permanent methods that cause sterility—such as vasectomy in men and tubal occlusion in women—and reversible methods. Reversible methods include oral contraceptives (OCs); subdermal implants (Norplant®); progestin injections (depot-medroxyprogesterone acetate; DMPA; Depo-Provera®); intrauterine devices (IUDs); barrier methods (male and female condoms, diaphragm, cervical cap, and spermicidal products); and "natural" methods such as celibacy, periodic abstinence (natural family-planning and fertility-awareness methods), and withdrawal.

General Considerations

It is unreasonable to assume that there is an ideal contraceptive method for each couple; more commonly, couples alternate among various methods over time. A number of general considerations can help to guide an individual (or couple) in the selection of an appropriate contraceptive method.

FREQUENCY OF SEXUAL INTERCOURSE. Couples who have frequent intercourse (arbitrarily defined as more than two to three episodes of intercourse per week) should consider the more continuous, non-coitusrelated methods of contraception: OCs, IUDs, implants, injectables, or if childbearing is completed, permanent sterilization. For less sexually active couples (those who have intercourse less than once per week), an episodic method, such as a barrier contraceptive, would provide protection without exposure to method-related risks at other times.

NUMBER OF SEXUAL PARTNERS. Individuals who have multiple sexual partners, or whose partners have other partners, should be advised to consider one or more barrier methods, with the dual purposes of protection against sexually transmitted infections (STIs) and prevention of pregnancy. For couples who desire an optimal degree of pregnancy prevention, a combined approach of a barrier method plus a highly effective contraceptive will compensate for the relatively high pregnancy rate associated with barrier methods. Additionally, women in this category should not wear an IUD, as the risk of pelvic inflammatory disease (PID) and tubal infertility in IUD wearers is increased significantly in women with multiple sexual partners. For couples who are involved in a mutually monogamous relationship, no method of reversible contraception, including the IUD, increases the risk of PID or tubal infertility.

USER ACCEPTABILITY. Personal attitudes regarding the acceptability of certain methods may influence the success of

use. These include religious beliefs, which may preclude the use of "mechanical" and hormonal contraceptives; tolerance of "nuisance" side effects, such as breast changes and vaginal bleeding; willingness to touch the genitals (of self or partner); and aesthetic concerns, such as tolerance of the "messiness" of spermicidal creams and jellies.

MOTIVATION AND SELF-DISCIPLINE. The degree of motivation to avoid pregnancy has a strong impact upon the successful use of contraceptives. Women who contracept to *delay* pregnancy have a higher failure rate than those who are intent on pregnancy prevention. Self-discipline also must be assessed, as women who are highly motivated may do well with intercourse-related (barrier) methods, while individuals who are poorly motivated should choose continuous non-intercourse-related methods such as OCs, IUDs, implantable or injectable methods, or sterilization.

ACCESS TO MEDICAL CARE. Because of the risk of medical complications, certain methods should be used only on the condition of reasonable access to medical care. This concern centers mainly on IUDs and to a lesser extent, hormonal methods. Users of barrier methods, natural methods, and those who have been successfully surgically sterilized have a negligible risk of life-threatening method-related complications.

EFFECTIVENESS. Desire for high effectiveness versus willingness to accept a degree of risk of failure is a primary concern for many contraceptors. Those who insist upon a high degree of efficacy are best advised to use a combination OC (discussed below), an IUD, an implantable or injectable method, or sterilization. Alternatively, for individuals who will accept a higher method failure rate, coupled with an understanding that such failures will result in a choice between delivery and abortion, less effective methods, including barriers and natural methods, may be used.

SAFETY. Medical safety is a major concern for most contraceptors, and concerns regarding health risks are a major reason for discontinuation of use. Paradoxically, adolescents are more likely to avoid or prematurely discontinue contraceptives for fear of adverse health effects, yet they comprise the age group least likely to experience them. The risks associated with contraceptive use are dependent on the following four variables, with an example of each:

1. Age. The risk of arterial complications (adverse effect on the heart and blood vessels, e.g., heart attack) of OCs is age-related; this risk is greatly compounded by cigarette smoking.
2. Underlying medical conditions. Women with underlying cardiovascular risk factors (e.g., hypertension, glucose intolerance, hyperlipidemia, cigarette use) are more likely to experience myocardial infarction (heart attack) while using OCs.
3. Sexual behaviors. A pattern of multiple sexual partners increases the risk of STIs. In particular, IUD wearers would have a greater risk of PID resulting in primary tubal infertility (fallopian tubes blocked by scar tissue).
4. Method-specific risk. Complications are intrinsic to the method, regardless of age, health, and sexual behaviors. Examples include the risk of hepatic adenomas (liver tumors that are noncancerous but that may hemorrhage) in OC users; and pelvic actinomycosis (infection) in long-term IUD users.

A key component of contraceptive efficacy and safety resides in the quality and clarity of instruction and counseling given to the user. Initial instruction should include a description of the methods of contraception currently available, their relative effectiveness, the advantages and disadvantages of each method, and, if appropriate, a comparison of short- and long-term costs. Once a method has been chosen, instruction should center on method-specific advice, such as information regarding method use and danger signals that should be reported to the provider. If the individual will be learning the use of a relatively complex method, or one with an increased likelihood of side effects, it is prudent to provide a simple backup contraceptive method, such as condoms, should the user decide to abandon the initial method. Method-specific counseling should be supplemented with a written fact sheet or other instructional material at a reading and comprehension level appropriate to the individual. Finally, the user should be encouraged to telephone or visit the office of the provider, as necessary, for further advice or modification of contraceptive use.

Oral Contraceptives

The oral contraceptive (OC) is the method of reversible contraception used most widely in the United States. Two types are available: combination OCs, which contain fixed (monophasic) or variable (multiphasic) doses of synthetic estrogen and progestin, and progestin-only pills (POPs, mini pills). OCs primarily prevent pregnancy by preventing ovulation (release of an egg from the ovary). The estrogen and progestin in the pill exert negative feedback on the hypothalamus (the part of the brain that controls hormone production by the pituitary gland) to suppress the release of the hormone GnRH, which in turn decreases secretion of the pituitary hormones LH and FSH, preventing ovulation.

OCs also thicken cervical mucus, which promotes an environment hostile to sperm and alters the endometrium (the lining of the uterus), so that implantation of an embryo is unlikely to occur even if an egg "breaks through" (is released) and is then fertilized. The failure rate of combined oral contraceptives when used correctly and consistently is 0.1 pregnancies per one hundred women per year. In typical use, the failure rate is three pregnancies per one hundred women per year.

Research continues on a male birth control pill. The initial study, announced in 1996, showed that the pill lowered sperm counts significantly with few, if any, side effects. This contraceptive is composed of a progestin and testostrone.

BENEFICIAL EFFECTS OF OCS. Prevention of pregnancy: When used correctly, OCs are highly effective in preventing pregnancy. This includes ectopic pregnancies (those that implant outside the uterus), thus preventing an important cause of maternal morbidity and mortality. There is no increase in the rate of spontaneous abortion or fetal anomalies in former users of OCs, and no long-term reduction in fertility has been demonstrated.

Prevention of acute salpingitis (also called pelvic inflammatory disease, or PID): Even when controlled for sexual behavior and for the coincident use of barrier contraceptives, studies have shown that OC users have a decreased risk of acute salpingitis. It also appears that cases of salpingitis are less severe in OC users overall when compared to controls. Paradoxically, OC users seem to have a higher rate of chlamydial endocervicitis (an STI, with inflammation of the cervix, which may or may not progress to PID).

Prevention of genital tract cancers: Data from the Centers for Disease Control and Prevention's (CDCP) Cancer and Steroid Hormone (CASH) study show a 50 percent reduction in risk for the development of both endometrial and ovarian cancer. Past use of OCs appears to bestow this protective effect for as long as fifteen years after the user has discontinued OC use. The relationship of OCs and cervical dysplasia (abnormal cells of the cervix that, if not monitored, sometimes progress to cancer) and carcinoma is somewhat more complex because of confounding biases, but overall, OC use neither causes nor protects against cervical neoplasia (abnormal tissue formation).

Relief of menstrual symptoms: OCs provide excellent therapy for primary dysmenorrhea ("normal" painful or difficult menstruation that is not related to a disease) because they suppress the endometrium (the lining of the uterus). Consequently, the endometrium does not produce as much prostaglandin, the substance that produces cramping of the uterus. There is a more variable effect on premenstrual syndrome, in that while many women have a decrease in symptoms, others have no change, and a small percentage have worsening symptoms. Because of shorter and lighter menses, the incidence of iron deficiency anemia is reduced by 65 percent. There is also a reduced risk of toxic shock syndrome.

Reduced risk of benign breast disease: OC users have a significant reduction in the incidence of benign (noncancerous) breast conditions, including fibroadenoma and fibrocystic change.

Prevention and treatment of functional ovarian cysts: As a result of the pharmacologic suppression of GnRH release and consequent blunting of pituitary gonadotrophin release, women who use OCs are less likely to develop functional ovarian cysts than women who do not use hormonal contraception. This effect appears to be dose-related, and users of low-dose OC products have less protection than those using stronger formulations. If OCs are given in an attempt to suppress an existing ovarian cyst, it is necessary to utilize a relatively strong product (e.g., Ovral) in order to achieve an effective degree of hypothalamic/pituitary suppression.

Other beneficial effects: For reasons that are unclear, OC users also have a lower incidence of rheumatoid arthritis and peptic ulcer disease.

ADVERSE EFFECTS OF OCS. The most common OC-related side effects are relatively minor. However, the patient may perceive them as major, and this may result in OC discontinuation and subsequent pregnancy. Effective management of minor or "nuisance" OC side effects consists mainly of patient education, and occasionally, medical intervention. Side effects include nausea, weight gain, spotting or breakthrough bleeding between menstrual periods, failure to have a menstrual period during the seven days off OCs, new onset or exacerbation of headaches, and chloasma (darkening of facial skin). Complications, while rare on low-dose combined oral contraceptives, can be serious.

Vascular complications: While initial studies indicated a direct relationship between estrogen dose and an increased risk of deep vein thrombosis (clotting) and pulmonary thromboembolism, more recent studies with low-estrogen-dose products have demonstrated only a minimally elevated attributable risk of these complications. For this reason, OC products containing thirty-five mcg of estrogen or less should be used routinely. In early studies of unselected women using relatively high-dose products, OC users also

demonstrated an increased risk of myocardial infarction and stroke in comparison to controls. As a result of exclusion of women with major cardiovascular risk factors and a progressive trend toward the use of lower-dose products, OC users as a group no longer have an elevated attributable risk of OC-induced morbidity or mortality from arterial disease.

Hypertension: The estrogen and progestin components of OCs act in concert to occasionally cause the development of blood-pressure elevation in a small number of OC users. Hypertension is reversible with discontinuation of OCs.

Carbohydrate intolerance: The progestin component of OCs is known to cause peripheral glucose resistance and consequent elevation of insulin levels. In most cases, these effects are minor and are not clinically significant. If a diabetic woman is started on OCs, frequent blood glucose monitoring is necessary initially, as insulin requirements may change. OCs should not be given to diabetics who have clinically manifested vascular or kidney disease or to those with such cardiovascular risk factors as smoking, hypertension, hyperlipidemia (elevated fatty substances in the blood), or age over forty.

Breast cancer: The relationship between OC use and breast cancer has been studied extensively since the mid-1970s. In aggregate, the studies show that the relative risk of breast cancer in a present or former OC user is 1.0, implying neither protection nor increased risk. This relationship was present with a number of subgroups, including women who had initiated OCs at an early age, those who used OCs for longer than ten years, women with a history of benign breast disease, and those with a positive family history. However, a number of studies performed in the early 1980s demonstrated a possible association between OC use and breast cancer in other subgroups. The only thread of consistency in these studies was to show a small increase in the risk of breast cancer for recent OC users who developed breast cancer at an age younger than thirty-five. In that there seems to be a small reduction in breast cancers in past OC users older than thirty-five, it has been hypothesized that OCs, like pregnancy and exposure to other hormonal contraceptives, may be a weak breast cancer promoter, and that OCs may hasten the growth of a tumor already in existence.

DMPA

On October 29, 1992, the U.S. Food and Drug Administration (FDA) approved contraceptive labeling for depot-medroxyprogesterone (DMPA); commonly known by its trade name, Depo-Provera. This culminated a twenty-year effort to make a long-acting injectable contraceptive available to American women. Based upon the findings of extensive clinical research done outside the United States over a decade, the FDA determined that while some concerns remained, DMPA was considered to be as safe as other hormonal contraceptives already on the market.

DMPA's mechanism of action is quite similar to that of all other hormonal methods of contraception: inhibition of ovulation; thickening of cervical mucus, which makes sperm penetration through the cervical mucus more difficult; and induction of endometrial atrophy, which prevents implantation in the highly unlikely event of fertilization. The chemical structure of DMPA is much closer to that of natural progesterone than that of the 19-nortestosterone progestins used in oral contraceptives and Norplant. This may account for the fact that DMPA users have little, if any, change in a number of metabolic parameters over time. In particular, there is no change in clotting factors, globulin levels, or glucose metabolism in DMPA users when compared to pretreatment levels. The slight decrease in total cholesterol levels seen in DMPA users is the result of a minor drop in high-density lipoprotein, the "good" cholesterol, although neither change is clinically significant. Interestingly, DMPA positively affects the central nervous system, causing the seizure threshold to increase, thus making seizures less likely in women with seizure disorders (e.g., epilepsy). Estrogen levels in DMPA users remain at early follicular phase levels, and while other menopausal symptoms do not occur, there is a possibility that some DMPA users may lose a small amount of bone mass over time.

With DMPA there are 0.3 failures per one hundred women during the first year of typical use. This high efficacy is due both to DMPA's efficiency in inhibiting ovulation and the fact that it is a relatively "user friendly" method of contraception. The long interval between injections, a two-week grace period for injections given beyond twelve weeks, and the absence of need for any user or partner intervention at intercourse all contribute to DMPA's high effectiveness.

DMPA is given as a deep intramuscular injection into the deltoid (upper arm) or buttocks every twelve weeks. Since administration most optimally is provided with a 11/2 inch needle, most DMPA users, particularly thin women, will prefer the buttocks site. The initial injection of 150 mg of DMPA must be given within the first five days after the onset of menses, unless the woman has effectively been using the pill or has an IUD, in which case the first injection can be given any time during the month. Subsequent 150-mg injections are given at twelve-week intervals, although pregnancy is highly unlikely during the following two-week grace period. If fourteen weeks or more have elapsed since the last DMPA injection, a negative highly sensitive urine pregnancy test must be documented before the next injection is given.

The ideal candidate for DMPA is a woman who is seeking continuous contraception; wants long-term birth spacing; desires a method that is neither coitus-dependent nor requires daily motivation; or who cannot use, or chooses not to use, a barrier method, an IUD, or an estrogen-containing method. It may be particularly appropriate for women who cannot use OCs because of a history of thrombophlebitis, hypertension, heavy smoking, or other cardiovascular risk factors. Women with sickle-cell anemia or seizure disorders actually may experience an improvement in their medical condition. DMPA is an excellent method for postpartum and post-abortal women and can be initiated immediately after completion of the pregnancy. Postpartum women who are lactating (nursing) should not be given DMPA until lactation has been established, usually one to two weeks after delivery. Women who desire a high degree of confidentiality in contraceptive use are attracted to DMPA because it does not require the personal possession of medications or devices, nor does it leave marks of administration or current use.

DMPA has few contraindications: active thrombophlebitis; undiagnosed abnormal genital bleeding; known or suspected pregnancy; active liver disease; a history of benign or malignant liver tumors; known or suspected carcinoma of the breast; and sensitivity (allergy) to the medication. Special conditions requiring more detailed medical evaluation and follow-up include a history of heart attack or stroke; diabetes mellitus; current migraine headaches; a history of severe endogenous depression; and chronic hypertension.

Menstrual changes are universal in women using DMPA and include episodes of irregular bleeding and spotting (lasting seven days or more during the first months of use) and amenorrhea (no menses). Sixty percent of women using DMPA for one year report amenorrhea, and the percentage increases with progressively longer use. Menstrual changes are the most frequent cause for dissatisfaction and discontinuation among women using DMPA, and appropriate patient education and selection and supportive follow-up measures can markedly reduce patient discontent. Medical intervention for irregular or heavy bleeding rarely is necessary, and anemia is uncommon. While counseling and reassurance are initial measures, medical therapy consisting of low-dose oral estrogen for one to three weeks may give temporary respite from bleeding. Women persistently dissatisfied may be better served by discontinuing this method and seeking alternative types of contraception rather than by repetitive medical or surgical intervention. In cases of heavy vaginal bleeding, gynecologic evaluation to rule out such unrelated conditions as vaginitis, cervicitis, or cervical lesions should be performed.

Another group of side effects that occur fairly frequently among DMPA users are pregnancy symptoms such as nausea, breast tenderness, abdominal bloating, and tiredness. While these symptoms are prevalent in the first few months of DMPA use, persistence is uncommon and they rarely are cause for discontinuation.

Weight gain occurs in two-thirds of DMPA users owing to the drug's anabolic effect and its resultant impact on appetite. On average, DMPA users gain four pounds per year for each of the first two years of use. Women concerned or dissatisfied with weight gain should be counseled that it may be controlled with adequate exercise and moderate dietary restriction. Many women notice weight stabilization or improvement with time. If these measures fail and weight gain becomes problematic, DMPA discontinuation may become necessary.

Headache is a relatively common complaint in DMPA users, although not all headaches are necessarily related to the hormone in the drug. If the headaches are mild and without neurologic changes, treatment may be attempted with oral analgesics.

After a 150-mg injection of DMPA, the mean interval until return of ovulation is four to six months. Conception usually is delayed in former DMPA users when compared with women discontinuing oral contraceptives or IUDs. The median time to pregnancy following the last injection is nine to ten months, and studies have shown that almost 70 percent of former DMPA users conceive within the first twelve months following discontinuation, and over 90 percent conceive by twenty-four months, a rate comparable to that of oral contraceptive users. Nulliparous women (those who have never given birth to a child) and those using DMPA for many years experience the same return of fertility as other women studied.

Recent medical studies have addressed other safety issues regarding DMPA use. A large study conducted by the World Health Organization (WHO) showed that in aggregate, there is no overall increased risk of breast, cervical, or ovarian cancers in users of DMPA. DMPA users have a reduction in endometrial cancer for as long as ten years after discontinuation of the method. While there was evidence of a weak association between DMPA use and breast cancer in the subgroup of women under thirty-five who had used the drug within the previous four years, most experts feel that this represents a very weak promoter effect at a level similar to OC use. A single study showed a 7 percent reduction in bone density in premenopausal DMPA users compared to controls, but it is not clear whether this is a true biologic effect caused by low estrogen levels or due to selection bias.

Until more work is done in this area, some believe that it is prudent to screen potential DMPA users for osteoporosis risk factors and to provide additional counseling or evaluation for those with multiple risk factors.

Norplant

Norplant is a sustained-release contraceptive system that acts continuously for five years. It consists of six silicone rubber capsules, each the length and diameter of a matchstick, which are surgically implanted under the skin of the upper arm. The synthetic progestin Levonorgestrel, a hormone found in many oral contraceptives, is slowly released into the bloodstream, resulting in a constant hormone level. The contraceptive effect of Norplant is due primarily to inhibition of ovulation, although secondary mechanisms include thickening of cervical mucus, and formation of an atrophic endometrium. Although 20 percent of Norplant users ovulate in year one and up to 50 percent ovulate by year five of use, studies suggest that when ovulation does occur, it is defective and the ovum is not subject to fertilization. The cumulative pregnancy rate of Norplant users is 3.8 pregnancies per one hundred women over five years; the first-year failure rate is only 0.09 per hundred women per year. Ectopic (tubal) pregnancies are reduced by two-thirds in comparison to noncontracepting women, although should Norplant fail, there is a greater conditional probability (proportionate risk) that the pregnancy will be located in the fallopian tube rather than in the uterus.

Studies that have evaluated the metabolic effects of Norplant have found minimal impact. There is no effect on cholesterol or lipoprotein metabolism, glucose metabolism, or propensity to blood clotting. Norplant is an appropriate method of contraception for women who desire long-term contraception, who have completed childbearing but do not desire permanent sterilization and have had problems with other methods of contraception (including combined OCs), and for postpartum women, whether nursing or not.

The technique of insertion of Norplant involves anesthetizing the skin with local anesthetic and creation of a four-millimeter incision, followed by placement of a twelve-gauge trochar to insert the capsules in a fan-shaped pattern. The procedure takes less than ten minutes and is well tolerated by most women. The method should be inserted within five days of the onset of the menses and provides a contraceptive effect within twenty-four hours. More problematic is Norplant removal, which requires substantially more skill and takes between fifteen and forty minutes. The ease of removal is related to a number of factors, including the correctness of the initial Norplant insertion, the amount of fibrous tissue that has developed around the capsules, and the skill of the clinician.

The most prevalent adverse effect of Norplant is the unpredictability and irregularity of menstrual cycles, especially in the first year of use. Cycles may be shorter or longer than usual and associated with more or less bleeding; there may be bleeding between cycles, or no bleeding at all. Although there is no *cure* for irregular bleeding patterns, short-term palliation of the problem can be achieved by the use of low-dose oral estrogen therapy (e.g., ethinyl estradiol 20 mcg orally per day for two to three weeks). Other side effects include mild weight gain, headaches, hair loss, and new onset or exacerbation of depression.

Intrauterine Devices (IUDs)

Although the IUD is used by only 1 to 2 percent of contracepting women in the United States, it is one of the most widely used methods worldwide. A popular method in the United States in the 1970s, IUD use dropped precipitously as a result of the high rate of pelvic infection and consequent tubal infertility experienced by women who used the Dalkon Shield IUD, which was removed from the market for this reason. Mainly because of business concerns related to the risk of product liability suits, manufacturers of most other IUDs voluntarily withdrew their devices over the next decade. The two IUDs currently available in the United States include a progesterone-releasing T-shaped IUD (Progestasert®), which must be exchanged yearly, and a copper-bearing T-shaped device called the Cu-T-380-A (ParaGard®), which exerts its contraceptive effect for eight years.

The IUD's mechanism of action is still a matter of conjecture. In copper IUDs, it is likely that copper ions released by the device have a toxic effect on sperm, rendering them incapable of fertilizing an ovum. Progesterone-releasing IUDs probably exert their contraceptive effect by converting the endometrium to a chronically atrophic state, preventing implantation of the zygote (fertilized egg). IUDs are known to be a relatively effective contraceptive, with failure rates in the range of 0.6 to 2.0 pregnancies per one hundred women per year. While many clinicians assume that the IUD increases a woman's risk of experiencing an ectopic (tubal) pregnancy, studies clearly show that users of progesterone-bearing IUDs have no increased risk of ectopic pregnancy when compared to nonusers of contraception, while users of copper IUDs experience profound protection.

Women best suited for the use of an intrauterine device are those who desire continuous contraception; who want long-term birth spacing or have completed their families but

do not want to be sterilized; who require very high contraceptive efficacy; who desire a method that neither is coitus-dependent nor requires daily motivation; and who cannot use or choose not to use a barrier method or a hormonal method of contraception. IUD insertion and removal are simple office procedures that may result in temporary uterine cramping, but rarely require the use of local anesthesia or analgesia.

IUD use may result in relatively minor side effects such as heavy menstrual periods or cramping (less so with the progesterone-releasing type) and increased vaginal discharge. The relationship between IUD use and pelvic infection and consequent infertility has been studied in great detail. Early studies demonstrated that the major risk associations were recent insertion (within twenty days) and the type of IUD used (the Dalkon Shield bestowing the greatest risk). More recent studies have suggested that an IUD wearer's sexual behavior is the single most relevant risk factor for pelvic infection; a woman in a mutually monogamous sexual relationship has no increased risk of pelvic infection or tubal infertility ("blocked" or scarred tubes from PID) compared to the sexually active woman who uses no method. Conversely, women who have multiple concurrent sexual partners, or those who themselves are monogamous, but whose male partner has other sexual partners, appear to be at increased risk of IUD-associated pelvic infection.

In light of these considerations, contraindications to IUD use include the following:

- pelvic inflammatory disease within the past twelve months or recurrent PID (more than one episode in the past two years);
- post-abortal or postpartum endometritis or septic abortion in the past three months;
- known or suspected untreated endocervical gonorrhea, chlamydia, or mucopurulent cervicitis;
- undiagnosed abnormal vaginal bleeding;
- pregnancy or suspicion of pregnancy;
- history of impaired fertility in a woman who desires future pregnancy;
- known or suspected uterine or cervical malignancy;
- small uterine cavity;
- history of pelvic actinomycosis infection (not asymptomatic presence of the organism);
- known or suspected allergy to copper or, for copper IUD only, a history of Wilson's Disease (an inability to metabolize copper).

While young age may be associated with certain risky sexual behaviors, young age alone is not an absolute contraindication to IUD use. Correspondingly, a history of previous childbearing should not be an absolute prerequisite for IUD use. If a young woman is involved in a long-term mutually monogamous relationship and has no other risk factors, she may be considered a candidate for an IUD.

Barrier Methods

Barrier methods include mechanical barriers such as male and female condoms, the female diaphragm and cervical cap, and chemical barriers such as spermicidal products. Nonprescription barrier contraceptives are an important contraceptive option because of their wide availability, relative ease of use, and acceptably high efficacy when used correctly and consistently. While the contraceptive efficacies of the various barrier methods when used alone are comparable to each other (typically about twenty pregnancies per one hundred women per year), their use in combination adds significantly to their effectiveness. In addition, male latex condoms and female vaginal sheaths, when used consistently and correctly, provide a high degree of protection against both the acquisition and the transmission of a number of sexually transmitted pathogens, including gonorrhea, chlamydia, syphilis, and some viral pathogens, including hepatitis B virus and HIV (human immunodeficiency virus), the virus that causes AIDS (acquired immunodeficiency syndrome). Spermicidal products, in addition to their contraceptive effect, have in vitro microbicidal properties and appear to provide some protection against gonorrhea and chlamydia. Nonprescription barrier contraceptives include male latex and animal membrane condoms; female polyurethane vaginal sheaths; the contraceptive sponge; and spermicidal films, foams, jellies, creams, and suppositories. Contraindications include allergy to latex rubber (in the case of male condoms, diaphragm, or cervical cap), a history of significant skin irritation with acute or chronic exposure to spermicides, and inability to understand instructions for use.

The contraceptive diaphragm is a dome-shaped latex device that serves as a mechanical barrier against the cervix and also holds a spermicidal preparation in place within the vagina. The diaphragm is one of the oldest barrier methods of the modern era, and has retained its popularity because of its nonhormonal nature, ease of use, and reasonable efficacy. It may be an appropriate method of contraception for women who prefer an intercourse-related nonhormonal method of contraception; desire a barrier method that can provide continuous protection over twenty-four hours; and feel that the diaphragm is less noticeable during intercourse than other barrier methods. The diaphragm should fit comfortably with the anterior (front) rim tucked behind the pubic bone in front and the posterior (back) rim seated deep

in the vagina and behind the cervix, so that the cervix is covered by the dome of the diaphragm. The largest, most comfortable diaphragm that fits well should be chosen. Use of a backup method of contraception until the return visit, or until the patient is sure that the diaphragm is staying in place during intercourse, should be advised.

No attempt should be made to use the diaphragm if the woman cannot be fitted with the device due to physical characteristics of the vagina, cervix, or uterus that interfere with proper placement, or if the proper size diaphragm is not available. Other contraindications include a recent history of frequent lower urinary tract infections (e.g., cystitis), especially if associated with prior diaphragm use; less than three months since cervical surgery; less than two weeks since midtrimester abortion or less than six weeks postpartum (after delivery of a child); allergy to rubber or to all spermicides; inability to understand instructions for use; and inability to insert, remove, and care for the device correctly.

The cervical cap is a thimble-shaped latex device that fits over the cervix and stays in place by mild suction. When used with a spermicide, it is a reliable barrier method of contraception that can be used continuously for up to forty-eight hours. In use in European countries since the 1930s, it was approved by the FDA for contraceptive use in the United States in 1988. The efficacy of the cervical cap in preventing pregnancy is similar to that of the diaphragm in nulliparous women, although the failure rate of the cap is greater in parous women.

The Prentif Cavity Rim Cervical Cap® is the only cap currently approved by the FDA. It is available in four sizes: 22-, 25-, 28-, and 31-mm internal diameter. Because cervix size may vary considerably, these sizes fit approximately 70–75 percent of women. The cap may be an appropriate choice for women who have experienced frequent urinary tract infections, especially if they occurred in association with the contraceptive diaphragm. Because there is less pressure on the urethra and bladder, the cap may be more comfortable than a diaphragm and less likely to predispose the user to a lower urinary tract infection.

Natural Methods

The most effective methods of fertility control are those in which sexual intercourse is avoided entirely. Abstinence is defined as a limited period of time in which intercourse is avoided, while celibacy refers to a lifestyle decision in which an individual chooses to avoid intercourse for a longer time interval, which may be lifelong in some cases.

Fertility awareness methods are those in which sexually active individuals avoid unprotected intercourse during the "fertile period," which is defined as the time in each cycle that ovulation is estimated to occur. Since the ovum survives for about 48 hours after ovulation and sperm can survive in the fallopian tubes for up to five days, the length of the fertile period is about seven days in most women. Couples who practice the fertility awareness method use a barrier method of contraception with intercourse during the fertile period and no method for the remainder of the cycle. In the "natural family planning" technique, a variant of fertility awareness, intercourse is avoided entirely during the fertile period and mechanical contraceptive methods are not used at any time in the cycle. The latter approach generally is endorsed by religious groups who object to the use of other birth-control methods, which they consider to be "artificial" in nature.

Four techniques, which can be used alone or in combination, are used to estimate the fertile period.

- The *calendar* method, in which previous menstrual cycling patterns are charted and from which future ovulatory patterns may be predicted. This method is comparatively inaccurate, as factors such as stress or illness can affect the time of ovulation and thereby shorten or lengthen a given cycle. In addition, many women have such variable cycle lengths that the estimated duration of the fertile period can be as long as two weeks.
- The *basal body charting* or *temperature* method, which is based upon the fact that a woman's basal temperature will increase by 0.5° to 1.0°F twelve to twenty-four hours after ovulation and will remain elevated until the next menstrual period. Women using this method are expected to check their temperature each morning upon arising until the temperature rise has been confirmed. Once two days have passed after the temperature rise, the fertile period is considered to be completed, and unprotected intercourse can resume until the next menstrual period.
- The *cervical mucus* method, also called the "Billings" or "ovulation" method, which relies upon the fact that a woman's cervical mucus becomes copious and watery in the few days before ovulation. The presence of characteristic mucus at the vaginal opening is a sign of impending ovulation and, hence, defines the existence of the fertile period.
- The *sympto-thermal* method uses a combination of two or more of the above techniques. The use of the cervical mucus to signal the beginning of the fertile period and the basal

body temperature rise to predict its completion is the most accurate of the fertility awareness methods.

The effectiveness of the fertility awareness methods depends upon the couple's consistency of use and ability to avoid unprotected intercourse during the fertile period. When practiced correctly and consistently, the sympto-thermal method has a failure rate as low as two failures per one hundred women per year, while for the typical use failure rate for all methods of periodic abstinence is twenty pregnancies per one hundred women per year.

Sterilization

Voluntary surgical sterilization (VSS) is the most prevalent form of contraception in the United States; 60 percent of those surgically sterilized are women who have had tubal ligation, and 40 percent are men with vasectomies. Most couples who choose surgical sterilization have completed their families, although for some individuals this choice is prompted by an inability or unwillingness to use reversible methods of birth control. Criteria once used to determine the appropriateness of sterilization based on age and parity (number of children born) are no longer appropriate, and a woman's considered, informed decision should be respected by the provider, regardless of her age, parity, and social circumstances.

TUBAL LIGATION. The most important point to be made in counseling a woman regarding tubal ligation is that the procedure must be considered permanent and should be performed only when she is sure that she desires no further children. Alternative (reversible) methods of birth control should be discussed to ensure that these methods have not been rejected on the basis of misunderstanding or other biases. Other important aspects of counseling include a description of the surgical risks of tubal ligation, failure rates, and a comparison to the various methods of sterilization available, including vasectomy for the woman's partner. If consent cannot be obtained from a severely mentally disabled woman, a legal guardian may provide consent in some cases.

Both the federal government and individual states have regulations regarding minimum age requirements and waiting periods from the time of written consent until the date that the operation may be performed if federal or state funding is to be used. For this reason, women who plan to undergo postpartum tubal ligation should receive counseling and consent before thirty-four weeks gestation.

The surgical approach to tubal ligation is primarily dependent upon whether the procedure is performed in the postpartum period, or longer than six weeks after delivery, in which case it is considered to be an interval tubal ligation. In a postpartum tubal ligation, a minilaparotomy performed within four to twenty-four hours of delivery is the preferred approach subsequent to a vaginal delivery. After receiving a regional or general anesthetic, a three-centimeter curvilinear or vertical incision is made immediately under the umbilicus. Once the peritoneal cavity has been entered, either the operator's finger can be used to sweep each tube into the incision or each tube can be grasped under direct vision. In either case, positive identification of the tube can be made by visualizing the fringelike portion at the abdominal end of each tube and by demonstrating that the nearby round ligament is uninvolved. After completion of the tubal occlusion, each excised tubal fragment must be sent for histological confirmation. In a woman delivered by cesarean section, any of the three techniques described below can be performed after repair of the uterine incision has been completed.

A number of techniques are available when there is direct access to the fallopian tubes via minilaparotomy or cesarean section. They include the following methods:

- modified Pomeroy method, in which two ligatures (sutures, "ties") are placed in the mid-portion of each of the tubes and then the pieces of tube between the ligatures are removed. The closed ends retract, leaving a gap between the closed-off tubal segments.
- Irving method, whereby the tubal stump nearest the uterus is tucked into a tunnel made in the myometrium (muscular structure) of the large upper part of the uterus.
- Uchida method, which involves excision of a five-centimeter segment of tube, followed by burying the tubal stump farthest from the uterus within the mesosalpinx (the free margin of the upper part of the broad ligament).

While the failure rates of the Irving and Uchida techniques are exceedingly low (less than 1/1,000) in comparison to the Pomeroy method (1/250), the former take longer to perform and therefore are relegated to special cases.

Interval tubal ligation may be performed with a laparoscope (a narrow lighted tube) via a low minilaparotomy incision (a small horizontal incision, 2–5 cm long, just above the pubic hairline), the former being much more prevalent in the United States. Laparoscopic approaches ("band-aid" surgery) include either open or closed laparoscopy, and both one- and two-puncture instruments (laparoscopes) are available. While a large majority of laparoscopic tubal ligations are performed under general anesthesia, there is a growing trend to perform these procedures under local anesthesia,

thereby reducing cost and avoiding the risk of general anesthetic complications, which is the most common cause of tubal ligation deaths. If local anesthesia is used, the tubes must be bathed in a long-acting local anesthetic, then banded or clipped, rather than electrocoagulated (coagulation or clotting of tissue using a high-frequency electric current).

Minilaparotomy for interval tubal ligation is performed via a three-centimeter low horizontal incision. Because of the difficulty entailed in working through a small incision, the procedure is facilitated by using a uterine elevator, an instrument placed in the vagina to lift the uterus. The procedure may be performed with general, regional, or local anesthesia. Minilaparotomy is contraindicated when the patient is obese, has an enlarged or immobile uterus, or when adnexal disease (in the areas adjacent to the uterus, e.g., ovaries and tubes) such as endometriosis is suspected. Nonetheless, minilaparotomy can be a safer, simpler, and less expensive procedure than laparoscopy, which requires more technical equipment and endoscopy experience.

If minilaparotomy is chosen, any of the occlusion techniques outlined above for postpartum tubal ligation may be used. In addition, spring-loaded tubal clips are available that can be easily applied through a minilaparotomy incision. With the laparoscopic approach, three methods of tubal occlusion are available:

- Electrocautery, with a coagulation or "blend" current, used at two or three sites along the mid-fallopian tube. Either unipolar or bipolar cautery may be used; while bipolar cautery is safer (since it is less prone to cause bowel burns), it takes longer and has a higher failure rate. Unipolar electrocautery is faster and more effective, but there is a risk of sparking between the electrode and the bowel, resulting in an unrecognized injury. Fallopian tubes occluded by electrocautery may be quite difficult to reanastomose (reconnect, in the event the woman changes her mind and wants to try to achieve pregnancy) because of extensive scarring.
- Silastic (silicone rubber) rings may be applied with a forceps-type applicator to a loop of mid-portion fallopian tube. This approach avoids the risk of electrical injury to the bowel and preserves much larger segments of healthy ends of the severed fallopian tube should later reversal be considered.
- Spring-loaded clips may be placed at a single site in the middle of the tube and can be used with double-puncture laparoscopy or at minilaparotomy.

The provider must explain that with tubal interruption alone, no organ is removed; tubal sterilization merely prevents conception. The operation is not "desexing" and will not reduce libido, vary the woman's menses, or alter her appearance. There is usually no adverse change in sexual function following tubal sterilization; on the contrary, many women who feared pregnancy before the operation report increased satisfaction in sexual intercourse and are pleased with the operative result. However, 2 to 5 percent report less frequent orgasm and a similar percentage have delayed regret that the procedure was performed.

Only hypophysectomy (excision of the pituitary gland), bilateral oophorectomy (removal of both ovaries), and ovarian damage by radiation are certain methods of sterilization. Abdominal and tubal pregnancies have occurred (rarely) even after total hysterectomy (removal of the uterus). Oophorectomy and sterilization by radiation are usually followed within four weeks by vasomotor reactions (symptoms associated with menopause such as "hot flashes") and a gradual diminution in libido or sexual satisfaction during the next six months.

VASECTOMY. Sterilization of the man by vasectomy is both less dangerous and less expensive than tubal ligation, as it is routinely performed as an office procedure under local anesthesia. Through one or two small incisions in the scrotum, the vas deferens (the tube or duct that carries sperm) is isolated and occluded and usually a small segment of each vas is removed. Neither physiologic impotence nor changes in libido result from the procedure. Sterility cannot be assumed until postoperative ejaculates are found to be completely free of sperm. Failure of the vasectomy, as manifested by pregnancy in a partner, occurs in 0.1 percent of patients. Medical risks of vasectomy include hematoma (blood clot or bruise) formation, epididymitis (congestion or inflammation of the epididymis, the coiled tubular structure where sperm cells mature), spontaneous recanalization of the vas (reconnection of the ends with restored patency) (incidence of less than 1%), and the development of a spermatocele (cystic nodule containing sperm). Atrophy of the testes very rarely results from ligation of excessive vasculature (blood supply). Vasectomy often is reversible—up to 90 percent in some reports—but requires expensive microsurgery and special skill with no guarantee of success. Pregnancy results in only about 60 percent of cases after reversal; factors that influence success include (but are not limited to) the surgeon's skill, the type of procedure used, and time interval since vasectomy.

II. SOCIAL AND ETHICAL ISSUES

The status of contraception, sterilization and abortion services in the United States has always been linked to the various social and political movements that have been engaged with issues of women's role in society, reproduction and sexuality. Different groups have advocated for and against family planning for different reasons and with different levels of success. While issues pertaining to reproductive control have always caused some degree of social conflict, this has been especially true since the 1970s when the abortion debate intensified and spilled over to other reproductive health services. The emergence of HIV and rising rates of other sexually-transmitted diseases have also contributed to the controversy surrounding fertility control in the United States and abroad as the new millennium dawns.

This entry begins with a discussion of fertility control in a historical context. One must be aware of this history in order to understand the current ethical debate and controversies surrounding family planning and abortion. The article then continues with discussions of the social, political, religious and moral perspectives. Although the circumstances may change, the issues surrounding fertility control will always be with us and will remain among the most unresolved in bioethics.

Historical Context

It is often said that if we are unaware of our history, we are doomed to repeat the mistakes of the past. Mistakes and dilemmas regarding birth control are particularly apparent when looked at from the perspectives of the women involved, rather than as a success of technology developed by the great men of medicine.

Advocates for birth control generally intended it to be an option for all women, regardless of race or class. The reality, however, was often that poor, otherwise unempowered women, often from minority backgrounds, were most in need of such advocacy, education and access to contraception. Upper-class women had greater access to information and methods of contraception through their private physicians and other social contacts. They could also pay for whatever was available at the time. They voluntarily reduced the number of children they had. The well-intentioned, beneficent efforts on the part of advocates for women and for birth control to improve access for poor minority women and empower them often had the effect of targeting these women for efforts to reduce the numbers of children they had. The ability of a woman to choose the number of children she had and when she had them might allow her to control other aspects of her life and family and to improve the quality of life for herself and others. It could also come dangerously close, on a population basis, to achieving the desires of eugenicists to reduce the numbers of poor minority, or otherwise undesirable people, in the population. One example of this tension is that involving immigrant Irish and Eastern European women in the late nineteenth century. There was a real concern on the part of eugenicists that the immigrant population was growing and reproducing while educated, upper class American women were successfully reducing the size of their families. Eugenicists may have wanted to control the fertility of immigrant women in order to maintain population proportions, especially those of the "desirable" component of the population. On the other hand, early advocates for birth control might have wanted to improve access to birth control in order to empower these women to control their own destinies to a certain extent. Promoting the autonomy of women and acting beneficently on their behalf, in this case, comes dangerously close to the less ethically acceptable motivation of the eugenicists.

The history of the birth control movement in this country over the past 125 years provides clear examples of the tensions which have always existed between empowering women to control their fertility and promoting limitations on fertility for the disadvantaged. Several important developments in the history of the American birth control movement have been chosen to illustrate these tensions and

provide a context within which to analyze contemporary social, ethical and political issues (Powderly).

CONTRACEPTION IN LATE NINETEENTH CENTURY AMERICA. Victorian beliefs regarding sexuality accepted promiscuity as a fact of life for men who were either not expected to or were unable to control their sexual urges. Women, on the other hand, were expected to control or even deny their sexuality (Gordon, 1981). Prostitutes were a common and accepted solution to this dichotomy. Despite the view that female sexuality was viewed as inextricably linked to reproduction, contraception was widely practiced among all social classes. The methods of contraception varied by class, however, due to cost and availability. The upper classes were more likely to use relatively expensive methods of contraception such as condoms, spermicides, and douches. They might also have had access to diaphragms and cervical caps smuggled in from Europe at a high cost. Withdrawal and rhythm were often the only methods available to the poor. At a time when menstrual cycles were only partially understood, pregnancies often resulted. Abortion, often self-induced and always dangerous, was resorted to frequently. It is estimated that one out of every five to six pregnancies in America ended with an abortion by the 1850s (Chesler). Mortality from septic abortions was extremely high. In 1888, it was estimated as being fifteen times greater than maternal mortality (LaSorte, Powderly).

During this era, American feminists supported the concept of "voluntary motherhood" (Gordon, 1981). Far from empowering women and providing them with sexual freedom, however, voluntary motherhood sustained traditional family roles for women. Limitation of family size enhanced their ability to fulfill their societal roles as wives and mothers according to this view. These feminists were joined by moral reformers who were concerned about excessive breeding among the lower classes. Immigrants were particular targets of this concern. Focusing efforts toward reduction of fertility on the lower class and members of minority groups has strong historical roots in the late nineteenth century (Powderly).

Although contraception was widely practiced in private and abortion was accepted as a necessity when it failed, many were not willing to risk expressing support for them in public or admitting to their use. This Victorian reluctance influenced public policy. Abortion was declared illegal for the first time in the United States in 1830. A majority of states had declared it so by 1870 (LaSorte). A great legal blow was dealt to contraception in 1873 with the passage of the statute that came to be known as the Comstock law. This federal statute made it illegal to transport obscene materials through the mail. Contraceptive devices such as condoms and diaphragms as well as literature were confiscated under this law, which was in effect until 1936. It lost its power in a case in which Margaret Sanger established the right of doctors and other qualified professionals to use the mail for such distribution. Contraceptives themselves remained in the obscenity statutes until 1971 (Wardell, Powderly).

MARGARET SANGER AND THE AMERICAN BIRTH CONTROL MOVEMENT. Perhaps no name is more associated with birth control, family planning, and reproductive freedom for women than Margaret Sanger's. Sanger was born in 1879, the middle child in an Irish immigrant family with eleven children. She was impressed at a young age with the effect of frequent pregnancies on her mother, who suffered from tuberculosis and died at the age of fifty. Her mother's frequent pregnancies and their ultimate role in her early death angered Sanger. She went on to play a strong role in the birth control movement in the United States and abroad until her death in 1966. While her decision to devote her life to the promotion of access to birth control for all women was influenced by many factors, her own family background and experience certainly played an important role.

Sanger was trained as a nurse, although she left her training program early to marry William Sanger. Because of prohibitions against married nursing students in this era, she could not remain in the program once she married. She would remain conflicted throughout her life between her obligations to her family and the demands of her passionate cause—access to birth control for all women. This is a conflict that remains for many working mothers today in an era where there is often no choice.

Margaret Sanger's experience as a visiting nurse and midwife on New York City's Lower East Side provided the stimulus for her crusade. She often cited the case of Sadie Sachs, a twenty-eight year old Jewish immigrant and mother of three who was married to a truck driver named Jake. Unable to deal with another pregnancy and an additional child, Mrs. Sachs nearly died from a self-induced abortion. Sanger nursed her for weeks and listened to her pleas for reliable contraception. It is likely that Sanger offered her personal experiences with condoms and coitus interruptus, the common methods readily available at the time. Mrs. Sachs knew another pregnancy would kill her. The only advice her physician could offer her was to "tell Jake to sleep on the roof." If only these immigrant men could control their sexuality, there wouldn't be so many problems! There was no better or more constructive advice available to her. Three months later, Mrs. Sachs died of septicemia after another self-induced abortion. Her husband was distraught and her children left motherless. Margaret Sanger called it "the dawn of a new day in my life … I knew I could not go

back merely to keeping people alive.…" (Chesler; Wardell; Sanger, 1931, 1938; Powderly).

Early in her crusade, Margaret Sanger used her connections to the Socialist Party to promote her cause. She published a column entitled: "What Every Girl Should Know" in *The Call,* a New York Socialist daily, in 1912 and 1913. The columns elicited a range of responses and were ultimately challenged by Anthony Comstock. Early in 1913, one of the columns was entitled "What Every Girl Should Know—Nothing; by order of the U.S. Post Office" and was followed by a blank space. Several weeks later the censored column appeared (Chesler; Sanger, 1938). Birth control was not to become a priority issue for the Socialists, however. It couldn't compete with suffrage and labor issues. Sanger was disillusioned and disappointed that birth control was not viewed by her comrades as a priority issue for women.

In 1914, Sanger abandoned her own failing marriage and devoted herself to the development of *The Woman Rebel,* a magazine for working women that would cover issues of sexuality and contraception. She was indicted under the Comstock laws for sending the first issue of this magazine through the mail. While awaiting trial, she wrote *Family Limitation,* a practical pamphlet on birth control methods. The world was about to go to war and Sanger's arrest and cause were not receiving as much publicity as she had hoped for. She decided to flee the country and her children and go to Europe until she could command more visibility. While she continued her research on contraceptive methods, her husband, still a supporter, went to jail for dispensing one of her pamphlets. Sanger returned to heightened publicity for her cause and the charges against her were ultimately dropped (Chesler; Powderly).

Sanger began a cross-country speaking tour to promote the importance of knowledge for women regarding sexuality and birth control. While she promoted access to birth control for all women, she focused primarily on the poor. Sanger believed that uncontrolled fertility and large families were inextricably linked to poverty. Her efforts to empower poor women, however, would be viewed by some as racist and by others as having eugenic propensities. While many eugenicists supported the ideas of limiting population growth, particularly among those they viewed as undesirable (e.g. the poor, immigrants, those with mental problems or disabilities), they were greatly troubled by the idea that the upper classes would use birth control and the lower classes would continue to breed.

Margaret Sanger brought birth control directly to the poor women of Brooklyn on October 16, 1916, when she opened a free-standing clinic in Brownsville. Immigrant women from many cultures lined up with their baby carriages to learn how to prevent future pregnancies. In the few weeks the clinic was open, 464 women were provided with sex education and contraceptive information (Chesler; Powderly). The clinic was raided by the New York City Vice Squad and Sanger and her sister, Ethel Byrne, the clinic's nurse, were jailed. The trial produced an important legal victory for birth control. The New York State Court of Appeals interpreted the law to allow for prescription of contraceptives by physicians not only to prevent or cure venereal disease—an interpretation largely applied to men—but also for any health reason. This opened the door for physicians to prescribe contraceptives for women. It also produced another dramatic effect, however. Birth control from that point on was a physician-dominated enterprise. While Margaret Sanger's Brownsville clinic brought contraception to the community level and to poor women, it did so at a price. Nurses, and to a large extent, women, were not to control the provision of contraceptives. This is a legacy that lingers today. In populations with limited access to physicians, it is a clear disadvantage (Chesler; Powderly).

The compromises struck with the medical community are evident in Margaret Sanger's interactions with Robert Latou Dickinson. Dr. Dickinson, a Brooklyn gynecologist, was a champion of studies of female sexuality, fertility and contraception. While he was not a strong supporter of contraception early in his career, he became one of its strongest supporters and was on the Board of Planned Parenthood at the time of his death in 1950 at the age of eighty-nine. Dickinson and Sanger fought for the right to contraceptives, but he viewed her techniques as propogandist. He sought initially to evaluate the effectiveness of contraceptive counseling and techniques, using more traditional scientific methods. Influential in his field, Dickinson used his platform as president of the American Gynecological Society to promote professional interest in birth control. He set up a committee on maternal health at the prestigious New York Academy of Medicine to promote contraceptive research. He found, however, that without Sanger's "propoganda" he had trouble recruiting patients. While he had access to the medical establishment, she had access to the women who would be the subjects of the research and the users of contraceptives. Dickinson also, ultimately, sought Sanger's assistance in securing diaphragms for his own patients. He had been unable to acquire enough diaphragms through legal channels. Sanger had been smuggling them into the country, sometimes in "Three-in-One oil boxes." She had married the millionaire head of the Three-in-One oil company and used his fortune and resources to promote her cause (Wardell; Powderly). Sanger and Dickinson often disagreed vehemently on strategy, but also cooperated to

achieve their mutually desired goals. Dickinson ultimately joined Sanger's Birth Control Clinical Research Bureau's advisory board. Together, they assured that birth control would be available to American women. It was, however, to be a male-dominated enterprise constructed on the medical model (Powderly).

STERILIZATION. Tubal sterilization was first proposed in the early nineteenth century for effective long-term contraception in women undergoing operative deliveries (C-sections). The first reported tubal sterilization was performed in 1880 (Lungren; Siegler and Grunebaum). While technology had evolved enough to attempt these procedures, it is important to recognize that they were still quite risky. A paper delivered at the Brooklyn Gynecological Society in 1891 reviewed the sixty-eight sections that had been performed in the United States from 1882–1891. The Brooklyn maternal mortality rate of 33 1/3 percent compared favorably with the national mortality rate of 40 percent (Powderly). Surely, if a woman survived one section, avoidance of another would be an important consideration. Many of the early tubal ligations were recommended to protect the life or health of the woman.

In the early twentieth century, however, eugenics was a dominant reason for tubal sterilization, particularly involuntary sterilization. Compulsory sterilization began to be recommended for individuals with hereditary disease, the "feeble-minded" (i.e. the insane and demented) and the mentally retarded. There were also racial overtones, as undesirable characteristics were perceived to occur more often in Negroes, Orientals, and the foreign-born. In addition, there were some moves to sterilize habitual criminals—a move that some promote to this day for repeat sex offenders. While recommendations for habitual criminals dealt largely with men, efforts to control hereditary and mental illnesses were most often directed at women (Reilly; Powderly). Efforts to "train" female inhabitants of mental institutions gave way to a priority to keep them from reproducing. The view that deviance was hereditary was supported in large part by studies of two families—the Jukes and the Kallikaks.

Richard Dudgale, a social reformer, studied 709 people over five generations in a family he called the "Jukes." Although Dugdale believed both heredity and environment were to blame for the propensity of the Jukes for crime, intemperance and prostitution, he gave real credence to heredity (Dugdale). He estimated that their care had cost society well over a million dollars. In 1912, Henry Goddard added to the belief that deviance was hereditary with his publication of *The Kallikak Family.* Goddard had been studing feeble-mindedness when he discovered the family, which he traced back over six generations. The progenitor had produced both a legitimate and an illegitimate line. The legitimate line produced upstanding citizens, while the illegitimate line produced large families with a disproportionate number of feeble-minded individuals (Reilly; Powderly).

Already concerned with the effects of immigration on population demographics, eugenicists were given superb ammunition with these two studies. The eugenics movement also received financial support from some of the country's most prominent philanthropists. Even Theodore Roosevelt supported the movement, urging Americans to avoid "racial suicide"—the upper classes must not be outnumbered in their progeny by immigrants and the lower class.

The nation's first involuntary sterilization law was passed in 1907 and 14 states had laws allowing involuntary sterilization by 1914. The effect of the laws varied. From 1907 to 1921, there were 3233 documented sterilizations performed under state laws. These sterilizations were seen by many within the mental hygiene movement as beneficial to society and, at the very least, as not harmful to the individual (Reilly). While there was much popular and professional support, eugenic sterilization was still controversial. Some statutes were drafted with more concern regarding constitutional constraints and more care about guardians'consent. Ultimately, however, the Supreme Court provided a boost for involuntary sterilization with its decision in *Buck v. Bell* in 1927. Oliver Wendell Holmes wrote: "It is better for all the world, if instead of waiting to execute degenerative offspring for crime, or to let them starve for their imbecility, society can prevent those who are manifestly unfit from continuing their kind." Sterilization programs were active through the 1940s and 1950s and not influenced by reaction to the Nazi sterilization programs (Reilly; Powderly; Lombardo). Eugenic sterilization virtually disappeared, however, in the 1960s in an era of awareness of patients' rights and the need for society to protect the vulnerable.

BIRTH CONTROL AND THE MODERN ERA. The 1960s and 1970s saw great technological advances in birth control, albeit all dependent on women. The development and approval of oral contraceptives, after controversial research on women in the third world, finally provided a highly effective form of contraception that was not associated with individual sex acts. Intrauterine devices (IUDs) also became popular choices for women and couples who wanted to control their fertility. Although IUDs would later become less available because of legal challenges related to side effects of the Dalkon Shield, they remained a method of choice for many women. By the end of the twentieth century, contraceptive rings and patches and long-acting contraceptives like Norplant, in addition to safer doses of oral contraceptives,

would provide many accessible and affordable options for fertility control. The reduction in the use of barrier contraceptives, however, would increase concern about transmission of sexually transmitted diseases, including HIV.

In addition to technological advances, there were legal and policy victories for birth control. A significant victory in this regard occurred in New York City in 1957 when Dr. Louis M. Hellman fitted a severely diabetic postpartum woman with a diaphragm in violation of the policies of the commissioner of hospitals. The media had been notified in advance and the resulting coverage precipitated a policy change that allowed women to receive contraceptive counseling and devices in municipal hospitals in New York City (Hellman). Dr. Hellman went on to serve as deputy assistant secretary for population affairs in the Department of Health, Education and Welfare under President Nixon. He oversaw the Title X family planning initiatives that provided family planning services to five million women who desired them but could not afford them (Powderly).

The Supreme Court declared contraception a constitutional right for married couples in 1965 in the case of *Griswold v. Connecticut.* The Comstock laws were finally repealed in 1971 and the Supreme Court guaranteed a woman's right to abortion in *Roe v. Wade* in 1973. Women were now entitled to access to contraceptives and abortion services. This, however, did not ensure that they would have access. Some women did not have access to Title X funded services and could not afford contraceptives. Barriers to health care in general often extended to family planning services. For others, partners or spouses prohibited the use of desired contraceptives. Cultural and religious beliefs and prohibitions may also prove problematic. In addition, the fight against legalized abortion rages on and has escalated to violent outbursts that threaten the providers and users of abortion services. Coercion and social pressure may also result in women who do not desire contraception being forced to use them (Powderly).

Social and Political Issues

Numerous social and political issues have influenced fertility control in the modern world.

INTEREST GROUPS AND FAMILY PLANNING. ***Providers of Family Planning Services.*** Family planning services in the United States are offered by both private and public agencies. Public providers of family planning services at the local level include public health clinics in hospitals or neighborhood health centers, school-based clinics, Medicaid managed-care organizations and hospital-based clinics. At the county, state, regional and national levels, various arms of government are involved with the setting of policy for these publicly supported clinics and in devising formulas to disburse funding. The major conduit for public funding of family planning services is Title X of the Public Health Act of 1970. Title X has never allowed funding for abortion services, however.

In the private sector, abortion and family planning services are offered both by for-profit and not-for-profit clinics, managed care organizations and by private physicians. The not-for-profit Planned Parenthood Federation of America, Inc., with affiliates across the country, continues to be one of the most important providers of family planning services in the private sector.

In theory, the public and private components of the family planning delivery system share similar goals: the dissemination of contraceptive services and education under a public health model, which includes the prevention of HIV infection and other sexually transmitted diseases as well as services specifically rendered to control fertility. The relationship between the public and private components is quite complicated and intertwined, however. Family planning services, like other publicly provided social services in the United States, are typically delivered through a system that relies at least partly on private agencies, or "subcontractors," rather than directly by the government itself.

In addition, family planning became intensely politicized in the United States after the election of Ronald Reagan in 1980. Since then, the agendas of public and private providers of family planning services have often been at odds. Difficulties with Title X-funded programs illustrate these contradictions. A significant proportion of Title X-funded services in many communities across the country is provided by Planned Parenthood, which is also a prime target of those who are politically conservative because of the organization's visibility as an abortion provider. Political appointees within the Department of Health and Human Services, which oversees Title X and related services, have, at times, been aligned with political groups committed to the defunding of this program, because of some conservatives' opposition to family planning programs. The number of publicly funded family planning programs and clinics across the country has declined; this decline reflects the bitter ideological wrangling over the concept of publicly funded family planning (Ettinger, 1992; Scott).

In 2002, nearly five million women received health care services at family planning clinics funded by Title X. They were predominantly young, poor, uninsured, and had never had a child. Seventy-one percent of women using Title X-funded clinics are 20 years of age or older and 63 percent are white. Sixty-five percent have incomes at or below the

federal poverty level. It is estimated that these clinics are the only source of family planning services for more than 80 percent of the women they serve (AGI, 2002a; Kaeser et al; Planned Parenthood).

The Women's Movement. Since the re-emergence of a visible women's movement in the United States in the late 1960s, various groups associated with the movement have been forceful advocates for family planning and abortion services. The new feminists have demonstrated a keen interest in issues of reproductive rights and sexuality (Joffe, 1986). The campaign to make abortion legal and accessible was a major focus of the feminist movement in the 1960s. During the 1980s, when a woman's right to a legal and safe abortion was threatened, women's organizations played a highly visible role in pro-choice activities, working closely with such organizations as Planned Parenthood and the National Abortion Rights Action League.

With respect to other reproductive issues, however, the relation of sectors of the women's movement to its abortion allies has been more complex. At times, the responses of some feminist health activists to prevailing contraceptive practices and new contraceptive innovations have conflicted with sometime allies, such as Planned Parenthood. These activists, for example, raised doubts early on about the safety of oral contraceptives, objected to testing new contraceptive technologies on women in developing nations and, more recently, voiced reservations about the likely social abuses of Norplant, a long-acting, implantable contraceptive device (Seaman; Gordon, 1976; Moskowitz and Jennings).

The Pro-Family Movement. Beginning in the 1970s, a movement of sexual conservatism—the "pro-family" movement—became a significant presence in family planning politics (Petchesky; McKeegan). This movement's main concern has been the breakdown of sexual morality in contemporary society, as evidenced by high rates of abortion, adolescent pregnancy, out-of-wedlock births, and sexually-transmitted diseases. For sexual conservatives, widely available family planning services—especially those supported by public funds—represent a temptation to break with traditional morality (Marshner). Though the pro-family movement is most visible in anti-abortion activity, its interests and interventions extend to a broad range of reproductive and sexual matters—contraceptive services, sex education, adolescent pregnancy prevention efforts, and HIV prevention (Joffe, 1986; Nathanson).

Family planning services for adolescents have been a major focal point of pro-family activity (Joffe, 1993). Conservative activists have persuaded legislators in a number of states to adopt parental notification and consent rules for teenagers seeking abortions, and have sought regulations that would include parental notification policies for federally funded clinics providing contraceptive services.

The "gag-rule" controversy, which has spanned the presidencies of Ronald Reagan through George W. Bush, is further illustration of the efforts of conservatives to link attacks on abortion to those on family planning. Originally written as an administrative guideline during the Reagan administration, the gag rule forbade employees in Title X-funded family planning clinics to provide counseling about abortion options, even when women asked for such information. For many within the healthcare community and the public at large, this ruling raised concerns about free speech for health professionals. In the space of several years, the gag rule was upheld by the Supreme Court, overturned by congressional legislation, and promptly vetoed by George H.W. Bush, under intense pressure from conservatives. In one of his first acts after taking office in 1993, Bill Clinton abolished the gag rule, under similar pressure from the pro-choice and family planning communities. On his first day in office, George W. Bush restored the Reagan–era gag rule for international family planning programs. This is a pattern that is likely to continue, illustrating the strong relationship between politics and women's health issues, especially those involving fertility control (Planned Parenthood; RowBoat).

Welfare Conservatives. In contrast to the pro-family movement, whose defining issue is the breakdown of sexual morality and traditional families, "welfare conservatives" are concerned about the rising welfare costs resulting from adolescent pregnancies, illegitimate births and failure of fathers to make child support payments. Welfare conservatives have made a number of policy proposals that either mandate use of contraception as a condition of receiving welfare or other financial incentives for such contraceptive use, that penalize recipients financially for having additional children and that forbid adolescent mothers from receiving welfare assistance directly, providing instead that the grant go to their parents or guardians (Nathanson; Peirce).

The contraceptive implant, Norplant, introduced in the United States in 1990, quickly became implicated in a number of policies advocated by welfare conservatives. Once inserted, the implant prevents pregnancy for up to five years. Both the insertion and the removal, however, must be done by a trained health professional. After the insertion, no further "user compliance" is required, making this a far more effective contraceptive device than other birth control methods. Within eighteen months of the introduction into the United States of this new method, virtually all states approved the public funding of Norplant insertion for welfare recipients. The potential for coercion is evident. There have been instances where judges have required Norplant use as a

condition of probation or child custody for women convicted on drug-related charges or of child abuse (Forrest and Kaeser). Provision of access to Norplant for adolescents has also raised ethical concerns (Moskowitz and Jennings). In addition, lack of access to providers trained to remove the implant may restrict choice for some women.

SERVICES TO POTENTIALLY VULNERABLE POPULATIONS. ***Minority Communities.*** Minority communities in the United States have long had a wary relationship with family planning advocates and services. The previously cited historical links between the founders of the birth control movement, such as Margaret Sanger, and those in the eugenics movement with an avowedly racist ideology created a lasting sense of distrust in minority communities as to the intentions of some within the family planning movement (Chesler; Gordon, 1976). Such distrust reached a height in the late 1960s and early 1970s when many of the Title X clinics appeared to be targeted specifically at African-Americans, leading some African-American leaders to accuse family planners of "genocidal" intentions (Littlewood). More recently, some community leaders—most notably, black clergy—have joined forces with the pro-family movement, arguing against such measures as condom distribution in inner-city high schools and offering Norplant to adolescent mothers (Moskowitz and Jennings).

At the same time, the rates of premarital sexual activity, sexually-transmitted diseases, adolescent pregnancy and abortion have been disproportionately higher for minorities than for others. Thus, there is a need for culturally-sensitive family planning and abortion services, and many minority organizations argue forcefully for their retention and expansion.

Adolescents. In the early 1990s, adolescents were entitled to receive low-cost or free confidential contraceptive services at Title X sites. Adolescents, as a group, did not receive any public funds for abortion. The field of adolescent medicine recognizes the need to provide education and family planning services to sexually active adolescents (American Academy of Pediatrics, 1999). The rising rates of sexual activity among adolescents, particularly young adolescents, has increased concern within the family planning community about adolescent pregnancy and this group's vulnerability to HIV and other sexually-transmitted diseases (Alan Guttmacher Institute, 1991). In the 1980s, a major response to both these issues was the establishment of school-based clinics on the theory that while few teens would make their way to a free-standing clinic, clinics located within the school would reach a much larger public. Programs were also established for pregnant adolescents and those with children to try to keep them in school. Predictably, such school-based programs were controversial from the start, strongly opposed by conservatives and just as strongly advocated by health professionals and public health advocates (Kirby et al; Moskowitz and Jennings).

A number of school districts, particularly those in large urban areas, began distributing condoms to students in response to the HIV epidemic. There has been massive controversy here as well, with many parent and church groups opposing such efforts. Generally speaking, however, HIV-related interventions in schools seem to be more acceptable to the public and to educators than specific efforts for pregnancy prevention. A national study of sex education in U.S. schools in the late 1980s found far more attention paid to HIV and sexually-transmitted diseases than to family planning education (Forrest and Silverman). While most would advocate abstinence for adolescents, particularly young ones, the alarming rate of unprotected sexual activity in this age group warrants realistic education and confidential access to safe, appropriate family planning services.

In October of 1998, there was an attempt to pass legislation restricting minor's access to family planning services. The proposed amendment would have mandated that parents of dependent adolescents be notified before their children received contraceptives from Title X-funded clinics (Congressional Record). Supporters of parental consent feel that available, confidential family planning services encourage sexual activity in adolescents and undermine parental authority. However, research has demonstrated that confidentiality is crucial to teens' willingness to seek services related to sexuality (American Academy of Pediatrics, 1999; Reddy et al; Planned Parenthood). Moreover, Planned Parenthood states that the fact that the average teen does not visit a family planning clinic until 14 months after she has become sexually active provides clear evidence that clinics do not encourage sexual activity. Requiring parental consent may not deter adolescents from having sex, but it could keep them from seeking reproductive health care in a timely fashion or at all. This could contribute to an increased rate of pregnancies as well as sexually transmitted diseases (AGI, 2000; Planned Parenthood). While the 1998 amendment was not passed, there is an ongoing attempt by political conservatives to fight access to family planning services for adolescents and even punish them for having sex. In a recent NYC case, a group of eighth graders who skipped school to attend a party where they allegedly had sex were forced to submit to pregnancy and other gynecological testing and to provide the results before they could return to school. A suit has been filed on their behalf by the New York Civil Liberties Union (Williams).

Services to the Disabled. Case law in the United States generally recognizes that developmentally disabled individuals have the same fundamental rights regarding procreative choice as those who are not disabled. There are, however, difficulties in implementing family planning services for disabled persons. The issue of informed consent for mentally disabled individuals is particularly relevant and remains ethically problematic. Is the individual capable of giving informed consent, and if not, who is the appropriate surrogate empowered to make such decisions (Stavis).

In spite of legal decisions supporting provision of such services, relatively few disabled persons are served in Title X clinics (Moore and Lieber). Few clinic staffs have received the specialized training necessary to work effectively with this population. In addition, many caretakers, particularly parents, have difficulty dealing with sexuality in this population and are reluctant to ensure that these individuals receive such services. In addition, disabled individuals and caretakers are often not aware of the entitlement of the disabled to family planning services, which implies a need for more outreach to this population.

In light of the compulsory sterilization programs of the past, the major ethical conflict regarding sterilization today is balancing the rights of a mentally retarded or mentally disabled person to sexual freedom with a protection of their best interests regarding childbearing. Many writings deal with the sterilization of the mentally retarded who are somewhat incapacitated or even totally incapable of giving informed consent (Macklin and Gaylin). The Committee on Ethics of the American College of Obstetricians and Gynecologists has issued a statement on "Sterilization of Women Who Are Mentally Handicapped," which urges all possible attempts to communicate with the person involved on whatever level is possible. Even in cases where it is clear that the individual has no ability to comprehend a pregnancy and childbirth and may be harmed by the experience, it is difficult to obtain a court order for sterilization because of the history of abuses. Perhaps it is more beneficent to take the middle ground in these cases. While routine sterilization of a mentally impaired individual without her consent is clearly wrong, restricting the sexual expression of a profoundly impaired individual who cannot comprehend her sexuality, much less pregnancy or coitus-related conception, is also not justified. In carefully considered circumstances, advocates for the patient may conclude that sterilization is in the patient's best interest. The decision should be made by an appropriate surrogate or proxy, based on the best interests of the patient after considering alternative methods of dealing with the situation. The prominence of this issue in the Senate confirmation hearings of Dr. Henry Foster as Surgeon General in the Clinton administration illustrates the importance of this issue and the lack of societal consensus (Powderly, 1996).

Religious and Moral Issues

Most people today, along with philosophical ethicists, religious ethicists and organized religions, generally accept the morality of contraception within marriage, often appealing to the need for family planning. While recognizing a link between marital sexuality and procreation, many concede that marital sexuality also has other significant purposes such as expressing and enhancing the love union of the partners and thereby the good of the marriage. Unlimited procreation, or at times any procreation, could be harmful to one of the spouses, the marriage itself, the good of already existing children or the needs of the broader society. Judgments about the ethical use of contraception outside of marriage depends upon one's understanding of the morality of extramarital sexual activity. As a matter of fact, many unmarried people today are sexually active. Indeed, the majority of adolescents in the United States have had sexual intercourse by the time they are nineteen years old (Demetriou and Kaplan; American Academy of Pediatrics).

Many feminists emphasize reproductive rights, freedom, control of one's body and autonomy to support their stand that women have the right to make contraceptive decisions in all cases (Harrison). Although society at large in the United States no longer condemns all extramarital sexuality as immoral and irresponsible, the mainstream churches and religions still generally maintain the immorality of sexual relations outside marriage (Lebacqz). The use of condoms enters into the discussion of extramarital sexuality not only because of the desire to prevent procreation, but also because condoms can help to prevent the transmission of HIV and other sexually-transmitted diseases. If one believes that extramarital sexual relations are morally responsible, then the use of contraception to prevent unwanted procreation is morally acceptable.

No perfect contraception exists, but most ethical reasoning sees no significant moral differences among the various means, provided they are not harmful to the individuals who use them or others. One could justify contraception on the basis of an absolute autonomy, giving the individual control over her body and the right to make all decisions concerning it, but most justifications of family planning, which by definition concerns more than the individual, avoid such a radical individual autonomy. The official teaching of the Roman Catholic church constitutes the strongest and the primary contemporary moral opposition to the use of contraception.

The widespread moral acceptance of contraception has taken place well within the twentieth century. Individuals do not make moral judgments in the abstract. As indicated previously, a number of significant social factors have influenced the acceptance of contraceptive practices. These include the increased life expectancy of all human beings, the massive improvements in infant and child health resulting in more survival, the realities and pressures of an increasingly urban and industrialized society, the changing role and function of women in society, the wider and more accurate understanding of the physiology of human reproduction, the recognition of the population explosion and the need to limit population, and the development of accessible, effective methods of contraception.

The Christian religions have played a significant role in ethical views on contraception in the West. The ancient world of both East and West knew the reality of contraception either by avoiding insemination of the female or by using potions or magic. In the Greco-Roman world, some philosophers and physicians apparently accepted attempts at contraception. On the other hand, the Roman Empire tended to encourage childbearing. Some influential philosophers insisted that procreation constituted the only purpose of sexual intercourse and thus, logically condemned contraception. The Hebrew scriptures contain no law condemning contraception.

The Christian approach to contraception also developed in a context in which contraception was associated with prostitution and extramarital sexuality, which Christians strongly opposed. In addition, early potions used for contraception (and some modern methods such as IUDs) could not clearly be differentiated from abortifacients and abortion was even less tolerable than contraception. The Christian condemnation of contraception followed from its understanding of human sexuality and the belief that the purpose of sexuality was procreation. Some medieval theologians and their successors, however, including Thomas Aquinas, maintained that procreation was not the only lawful purpose for sexuality, at least within marriage. The church, for example, accepted the marital sexuality of the sterile and those no longer able to procreate. The procreation of offspring also included the responsibility for the well-being and education of the children—some would extend this to justify not having so many children that you could not care for the pre-existing ones. However, the condemnation of contraception remained, with emphasis on its violation of the order of nature calling for the depositing of the male seed in the vagina of the female. This nature-based rationale also served as the basis for the condemnation of sodomy, oral and anal sex, and masturbation. This view is closely related to the Hebrew prohibition on "spilling" seed.

Although some Protestant laypersons were involved in the Anglo-Saxon countries, the Christian churches remained firm in their condemnation of artificial contraception, as distinguished from abstinence, well into the twentieth century. The Church of England became the first Christian church to accept officially the morality of artificial contraception for spouses. In 1930, the Lambeth Conference, by a vote of 193 to 67, adopted a resolution recognizing a moral obligation to limit or avoid parenthood and proposing complete abstinence as the primary and most obvious way while also accepting other methods (Fagley).

The Committee on Marriage and Home of the U.S. Federal Council of Churches issued an influential statement in 1931 in which the majority of its members accepted the careful and restrained use of contraception by spouses. Subsequently, the major Protestant churches and the most significant Protestant theological ethicists accepted contraception as a way to ensure responsible parenthood. The proponents of change pointed to aspects in the Christian tradition supporting such a move. Christians had gradually come to recognize the loving or unitive aspect of marital sexuality in addition to the procreative aspect. The procreative aspect itself included not only the procreation but also the education of offspring. This called for the good health of the parents. Protestantism justified the use of contraception as a way for spouses to realize responsible parenthood (Fagley).

Roman Catholic official teachings continue to steadfastly oppose artificial contraception, even within marriage. Some Catholic theologians have advocated the use of the infertile period for sexual intercourse, or the rhythm method. In 1951, Pope Pius XII taught that serious medical, eugenic, economic and social indications justified the use of the sterile periods even on a permanent basis. Unfortunately, the rhythm method often proves to be a rather ineffective method of contraception. This can have devastating consequences, especially if there are serious medical contraindications to pregnancy. Pope John XXIII and Pope Paul VI established a commission to study the question. The majority of the commission favored changing the teaching to allow for artificial contraception, but Pope Paul VI and Pope John Paul II have reiterated an absolute condemnation of artificial contraception. In *Humanae Vitae,* Paul VI states that the natural law "teaches that each and every marriage act must remain open to the transmission of life" and refers to "the inseparable connection, willed by God and unable to be broken by man on his own initiative, between the two meanings of the conjugal act: the unitive and the procreative meaning" (Paul VI). In practice, the vast majority of Catholic couples use contraception (Curran). The Catholic Church's

continued prohibition of any method of artificial contraception is especially problematic in poor, overpopulated developing countries with large Catholic populations. In such countries, uncurtailed childbearing can have dire consequences for women and children.

The Catholic Church also opposes voluntary sterilization for contraceptive purposes. As far as therapeutic sterilization is concerned, the principle of double effect is generally applied. Therapeutic sterilization is that done for the good or health of the individual and not primarily for contraceptive purposes. Direct sterilization is that which aims at making procreation impossible either as a means or as an end and is always considered wrong. Indirect sterilization aims directly at the health or good of the individual and the actual procreative effect is secondary. Thus, a cancerous uterus can be removed, but hysterectomy to prevent harm to the pregnant woman would be considered direct and morally wrong (Boyle).

The fact that there is little or no discussion of punitive sterilization in the more recent literature hints at a consensus against the practice. However, Francis Hurth, a conservative Roman Catholic theologian in the 1930s, proposed limited cases in which punitive sterilization might be justified. Pope Pius XI went out of his way not to directly condemn punitive sterilization. This is interesting in light of the absolute prohibition on sterilization for contraceptive purposes in women desperate to limit the size of their families. Proponents of punitive sterilization maintain that if the state can inflict capital punishment for certain crimes, it can also inflict the lesser punishment of sterilization in limited, appropriate cases. Critics reply that punitive sterilization does not achieve the purposes of punishment and does not even inhibit future sex crimes (McCarthy). Punitive sterilization is virtually unsupported (Mason).

Other religious bodies today generally support artificial contraception in the context of responsible parenthood. The Eastern Orthodox church accepts responsible contraception while condemning abortion and infanticide. The multiple purposes of marriage, the lack of any definitive statement against contraception by the church, a synergistic cooperation between God and humans, and the need for responsible parenthood serve as the basis for the responsible use of contraception within marriage (Harakas; Zaphiris).

Orthodox Judaism gives a limited acceptance to some forms of contraception. Jewish law puts the duty of procreation on the male, and this obligation militates against the use of condoms or coitus interruptus. In this view, the most acceptable contraception is that which interferes the least with the natural sex act (Rosner). Conservative and Reform Judaism fully accept and endorse contraception provided it is not harmful to the parties involved.

Islam accepts contraception if it does not entail the radical separation of procreation from marriage. All forms of contraception are acceptable provided they are not harmful and do not involve abortion. Justification for contraception in Islam rests on reports that the Prophet Muhammad did not forbid the contraceptive practices of some of his companions (Hathout).

Ancient Hindu medicine and Hindu tradition did not contemplate contraception, but did sanction means to enhance contraception. In time, medical texts began to address contraception by advising a few oral preparations to prevent conception. When India embarked on a national family planning program after its independence in 1947, the discussions accepted the morality of contraception, but the main focus was the relative population size of the higher and lower castes (Desai).

Contemporary popular morality—the behavior and values of ordinary people—as well as contemporary philosophy, theological ethics, and religious bodies (with the major exception of the Roman Catholicism), accept the morality of contraception for spouses in practicing responsible parenthood. General agreement exists that on the microlevel of the family, the decision about contraception should be made by the spouses themselves in the light of their own health, the good of their marriage, the education and formation of their children, and population and environmental needs, both local and global (Curran). In fact, with the exception of those who are politically conservative and/or pro-family, most accept the right to fertility control even for those who are unmarried.

International Population Control

The highly politicized nature of family planning in the United States has had major implications for the developing world. In response to pressures by conservatives, the emphasis of U.S. population programs abroad shifted heavily to programs promoting natural family planning rather than the more reliable methods of artificial contraception. Most notably, the "Mexico City policy" adopted by the Reagan administration in 1984 stipulated that no U.S. aid would go to any international organizations that supported abortion, even if the U.S. funds were separated and used only for nonabortion services. The Mexico City policy was overturned in the early days of the Clinton administration in 1993, thus renewing a commitment on the part of the United States to international family planning efforts after a period of marked decline. The policy again became an issue in the administration of George W. Bush who withheld $34

million in funding for birth control, maternal and child health care and HIV prevention from the United Nations Population Fund in 2002 (Rosenberg; Planned Parenthood; UNFPA Funding Act, 2003). The loss of U.S. funding has a grave impact on UNFPA programs and the people they serve. UNFPA estimated that the $34 million loss would lead to two million unwanted pregnancies, 800,000 induced abortions, 4,700 maternal deaths, and 77,000 infant and child deaths. Restoration of U.S. funding would also save lives through HIV prevention campaigns. The $34 million would provide one-third of the annual needs for mass HIV prevention information campaigns aimed at behavior change. It would also cover the cost of 13 per cent of the condoms needed worldwide to prevent sexually transmitted infections, including HIV. President Bush also reversed the U.S. position in support of the 1994 global agreement that affirmed the right of all couples and individuals to determine freely and responsibly the number and spacing of their children and to have the information and means to do so (United Nations; RowBoat). Walking a political tightrope, he then announced major programs to deal with HIV infection abroad.

Family planning issues are an increasingly high priority for many developing nations. Concerns about the ability to feed rapidly growing populations, the dramatic spread of HIV infection and AIDS in the Third World, especially in parts of Africa, Asia, and Eastern Europe, and the large number of deaths that occur each year from illegal abortions create constituencies for family planning services within these countries. There are, of course, also often significant religious and cultural objections.

The rise of indigenous women's movements in the developing world has also served as a particularly important stimulus for additional family planning services which must be provided in a culturally sensitive manner (Bruce; Dixon-Mueller). The International Women's Health Coalition has been one of the most successful international population groups in terms of its ability to work closely with local, grass roots women's organizations in the design and delivery of family planning programs.

Current and Future Controversies

The future of accessible family planning services in the United States and abroad is unclear. During the administration of Bill Clinton, the influence of political conservatives in public policy debates about family planning was greatly diminished. Clinton's appointments to key health policy positions of individuals strongly committed to family planning, especially in the area of adolescent pregnancy prevention, sharply reversed the trends of the Reagan-Bush era. Ideological battles were temporarily muted, but they will never entirely disappear because of a change in presidential administration. At the state and local levels, many of the bitter struggles over the public provision of reproductive health services continued. Bill Clinton attempted to reform health care in general and largely failed. The election of George W. Bush signaled an immediate return to the ideologically conservative policies of his father.

The abortion issue remains among the most politically explosive and unresolved issues in bioethics. Provision of abortion services has endangered funding for other family planning services and endangered the lives of providers and consumers alike. Concerns of political conservatives and anti-abortion groups have affected policy debates as diverse as end of life decision-making in New York State and Federal regulation of embryonic stem cell research. In August of 2002, George Bush revealed his decision on stem cell research. Had it not been for the terrorist attacks that occurred shortly thereafter, stem cells might have been the defining issue of his presidency. Bush allowed future work with stem cell lines already produced, but his policy did not allow for the development of additional cell lines. By sitting on the fence, Bush did not satisfy either side in the debate. Anti-abortion forces were not happy that the existing cell lines, obtained from aborted fetuses, would still be used. Those in favor of stem cell research did not think that the existing cell lines would be adequate to study the possible benefits of stem cells for those with diseases such as Parkinson's Disease, Alzheimer's Disease, and diabetes.

The historical context is important for the current ethical and policy debates related to fertility control. Efforts to empower all women, including poor women of color, must be balanced with a keen sense of the abuses evident in the history of the birth control movement. Racism and eugenic concerns have been consistent issues in debates about controlling fertility, and our targeted educational programs and initiatives must be sensitive to community concerns. Empowering women to make their own reproductive choices is a praiseworthy goal, but it is not a desirable one for some.

III. LEGAL AND REGULATORY ISSUES

The ability to control fertility depends on available technology, moral and religious acceptability, and legal permissibility or the threat of sanction. The major fertility-control mechanisms are contraception and sterilization and, when neither is used or the chosen method fails, abortion. The mechanical and physiological characteristics of each method determine the ease and comfort of individual use, the likelihood of success, and the potential for coercion.

In many cultures men view children as proof of virility and power. They see attempts by women to limit or terminate pregnancy as an attack on male authority and reproductive potential, which in many societies equals wealth. For many women a desire to limit pregnancy must often be pursued furtively, with fear of violence and retaliation. Biology and the threat to a woman's independence, health status, and well-being make the control of fertility primarily a woman's concern. A woman's ability to limit and control her fertility may be a necessary precondition for equality and personal economic status.

Because they affect relationships between the sexes, population growth, and a woman's status, contraception,

sterilization, and abortion are and have been problematic for many societies. Secular societies committed to individual rights and liberties are less likely to intervene in reproductive decisions. But all societies to some degree attempt to influence individual reproductive choices.

History of Contraception Use and Control

GENERAL. Various societies have interceded for centuries in the free use of contraception, largely for moral and/or religious reasons. Classical Islam permitted the use of birth control and even early abortion (Fathalla et al.). Biblical Judaism, based on interpretations of the story of Onan in Genesis 38: 8–10, condemned *coitus interruptus* and the use of male condoms. Christianity gradually evolved a doctrine, based on biblical references, interpretations of natural law, and the writings of Saint Augustine (354–430), that prohibited use of all contraceptive devices (St. John-Stevas). Widespread, class-linked knowledge of contraceptive practices was effectively withheld from most of the population following the condemnation of birth control by philosopher and religious Thomas Aquinas (1224 [or 1225]–1274] in the mid-thirteenth century (Fathalla et al.). As religion formed part of the basis for modern secular law, control of fertility became a subject of legal attention and regulation.

Abortion, as a method of fertility control, has always been especially controversial. Despite its morally and legally complex past and its tendentious present, there is evidence today that abortion remains a favored method of birth control for many women, both as a preferred method of fertility control and as a backup to failed contraception. An estimated 46 million abortions are performed worldwide each year (Alan Guttmacher Institute). Unintended pregnancy is the leading cause of abortion. Approximately 150 million married women want to stop having children but are not using contraception (World Health Organization [WHO]). In the United States, where contraception is readily available, 49 percent of pregnancies are unintended (Henshaw). The United States Center for Disease Control (CDC) reported 884, 273 legal induced abortions in 1998, a ratio of 264 abortions per 1,000 live births.

While contraception and abortion address the prevention or termination of any specific pregnancy, sterilization terminates individual fecundity. With the development of modern, comparatively safe, and effective means of sterilization (vasectomy, or surgical excision of the duct carrying sperm from the testicles; and salpingectomy, or surgical removal of one or both fallopian tubes), individuals can choose, by means of one medical intervention, to detach sexual intercourse from reproductive consequences. If chosen by individuals, these simple and almost always irreversible interventions extend autonomy; if imposed by the state, they can become instruments of repression.

Whether contraception, sterilization, and abortion should be permitted, prohibited, or coerced by government has generated intense controversy in countries as different as the United States, Romania, India, Ireland, and China. In each country, legislators, judges, individuals, and special-interest lobbies have struggled to affect how citizens will think about their options for controlling fertility, how the individual decision-making process will be informed and supervised, how access to contraception, abortion, and sterilization will be ensured or precluded, and whether coercion will be encouraged, permitted, or prohibited (Weston; Thomas).

Both female and male condoms have been available for centuries. Roman women attempted to use goat bladders (Fathalla et al.), and some African women hollowed out okra pods (Robertson). A picture of a penile sheath is recorded as early as 1350 B.C.E., although male condoms did not come into general use in Europe until 1671 and became reliable only with the vulcanization of rubber in 1843 (Robertson). Monitoring and prohibiting use of birth-control devices such as condoms are difficult because of the inherently private nature of their use. Manufacture, distribution, sale, and advertising are more easily regulated and prohibited.

Despite the long history and the private nature of fertility control, various legal and theological systems have attempted prohibition. The early Christian (Roman Catholic and Protestant) argument against contraception, influential as the model for legal regulation, holds that God's purpose for sex is conservation of the species, which is frustrated when people have intercourse for nonprocreative purposes (St. John-Stevas). The Catholic Church first proscribed contraception in canon law in 1140 (St. John-Stevas). While not all religions have been as resistant to the idea of contraception as the Catholic Church, contraceptive use has traditionally been considered an appropriate area for moral guidance and proscription and not until the beginning of the twentieth century did significant numbers of Protestant theologians provide moral approval (Larson).

Religious regulation has been selective. Some forms of birth control were interdicted, while others were and have remained relatively unnoticed. In addition prolonged lactation, postpartum abstinence, delayed marriage, celibacy, and to some extent infanticide, are all techniques of fertility management that have been and continue to be used.

U.S. HISTORY. Puritan theology dominated the early American colonists. The Puritans considered sex-related matters

part of the devil's province, to be shunned and ignored, and they tolerated little open discussion (Robertson). In the 1830s some popular literature on contraception, such as Robert Dale Owen's *Moral Physiology,* began to be generally available (Robertson, Reed). Not until 1873 did law begin regulating distribution of contraceptives in the United States. The Comstock Act ("An Act for the Suppression of Trade in, and Circulation of, Obscene Literature and Articles of Immoral Use") equated contraception with obscenity and made it a federal offense to use the postal service for transporting obscene materials, defined to include contraceptive and abortion information and equipment. The act also banned importation and interstate transportation of such items (Sloan). After the act's passage, many states adopted their own regulations on the sale, advertising, and display of contraceptive devices.

Margaret Sanger, a nurse affected by her work in poor communities where morbidity (the incidence of disease) and mortality from abortion was high, was a vociferous advocate for birth control (Reed; *People v. Sanger,* 1918). She founded a monthly magazine, *The Woman Rebel,* for which she was arrested and indicted under the Comstock Act. She fled to Europe and returned in 1916 to establish the first American birth-control clinic in Brooklyn, a borough of New York City (Chessler). In 1918 she was convicted and sentenced to thirty days in the workhouse under New York State's Comstock law. Years later a physician in one of Margaret Sanger's clinics who had ordered a package of contraceptives through the mail was charged with violating the Tariff Act of 1930, a statute based on the Comstock Act that prohibited importation of "any article whatever for the prevention of conception or for causing unlawful abortion." On appeal the federal circuit court for the second circuit held that the act did not apply when the article imported was not intended for an immoral purpose. Judge Augustus Hand declared that the Tariff Act was part of a "continuous scheme to suppress immoral articles and obscene literature," and refused to find proper medical use of a contraceptive by a licensed physician to be immoral or obscene (*U.S. v. One Package …,* p. 739). Though the court did not invalidate the statute, its interpretation limited the sweeping definition of morality and obscenity that had previously held sway.

Statutes modeled after the Comstock Act continued to exist, however, until 1965, when the U.S. Supreme Court in the case of *Griswold v. Connecticut* invalidated a Connecticut statute prohibiting the use of contraceptives. The Court held, citing prior cases that had created a zone of privacy protecting certain personal behaviors, that these penumbral rights of "privacy and repose," based on several fundamental constitutional guarantees, protected the use of contraceptives by married persons (*Griswold v. Connecticut,* p. 481). *Griswold* was followed by *Eisenstadt v. Baird* (1972), extending this reasoning to nonmarried individuals. The statute that was invalidated in *Eisenstadt* prohibited single persons from obtaining contraceptives to prevent pregnancy, and permitted contraceptives only on a physician's prescription for the purpose of disease prevention. The statute was held to violate the equal protection clause of the Fourteenth Amendment:

> [W]hatever the rights of the individual to access to contraceptives may be, the rights must be the same for the unmarried and the married alike.… If the right of privacy means anything, it is the right of the individual, married or single, to be free from unwarranted governmental intrusion into matters so fundamentally affecting a person as the decision whether to bear or beget a child. (*Eisenstadt v. Baird,* p. 452–453)

Minors gradually attained access to contraceptive advice and devices. In 1977, in the case of *Carey v. Population Services International,* the U.S. Supreme Court invalidated a New York State statute that had banned the sale or distribution of contraceptives to persons below the age of sixteen and had prohibited the advertising or display of contraceptives by any person, including a pharmacist. In 1983 the Supreme Court struck down a federal statute prohibiting unsolicited advertisements of contraceptives (*Bolger v. Young Drug Products Corp.*). In addition, under Title X of the Public Health Services Act and Title XIX of the Social Security Act, receipt of federal funds prohibits a requirement of parental consent for services and requires confidentiality. Efforts to require parental notification under these acts have been held unconstitutional (*Jane Does 1 through 4 v. State of Utah Dept. of Health, Planned Parenthood Association of Utah v. Dandoy*), and federally funded clinics provide a full range of advice and service for fertility control for adults and minors.

New Contraceptive Technologies

A revolution in birth control techniques has created new possibilities for individual choice and new dangers of coercive action by legislatures, bureaucrats, and judges. Additional dangers arise from inadequate new-product testing and from lack of information or misinformation about risks and benefits of use. Female condoms, levonorgestrel (Norplant), and Depo-Provera are increasingly available to women for contraception.

The female condom or vaginal pouch was approved by the U.S. Food and Drug Administration (FDA) in 1993. The device, developed and marketed by Wisconsin Pharmaceuticals, consists of a polyurethane sheath secured inside

the vagina by a small metal ring and outside by a large metal ring. It is the only barrier contraceptive that is under the control of a woman, an increasingly important factor for women seeking to protect themselves from sexually transmitted diseases and human immunodeficiency virus (HIV) infection when their partners refuse or neglect to use condoms. The device was approved by the FDA despite concerns that it was not proved as effective as the male condom for prevention of pregnancy or prevention of transmission of infection.

Norplant, approved by the FDA in 1990, is a long-term implantable contraceptive comprised of six capsules that gradually release progestin, thereby providing effective contraception for five years. A two-capsule version provides protection for three years. Norplant, like other contraceptive devices, is morally neutral; it may enhance the range of individual choice or, because of its long-acting nature, lend itself to coercive action by others. It permits a woman to protect herself without conscious attention to contraception but makes her dependent on medical intervention for removal, a dependency many women resent.

Norplant suppresses ovulation, and changes the female physiology to discourage pregnancy. For women who choose this contraceptive technique, it offers 100 percent compliance and effectiveness without the need to attend to individual acts of intercourse or to daily medications. There are some side effects and contraindications for use, including the possibilities of weight gain, headaches, and a general feeling of malaise. Implantation and removal remain expensive in the United States, costing between $500 and $750 (Planned Parenthood).

The only way to stop the contraceptive effect of the device is to have it surgically removed. Removal is more complicated than insertion and more than one session may be required to remove all the capsules; removal may also be painful. Norplant provides either long-acting contraception or time-limited sterilization (Mertus and Heller; Arthur).

Norplant presents an easy potential for coercive use by judges and legislatures. Problematic uses include requiring Norplant as a condition of parole following a conviction for child abuse, and paying women on welfare for consenting to initial and continued placement of the contraceptive. The first is clearly coercive. The second is potentially coercive depending on the context of a woman's poverty. Various state legislatures have considered statutes that would pay women receiving welfare to use Norplant or mandate its use by women convicted of child neglect and drug use, or both (Mertus and Heller; American Medical Association Board of Trustees [AMA]).

Judicial or legislative imposition of Norplant may violate a woman's constitutionally protected rights to choose how to manage reproduction and to choose whether or not to consent to or refuse medical care (*Cruzan v. Director, Missouri Department of Health*). Any long-acting male contraceptive would implicate these same rights. In addition, because long-acting contraception amounts to temporary sterilization, it raises the specter of eugenics—policies that are often directed at people of color, the poor, the retarded, the mentally ill, and other persons designated by those in power as undesirable. Norplant offers effective contraception when chosen voluntarily by a woman informed of the risks and benefits, and a potential for tyranny when imposed by judges or legislatures.

Regulation of Contraceptive Technologies

In addition to enhancing individual choice and restricting abuse, regulation of new technologies must ensure access and quality control. The development of new technologies is regulated formally by the approval process of the FDA, and informally by compensation awards under tort law for harm caused by defective products.

The FDA regulates the development of new drugs and contraceptive devices under the Federal Food, Drug and Cosmetic Act of 1938. Under this law, a company interested in marketing new contraceptive drugs or devices must submit data, including results from various tests for safety, effectiveness, and dosage, as part of an extensive approval process. In addition to approving new drugs and devices, the FDA reviews labeling and assesses data in a postmarketing surveillance program. The FDA approval process has been criticized as expensive, time consuming, and a barrier to new techniques. It has also been praised for protecting consumers from the harm of untested substances.

The FDA approval process is not the sole factor dictating whether a reproductive technology reaches U.S. consumers, however. The American tort system is designed to compensate those injured, deter the marketing of dangerous and defective products, and resolve disputes between the injured person and the manufacturer.

A person may recover damages for dangerous or defective products, including contraceptive devices, if either negligence or a strict liability is established. Negligence requires proof that the manufacturer was at fault. However, sometimes the fault of a large company is difficult to establish, and therefore the interests of justice dictate that a victim should be allowed to recover damages without proving specific fault. According to the strict products-liability principle, if a product is sold in a defective condition, and is

unreasonably dangerous to the consumer, there is liability regardless of the care taken, that is, regardless of negligence in any individual case. Strict liability may make manufacturers apprehensive about putting new contraceptive products on the market.

This is the case especially since the litigation experience of the A. H. Robins Company, developer and marketer of the Dalkon Shield, an intrauterine contraceptive device. In a series of court cases in the early 1980s, this device was proved to cause pelvic inflammatory disease, infertility, birth defects, perforated uterus, and spontaneous abortion. In a series of jury verdicts throughout the United States, A. H. Robins was forced to pay compensatory damages and punitive damages because plaintiffs proved that the company had understood the dangers of the device, withheld this knowledge from prospective users, and misrepresented the nature and safety of the device (Mintz). Despite this experience, cases brought by women seeking recovery for harm from contraceptive devices have usually found the manufacturer liable only under theories of negligence—for example, negligent failure to comply with the duty of care, negligent failure to warn of risks, or fraudulent misrepresentation (*Hilliard v. A. H. Robins Co., Tetuan v. A. H. Robins Co.*). In fact, even those courts purporting to apply strict liability seem to be applying a theory of negligent failure to warn under the rhetoric of strict liability (Henderson and Twerski; Fox and Traynor).

How tort law is interpreted is in a state of flux. Some judges and juries appear to view manufacturers as *deep pockets* (Reilly) and to see tort law as a vehicle for providing social insurance for injury victims. Many critics of large jury awards argue that the size of jury awards often bears no relationship to actual economic loss or to pain and suffering, and that awards of punitive damages are arbitrary and unfair. Supporters of the present pattern of trial awards argue that claims of a law crisis in this area are exaggerated because of manufacturers's dislike for how the law determines their liability (Fox and Traynor). However as long as manufacturers fear they will have to pay large financial penalties to women who suffer the consequences of their new products, many may be reluctant to market new products, a trend that may limit women's access to new contraceptive technologies.

Postcontraception, the *morning-after* pill, is widely dispensed on college campuses after unprotected intercourse and in emergency rooms for rape victims; it promises to be another barrier to unwanted pregnancy. The process generally entails two treatments of oral contraceptives within seventy-two hours of intercourse and is thought to prevent pregnancy either by blocking fertilization or by blocking implantation of the fertilized egg. An antihormone (mifepristone) product called RU-486, discussed in the following section, has also shown promise as a morning-after pill.

Abortion

This article will not survey the legal history and the current status of abortion law and regulation. This discussion will be limited to RU-486 which, while functioning as an abortion inducer, is thought of by many users as similar to oral contraceptives.

RU-486 is a steroid analogue that, when used with prostaglandin (PG), is able to induce menses within eight weeks of the last menstrual period. It has been called a *menstrual regulator* in an attempt to distinguish it from contraceptives and abortion inducers, although to theologians the physiological function is clearly that of an abortion inducer. It was approved for use in France in 1988. Limited trials in the United States began in 1994. Shortly after its introduction in France, the manufacturer, Roussel Uclaf, attempted to halt distribution for fear of anti-abortion protests. The French government, a one-third owner of the company, ordered continued manufacture and distribution (Banwell and Paxman).

Whether RU-486/PG will become readily available will depend on each nation's interpretation of relevant abortion laws and regulations. If abortion "is defined to include techniques that operate before implantation is complete, RU-486/PG will be regulated by abortion law. If not, RU-486/PG might be considered similar to a contraceptive and could be made more widely available. This distinction is particularly important because abortion legislation generally imposes criminal penalties" (Banwell and Paxman, p. 1400).

While France considers RU-486/PG an abortion inducer, Germany, New Zealand, and Liberia use a definition of pregnancy in their abortion statutes providing that pregnancy begins only after complete implantation. In these countries, RU-486/PG and any other menses-inducing technique is regulated as a form of contraception. In countries with strict abortion laws in which pregnancy is defined as beginning with fertilization, even early use of RU-486/PG might be barred (Banwell and Paxman).

Many countries in Latin America and Africa have restrictive abortion statutes that require proof of pregnancy. Statutes that require proof of pregnancy will be difficult to use as a barrier to RU-486/PG. Other national statutes criminalize the intent to abort whether or not the woman is pregnant. In these countries, many of which are former French colonies, the widespread use of RU-486/PG is effectively precluded. In societies governed by Islamic law,

where pregnancy may be terminated until quickening—when fetal movement is felt—RU-486/PG would likely be acceptable (Banwell and Paxman).

Sterilization

Sterilization is a particularly useful technique for men and women who are certain that they have fulfilled their reproductive agenda. For these individuals sterilization provides an uncomplicated and generally certain method of limiting fertility. Whereas sterilization done competently is 100 percent effective, cases have claimed damages for children conceived as the result of incomplete sterilizations.

The key legal issues in sterilization involve the need to ensure that the choice is made by a competent adult who has chosen voluntarily; the need to decide for some persons, almost always women, who are clearly incapable of deciding for themselves; and the need to prevent notions of eugenics from dictating sterilization policy and practice. Sterilization, because it requires only one medical intervention, has been particularly susceptible to government abuse.

Women or men who choose sterilization must be counseled about the risks and benefits of the intervention itself and about the very slim chances for reversal if permanent infertility is no longer desired. Some localities have regulations requiring a waiting period between a request for sterilization and the actual procedure. Others preclude caregivers from soliciting consent for sterilization from women during the birthing process. Both restrictions offer protection against coercion, especially for low-income women and women of color who have been historically at risk for nonconsensual sterilization.

Sterilization has been used by physicians and by state and federal governments since the turn of the century (Mertus and Heller), in order to limit the reproduction of low-income women and women of color. It has also been used as a method of eugenics "to weed out traits or characteristics that are held to be undesirable. Further, sterilization was simultaneously discouraged among affluent white women" (Mertus and Heller, p. 377).

The history of involuntary sterilization of incompetent and developmentally disabled individuals in the first half of the twentieth century is a history of "wholesale violations of constitutional rights carried out with the approval of the highest judicial tribunals." Eugenic sterilization—the attempt to rid the collective gene pool of hereditary mental and physical defects—was the result of the "enthusiastic application of Mendelian genetics" to population policy (*In re Conservatorship of Valerie N.,* p. 148).

In the early-twentieth century, thousands of young women and men were sterilized as the result of decisions by the directors of mental institutions or prisons in which they were housed, or by decisions of their conservators or guardians. The impulse to control the reproductive capacity of these people was fueled by the dual fears that children would perpetuate their parents's mental or physical *deformity* and would be a drain on state coffers. But there is another basis, never articulated as such in legislation or by the courts, and that is a general revulsion at the concept of mentally *defective* persons acting sexually. Indeed a 1913 California statute granted authority to *asexualize* committed mental patients and developmentally disabled persons prior to their release from state institutions (*In re Conservatorship of Valerie N.*). Sexuality, as well as reproductive capacity, was at issue.

By the second decade of the twentieth century, twenty-two states had eugenic sterilization statutes. Between 1907 and 1921, 3,233 sterilizations were performed, of which California was responsible for 2,558. By 1927 California had performed over 5,000 sterilizations, four times as many as had been performed by any national government worldwide. By 1960 approximately 60,000 persons had been subjected to compulsory sterilization in the United States, with nearly 20,000 in California (Mertus and Heller).

In 1927 the U.S. Supreme Court upheld a Virginia statute permitting the sterilization of the *mental defectives* (*Buck v. Bell*). The Court based its decision on two lines of reasoning: that if rendered unable to procreate, the person might more easily become self-supporting; and that society can choose to protect itself from further dissemination of defective genes. Justice Oliver Wendell Holmes wrote, "The principle that sustains compulsory vaccination is broad enough to cover cutting the Fallopian tubes.… Three generations of imbeciles are enough" (*Buck v. Bell,* p. 207).

Buck v. Bell, though never overruled, has been severely limited by later decisions. In 1942 the U.S. Supreme Court invalidated the Oklahoma Habitual Criminal Sterilization Act, which ordered the sterilization of anyone convicted of three crimes involving *moral turpitude;* however, the contested law excepted certain white-collar crimes. In *Skinner v. Oklahoma* (1942), declaring the Sterilization Act unconstitutional on equal-protection grounds, the Court ruled that procreation is a basic civil right that can be abridged only by showing compelling state interest. The Court referred to the right to marriage and procreation as a basic liberty and as one of the basic civil rights. The Court's reluctance to approve the Oklahoma statute appears to reflect apprehension that sterilization could be used oppressively.

The second half of the twentieth century has witnessed a revulsion against nonconsensual sterilization, based on the

revelations of Nazi abuses and the emergence of various rights movements in the United States—civil, women's, welfare, mentally ill, the disabled, and prisoners. Sociological and medical research regarding the nature of mental illness and developmental disability also enlightened the public regarding the ability of developmentally disabled and mentally ill persons to lead constructive, competent, loving lives as partners and parents.

Beginning in the 1950s, numerous states repealed legislation permitting eugenic sterilization for institutionalized persons or limited the powers of conservators and guardians to procure individual sterilization. Yet in many states these statutes are still law. This has led to the ironic position, in many states, that no one can consent for the incapable, thus denying them access to sterilization even when sterilization is the only or arguably the best contraceptive solution—and even when it is required to protect health or life itself.

Arguments regarding sterilization for incompetent persons pit advocates of reproductive choice for the disabled against those who argue that the right to *bear or beget* a child includes the right to choose reproduction, contraception, or sterilization. Federal (*Hathaway v. Worcester City Hospital, Ruby v. Massey*) and state courts (*In re Moe*; *In re Grady*; *In re A. W.*) have generally held that developmentally disabled persons have fundamental privacy and liberty interests in making decisions about procreation and that these interests require sterilization to be an option for fertility control. Some state courts, however, have refused to authorize sterilization of an incompetent person unless the state legislature has specifically authorized the decision and specified a process (*Hudson v. Hudson, In re Eberhardy*). The U.S. Supreme Court has yet to examine the issue, but prior cases would seem to support a right of access to sterilization for incompetent persons.

Cases claiming rights of protection from sterilization most often involve consent for severely disabled young women for whom menstruation and pregnancy would be painful, provoking, upsetting, or possibly life-threatening (for example, one woman for whom the sight of her own blood caused a pattern of severe self-mutilation [*In re P. S.*]). In most states, courts appoint an independent guardian to protect the interests of the person and then base their decision on the standard of *best interest* (*In re P.S., In re Hayes*) or substituted judgment (*In re Moe, In re Grady*).

The dangers of forced sterilizations are apparent outside the realm of prisoners, developmentally disabled, and incompetent individuals, largely where issues of race and class are present. The indigent, who are often persons of color, have been particularly subject to sterilization abuses by public officials and collaborating physicians. Numerous cases have been documented of coerced sterilization of Native Americans (Kelly), Latinos (particularly those who spoke little or no English), and African Americans (*Relf v. Weinberger,* 1977). In response to one egregious incident (*Relf v. Weinberger*), the district court examined the practice of physicians at federally funded clinics who were using sterilization to limit the reproduction of African-American teenagers. The court invalidated federal regulations that permitted involuntary, coerced sterilization, including sterilization of minors or persons incapable of providing consent. The court further held that such sterilizations could not be funded under the Social Security Act or the Public Health Service Act. The court found that minors and other incompetents had undergone federally funded sterilization and that an indefinite number of poor people had been improperly coerced into accepting sterilization operations under the threat that various federally supported welfare benefits would be withdrawn unless they submitted.

Local statutes and federal regulations have further limited the use of sterilization. In New York City, for example, statutes passed in 1985 require completion of a complicated informed-consent process and a thirty-day waiting period before sterilization is permitted (New York City Charter and Administrative Code §17–401 et seq.). Federal regulations also prescribe special informed consent procedures and waiting periods for federally funded sterilizations (Code of Federal Regulations 1993b, 1993c).

Much current law attempts to protect vulnerable women and limit potential abuse by emphasizing voluntary, informed consent and limiting sterilizations to which individual, capable consent is not given. Even where there is no specific legislation to that effect, compulsory sterilization has become rare; those states that have retained compulsory sterilization statutes on the books have, for the most part, let them slip into disuse (Haavik and Menninger).

Discussion of eugenics as appropriate public policy for the protection of future generations has largely been discredited because of the Nazis's horrendous abuse of the concept, because of scientific and societal disaffection with eugenic theories, and because of increasing respect for those with developmental and other disabilities. Nonetheless eugenics is not yet dead. Increasing knowledge about genetics and new reproductive technologies such as in vitro fertilization, artificial insemination, and surrogate motherhood, may allow people to selectively create babies of *higher quality,* and may renew the specter of eugenics, albeit in a new light (Neuhaus).

An ethical policy controlling reproduction must offer a range of contraceptive services to women and men and

simultaneously protect adults with reproductive potential from state coercion. New technologies offer increased protection from unwanted pregnancy and increased potential for overriding individual preferences.

FETAL RESEARCH

• • •

All of the research discussed in this entry involves women and men, as well as human embryos and fetuses. When implantation is a necessary condition for the research, as in the case of most fetal research, the fetus is implanted in the uterus of a woman. For all of the research considered in the entry, the oocytes (eggs) of at least one woman are required; in cases involving in vitro fertilization (IVF), the oocyte retrieval process can be onerous for the woman involved. In addition, sperm from at least one man are required for fertilization. Finally when research is conducted on the developing fetus, interventions also directly impact and take place through the body of the pregnant woman. For reasons of brevity, this entry focuses primary attention on the developing human embryo and fetus. However recognition of the inextricable connection between the fetus or embryo and the woman and man who provide the gametes that give rise to it or to the woman in whom gestation occurs is critical to ethical discourse, and is explicity discussed where possible.

Four major types of research will be analyzed in this entry:

1. research on preimplantation embryos;
2. research on unimplanted embryos and fetuses beyond the fourteenth day of development;
3. research on implanted embryos and fetuses; and
4. research on aborted, live embryos and fetuses.

The topic of research on living tissue derived from fetal remains is discussed in a separate entry.

Preimplantation Embryo Research

The human preimplantation embryo can be defined as the developing organism from the time of fertilization to approximately the fourteenth day after fertilization, assuming a normal rate of development. The major preimplantation stages in human and other mammalian embryos are usually distinguished by such names as zygote, morula, and blastocyst. By the end of fourteen days the early human embryo has, except in rare cases, lost the capacity to divide into two

individuals; it has also begun to exhibit a longitudinal axis that forms the template for the spinal column, an axis called the primitive streak (McLaren; Dawson, 1990a).

Preimplantation embryo research generally requires the associated procedure of IVF (although it would in principle be possible to retrieve an early embryo by flushing it from the uterus of a woman following in vivo fertilization of an ovum). Thus the question of research on preimplantation embryos did not arise until IVF techniques had been developed and validated, first in laboratory animals, then in humans. In 1959 M. C. Chang of the Worcester Foundation in Massachusetts was the first scientist to demonstrate unambiguously the fertilization of nonhuman mammalian oocytes in vitro. Chang's success was followed in 1969 by the first confirmed report of IVF with human gametes by three British researchers (Edwards et al.). Only nine years later the first human birth after IVF—the infant's name was Louise Brown—was reported by members of the same British research team (Steptoe and Edwards).

Given that IVF is required for preimplantation embryo research, the risks to the woman of ovarian stimulation and oocyte retrieval are relevant to the discussion. Ovarian stimulation with injectable gonadotropins has been associated in some studies with an increased risk of ovarian tumors (Harris et al.), though the association is controversial. In addition gonadotropins are associated with a risk of ovarian hyperstimulation syndrome, which is associated with ovarian enlargement, massive fluid and electrolyte imbalances, renal insufficiency, and in rare cases thromoembolism and death.

There are two major contexts for research on preimplantation embryos. The first is one in which the transfer of the embryo into the uterus of a woman (or perhaps, in the future, into a device that can support full-term fetal development) is planned. In the second context, no embryo transfer is envisioned and, accordingly, the death of the embryo or later fetus at a stage before viability is intended. These two research contexts raise somewhat different ethical issues.

RESEARCH FOLLOWED BY EMBRYO TRANSFER. In the years preceding the birth of Louise Brown in 1978, researchers devoted substantial attention to improving the prospects for successful IVF and embryo transfer. This research focused on methods for maturing oocytes, facilitating fertilization, and culturing or cryopreserving early embryos (Biggers). During the 1990s, researchers continued this type of research. New methods for assisting fertilization have been devised, including the drilling of a small hole in the outer shell of an oocyte or the injection of a sperm directly into an oocyte, a process known as intracytoplasmic sperm injection (ICSI) (Van Steirteghem). Similarly researchers have developed methods for removing one or two cells from an eight- or sixteen-cell embryo in order to perform preimplantation diagnosis of genetic or chromosomal abnormalities (Edwards, 1993). These techniques are performed so that only embryos without genetic abnormalities are transferred to the uterus, while affected embryos are discarded. In the twenty-first century, one can anticipate research that attempts to prevent the later development of a genetic disease (for example, cystic fibrosis) by treating an individual at the embryonic stage of life. If successful this kind of disease prevention by means of gene modification would be likely to affect all of the cells of the person, including his or her reproductive cells (Wivel and Walters).

The ethical issues that arise with preimplantation embryo research when embryo transfer is planned are at least analogous to those that arise with fetal research in anticipation of birth, with research on infants, and with research on children. That is, one attempts to perform a careful analysis of the probable benefits and harms of the research to the individual and to others; one seeks an appropriate decision maker, usually a genetic parent or a guardian, who can represent the best interests of the potential research subject; and one looks for a disinterested mechanism for prior ethical review of the proposed research. This kind of embryo research, in which the research procedures are often designated *therapeutic* or *beneficial,* is generally approved by commentators on the ethics of such research, even if they diverge widely in their attitudes toward IVF, the moral status of preimplantation embryos, and abortion (see, e.g., Ramsey, 1970; Catholic Church; Singer et al.).

RESEARCH NOT FOLLOWED BY EMBRYO TRANSFER. Research in this context may be proposed for a variety of reasons. The goal of the research may be to assess the safety and efficacy of clinical practices, for example, IVF or the use of contraceptive vaccines. Alternatively the goal may be epidemiological, for example, to estimate the frequency of chromosomal abnormalities in early human embryos. Another goal that has gained significant national and international attention is the use of embryos for the creation of stem cells (Thompson et al.). Stem cells are a unique type of cell that have the potential to mature into cells of a particular type (e.g., heart, blood, muscle, or brain cells). This versatility has been thought to hold significant scientific and therapeutic promise for treatment of such diseases as Alzheimer's, heart disease or kidney failure; furthermore, these cells may be essential to understanding early stages of human development. Finally in other cases research on embryos may have little reference to clinical medicine or

human pathology. That is, research with preimplantation embryos may be much more basic, seeking to compare early development in various species of mammals or to explore the limits of embryo fusion or hybrid creation among different species.

Two distinct ethical questions have received primary attention in the international bioethics debate about preimplantation embryo research without embryo transfer. The first question is: Is research on such embryos morally permissible if it is not intended to benefit the embryos themselves? If the answer to the first question is negative, the second question is irrelevant. However, if the answer to the first question is affirmative, there remains a second question: Is it morally permissible to fertilize human oocytes for the sole purpose of performing research on the resulting embryos and in the absence of any intention to transfer the embryos for further development?

In their responses to the first question, proponents of nonbeneficial (to the embryos) research procedures adduce several arguments. First the research may produce benefits, either for clinical practice or in terms of basic knowledge, that are not attainable by any other means (U.S. Department of Health, Education and Welfare [HEW]; Warnock; Ethics Committee of the American Fertility Society; Robertson; National Bioethics Advisory Committee [NBAC]). One variant of this argument asserts that it is morally irresponsible to introduce new techniques (for example, cryopreservation of embryos) into clinical practice without first performing extensive laboratory studies of the technique (International Society of Law and Technology [ISLAT] Working Group).

Second, proponents of preimplantation embryo research note that the biological individuality of the embryo is not firmly established until approximately fourteen (or perhaps twenty-one) days after fertilization. Before that time twinning can occur, or two embryos can fuse into a single new embryo called a chimera (Hellegers; Dawson, 1987; Grobstein). If developmental individuality does not occur until after the preimplantation stage, research proponents argue, the preimplantation embryo is not protectable as a unique human being.

Third, proponents of research cite the apparently high embryo loss rate that occurs in natural human reproduction. The most reliable estimates are that approximately 50 percent of the human eggs that are fertilized either fail to develop or die within two weeks after fertilization occurs (Chard). To this factual evidence is added the metaphysical assertion that entities with such a high rate of natural death within two weeks of coming into being cannot be morally significant at this early stage of their existence. Proponents of embryo research may acknowledge that adult persons have some moral obligations toward early embryos, but these obligations are viewed as relatively weak and are thought to be outweighed by, for example, substantial clinical benefits to many future patients (NBAC).

Opponents of preimplantation embryo research have replies to these arguments and adduce other arguments of their own. In response to the first argument of proponents, the opponents assert that the end of desirable clinical consequences does not justify the means of performing research that seriously damages or destroys the embryo. To the consequential argument of proponents, conservatives may counterpose a consequential argument of their own, namely, that negative consequences will result from research on early embryos. For example researchers may become desensitized to the value of human life, or bizarre human-nonhuman hybrids may be produced in the laboratory (Catholic Church, Dawson, 1990b).

The second and third arguments of the proponents are viewed as mere descriptions of natural phenomena that carry no particular moral weight. Twinning, recombination, and embryo loss, if they occur naturally and are beyond human control, are in this view no more morally relevant than other natural evils like earthquakes or volcanic eruptions. For their part, opponents put forward two additional arguments. First, the genotype of a new individual is firmly established at the time when the pronuclei from the sperm cell and the ovum fuse. This fusion, sometimes called syngamy, occurs at the conclusion of fertilization. Thus from a genetic standpoint, a new individual exists from syngamy forward. Second, opponents of preimplantation embryo research often adduce the potentiality argument: that the early embryo contains within itself all of the genetic instructions necessary for the development of a fetus, an infant, and an adult, provided only that the embryo is placed in an environment that will nurture its further development. Therefore the person that the early embryo may one day become should be respected in an anticipatory way even at the early stages of development, when it lacks many of the characteristics of persons in the full sense.

Proponents of research do not deny that a new genotype is established at the time of fertilization. They simply point to other factual considerations that are in their view more relevant to moral judgments about the acceptability of embryo research. In response to the potentiality argument, research proponents note that a single sperm cell and a single oocyte have the potential to become an embryo, yet opponents of embryo research do not accord special moral status to reproductive cells. Further only a few cells of the preimplantation embryo develop into the embryo proper;

the rest become the placenta, the amniotic sac, and the chorionic villi (McLaren). Finally with the advent of cloning technology (the creation of an embryo from a single somatic cell), a single somatic (i.e., skin, breast, or other) cell theoretically has the potential to become an embryo, and it would be impossible to accord special moral status to every somatic cell in a human's body. In other words potentiality is a continuous notion, or a matter of degree, not an all-or-nothing concept (Singer and Dawson).

Among proponents of research on preimplantation embryos there is a division of opinion on the second question noted above—whether the creation of human embryos specifically for research purposes is morally permissible. Proponents of the conservative answer to this question argue that only embryos left over from the clinical practice of IVF and embryo transfer should be used in research (Steinbock). Such embryos might include those selected out when the number of embryos available for transfer exceeds a number that is considered safe for the woman (between two and five, depending on patient age and other prognostic factors (American Society for Reproductive Medicine [ASRM]). Leftover or surplus embryos might also become available in the context of cryopreservation, if a couple completes its desired family size or if both genetic parents die in an accident while some embryos remain in frozen storage.

The principal argument of conservatives on the deliberate-creation question is a Kantian argument against using early human embryos merely as means. In the opinion of conservatives, creating embryos with the prior intent of destroying them at an early stage of development is incompatible with the respect that should be accorded to human embryos. Conservatives can accept the use of leftover embryos for research because there was at least at one time an intention to transfer the preimplantation embryos to the uterus of a woman, where they could develop into viable fetuses. In their view the research use of such *spare* embryos is a morally acceptable alternative to donation or discard (Steinbock). The primary argument of those who do not object to creating embryos for research is a composite. Proponents of this view argue, first, that our moral obligations to early human embryos are relatively weak. Further proponents of the liberal view note that good research design may require either a larger number of embryos than the clinical context can provide or unselected embryos rather than those that have been rejected for embryo transfer, perhaps because they are malformed or slow in developing (Ethics Committee of the American Fertility Society). Indeed while estimates are that approximately 400,000 cryopreserved embryos are in storage, only 2.8 percent of these are available for research (Hoffman et al.).

PRACTICE VS. ETHICS. In the 1990s international practice and ethical opinion regarding human embryo research diverged sharply. One polar position in practice was that of the United Kingdom, where research on preimplantation embryos was conducted in numerous laboratories under the supervision of voluntary and (later) statutory licensing authorities (United Kingdom, 1992). At the other pole was Germany, which prohibited the fertilization of ova for the practice of research, as well as any research that was likely to destroy or damage the embryo. In the United States, embryo research was legal though practically limited due to a legislative prohibition of federal funding for: (1) any research involving the creation of a human embryo for research purposes; or (2) any research in which a human embryo is destroyed, discarded, or knowingly subjected to risk of injury or death. This prohibition has been implemented yearly through a provision included in Congressional appropriations for the Department of Health and Human Services (DHHS) since 1996 (P.L. 107–116 [2002]).

Ethics advisory bodies have been far from unanimous in their evaluations of research involving preimplantation embryos. The earliest report on this topic, produced by the Ethics Advisory Board in 1979 for HEW, judged embryo research to be ethically acceptable if it was designed primarily to "assess the safety and efficacy of embryo transfer" (p. 106). During the 1980s and early 1990s, there emerged three general positions among such advisory bodies. Several Australian committees rejected the idea of any human embryo research. A few Australian committees and most of the committees based in continental Europe approved embryo research but rejected the deliberate creation of embryos for research purposes. In the Netherlands, the United Kingdom, Canada, and the United States, advisory committees tended to approve both human embryo research and the creation of embryos for research (Walters; National Institutes of Health [NIH]).

In the late 1990s and early 2000s, reports of stem cell derivation from human embryos (Thompson et al.) prompted reexamination of ethics and policy regarding embryo research (Green). International practice and ethical positions remain polarized. In 1999 the NBAC issued a report and recommendations that federal agencies should fund research on embryos left over after IVF for derivation of stem cells but not research involving embryos created solely for research purposes. Despite this recommendation, in 2001, the Bush administration decided to allow federal funding only for research on existing cell lines. In contrast the Human Fertilisation and Embryology Authority (HFEA) in the United Kingdom has continued to permit and license human embryo research and the creation of embryos for

research but with enhanced guidelines specific to the derivation and use of stem cells.

Research on Unimplanted Embryos and Fetuses Beyond the Fourteenth Day of Development

The developing human organism is technically called an embryo during the first eight weeks following fertilization. It is called a fetus for the remainder of its development. In this section, prolonged in vitro culture of embryos and fetuses will be evaluated.

Prolonged embryo culture has been undertaken in several species of nonhuman mammals, especially rats and mice. In the early years of research, embryos at various stages of development were removed (or *explanted*) from the uteri of pregnant females and sustained in various kinds of laboratory devices that delivered oxygen and nutrients (New). More recently unimplanted mouse and cattle embryos have been sustained in culture to developmental stages more complex than those attained by preimplantation human embryos (Chen and Hsu; Thomas and Seidel).

As of 2003 no researchers are proposing to perform studies of either of these types with human embryos. The explantation mode of research will probably not be undertaken in humans because of the risks to the pregnant woman and because the need is questionable. However sustained culture of human embryos after IVF would in principle be possible. It is not clear whether the current lack of proposals to culture embryos in vitro beyond fourteen days is based on technical, ethical, or financial (given the bans on funding for embryo research) considerations. The longest well-documented periods for human embryo culture are eight days and thirteen days (Fishel et al.). Possible rationales for extending embryo culture beyond fourteen days could include studying differentiation, the anatomy and physiology of the embryo, the implantation process, or the effect of drugs or radiation on the developing embryo (Karp; Edwards, 1989; Sass).

There has been relatively little ethical discussion of embryo research beyond fourteen days. Most advisory committees have simply accepted the fourteen-day limit without extensive discussion. In the case of the Warnock Committee report from the United Kingdom, this limit was said to be appropriate because it correlates with the appearance of the primitive streak in the embryo (Warnock, 1984). The primitive streak is the first indication of the embryo's body axis, the last opportunity for twinning to occur, and a point before sentience is attained. Several commentators have suggested that the justification for the fourteen-day limit is relatively weak and have proposed extending the limit for in vitro human embryo research to approximately twenty-eight days (Edwards, 1989; Kuhse and Singer).

If embryo culture methods improve sufficiently, it may one day be possible to sustain either a nonhuman or a human embryo and fetus in vitro for an extended period, or even through an entire gestation. The technological support system that sustains such development will probably be called an artificial placenta. If prolonged embryo culture is employed with human embryos and fetuses, decisions will be required about whether to sustain development to the point of viability. At some point a transition will undoubtedly be made from laboratory research designed to test the technical feasibility of long-term culture to an actual attempt to produce a human child by means of ectogenesis (extrauterine development) (Kass; Fletcher; Karp; Walters).

Research on Implanted Embryos and Fetuses

The ethical questions that surround research on implanted embryos and on implanted fetuses are virtually identical, except for the different stages of development involved. This continuity in biological development and similarity in ethical analysis is so striking that both the U.S. National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research (U.S. Commission for the Protection of Human Subjects) and the British Polkinghorne Committee employed the term *fetus* to refer to the developing entity from the time of implantation through the whole of gestation. In the following discussion the word fetus and its derivatives will be employed to refer to the embryo or fetus from the time of implantation in the uterus of a woman through the point at which physical separation from the woman occurs.

As in the case of preimplantation embryo research, one can distinguish two major contexts for fetal research. The first is one in which further development and delivery of an infant are anticipated. The second context is one in which induced abortion is either planned or in progress.

FETAL RESEARCH IN ANTICIPATION OF BIRTH. Many of the ethical issues involved in fetal research conducted at any stage of gestation in anticipation of birth closely parallel the ethical issues in research on newborns. The main reason for the close parallel is that the further development of the fetus or newborn into an adult person is planned. No research procedure that is likely to threaten the life or damage the health of a future person would be either proposed or carried out by responsible scientists. For this reason research not intended to benefit a particular fetus (in anticipation of

birth) or a particular newborn is generally constrained by the no-risk or minimal-risk rule (U. S. Commission for the Protection of Human Subjects, Polkinghorne). That is, the research must be judged to pose either no risk at all (as in certain observational studies) or only minimal risk to the potential subject. For research intended to benefit a particular fetus or newborn, a careful weighing and balancing of likely benefits and harms to the subject is required (Polkinghorne; 45 C.F.R. 46.204).

The major difference between neonatal research and fetal research in anticipation of birth is that the fetus is contained within the pregnant woman's body, and any research intervention will require physical contact with, or at least physical proximity to, the pregnant woman. Thus fetal research inevitably and simultaneously affects a pregnant woman. For this reason it requires a careful weighing and balancing of the risks to her, as well as her informed consent.

Just as fetal research inevitably affects a pregnant woman, research on pregnant women inevitably affects the fetus. In the 1990s some commentators noted that a tendency to focus on fetal well-being resulted in the exclusion of women from clinical trials and in a paucity of information about the impact of medications and interventions on pregnant women or fetuses (Institute of Medicine). Their recommendations included presumed eligibility of pregnant women for participation in clinical studies, whether or not direct fetal benefit is anticipated. In the United States the revised Code of Federal Regulations accounts for the connectedness of the woman and fetus and modifies the minimal risk standard in that it allows for greater than minimal risk research in which the risk to the fetus is caused solely by interventions or procedures that hold out the prospect of direct benefit for the woman *or* the fetus (45 C.F.R. 46.204).

Many clinical procedures that are now routinely employed in obstetrical practice were first tested on pregnant women and fetuses in anticipation of birth. One early therapy was the use of exchange transfusions to overcome Rh incompatibility between a pregnant woman and her fetus. The worldwide epidemic of HIV infection and AIDS provided the context for important research affecting fetuses in the 1990s. In one groundbreaking randomized clinical trial, the antiviral drug azidothymidine (AZT) was administered to HIV-infected pregnant women in an effort prevent the transmission of infection to their fetuses, and was found to reduce the risk of vertical transmission by 66 percent (Sperling et al.).

One of the problems associated with early HIV research was that the impact of interventions to prevent maternal to child transmission was only measured with respect to fetal well-being; outcomes affecting pregnant women were not measured (Faden et al.). In the late 1990s the tendency to focus on fetal outcomes while ignoring those of women gained greater attention as one of several ethical issues surrounding experimental techniques now known as maternal-fetal surgery.

While surgical therapies for prenatally diagnosed lethal conditions have been investigated since the early 1980s, this type of fetal research gained considerable attention in the late 1990s and early 2000s due to several ethical issues associated reports on the use of maternal-fetal surgery to correct fetal myelomeningocele (Lyerly et al.). Myelomeningocele is a condition involving incomplete closure of the spinal cord during fetal development and may be associated with bowel and bladder dysfunction, weakness or paralysis of the lower extremities, and cognitive difficulties. Investigators hypothesized that some of the neurologic damage associated with myelomeningocele occurred in utero due to exposure of the spinal cord to amniotic fluid, and thus that closure of the defect prior to birth would be associated with fewer adverse consequences in the neonate. Therefore, surgical closure of the spinal cord defect before birth, involving an operation on the pregnant woman and fetus, has been attempted and has raised many clinical and ethical issues.

One issue raised was whether it was appropriate to perform interventions associated with greater than minimal maternal and fetal risks in order to correct a non-lethal fetal anomaly. Previously the risks of maternal-fetal surgery had been justified in part because their aim was to correct otherwise lethal fetal anomalies, such as severe urinary tract obstruction, hydrocephalus, and congenital diaphragmatic hernia. Myelomeningocele, on the other hand, is an anomaly that is compatible with a normal life. A related concern was that willingness to perform this procedure reinforced discriminatory attitudes toward individuals with disabilities, like those with spina bifida (Myelomeningocele). Another concern raised was the failure to collect data on outcomes related to women, even though the techniques involved experimental surgery on both women and fetuses. Commentators emphasized that both the woman and fetus needed to be considered research subjects. Other concerns included the tendency to view these procedures as *innovative therapy* rather than *research,* and the adequacy of the informed consent process in pregnant women with a potentially sick fetus. As techniques to diagnose and potentially treat prenatally diagnosed conditions improve, the ethical issues surrounding maternal-fetal surgery for myelomeningocele will continue to be relevant to the conduct of fetal research in anticipation of birth.

FETAL RESEARCH IN ANTICIPATION OF OR DURING INDUCED ABORTION. Fetal research conducted before or during induced abortion could have various aims. One possible goal would be to develop better techniques for prenatal diagnosis, for example, by means of fetoscopy or chorionic villi sampling. Another possible goal would be to study whether drugs, viruses, vaccines, or radioisotopes cross the placental barrier between pregnant woman and fetus. A third aim of such studies could be to develop techniques for induced abortion that are safer for pregnant women or more humane in the termination of fetal life. Fourth, during abortion by hysterotomy (a seldom-used procedure similar to a cesarean section), fetal physiology can be studied after the fetus has been removed from the uterus of the pregnant woman and before the umbilical cord has been severed (Walters, 1975).

Commentators on the ethics of fetal research in anticipation of induced abortion have always been aware that a pregnant woman who intends to terminate her pregnancy can change her decision about abortion even after a research procedure has been performed. In addition in rare cases an attempt at induced abortion results in a live birth. Thus except in the case of research procedures performed during the abortion procedure itself, the distinction between a fetus-to-be-aborted and a fetus-to-be-born is statistical rather than metaphysical. One study performed for the U.S. Commission for the Protection of Human Subjects in the 1970s estimated the change-of-decision rate between a visit to an abortion facility and the scheduled time of termination to be in the range of 1–2 percent (Bracken).

The possibility that a pregnant woman may change her decision to undergo induced abortion after a research intervention sets an outer limit on the types of interventions that prudent researchers would be willing to perform. For example it would be useful to know at what stages of pregnancy alcohol, drugs, or viral infections are most likely to produce malformations in human fetuses; however, in the view of most commentators on the ethics of fetal research, such studies ought not to be performed in humans. In the words of the Peel Committee report, "In our view it is unethical for a medical practitioner to administer drugs or carry out any procedures on the mother with the deliberate intent of ascertaining the harm that these might do to the fetus, notwithstanding that arrangements may have been made to terminate the pregnancy and even if the mother is willing to give her consent to such an experiment" (United Kingdom, 1972, p. 6).

Even if research likely to cause serious damage to the fetus is ethically proscribed, there are at least two different ethical standards that can be adopted with respect to fetal research in anticipation of or during induced abortion. The first standard asks for equal treatment of the fetus-to-be-born and the fetus-to-be aborted. In brief this standard requires either that one should perform research procedures on fetuses-to-be-born concurrently with performing the same procedures on fetuses-to-be-aborted, or at least that one should be *willing* to perform the same procedure on both groups of fetuses. In practice this standard would be virtually equivalent to the no-risk or minimal-risk rule discussed in connection with fetal research in anticipation of birth (McCormick; Walters, 1975; Ramsey, 1975; Polkinghorne).

An alternative standard would reject the equal-treatment requirement. What is proposed instead is a kind of case-by-case approach to fetal research (U.S. Commission for the Protection of Human Subjects; Fletcher and Ryan). For example if the primary risk of a research procedure like chorionic villi sampling is that it will cause abortion in a small percentage of pregnant women, then it can be argued that research on this diagnostic procedure should be performed on women who plan to undergo induced abortion. If the research procedure itself is unlikely to injure the fetus, then the major remaining risk is that the abortion that the pregnant woman planned to have induced in the future would instead occur spontaneously. The major ethical questions remaining in a case of this kind have to do with the timing of abortion: Is a later rather than an earlier induced abortion less respectful of the developing fetus? Does a later abortion entail greater risks to the physical and mental health of the pregnant woman?

An important dimension of the fetal research discussion is the possibility that research procedures will cause pain to the fetus (Steinbock). One of the difficulties in coming to terms with this issue is that the word *pain* probably has different meanings at different developmental stages. The anatomical basis for simple spinal reflexes seems to be present in human embryos at about 7.5 weeks post fertilization. Between the ninth and twelfth weeks of development, the fetal brain stem begins to function as a rudimentary information processor. However only at twenty-two to twenty-three weeks of gestation is the cerebral neocortex connected to the other parts of the brain (Flower). Presumably the fetal capacity to perceive pain would differ at each of these three steps, but it is difficult to know precisely to what extent painful stimuli would be felt or remembered.

Research on Aborted, Live Embryos and Fetuses

There are major conceptual difficulties involved in describing a previously implanted entity that is expelled or removed

alive from a pregnant woman's body (or removed alive from attachment to an artificial placenta). One candidate term is *abortus;* another is *fetus ex utero* or *embryo or fetus outside the uterus.* Adjectives applied to such entities include *previable* or *nonviable* and *viable.* A *viable fetus outside the uterus* is in fact a newborn infant, albeit one that may be seriously premature. In addition the notion of viability is elastic, sometimes seeming to mean the gestational age, weight, or length at which the smallest known infant has survived, at other times seeming to mean the stage at which a stipulated percentage of infants survive, given the assistance of technological means of life support.

Three circumstances can be envisioned in which the question of research on formerly implanted, living embryos or fetuses could arise. First, the surgical removal of an ectopic pregnancy could provide a still-living embryo or fetus. Second, a spontaneous miscarriage could result in the delivery of a live embryo or fetus. Third, an already implanted embryo or fetus could be aborted by means that make it either possible or likely that an intact, living embryo or fetus will result from the abortion procedure.

There is no clear consensus on the ethical justifiability of research on living human embryos or fetuses outside the uterus. In the United Kingdom, two official reports reflect a clear trend in a more conservative direction. In 1972 the Peel Committee affirmed the scientific value of research on clearly previable fetuses outside the uterus and permitted many kinds of research on such fetuses (United Kingdom, 1972). However the Polkinghorne Committee report of 1989 expressly rejected the position of the Peel Committee, arguing that the only morally relevant distinction was between living and dead fetuses, not the distinction between previable and viable fetuses (Polkinghorne). In the United States the U.S. Commission for the Protection of Human Subjects allowed no significant procedural changes in the abortion procedure solely for research purposes and restricted what could be done with the live, delivered embryo or fetus to intrusions that would not alter the duration of its life. Recommendation 1100 by the Parliamentary Assembly of the Council of Europe (1989) also discussed "the use of human embryos and fetuses in scientific research." Its recommendation clearly reflected the ambivalence of ethical opinion on research involving live embryos or fetuses outside the uterus. After stating that "Experiments on living embryos or foetuses, whether viable or not, shall be prohibited," the recommendation continued as follows: "None the less, where a state authorises certain experiments on nonviable foetuses or embryos only, these experiments may be undertaken in accordance with the terms of this recommendation and subject to prior authorisation from the health or scientific authorities or, where applicable, the national multidisciplinary body" (Council of Europe, p. 6).

Conclusion

Since 1978 the ethical discussion of research involving implanted fetuses and live, aborted fetuses has matured, but it has proceeded largely along the lines established in the 1970s. In contrast the success of clinical IVF has given new impetus to the ethical debate about research on preimplantation embryos. In the future it is at least possible that new methods for sustained embryo and fetal culture in vitro will give rise to additional ethical challenges.

FREEDOM AND FREE WILL

• • •

Freedom is widely regarded as a highly desirable component of human personalities, interpersonal relations, and social and governmental arrangements. Despite multiple meanings, the main types of freedom can be defined and distinguished.

Types of Freedom

Diverse freedoms contrast with different types of restrictions, limitations, or restraints that negate them. Some freedom-inhibiting conditions are internal to persons, some external, some negative, some positive. Joel Feinberg (1980) developed a useful four-way typology of constraints: external positive, external negative, internal positive, and internal negative. Examples of these, respectively, are lack of money, being handcuffed, fear, and weakness. In the free will controversy, freedom of action equates with external freedom, both positive and negative, while freedom of will is a variety of internal freedom.

POSITIVE EXTERNAL FREEDOM. Positive external freedom is having the external means to achieve our ends and fulfill our desires or interests. These means are positive conditions in our environment such as money to pay our way, schools open to all, or accessible medical resources and personnel. A pregnant woman who desires an abortion but lacks the money to pay for it has insufficient positive external freedom. Whether society should pay for contraception services and abortions for the poor, thereby enhancing their positive freedom, is highly controversial (Edwards, 1997). Patients in great pain who desire analgesic medication may or may not have compassionate doctors who will prescribe adequate means to pain relief; if denied such means by uncaring, inattentive, or intimidated doctors, these patients lack external freedom.

NEGATIVE EXTERNAL FREEDOM. Negative external freedom is the absence of external pressures, constraints, or

restraints that inhibit or prevent us from doing what we want or choose to do. Many negative conditions interfere significantly with freedom of action. We are negatively free externally when unencumbered by such restraints as chains, shackles, walls, and jails, and/or by such constraints as laws, institutional prohibitions, threats, intimidations, and coercive or covert pressures from others. Absence of external encumbrances usually correlates very directly with increased options for choice and action.

Many types of positive external freedom are widely recognized and cherished. Some of the most important are political freedoms or rights guaranteed by government. The Bill of Rights to the U.S. Constitution identifies and affirms such varieties of external freedom of action as freedom of religion, freedom of speech, freedom of the press, freedom to assemble peaceably, and freedom to petition government for redress of grievances. Other amendments guarantee the freedom to participate in political processes on an equal basis. These constitutionally guaranteed forms of freedom of action declare that government, other institutions, and specific individuals may not interfere with a person's choice of religion, with people expressing their thoughts, or with people communicating their beliefs, knowledge, and ideas through the press and other media. All of these kinds of freedom of action are both permitted and limited by our laws; none is absolute without qualification. All are highly desirable whether or not humans have free will and would be so even in a totally deterministic universe.

Historically, many classes of individuals were externally unfree in a great variety of undesirable ways. The fullest enjoyment of external freedom in the United States was once limited to competent, landowning, white males, whereas severe restrictions were imposed on the freedom of action of females, slaves, nonwhites, minors, mentally disturbed persons, the landless, homosexuals, and other disfavored groups such as animals. Gradually, as prejudices waned, usually after prolonged and bitter struggles, both the scope and types of freedom were extended to victims of unjust discrimination; but the process has not yet come to an end.

External social and governmental restrictions on freedom of action are not always undesirable. We are not and should not be free to do many things that would be harmful to the person and/or property of others or, more controversially, even to ourselves. Some external legal, moral, and social restraints on freedom of action are perfectly legitimate. When freedom of action conflicts with more legitimate goals and values, it must yield to their superiority.

External freedom of action is extremely valuable, but it is not sufficient for freedom in its fullest sense. Other kinds of freedom internal to persons are also highly desirable.

POSITIVE INTERNAL FREEDOM. Positive internal freedom consists of the effective presence of internal factors that contribute to people fulfilling their goals, desires, and interests; being self-reliant and self-directed—their own masters; and being in control of their own lives and destinies. These are elements of personality such as knowing who we are, our circumstances, the alternatives among which we must select, and the norms and facts relevant for making informed decisions; the ability to think, deliberate, and reason about our ends or goals, to prioritize and harmonize them, and to recognize effective means to achieve them; conscience, a moral sense of right and wrong; feelings, emotions, motives, desires, purposes, interests, and affections; and the ability to make our own choices for ourselves and to identify with our own purposes and projects, and the inner resources for acting as we will to act.

Occasionally freedom is said to consist of valuing and actualizing certain inner processes and states above all others. Saint Augustine (354–430), the early Christian church father, identified true freedom with complete conformity to the will of God; and the Stoics and the seventeenth-century Dutch philosopher Benedict Spinoza identified it with being rational and controlling or suppressing one's emotions.

Positive internal freedom may include free will, but most of its components would be highly desirable even in the absence of free will. Being positively free is what most bioethicists mean by being autonomous, or rationally autonomous, though whether this includes free will is not always clear. Respecting the rational autonomy of patients is a matter of valuing their positive internal freedom and acting accordingly.

NEGATIVE INTERNAL FREEDOM. Negative internal freedom is the absence of internal psychological or physiological obstructions that inhibit the proper functioning of the constituents of positive internal freedom—the absence of factors that inhibit knowing, deliberating, feeling, preferring, valuing, discerning right from wrong, self-control, making our own choices for ourselves, and acting effectively. Exercise of positive freedom is inhibited by such internal conditions as being overwhelmed by unconscious processes or motives, or by psychoses, neuroses, compulsions, addictions, or other nonvoluntary character defects and disorders. Genetic and neuromuscular conditions involving pain, weakness, disability, or hyperactivity may also undermine negative internal freedom.

Many conditions that undermine negative internal freedom have external causes, some medical in nature, some not. Negative internal freedom is absent in individuals who are temporarily stupefied by alcohol or by recreational or poorly administered psychotropic drugs, and in those who

are more permanently impaired by brain damage, retardation, or a degenerative disease. People may also lose or lack independence if their capacities and options are reduced by lobotomies, psychosurgery, hypnosis, behavior modification, brainwashing, indoctrination, or massive ignorance. When used skillfully with the informed voluntary consent of patients, psychotherapy can increase human freedom, not decrease it. The Austrian neurologist Sigmund Freud (1856–1939) thought that the major purpose of psychoanalysis is to increase the freedom of otherwise freedom-impaired patients.

All four types of freedom have significant worth for human beings with or without free will and may be classified as intrinsic goods, valuable for their own sakes; as indispensable extrinsic goods, valuable as essential means to other human ends; or as both at once; but we can make such judgments justifiably only if we are sufficiently enlightened, fair-minded, and free!

Because healthy bodies and selves are our most directly efficient instruments, and because so many conditions that interfere with freedom are medical in nature, physicians and other healthcare professionals are uniquely positioned by their knowledge and power to enhance human freedom.

Free Will, Obligation, Responsibility, and Related Concepts

The concept of free will is inextricably bound up with many related but elusive concepts such as duty or obligation, responsibility, blameworthiness, and praiseworthiness.

THE FREE WILL POSITION. Defenders of free will insist that freedom in the most inclusive and desirable sense is something more than mere external freedom of action; it is a fundamental type of positive internal freedom. Free will involves more than a mere internal capacity for making choices, for choices may be either free or unfree. Free choices are informed and intentional as well as creative, originative, or "contracausal." Choices are not free if they are completely determined by ignorance or by preexisting desires, habits, beliefs, or by other psychological, physiological, genetic, social, or environmental conditions. When choices are so determined, we lack the power to choose otherwise and are inevitably destined to make exactly the choices we make and do exactly the things that we do. Representative defenders of free will include the fourteenth-century English philosopher William of Ockham, the eighteenth-century Scottish philosopher Thomas Reid, and such contemporary figures as C. A. Campbell, Roderick Chisholm, Rem B. Edwards, and Robert Kane.

Defenders regard free will as essential to human worth and dignity, partly because of its inherent value and partly because it is interwoven inextricably with other indispensable moral and legal concepts and practices such as obligation, responsibility, blameworthiness, and praiseworthiness.

Being *obligated*—having duties, whether moral, prudential, or whatever—is possible only if we have free will, genuinely open alternatives, and the ability to choose and act otherwise, defenders claim. Obligation presupposes being able to choose freely and act dutifully. Ought implies can, and cannot implies not obligated. In a deterministic universe devoid of free will, those who choose to do their duty can and must do so; oddly, those who do not cannot, and thus never have or had any duties at all. Actually, because neither ever encounters open alternatives or could ever choose or act otherwise, no one ever has any duties of any kind, for all persons are rigidly determined to choose and act exactly as they do.

Similarly, being *responsible* for our choices and the actions that issue from them just means that we understand the genuinely open alternatives before us, that we desire or intend some of them, and that our final decisions originate with us, rather than being programmed into us by heredity, our physical or social environment, fate, God, or any kind of external causes, however near or remote. These things may influence us, but they cannot completely determine us if we are to be responsible for what we decide and do.

The free will position also insists that blame and punishment as well as praise and reward are inextricably linked to being responsible. When we do wrong and are *blameworthy,* we may be justly blamed or punished only if we are responsible for our decision to do wrong, and only if we do it knowingly and intentionally, it originates with us, and it could have been otherwise—that is, only if it is informed, intentional, and free. And when we do what is right and are *praiseworthy,* we may be justly praised and rewarded only if we responsibly, knowingly, intentionally, creatively, and freely decide to do so. Blameworthiness cannot be defined simply as susceptibility to blame or punishment; nor can praiseworthiness be defined simply as susceptibility to praise or reward. The susceptibility must be just or appropriate, free will advocates insist; and this condition is satisfied only when we choose responsibly, that is, originatively or freely, knowingly, and intentionally and have the power to choose otherwise from genuinely open alternatives. If our choices do not originate with us, if they are programmed into us and we are predetermined to make only and exactly the choices that we make, then our programmers, but not we ourselves, are responsible for our decisions, and we cannot justly be held responsible or subjected to blame, punishment, praise, or reward.

Free will champions usually affirm *indirect* as well as the *direct* responsibility. We are indirectly responsible for our choices and actions, even when they are completely determined by our present character and strongest inclinations, as long as that character and those inclinations were significantly shaped by choices and efforts that we made earlier in life. Advocates of free will and self-creative responsibility typically do not hold that all our responsible choices are directly free or originative. Determinists are right that most of our present choices are completely determined by our existing dispositions and interests; but if we actively participated in forming them by earlier self-creative choices and efforts of will, then we are indirectly responsible for the choices and actions that issue from our self-established character.

HARD AND SOFT DETERMINISM. In his influential 1884 article, "The Dilemma of Determinism," the American psychologist and philosopher William James (1842–1910) distinguished between hard and soft determinism. *Hard determinists* usually accept every feature of the free will position except causal indefiniteness. They agree that a free will would be an originative or self-creative will, and that being obligated and responsible just means knowingly, intentionally, and originatively making right or wrong choices that could have been otherwise. Social practices involving obligation, blame/punishment, and praise/reward are just and justified only if we are free and responsible. Nevertheless, determinism is true and all our choices are caused or determined by antecedent conditions; none could be otherwise. Because we are not free and responsible, we are never justified in holding anyone obligated or responsible for anything. We can never justly blame or punish wrongdoers or praise and reward those who do right. Representative hard determinists include Spinoza; the English clergyman and chemist Joseph Priestley; the young Benjamin Franklin; the eighteenth-century American statesman and philosopher, who later recanted this position; and Paul Edwards.

Some hard determinists acknowledge that our established practices of being morally obligated as well as blaming, punishing, praising, and rewarding are so valuable morally and socially, so indispensable for the very existence of a livable community, that the illusion of free will should be sustained in order to perpetuate them (Smilansky, 2000). Others insist that hard determinists may legitimately abandon blame and punishment but retain obligation, praise, and reward. Without deluding anyone, hard determinists can approve, commend, encourage, praise, and reward right actions, even if they are not strictly obligatory. Such activities become integral parts of causal processes calculated to bring about decent social orders (Wolf, 1980, 1990; Pereboom, 1995, 2001).

Soft determinists do not embrace these drastic conclusions. They hold that causal determinism is perfectly compatible with human obligation and responsibility and the moral and social practices normally associated with them. Representative soft determinists include the seventeenth-century English philosopher Thomas Hobbes, the eighteenth-century American clergyman and theologian Jonathan Edwards, the eighteenth-century Scottish philosopher and historian David Hume, the nineteenth-century English philosopher and economist John Stuart Mill, and more recent figures such as Harry G. Frankfurt, Daniel Dennett, and Kai Nielsen.

COMPATIBILISM. Soft determinists are compatibilists who attack almost every element of the free will position and reject the free will view that causal determinism is incompatible with human freedom, obligation, responsibility, and just susceptibility to blame/punishment or praise/reward.

Compatibilists hold that freedom of action combined with inner conditions that do not presuppose causal indeterminism are quite sufficient for human obligation and responsibility—that free will is not needed in the first place. If we are free to do what we knowingly and intentionally most want to do, then we are responsible for doing it, and we can have moral and other kinds of obligation. Compatibilists attack the free will meaning of the term *responsible* and redefine the concept.

For the free will position, being responsible for making choices and the actions that flow from them means:

(1) Recognizing and understanding the alternatives, which are genuinely open metaphysically.
(2) Intending to or being motivated or predisposed to choose one or more of these alternatives without their being completely predetermined by our desire(s), dispositions, or anything else.
(3) Deliberating about the alternatives.
(4) Knowing that some alternatives are good or right, some bad or wrong, and perhaps some indifferent.
(5) Originating the choices and efforts that we make.
(6) Having the power to choose otherwise.

Compatibilistic soft determinists omit the self-originative features of this definition. For them, being responsible just means:

(1) Recognizing and understanding the alternatives, which need not be metaphysically open.
(2) Intending or being more strongly motivated or predisposed to choose one alternative over the

others, especially when these belong to our deep rational selves.
(3) Deliberating about the alternatives.
(4) Knowing that some alternatives are good or right, some bad or wrong, and perhaps some indifferent.

Origination, open alternatives, and the ability to choose otherwise are irrelevant; so, free will is irrelevant. Determinism is compatible with holding people under obligation and regarding them as responsible for what they choose and do. But is this compatibilistic redefinition of the term responsible acceptable? Can we really escape the deep-rooted intuition that we are not responsible for any choices and efforts that are programmed into us from beyond?

Objections and Responses

Past and present debates incorporate many objections to free will with corresponding replies.

CHOICE AND CHANCE. Free will itself is not compatible with having duties and being responsible because free choices are by definition uncaused and indeterministic, which means that they are mere uncontrolled chance events or accidents.

But, say free willists, chance events do not satisfy many conditions that define responsible free choices. They do not involve deliberation, knowledge of alternatives or of right and wrong, desires, dispositions and intentions, or the subjective experience of selecting or trying. When free choices are made, these conditions bring about inclinations without necessitating a particular choice. These conditions are the very essence of self-control and self-causation, not of chance.

UBIQUITOUS CAUSATION. Because all events have causes, free choices and all effort-makings have causes. There are no exceptions to deterministic causation.

Free will defenders respond that the very concept of causation is ambiguous, not clear and distinct. Free originative choices can be uncaused or "contracausal" in one sense, yet caused in another. Free choices have *necessary causal conditions* such as knowledge, desires, and (if moral) a sense of right and wrong; in their absence, free choices cannot occur. But these are not *sufficient causal conditions* in whose presence only one outcome must occur. Only with respect to sufficient causal conditions are free choices uncaused. With respect to necessary conditions, they are caused. The philosophical options are more complex than simple *indeterminism,* which denies the relevance of all causal considerations to free choice, versus *determinism,* which affirms the rigid causal determination of all choices. Partisans of free will may adopt *libertarianism,* which affirms that existing causal conditions limit but do not necessitate choices that cannot occur in their absence.

Some proponents of free will claim that self-creative choices are made by an enduring substantive self that is exempt from normal event-causation (Chisholm; O'Connor). Others hold that choices are made by events within that stream of consciousness that constitutes personal selfhood (Edwards, 1969; Kane, 1985, 1996, 2002). Still others claim that agency causation is not so radically different from event causation (Clarke).

CAUSATION BY STRONGEST MOTIVES. Experience shows that all our choices are determined by the strongest desires or sets of cooperating desires belonging to our settled character.

In response, free willists argue that experience actually shows that effort-making and self-creative choosing occur only when character, dispositions, and desires are in conflict and prevailing inclinations are not settled in advance—only when given motives are not sufficiently powerful to resolve motivational conflict. Free choices function to resolve conflicting motives when none are sufficiently powerful themselves to overcome their competitors. Sometimes choice boosts an inclination that is in conflict with others and makes it the strongest. Usually our choices are completely determined by our strongest inclinations, but even then we are indirectly responsible for them if our earlier choices and efforts helped to create them.

THE ABILITY TO CHOOSE OTHERWISE. Being able to choose otherwise is merely hypothetical, not categorical or absolute. Even on deterministic grounds, we can choose or could have chosen otherwise *if* our desires, dispositions, character, or other conditions are or were otherwise. This is quite sufficient for responsible choice.

On the contrary, free willists respond, hypothetical conditions are still incompatible with the deep and ineradicable intuition that we are responsible only if our choices and efforts originate with us; if they originate in heredity and/or environment, these, not we, are responsible for them and the actions that issue from them. Complete determination is incompatible with individual responsibility, blameworthiness, and praiseworthiness.

THE SCIENTIFIC WORLDVIEW. Free will is incompatible with what natural science tells us about the universe and about ourselves.

Free willists reply that Newtonian science had no place for free will because it regarded everything, including human choices, as completely determined and absolutely predictable, given existing facts and natural laws; but this

worldview is now obsolete. Quantum physics recognizes indeterminateness and unpredictability within the depths of nature, including human brains. Random quantum events are themselves not within our control, admittedly, but they make room for creative self-control, just as Newtonian physics excluded it. On a more macroscopic level, modern brain scans reveal indeterminate, unresolved conflicts within and between different regions of the brain that are resolved when "executive control" is exercised (Posner and DiGirolamo).

Objections and replies to problems of free will are almost inexhaustible, and every response seems to generate another round of objections and responses. Free will and philosophical issues relating to it have been debated for over 2,000 years and will be, perhaps, for thousands more.

FUTURE GENERATIONS, REPRODUCTIVE TECHNOLOGIES AND OBLIGATIONS TO

• • •

Since the early 1960s, scholars have struggled to define the nature and content of our obligations, if any, to future persons. These discussions began in the fields of environmental ethics and population policy and have had their most robust recent expression in the debate over risky reproductive technologies. This entry reviews the issues as they arise in decisions about reproduction, especially decisions involving reproductive technology.

The threshold issue is whether living persons have any duty to consider the welfare of future people. If that question is answered in the affirmative, then the content of the duty needs to be defined. The fact that reproductive conduct is existence inducing, however, greatly complicates the effort to determine exactly when a risky reproductive decision threatens the welfare of future persons.

Duties to Future Persons

Duties not to harm persons seem to presuppose their existence (Narveson). Yet, the future children whose interests are threatened by today's decisions do not exist and may never exist. Because their existence is entirely contingent, skeptics question whether it is coherent to talk of a duty to these "potential" people.

Until the middle of the twentieth century, courts in the United States agreed. Since then, however, nearly all courts have abandoned that view, concluding as most bioethicists do, that duties can run to future people who are foreseeably endangered by our actions (Buchanan et al.).

Moral philosopher David Heyd, in his 1992 book, *Genethics,* argued that an exception must be made for people who control whether or not a future person exists. He contended that creators, such as parents making reproductive decisions or scientists deciding whether to clone a human, cannot have obligations to future persons whose very existence they control. Although he conceded that we ordinarily do owe duties to future persons, he contended that this duty does not extend to persons whose existence we determine. Thus, a baby food manufacturer has an obligation not to harm babies who are born after its pureed peas are canned, but parents or scientists cloning humans have no obligation to future persons whose very existence they control. "There are no moral constraints," he argued, "in genesis decisions" (Heyd, p. 16).

Heyd's argument has central implications for the law and ethics of reproductive behavior. Heyd seems to assume that the right to deny existence includes the freedom to create people without accountability. This would excuse parents and fertility clinics from any obligation to consider the welfare of the children whom they are trying to create.

Heyd's view, however, does not appear to be widely shared. For example, in her 1998 book, *Child versus Childmaker,* Melinda A. Roberts noted that Heyd's view "implies that my neighbor's future child, but not my own, has a claim to my good behavior" (p. 20). Using his analysis, a homeowner who breaks a glass bottle in the backyard may have a duty to the neighbor's future children to pick up the glass, but not to the homeowner's own future children. That conclusion is difficult to defend persuasively. Heyd's theory assumes that the power to create a person implies the absence of any obligation to use that power responsibly. In his view, childbearing is inherently a selfish choice. Yet, this assumption is certainly not self-evident and it conflicts with commonplace expectations of responsible parenting.

Perhaps the key issue in the debate over the duty to future persons is whether a duty can be owed to a "person" who does not yet exist and may never exist. So characterized, the duty appears to be owed to preconception phantoms. Advocates of the duty contend, however, that the obligation being asserted is better understood as a conditional obligation that ripens only if and when an actual person is harmed (Peters, 1999). Whereas it may not be sensible to talk of duties to people who may never exist ("potential people"), it is sensible to talk of a duty to the people who do come to exist in the future ("future people"). Thus, the baby food manufacturer's duty runs only to actual, living people who consume its baby food. At that moment, the potential harmfulness of the earlier negligence crystallizes.

Harm to Future Persons

Many different theories have been offered to identify the circumstances in which reproductive behavior can cause

harm to future persons. Each theory identifies a different vantage point from which to understand the interests of future persons. Collectively, they provide a useful set of tools for evaluating the impact of a novel reproductive technology.

At the outset, the inquiry into harmfulness requires a definition of what it means to harm someone. Under conventional analysis, harmful conduct is conduct that makes a person worse off than he otherwise would have been (Fishkin). Lawyers call this a "but for" test because it asks whether the victim would have avoided injury but for the conduct in dispute. Although this test can sometimes be applied to reproductive behavior without any novel difficulties, its application is often complicated by the fact that the injuries believed to be harmful could not have been avoided except by preventing the child from being born at all. A child conceived by cloning, for example, owes his life to this technology. When a disputed act is existence inducing, the only alternative to life with the disability caused by the existence-inducing technology is no life at all. If the conventional test for harmfulness is used, then the disability-causing technology is not harmful unless life with the disability is worse than the alternative—never existing at all. This comparison does pose special problems.

The remainder of this entry begins by exploring the simplest cases—those in which the traditional test of harmfulness seems most apt. The entry then examines the application of this test to injuries that are inextricably associated with life itself and reviews some alternatives that have been suggested to the comparison between life and nonexistence. Finally, it examines the dilemma posed when parents or clinics have a choice between two alternative paths to reproduction, one of which is safer than another.

Ordinary Harm

The easiest cases to analyze do not require a comparison between life and nonexistence. This is true whenever the behavior that caused the injury was not essential to the birth of the child. Consider, for example, the negligent repair of a fertile woman's uterus. A child who is subsequently born prematurely because of this carelessness has suffered injuries that could have been prevented if more care had been taken. Measuring the extent of her harm, therefore, does not require a comparison between life with her injuries and never existing at all. Instead, it requires only a comparison between life with her injuries and life without them.

In the context of reproductive technology, this kind of harm can occur both in routine settings and in exotic ones. Injuries caused by a fertility clinic's failure to properly store its frozen embryos are a straightforward example of this kind of ordinary, avoidable harm. Ordinary harm, however, can also occur in settings typically assumed to trigger the nonexistence comparison, such as multiple cloning or multiple embryo transfer. In a 1996 article, Roberts pointed out that any emotional injuries associated with being one of many identical clones can be avoided by cloning only one person from each source. That single child will consequently be better off than he would have been if additional identical siblings had been cloned.

Injuries caused by germ-line genetic engineering can also be understood in this way. A child who suffers injuries from the genetic engineering of her embryo need not have suffered these injuries if the embryo had been implanted without first manipulating its genes. Of course, she also would not enjoy the benefits, if any, conferred by the manipulation. Thus, she has been harmed by the manipulation if, but only if, it did more harm than good. Answering this question does not require a comparison between life and nonexistence.

The most interesting interpretive debate regarding the applicability of ordinary harm analysis to reproductive behavior involves parents who say that they will not conceive at all if they are not able to use a risky reproductive technique. Consider the case of a fertile couple who could conceive naturally but choose instead to employ a surrogate because the genetic mother fears the risks of childbirth, as occurred in the notorious case of "Baby M" (*In the Matter of Baby M,* 1988). If the parents would not have conceived at all had they been prevented from employing a surrogate, then their child's only alternative to surrogacy was nonexistence. For this reason, scholars such as John A. Robertson believe that no harm is done to this child by use of a surrogate unless the child suffers harms so serious that its life is worse than not existing at all.

The same surprising conclusion arises in other reproductive settings. Assume, for example, that parents can honestly contend that they will not have any children at all if they are not permitted to use a risky reproductive technique such as germ-line genetic engineering. If their claim is correct, then their future child's only alternative to the risks associated with germ-line genetic manipulation is not existing at all.

Roberts rejects the conclusion that no harm has been done in these cases. She has persuasively argued that children such as these are harmed whenever people could have prevented their injuries and chose not to do so (Roberts, 1996, 1998). From her perspective, the fertile couple's choice is a harmful one if it exposes the child to extra unnecessary risks. That the parents preferred not to avoid those risks does not make the choice any less harmful to the child. That child could have been born without his injuries.

Roberts's analysis squares with our intuitions. Surprisingly, however, it is less consistent than Robertson's is with the but-for test of causation. What matters under this test is what *would* have happened had the technology been banned, not what *could* have happened. If surrogacy had been prohibited, for example, the child would not have been born. The test does not take into account the fact that the same embryo could have been implanted in the genetic mother.

Nevertheless, the but-for test is only a starting point for the analysis of causation. Both philosophers and courts have recognized its occasional deficiencies and have fashioned a number of exceptions to ensure that the attribution of causation comports with common sense. Roberts's case for yet another exception is quite credible. Taken to its logical conclusion, conventional harm analysis would excuse even the intentional infliction of harm on future children, as long as being able to inflict it was essential to the procreative intent of the would-be parents. Thus, deaf parents who genetically engineer their children to be deaf cause no harm if this is the only way in which they are willing to have children. This makes no sense. The very intention that makes their conduct culpable also insulates it from moral responsibility.

In ordinary settings, the plaintiff's inability to satisfy the but-for test implies that the plaintiff would have been no better off if the defendant had behaved more responsibly. In the special context of existence-inducing conduct, however, the failure to satisfy the traditional but-for test of causation does not have this meaning. Nonexistence was not the child's only alternative to life with her injuries. Instead, the defendant could have prevented the child's injuries. The mere fact that the parents preferred not to do so seems an insufficient basis for concluding that no harm has been done by their choice.

To recap, reproduction decision making sometimes threatens future children with ordinary harm. Analyzing the harmfulness of these decisions is straightforward except when parents claim that they would not have conceived at all if not permitted to reproduce in a dangerous manner. In such cases, one can either treat the choice as harmless unless the injuries are so serious that life itself is harmful (a threshold that is the subject of the next section) or else replace the inquiry into what would have happened with an inquiry into what could have happened.

Life as a Harm

Sometimes, the underlying objection to a risky form of reproductive conduct is not that safer alternatives were foregone, but that the conduct in question is simply too dangerous to use, even as a last resort. Imagine, for example, an infertile couple who have been unable to conceive despite undergoing several cycles of in vitro fertilization (IVF) in which three embryos were implanted each cycle. For this couple, implanting a higher number of embryos may be the only feasible way to conceive. Yet, doing so greatly increases the risk of a dangerous multiple pregnancy and, with it, the risk of serious injury. Not using the higher number of embryos would reduce this risk—not by allowing the children to be born without injury but by preventing their birth. If the only alternative to the use of a risky reproductive technology is not having children at all, then no harm is done to the children under the but-for test unless life with the anticipated disabilities is worse than never existing at all. Thus, no harm is done unless life is worse than nonexistence.

The idea that life itself can be harmful has been very controversial, even though the nonexistence comparison is actually just a special application of the but-for test. Indeed, most American courts have concluded that the notion of a harmful life offends public policy because it suggests that life with a disability is less valuable than life without it and because it is logically incoherent. For these reasons and others, most courts in the United States have refused to allow lawsuits claiming that a child was harmed by birth with a serious disability. Most scholars and a few courts, however, disagree. Although evaluating the harmfulness of life itself does involve some conceptual puzzles, these puzzles seem soluble.

Because "it is necessary to be in order to be better off," critics believe that it is logically incoherent to say that someone could "be" better off if they had never been born (Feinberg). A related objection is that humans know nothing about nonexistence and, thus, cannot compare it to life. One judge put his concerns this way: "Ultimately, the infant's complaint is that he would be better off not to have been born. Man, who knows nothing of death or nothingness, cannot possibly know whether that is so.… To recognize a right not to be born is to enter an area in which no one can find his way" (*Gleitman v. Cosgrove*). Many scholars, however, argue that reference to nonexistence is not necessary to determine whether life with a catastrophic disability is harmful. Instead, the benefits of life can be balanced against the burdens. A life in which the burdens exceed the benefits can reasonably be characterized as harmful. Fortunately, injuries this serious are rare. The birth defects most commonly offered as examples are Lesch-Nyhan syndrome and Tay-Sachs disease.

Critics also contend that treating life itself as harmful is a repudiation of the value of human life and a threat to the welfare of living people with disabilities (*Blake v. Cruz*). Others believe, however, that respect for future persons

dictates that they be spared these terrible injuries (*Turpin v. Sortini*). They also note that preventing the birth of a person with a disability is not inconsistent with vigorously protecting the welfare of people who are born with disabilities. Finally, they note that our comfort with decisions to refuse death-prolonging care reflects our recognition that life is not always a blessing (Peters, 1989).

Courts commonly offer one additional reason for rejecting wrongful life cases. They doubt that any harm ascertained using the nonexistence comparison can be rationally translated into money damages. Whether or not this is correct, it is not a reason for refusing to apply the nonexistence comparison in settings where money damages are not an issue. The difficulty of calculating damages for the injuries suffered by a cloned child, for example, may be a plausible argument for denying the child a civil action for compensatory damages, but it is not an argument against prohibiting cloning until it is more safe to perform.

In fact, outside of the courts, the most common objection to the nonexistence comparison is not that it is unmanageable or too readily assumes that life is not worth living, but that it is underprotective, that is, it dictates restraint only when the risks are truly catastrophic. The critics can be loosely sorted into two groups. The first group contends that the nonexistence comparison sets the threshold too high. They prefer a more demanding threshold such as a minimally decent quality of life or a probability of harm no greater than the risks associated with natural conception. Critics in the second group believe that reproductive conduct is harmful to future children, regardless of the absolute severity of the injuries, whenever parents or providers choose a risky route when a safer one is available.

The debate over a more demanding threshold was led at one time by scholars who felt that it was unethical to expose future children to the unknown risks associated with a new reproductive technology (Ramsey). They contended that it was unethical to impose this risk without the child's consent. The consent objection has lost emphasis in recent years, perhaps because parents have the same moral authority to consent to these risks on behalf of their future children as they have to consent to risky new treatments for their living children.

Although the consent objection has largely disappeared, it is still common to see discussions of reproductive conduct that measure the safety of a new technology against the risks of natural conception (Green). Despite the intuitive appeal of the comparison to natural conception, however, this benchmark is vulnerable to several objections when it is applied to treatments of last resort. First, the current level of risk for natural conception is not *natural* at all, but the product of modern medical technology. Thus, the current level of risk is merely a historical coincidence. Second, though matching this level of risk may be desirable, it is not obvious why parents who face greater risks, but who have no safer alternatives, are acting unethically. The only alternative for their children is not existing at all. Finally, using the average risks of natural conception as a baseline, which means treating a riskier than average procedure as immoral, even if the injuries associated with the procedure do not prevent the affected children from having fulfilling lives. This is counterintuitive. For these reasons, no consensus in support of routine comparisons to natural conception has emerged.

Another school of ethicists offers a very different threshold for deciding when reproduction violates our obligations to future persons. Starting at least with the nineteenth-century English philosopher and economist John Stuart Mill, philosophers have argued that we owe our children a minimally decent quality of life (Cohen, 1996, 1997; Steinbock and McClamrock). Support for this benchmark is found not only in the ethics literature but also in the daily decisions that prospective parents make to avoid the birth of children with serious birth defects, through either preventive sterilization or prenatal screening and abortion. Support of the idea of a minimal quality of life is also found in the regulatory stance of the U.S. Food and Drug Administration (FDA). Unquestionably, the FDA would deny approval for an effective fertility drug that caused significant birth defects, even if those injuries were not so catastrophic as to make life itself harmful.

Given its intuitive appeal, it is surprisingly difficult to explain why the goal of a minimally decent quality of life should be obligatory and not merely aspirational. Although it may be useful after birth as a measure of the support obligations that parents and society owe to their living children, this benchmark seems less apt as a determinant of reproductive obligations. Its advocates have yet to explain convincingly why it is wrong to create a child whose life—despite being considered to be below the quality of life threshold—will, on balance, be beneficial. Thus, some respected scholars reject it (Robertson; Roberts, 1998).

Nevertheless, the persistence of the minimally decent life standard and its relatively broad support suggest that it is driven by an important intuition. Thus far, the best attempts to identify the source of this intuition turn on the distinction between death and nonexistence (Cohen, 1996; Kamm; Peters, 1989). Because death is a fate faced by actual persons, it seems more tragic than never existing at all. And because we view life as precious, we are hesitant to conclude that a living person's suffering is so profound that death would be better. This skews our burden–benefit calculus in favor of life.

Decisions regarding whether or not to reproduce are materially different. Although a decision not to reproduce does mean that a potential future person will never come to exist, it does not lead to the death of a living person. As a result, we may feel comfortable imposing a more demanding test for preconception decisions than we would impose for the discontinuation of life support. Injuries that are not so catastrophic that death would be a blessing may, nonetheless, be so serious that it would be better never to have had the child at all. According to this view, one can rationally decide to treat disabled babies aggressively while simultaneously concluding that it would be better not to conceive more children who will suffer from these injuries. Using this distinction, the FDA's decisions make sense. If this insight is persuasive, then any application of the nonexistence comparison that overlooks this distinction threatens to underprotect future children.

To summarize, the mere fact that a reproductive technology is more risky than natural conception does not mean that its use violates our obligation to future children. However, technologies that cause injuries so serious that life is not worth having do cause harm and, thus, require justification. When policymakers ask whether the risks of a reproductive practice are so serious that nonexistence would be better, they need to remember that preconception decisions do not lead to the death of a living person and, therefore, a more demanding minimal threshold can be imposed than would be appropriate after birth.

Avoiding Injury by Substituting a Different Child

Even if the but-for test is applied in a way that recognizes that life itself is sometimes harmful, the test remains vulnerable to the criticism that it overlooks an important and quite different category of harmful conduct. This category is composed of decisions to engage in risky reproductive behavior when a safer alternative is available. In this category of cases, parents and clinics can minimize future suffering by taking the safer route. Thus, for example, sperm banks can materially improve the health of the babies that they help to create by screening their sperm donors for transmissible illnesses.

Yet, the but-for test of harm cannot explain why a choice not to screen sperm is harmful. That is because screening would result in the birth of different children. Whenever the choice between two reproductive alternatives would result in the birth of different children, the but-for test dictates that the harmfulness of the choice be determined by asking whether the child who is born would have been better off not existing at all. That is because choosing the safer route would not have made this child better off. Instead, this child would not have existed, and a different child would have been born. As a result, the options for the injured child were life with a disability or no life at all. If the injuries suffered are serious, but not so serious that never existing would be better, then no harm has been done to children created by the sperm bank. Even a clinic's failure to screen for HIV infection may not meet this threshold (Robertson).

This conclusion defies common sense. Because it focuses exclusively on the magnitude of the injury to a specific child, rather than on the presence or absence of safer alternatives, conventional analysis overlooks the harm caused when injuries could be avoided by substituting one future child for another. The harmfulness of a decision not to avoid injury by substitution lies not in the absolute magnitude of the threatened harm, but in the decision to take a risky route when a safer one was available. The but-for test cannot explain the harmfulness of these choices because choices such as these do not make a specific child worse off than she otherwise would have been. Instead, they substitute a different child. Yet, conventional analysis overlooks the fact that substituting improves the collective welfare of the class of future children.

Proponents of a duty to choose the child who will suffer least concede that tort compensation for the injured children will not be appropriate unless the injuries meet the wrongful life threshold (Peters, 1999). That is because these children could not have been born without their injuries. Their only options were life as it is and nonexistence. As a consequence, only those whose lives are worse than nonexistence have been individually harmed. Yet, taking avoidable risks can harm the welfare of the class of future children, even though there are no individual victims. Cumulatively, responsible decisions improve the welfare of future children as a class by substituting healthier children and, thus, reduce the suffering experienced by these children.

Giving content to our obligations to future persons in this manner was first discussed at length by Derek Parfit in his 1984 book, *Reasons and Persons.* Since then, others have applied the idea to reproductive technology (Brock; Peters, 1989). Parfit offered the example of a woman who is advised by her doctor not to become pregnant until she recovers from a temporary illness that causes moderate birth defects. Under the but-for test, she does no harm by refusing to wait, because waiting would change the identity of the resulting children. Parfit called this counterintuitive result the "nonidentity problem." To cure this gap in our understanding of harmful conduct, Parfit proposed a principle that he called *Q* that obliged parents and providers to have the child who will suffer least.

A primary obligation to avoid unnecessary suffering is intuitively appealing. It also seems consistent with the moral reasoning of John Rawls, outlined in his 1971 book, *A Theory of Justice.* Presumably, people acting under a veil of ignorance about their own circumstances, as according to Rawls, would agree that parents should try to have the children who will suffer least. This principle is also consistent with the utilitarian emphasis on beneficence because it calls for decisions that will maximize the welfare of the resulting children. When we are able to avoid injuries by substituting one child for another, we should do so unless doing so will threaten even more important interests.

This principle has surprisingly broad application to reproductive decision making. Parents deciding which embryo to transplant as part of an IVF procedure are making a choice that would be governed by this principle. Infertile patients deciding whether to clone a genetically related child or use donated embryos are making a similar choice, as are couples deciding whether to use donated sperm or to accept the risks associated with intracytoplasmic sperm injection (ICSI). ICSI is a treatment for male infertility that involves injecting a woman's egg with her partner's sperm. It poses extra risk because it bypasses the natural process for willing defective sperm.

The duty to choose the safest route to conception also provides an alternative way of resolving the debate, described briefly above, between Robertson and Roberts over the significance of reproductive alternatives that parents have available to them but decline to use. If avoiding injuries by substitution is better than declining to do so, then the disinterest of prospective parents in the safer option is not relevant to the assessment of harmfulness.

Concerns

One consequence of offering a more robust understanding of the interests of future children, like the theory of avoidability by substitution, is to expand the number of cases in which the interests of future children conflict with the interests of prospective couples, both fertile and infertile. Prospective parents have a liberty interest in making their own decisions free from governmental restriction. Critics charge that a broad conception of our obligations to future children will impose upon prospective parents an unwanted duty to undergo prenatal screening and to abort if tests are positive (Robertson). The enriched conception of the interests of future children described here does have broad implications, which apply to both artificial and natural conception.

While it is true that a broad conception will increase the number of cases in which we will appreciate that the children's interests conflict with parental liberty, rejecting that conception will not eliminate the conflicts—it will only reduce them. In either event, a model for reconciling these competing interests will need to be developed. The strength of the notion of avoidability by substitution is that it helps us to appreciate potential conflicts that are overlooked entirely by conventional analysis. The significance of this new methodology is not that it requires intervention in every case, but that it requires justification in cases overlooked by more conventional notions of harm.

A second concern expressed about avoidability by substitution is that it characterizes conduct as harmful in circumstances in which no specific person has been harmed. For some philosophers, this is a serious problem (Roberts, 1998). One critic called it merely a "norm against offending persons who are troubled by gratuitous suffering" (Robertson, 1997, p. 76). Advocates claim, however, that it is genuinely person-affecting insofar as it reduces unnecessary human suffering (Brock).

Finally, proponents of avoidability by substitution have struggled to find a method for handling "different number" cases. Different number cases arise when the use of a risky reproductive method (such as cloning or the use of fertility drugs at a dosage associated with multiple pregnancies) will result in a different number of children than would have been produced using a safer alternative (such as natural conception or lower doses of the fertility drug). Moral philosophers have discovered that startling paradoxes plague the effort to compare the welfare of groups of different sizes. A tentative solution has been offered that combines average utility and total utility into a combined index that can be used to compare the moral implications of different number reproductive choices (Hurka). This proposal, however, has not yet been thoroughly tested.

The debate over avoidability by substitution is far from resolved. While avoidability by substitution seems to provide a useful explanation consistent with our intuitions, it raises problems that make it unattractive to some ethicists. Even if it is persuasive, it must be supplemented by the nonexistence comparison in cases in which prospective parents want to engage in a risky reproductive practice for which no safer alternative exists, such as postmenopausal pregnancy.

Conclusion

Reproductive behavior can be harmful to future children in three ways. First, reproductive practices can sometimes cause ordinary harm. These are injuries that could have been avoided if more care had been used, such as injuries caused by failure to store frozen embryos properly. Second, reproductive technology can result in a harmful life when the

child who is born has a life that is not worth having. Finally, the interests of future children are harmed when the birth of an injured child could have been avoided by changes in conduct resulting in the birth of a different, healthier child. This kind of harm is avoidable by substitution. Clinics performing artificial insemination, for example, can prevent needless suffering by screening out high-risk donors. Responsible efforts to protect future children from harm should aim at minimizing each of the three types of harm to the extent that is consistent with parental procreative liberty.

G

GENDER IDENTITY

• • •

The term *gender* has a long history, with Greek roots signifying "birth, race, and family" and Latin roots signifying "birth, race, and kind." The psychologist John Money was among the first to use the term to refer to a person's felt identity as male or female, as distinguished from that person's biological sex traits (Money). The term also is used to refer to a person's nature or identity as male or female and to social aspects of sex such as the cultural roles of men and women.

Various biological traits distinguish male from female, but males and females are not distinct in categorical ways and the boundary between male and female is fluid rather than fixed: Human beings can exhibit atypical traits or intersexed conditions (Fausto-Sterling). Rather than having an XX or XY sex chromosome complement, for example, some people have an XXY or XYY complement. In some cases an individual may be born with only a single X chromosome. Some humans have indeterminate genitalia or both testicular and ovarian tissue. In regard to social roles male and female traits can overlap as well.

Gender Assignment of Newborns and Children

The sex of a newborn child is of keen interest to the parents, but some children are born with ambiguous genitalia, having both testicular and ovarian tissue, or genetic syndromes that confound a simple designation as male or female. The term *gender assignment* refers to practices that are used to discern and impose a gender identity on a newborn child. Suzanne J. Kessler has described how cultural ideals of sex influence the practice of gender assignment. She showed that some physicians have made decisions about gender assignment in accordance with the size and expected function of a child's genitalia rather than in accordance with more complex hormonal and genetic assessments (Kessler, 1990; 1998). If a male child was likely to have a very small penis, for example, some physicians and parents used surgery to assign a female identity to that child. Advocates of this kind of intervention argue that a secure gender identity depends on having appropriate sexual genitalia.

The gender assignment of John/Joan has received a great deal of attention (Colapinto, 1997). In 1966 a physician burned the penis of boy beyond repair during a circumcision that involved an electrocautery needle. Fearful of what the boy's life would be like, his parents took him Johns Hopkins University for evaluation. The psychologist John Money proposed gender reassignment from male to female on the assumption that the loss of the penis was so damaging that it would be better for the child to be raised as female; he also believed that gender identity can be shaped after birth. With the consent of the parents, in 1967 physicians removed the boy's testicles at the age of 22 months, repositioned the urethra, and induced a preliminary vaginal cleft. The parents selected a girl's name and began to treat and raise the child as female (Colapinto, 2000).

From 1972 on Money reported the child's gender assignment as successful. He said that the case showed that gender identity is plastic and can be shaped during early childhood. One's sense of self as male or female is not, he held, determined by anatomy, genetics, or prenatal history. Health practitioners translated that evidence into practice guidelines and encouraged gender interventions. One advocate said that the possibility of female sex assignment with

genetic males "must be considered whenever the severity of the genital abnormality is such that it is likely to be extremely difficult or impossible to correct for normal adult functioning" (Baker, p. 266).

In fact, the gender reassignment of this child failed. The child consistently rejected female identification and exhibited male-typical interests and behaviors. Eventually the child refused further interventions, and at that point the family told the child the truth. The fourteen-year-old immediately reclaimed a male identity, adopted a male name, started male hormone treatments, underwent breast removal, and eventually was treated with phalloplasty, the construction of a penis. None of those events were reported in the professional literature until 1997. Thirty years passed between the beginning of this experiment and its publicly described failure (Diamond and Sigmundson).

Some commentators believe that that failure provides evidence that gender assignments do not work, but that conclusion is not fully supported by the evidence. Gender assignment in children has not been well studied, but even if this case failed spectacularly, other interventions might succeed. It also should be noted that the intervention made sense at the time of an unsettled debate about the extent to which gender identity can be influenced after birth. The unfortunate outcome has rightly forced broad reconsideration of gender assignment practices. Various commentators have noted that gender assignment can reinforce dubious notions such as the view that a person cannot be male unless he has a large and intact penis and that it is better for a child to grow up as a sterile female than as a male with a very small or damaged penis.

Some commentators have argued that gender assignment violates children's autonomy (Dreger, 1999). That argument is not convincing because newborns and very young children lack the cognitive powers that justify respect for people's choices. More convincing are worries that early gender interventions are not effective or work to the advantage of anxious parents, not to the benefit of the children. Concerns of this kind suggest that gender assignment in the case of ambiguous genitalia or intersex conditions at the very least should not be treated as inherently shameful or as a social emergency.

Physicians should propose gender interventions to parents only after a rigorous evaluation of the risks and benefits. Among other things, practitioners should advise parents that some individuals live happily with atypical genitalia or intersex conditions and that gender assignment can be carried out later on if that is desired by the child (Dreger, 1998). Parents need support as they think through decisions about gender interventions with their children, and this support should include nonpathologized images of intersex people. In the 1990s the Intersex Society of North America began its education and advocacy efforts to improve options for intersex people and their healthcare providers, and this group explicitly rejects a pathological view of intersexuality.

Gender Identity Disorders

Some people assert a gender identity that is at odds with their anatomy and genetic traits. The American Psychiatric Association (APA) treats some of those people as suffering from gender identity disorder (GID). GID sometimes is called gender dysphoria, and it occurs in children, adolescents, and adults. According to the APA, people with this disorder are characterized by a "strong and persistent cross-gender indentification" (American Psychiatric Association, 2000, p. 581).

This preoccupation is said to pass into the pathological when there is strong and persistent cross-gender identification and clinically significant distress or impairment in social, occupation, or other important areas of function. The diagnosis is not applied to persons with cross-gender identification who have intersex conditions. To some extent *gender identity disorder* replaces what previously has been treated as *transsexualism,* a term that came into use in the 1940s. Although some commentators still use that term, *transgenderism* and *cross-gendered identities* have come into common use.

The prevalence of cross-gender identities has been poorly studied. There have been no studies of prevalence in the United States, although there have been some studies in smaller countries. According to those studies, cross-gender identities occur in 1 in 30,000 adult males and 1 in 30,000 adult females (American Psychiatric Association, 2000). There are various theories about why some people come to have cross-gender identities, although no single theory is accepted as conclusive. Researchers have explored prenatal hormonal exposure, birth order, genetics, brain structure, and various psychological and social learning theories (Green and Blanchard; Devor). Whatever the origins of cross-gender identification are, there is a general pattern of development: People have a sense of dissatisfaction with their sex characteristics and assigned gender, conclude that that dissatisfaction would be alleviated by change and therefore pursue varying degrees of reassignment (Devor).

Adults with cross-gender identities differ in regard to expectations from medicine and how far they want to conform their bodies to a particular gender (McCloskey).

Not everyone wants to assume every male or female trait. Transgendered men may elect to have testosterone treatment, excision of the breasts and genitals, reduction in thyroid cartilage to minimize the Adam's apple, and the construction of a vagina. Transgendered women may elect to have estrogen treatment, electrolysis of unwanted hair, and the construction of male genitalia. However, some transgendered people continue to value aspects of their originally assigned sex and want to keep them even as they add other transfomations. Also, not all instances of cross-dressing or atypical gender expression represent cross-gender identities. Some men and women cross-dress for sexual reasons; this phenomenon is known in psychiatry as transvestism. In these instances there is no discordance between one's biological traits and one's desired gender identity. The issue here is gender expression rather than identity.

There are no specific clinical or psychological tests to diagnose cross-gendered identities; the diagnosis is made on the basis of the case presentation. Moreover, there are no pharmaceutical or surgical treatments for this condition. Generally, behavioral or psychosocial treatments are used to orient a person to a gender identity; no hormonal or pharmacological treatments are known. Some studies have shown that cross-gender identification can be reduced in children through a variety of psychological and social interventions (Green). Advocates of treatment with children focus their interventions on helping children become content with their birth sex. They counsel, for example, that "young children should be taught that sex is irreversible" (Green and Blanchard, p. 1658).

Some practitioners justify therapy for children to alleviate the distress associated with cross-gender identities and behaviors and prevent the emergence of a homosexual orientation in adolescence and adulthood (Rosen et al.). Critics have contested both of those goals. In 1996 the Human Rights Commission of the City and County of San Francisco condemned the use of the diagnosis of GID. According to that group, the diagnosis of GID in children is used to screen for homosexuality and stigmatize gender nonconformity. Others have defended the use of the diagnosis and therapy: "Whether or not someone else agrees, parents have the legal right to bring a child for therapy to modify behavior they disapprove of and with the goal of preventing a later behavior of which they disapprove" (Green and Blanchard, p. 1659). Those commentators compare this option to parents' rights with respect to their children's education, religion, and diet.

Parents have a prima facie right to choose on behalf of their children, but that right is tempered by the moral right of children to be protected from undue risk and useless treatments. For reasons of beneficence parents should not use therapies that bring more harm than good to their children. Medical ethics also recognizes that maturing adolescents deserve a degree of choice in regard to birth control practices, psychiatric treatment, and involvement in research even when those choices conflict with parental wishes. Gender therapies for maturing adolescents require much stronger justifications than do those undertaken with much younger children.

Harry Benjamin holds a central place in the scientific study of transsexualism or transgenderism. Benjamin was a German national who immigrated to the United States and published *The Transsexual Phenomenon* in 1966. In that book he offered the first comprehensive treatment guide for transsexuals. In late 1970s a group of healthcare professionals codified his approach in the Harry Benjamin Standards of Care. Among other things, those rules require that people who seek gender interventions:

1. obtain a diagnosis of gender disorder;
2. begin a relationship with a therapist;
3. receive hormone therapy;
4. live as cross-dressed for a sustained period; and
5. after therapists authorize it, receive desired surgical interventions (Harry Benjamin International Gender Dysphoria Association).

These standards are observed widely in professional relationships with transgendered people. However, some commentators believe that the standards are paternalistic in the sense that they represent a degree of control over medical interventions that is not required elsewhere, for example, in cosmetic surgeries.

Transgender therapy has important implications for a person's social and legal status. The physician and tennis player Renee Richards, formerly Richard, gained the right to play in women's professional tennis as a transgendered woman (Richards). Other transgendered men and women have not been as successful in finding accommodation in society and the law. Individuals who undergo transgender therapy often face legal difficulties insofar as they may violate laws regarding cross-dressing and the use of public washrooms. Those people are sometimes restricted in their right to marry and have children. Prison housing also raises special problems because transgendered persons are especially vulnerable to mistreatment and violence. Some jurisdictions have adopted laws that prohibit discrimination against people having or being perceived as having a self-image or identity not traditionally associated with one's biological sex. Most jurisdictions have no such laws.

The Ethics of Transgender Interventions

Insofar as male-to-female transgenderism is more common than its opposite, some critics have seen in transgender therapy the extension of male privilege. Janice Raymond has argued that male-to-female transgenderism trivilalizes women because it treats femaleness as a trait that men may adopt as they wish. She characterizes female-to-male transgenderism as an attempt to bypass constraints on female participation in a male-dominated society (Raymond). Raymond would not ban transgender therapy, but she believes that a greater social emancipation of women would eliminate the reasons for seeking it. By contrast, other commentators believe that the origins of cross-gendered identities are ultimately beside the point: Those commentators think that the proper focus of interest in these identities is not prevention and treatment but social accommodation so that people may live in whatever modes of sex or gender expression they find desirable (Devor).

Some commentators object to gender interventions for adults on the grounds that medical interventions violate the natural law principle of bodily integrity. However, other commentators working within the same tradition have defended medical interventions on the grounds that they protect psychic health (Springer). It is also possible to argue on utilitarian grounds that if psychiatry has no meaningful treatment for cross-gendered identities, gender interventions can help people achieve happiness. Even commentators who defend a pathological interpretation of cross-gender identities agree that "the most reliable conclusion is that the overwhelming majority of post-operative transsexuals are content with their decision to undergo sex reassignment" (Green and Blanchard, p. 1660). Utilitarian ethics not only advocates the greatest happiness for the greatest number of people, as in the philosopher John Stuart Mill's formulation, it also asserts the liberty principle, a principle of noninterference with individual pursuits insofar as they do not harm others. A case can be made that atypical gender choices do not intrude on the rights of others any more than atypical religious or political views do.

Defending atypical gender identities and expression in adults does not of course establish what priority gender interventions should have in a health-care system. Some critics argue that too little research has been done on ways to improve the surgical needs of transgendered people (Devor). Some people have found that private insurers and government health programs are unwilling to pay for interventions because the interventions are voluntary and do not cure an underlying disorder. Other commentators have argued that gender interventions meet an important psychic need, that they work, and that their limitations can be overcome through better selection standards (Gordon). Those commentators therefore argue that private insurers and the government should pay for gender therapies.

Gender, Identity, and Gender Expression

One of the striking aspects of recent medical history is the way in which affected parties have worked to mitigate injurious or harmful medical practices. For example, women's advocacy groups have helped reshape health-care practices that worked against the interests of women. Men and women with homosexual orientations have worked to change the medical perception of homosexuality as pathological (Bayer). People with AIDS have forced a reconsideration of problematic language and representations used to describe them (Treichler). In a similar way people with cross-gender identities and intersex conditions have challenged the assumptions behind diagnoses and treatments related to gender.

In 1993, participants at the International Conference on Transgender Law and Employment Policy issued the first version of the International Bill of Gender Rights. Among other things, that bill asserts the right of all people to self-definition in regard to gender and the right of free gender expression. It also asserts the right of people to control their bodies in regard to chemical, cosmetic, and surgical interventions as well as the right to receive competent and professional medical care. It also rejects the pathological interpretation of gender: "[I]ndividuals shall not be subject to psychiatric diagnosis or treatment as mentally disordered or diseased solely on the basis of a self-defined gender identity or the expression thereof" (International Conference). In the long run it is a goal of gender activists to move society away from the treatment and prevention of GID and toward acceptance of a much broader range of gender expression.

Gender activism generally rejects the idea that only people with a particular biological endowment may participate in masculinity or femininity. This approach is part of a larger critique of gender roles that are constructed from opposed conceptions of male and female (MacKenzie; Feinberg). A number of commentators point out that some societies have successfully incorporated more diffuse notions of gender identity and gender roles; Native American tribes are commonly cited examples (Williams; Jacobs, Thomas, and Lang).

This critique raises questions about whether gender assignment in children and the category of GID serve social rather than medical purposes. The APA has attempted to divest itself of responsibility for the enforcement of moral or

political values: "Neither deviant behavior, e.g., political, religious, or sexual, nor conflicts that are primarily between the individual and society are mental disorders unless the deviance or conflicts is a symptom of a dysfunction in the person" that generates persistent stress, disability, or significant risk of suffering, death, pain, disability, or loss of freedom (American Psychiatric Association, 1987, p. xxii). Some commentators believe that the stress suffered by children, adolescents, and adults with cross-gender identities is primarily social in nature and thus is primarily a social problem, not an issue to be addressed through diagnosis and treatment.

Some commentators wonder whether medicine will continue to identify cross-gender identifications as pathological or whether another view will prevail. Certainly, attention to the views and counsel of the people under discussion and resistance to easy slippage between biology and culture will help medicine and ethics serve human beings as the people they are rather than as the people society would have them be.

GENETIC COUNSELING, ETHICAL ISSUES IN

• • •

Genetic counseling is a complex communication process that takes place between a genetic counselor and one or more counselees, also called clients. It may involve a single encounter lasting thirty to sixty minutes or multiple encounters over months or years. The type and duration of the encounter is determined by the nature of the condition that led to the encounter. This includes whether the condition under discussion is genetic or nongenetic, the mode of inheritance, and the severity of the disorder, including its prognosis. Therapeutic and reproductive implications play a significant role as well as the counselor's evaluation of the effectiveness of the counseling encounter.

Effective and helpful genetic counseling should be guided by several ethical principles and human values judged by most workers in the field to be of vital importance (Wertz et al.). These include autonomy; beneficence and nonmaleficence; confidentiality; veracity and truth-telling; and informed consent. It is also crucial that varied cultural and ethnic factors be taken into account. The professional code of ethics for genetic counselors should also be considered (Palmer).

Since genetic counseling usually occurs in medical settings such as clinics, medical centers, or private offices, the ethical values that prevail in medical and nursing practice should also play a role in genetic counseling. These principles or values influence different aspects of the counseling process to different degrees. Their influence may also vary according to the cultural background, ethnicity, or religious beliefs of the counselees and their families. The latter factors should receive serious attention, since cultural, religious, or ethnic differences can profoundly influence the relative weight given to one value or principle over another. This is especially true when counseling involves individuals from other countries (Wertz et al.). Counselees from the so-called Third World may cherish religious tenets and ethical values drastically different from those of the Jewish and Christian faiths that inform so much of Western medical ethics (Fisher).

Autonomy and Nondirectiveness

A major facet of the counseling process, and one important goal of a successful counseling process, is a course of action (or inaction) that is determined according to the best available evidence. Genetic counselors generally agree that this decision should be made by the counselee, and that it should be made freely and without coercion (Fraser, 1974; Ad Hoc Committee on Genetic Counseling). Counselors want to avoid, to the extent possible, being accused of "playing god" and to resist any temptation to practice eugenics, the process of manipulating genes in order to "improve" genetic makeup. The manipulation is accomplished by directing the counselees about what reproductive decisions they should or should not make. This is inappropriate because respect for autonomy should be a predominant ethical value guiding the counseling process and its outcome. This is the clear consensus of genetic counselors from all over the world (U.S. President's Commission; Wertz and Fletcher).

If counselees are to make autonomous decisions, they must be fully informed about the disorder in question, free of coercion, aware of all the possible choices, and have access to any facilities and/or services to implement their decision. In its purest sense and with only rare exceptions, the nature of the decision is not an issue as long as the counselee has decided that such a decision is in her or his best interest. In this model of counseling the counselor makes every effort to be "nondirective," that is, to refrain as much as possible from providing any suggestion directly or indirectly to the counselee as to what decision she or he should make (Fraser, 1974, 1979; Hsia). No counselor can be totally unbiased and without any interest in the decision that is made. However, the aim in counseling is to create "an accepting psychologic climate" and thereby the possibility of a nondirective relationship (Antley).

An ethical dilemma may arise for the counselor if the counselee wants to make a decision that will have what the counselor strongly feels are mostly negative consequences. For example, a man and a woman are both affected by a serious homozygous recessive disorder (e.g., sickle-cell anemia) and are advised that all their children will be similarly affected. After being counseled, and with full knowledge of the genetic consequences, they decide to have their own biological children. This kind of decision is called dysgenic by some, because it has the potential of resulting in an increase in the number of deleterious genes in the next generation. This will be true if the couple has more than two children and they in turn live to reproduce in an environment where these genes have no selective advantage. Some counselors feel that the counselor may be justified in not honoring the principle of nondirectiveness because the net

reproductive effect is likely to produce more harm than benefit (Yarborough et al.). It further results in a situation in which children who are destined to live a life of pain and suffering are knowingly brought into the world. Furthermore, there is the possibility of genetic harm to this population if this practice becomes more common. These harms must be balanced against the benefit to these parents of having their own biological children, even if these children are much more likely to suffer or to die an early death.

The counselor who feels that the principle of nondirectiveness ought not be violated under any circumstances should at least explore with the counselees the psychosocial and emotional reasons that led them to this decision. The counselor should assist them in a careful and deliberate examination of the benefits and harms that may effect them and their offspring (Kessler). Strong arguments have been advanced suggesting that by applying the principle of beneficence, the counselor is justified in attempting to persuade counselees to reconsider their decisions in certain cases without violating the rule of nondirectiveness (Yarborough et al.).

Beneficence/Nonmaleficence: Whose Needs Come First?

When the counselee is trying to balance the benefits and harms of a particular decision against one another, there may be a tendency to emphasize the benefits over the harms. In some cases, the benefit or beneficence for the counselee(s) may mean maleficence or harm for the child. If parents who know they will have a child with a serious genetically determined disease decide to go ahead because they believe they have a "right to bear children," they may benefit in having their own biological children. At the same time they might not be judged "responsible parents" because they may not have given serious enough consideration to the suffering and discomfort their offspring will suffer. Even if this factor has been considered, the parents may justify their decision on the religious grounds that they are merely following the dictates of a higher power, leaving it to God to determine whether or not they have children.

In some cases it may be difficult for counselor and counselee to agree on what constitutes a benefit and what a harm, since such determinations are often rather subjective, governed primarily by the counselee's values. For example, abortion of an affected fetus might be considered a benefit to some and harmful to others, depending on whose needs are considered primary. Providing information that there is a high probability that a counselee at risk to inherit a serious genetically determined disease of late onset has in fact inherited it might seem a beneficent act by some who value knowledge of any sort, and a maleficent or harmful act by others who value information only when it leads to the prevention or correction of harm. In the tension between these contrasting ethical principles, medical ethical tradition suggests that nonmaleficence should be weighted more heavily than beneficence in cases where they are in conflict. This position is consistent with the maxim of *primum non nocere,* first do no harm (Beauchamp and Childress), since providing information without clear benefit has the potential for causing social and emotional harm.

Veracity and Truth-telling in Genetic Counseling

A major part of the genetic counseling process is the exchange of information about the medical and family history provided by the counselee and comprehensive genetic and medical information about the disease in question provided by the counselor (Fraser, 1974; Hsia). The counselee needs accurate information, including the correct diagnosis, in order to choose a beneficial course of action. Truth-telling is an essential ingredient of the relationship between genetic counselors and counselees. Part of the trust that exists between them is based on this virtue. As a consequence, the genetic counselor should provide truthful, accurate, and complete information to the counselee concerning the genetic disorder being considered.

On some occasions the genetic counselor might have very good reasons for violating this important trust. Failure to tell the truth will most often involve withholding information rather than lying. But the counselor bears the burden of justifying failure to tell the whole truth. This is the case even if the counselor is keeping back some information until a time when it may be more readily received, that is, when the counselee is judged to be better prepared to accept negative information and its attendant consequences. Some reasons that might be given for holding back information include:

1. The information, if transmitted, is likely to cause permanent damage to the self-image of the counselee or result in a serious or severe emotional reaction. This is the case when a female is found to have an XY sex chromosomal constitution rather than the normal XX sex chromosomes.
2. Refraining from transmitting the information will not have a significant effect on the options open to the counselee or her or his family nor will it compromise any therapy the counselee or the family should receive.

3. The counselee has a history of serious depression and the information, if fully given, has a good chance of exacerbating the depression with a significant risk of suicide.
4. The information reveals evidence that the putative father in a family is not the biological father of a particular child; if this information is provided, it is likely to lead to the breakup of the family and the child will no longer have a father.
5. A young man or woman has been found to be a presymptomatic carrier of a late-onset, autosomal (related to chromosomes that are common to both sexes), dominant condition and does not want a fiance to be told because it is feared she or he might break off the relationship.

The latter two cases, in which information is withheld from third parties, raise the question of the counselor's obligation or "duty to warn" others who might be affected by the presence of the genetic condition in a spouse or significant other. For some counselors, the "right to know" or the "duty to warn" provides strong justification for telling the whole truth at all times during the counseling process, regardless of the potential consequences. At the same time, a minority of counselees feel they have a right "not to know." These people would rather not be told about a serious genetic condition of late onset, especially if there is no effective therapy or other maneuver that will forestall its onset or significantly reduce its symptoms. If counselees do not wish to know about their incurable condition, the information may nevertheless have to be placed in the medical record so that future health-care givers will be alert to the counselee's status. The information can also be provided if counselees should change their minds. In general, genetic counselors will withhold information only where there is a strong likelihood for serious harm to the family or to the self-image or status of the individual (Wertz et al.).

Confidentiality and the Control of Genetic Information

Medical genetics is more concerned with the family than almost any other medical subspecialty. As part of the evaluation of a clinically significant genetic disorder, the genetic counselor is required to collect detailed family data and record it in the form of a *pedigree.* This enables the counselor and the medical geneticist to determine whether there is a pattern of occurrence in the family consistent with control by a single gene of major effect (often referred to as a "Mendelian" gene). The pedigree may also provide information that may indicate the presence of inherited chromosomal structural rearrangements called translocations. More often than not, the pedigree information is insufficient to make this determination. But when it does demonstrate the presence of an inherited defect, this knowledge can have serious, even grave, implications for the other genetically related members of the family. This is especially true when one is dealing with conditions that demonstrate autosomal or X-linked dominant or X-linked recessive modes of inheritance, because inheritance of a single mutant gene on an X or non-X chromosome can cause the full-blown clinical disorder.

Under the medical model that governs medical geneticists and genetic counseling, the counselee has the status of a patient. All information relative to his or her case is covered by the guarantee of privacy and confidentiality that is required of health professionals (Beauchamp and Childress). The medical geneticist or genetic counselor should get permission from the counselee to contact other family members to inform them that they are at risk for a serious genetically determined disorder. In general, this is not a problem; most counselees readily consent to having their relatives contacted or are willing to do this themselves. But in at least two instances the genetic counselor may face an ethical dilemma concerning the release of information to third parties.

1. The disorder is *not* treatable and can be diagnosed by prenatal diagnosis, so a couple at risk could theoretically avoid the birth of an affected child; or individuals at risk for this might wish to take special predictive tests and use the knowledge to get their affairs in order or in other ways to alter their life situation.
2. The disorder is treatable and can be cured or can have the symptoms and any complications significantly reduced by safe and readily available therapy; or the expression of the disorder can be prevented if it is detected before the symptoms have appeared.

The obligation to maintain confidentiality of patient records and genetic information obtained in a medical setting is not absolute and may be breached when there is adequate justification. The exceptions may be invoked only if there are extenuating or overriding personal or social circumstances. The State of Texas statute on confidentiality, for example, allows confidential information to be disclosed if there is the probability of imminent physical injury to the patient or others (Andrews). In the case of genetic disorders, the most compelling argument for breaching confidentiality besides those instances where it is required by law is the protection of third parties from harm (Andrews). In ethical terms this is sometimes cited as "the duty or obligation to warn" when there is a clear or imminent danger.

In the cases shown above, there would appear to be clear justification for breaching confidentiality in the second case but not in the first. In the first example, useful information might be provided to third parties, but there is no evidence of harm because the condition identified is not treatable. In the second example, the fact that there is a treatment or a method of preventing the condition means that failure to warn would result in harm to a third party. Since the burden of justification would be on the genetic counselor to show that the harm, however, conceived, is correctable or preventable, it makes sense not to breach confidentiality in instances where the potential harm is not clearly defined. The U.S. President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research regarding confidentiality provided four conditions under which the requirements of confidentiality can be overridden and genetic information released to relatives or their physicians (1983).

Revealing genetic information, especially in cases of presymptomatic diagnosis, has other important implications for the counselee's eligibility for health insurance and possibly for life insurance. Depending on the condition involved, such information if revealed can also affect employability and opportunities for promotion. There is always a significant risk that sensitive information, if released, may find its way to individuals or agencies that might harm the counselee in the future.

Informed Consent in Genetic Counseling

Since a major component of genetic counseling is communication of information, and since the counselee is encouraged to make her or his own decision, problems or conflicts with informed consent are unusual. Informed consent is especially relevant in the counseling process when a procedure may result in potentially harmful or ambiguous outcomes, for example:

1. in connection with prenatal diagnosis, when the counselee or woman who is to undergo the test needs to understand its risks, benefits, errors, and limitations;
2. as a prelude to presymptomatic testing for a serious disorder without available treatment or methods of prevention, where a positive result can have profound implications for the individual's future life;
3. in connection with participation in a research protocol in which there may be questions about the future use of data or tissue or blood (especially DNA) in future studies or in the search for other genetic markers.

Ethnic and Cultural Influences

The population of the United States and many other industrialized nations is becoming more diverse. It is estimated that by the year 2010 nearly one-third of the population of the United States will be made up of minorities. Genetic counseling that promotes individual autonomy and is consistent with the ethical values discussed here will require that counselors be aware of and responsive to a wide and growing range of ethnic and cultural variations among those who are now and will be seeking genetic counseling (Fisher). Conflicts are almost certain to arise when the values and decisions of the ethnically and/or culturally different counselees conflict with those of the counselors and the Western values derived from Jewish and Christian sources that in general govern the decision-making process. The value systems that have been used traditionally in counseling will probably have to be applied in significantly different ways if the process and outcome of counseling is to be helpful and effective.

GENETIC COUNSELING, PRACTICE OF

• • •

Genetic counseling is a relatively new medical counseling service that aims to help those affected by genetic conditions or who face increased genetic risk. Clients seek this service asking questions about why a condition occurred, the chances that it may occur again in the future, and how they may be helped to cope with the uncertainty, risk, or prognosis of a diagnosis. Genetic counseling is often provided by a team of genetics providers (medical geneticists, master's level genetic counselors, and genetic nurses) in a specialty clinic within a hospital, university medical center, or in a community outpatient setting. Attention is paid to the medical, informational, and emotional needs of clients and their family members related to genetic conditions or birth defects.

History

Genetic counseling began in the United States in the 1930s when the academic discipline of genetics emerged and Mendelian principles of single gene inheritance could be applied to human conditions. The first *practitioners* were academic geneticists who were approached by individuals with concerns about their own family history. In the 1940s the field of human genetics was established, followed by medical specialization in genetics that focused on the diagnosis and natural history of genetic conditions. Shortly thereafter in the 1970s, the profession of genetic counseling was established in the United States. Practitioners earn a master's degree and are trained in both human genetics and

psychological counseling skills. As of 2002 there were estimated to be over 2,000 genetic counselors practicing in the United States and Canada. Genetic counselors are credentialed by the American Board of Genetic Counseling to uphold practice standards. These professionals work with medical geneticists and obstetricians to provide education and counseling related to risk or diagnosis of a genetic condition or congenital anomaly.

Definition

Genetic counseling makes genetic information available to clients and facilitates their use of that information. Genetic information is important to understanding the cause of conditions, making informed choices, and adapting to genetic risk. The range of information provided includes the medical diagnosis, the inheritance pattern, the risk of recurrence, medical management or surveillance, prognosis, schooling needs, support groups, financial issues, and reproductive options. Since clients often seek services around significant life events or crises, the information is often highly sensitive, such as predicting the health of future children, the likelihood of a late onset condition, or the loss of an affected child. Discussion of genetic conditions or risks may therefore elicit feelings of lowered self-esteem, guilt, shame, loss, and blame for parents of affected children. Overall addressing the cognitive, affective, and behavioral aspects of clients' responses to the information are central components to genetic counseling. A practice definition states that:

> Genetic counseling is a dynamic psychoeducational process centered on genetic information. Within a therapeutic relationship established between providers and clients, clients are helped to personalize technical and probabilistic genetic information, to promote self-determination, and to enhance their ability to adapt over time. The overarching goal is to facilitate clients' ability to use genetic information in a personally meaningful way that minimizes psychological distress and increases personal control. (Biesecker and Peters, p. 195)

Settings and Practice Goals

There are a variety of different settings for genetic counseling, including reproductive, pediatric/adult, and common disease clinics. Each one embodies a different set of aims. In the reproductive setting, the focus is primarily on decision making. Most often clients seen in a prenatal genetics clinic seek to understand their age-related risks for having a child with a chromosomal abnormality, such as Down syndrome. Increasingly they may also be seen in follow-up to an abnormal screening test that implicates higher chances for having a child with a birth defect or chromosomal disorder. These clients most often have no family history of the disorder(s) in question and are helped to understand what the conditions are, their likelihood for occurrence, and the options for managing or terminating the pregnancy. The goal is to promote client self-determination in exercising choice about the use of prenatal tests. Reproductive genetic counseling aims to deliver personalized genetic information to the client in a useful way; to explore the meaning of the information with the client in light of personal values and beliefs; to promote the clients' preferences for reproductive options with consideration of alternatives, consequences, and barriers; and to prepare the client for adapting to the outcomes of the choice(s) (Biesecker). When an abnormality is detected, there are few options for treating the condition and couples face painful decisions about whether or not to abort a desired pregnancy. Genetic counseling is particularly important when couples face such irreversible life-altering decisions.

In the pediatric and adult genetics setting, the goal is to facilitate client understanding and adaptation to a condition. In this setting clients often have a child or other relative who is affected with a genetic condition that they seek to better understand as part of their adaptation to (often unexpected) circumstances. Obtaining an accurate diagnosis of the condition by a medical geneticist is an essential component. Medical information provided to clients includes a description of the condition and its potential long-term consequences. The aims of genetic counseling in the pediatric or adult genetics setting are to discuss client understanding of cause as it relates to a scientific (genetic) explanation and the client's interpretation, to explore the role of personal beliefs in adaptation, and to promote feelings of personal control and mastery over the condition (Biesecker). Genetic counseling helps clients to cognitively integrate genetic information into their personal beliefs and frame of reference in a manner that is personally useful to them. Referrals are often made to support groups or to other parents with similarly affected children. School referrals for attention to special learning needs for the child may also be made. Parents often require a great deal of follow-up medical, educational, and support services for their child and themselves.

In the common disease setting, such as cancer genetics, cardiovascular genetics, or neurogenetics clinics, most often adults seek to understand their own risk for disease. The goal is to maintain the health of at-risk individuals. Specific aims are to increase accurate risk perception, to facilitate adaptation to genetic risk, to promote health-enhancing behaviors, and to prevent disease (Biesecker). Predictive genetic testing may be offered as part of the effort to refine risk more

precisely and as a basis for making screening or prevention recommendations. Yet decisions about predictive testing are highly personal due to the lack of empirical evidence to guide practitioners in making medical recommendations based on test results. In many cases genetic testing offers risk estimates but little else. Clients' decisions about undergoing predictive testing often lie with the meaning the test result would have for adapting to living at risk. Increasingly such testing will also be used to manage risk by offering targeted interventions for those identified to be at increased genetic risk, but this is rarely the case.

Cancer genetics services have been established in response to the research and commercial availability of predictive testing for cancer risk. Tests have been developed for breast and ovarian cancer risk, colorectal cancer risk and for certain rare cancer syndromes. While medical recommendations are made for tested individuals found to be at increased risk, there remains a paucity of empirical evidence to support the majority of these recommendations. With time more precise risk estimations will be made using testing, targeted interventions will be known to be effective, and reduction in morbidity and mortality will be achieved. In the meantime, however, the imprecise nature of cancer genetics testing necessitates informed consent and emphasizes the importance of pre-test education and counseling in the common disease setting.

Non-Directiveness

Genetic counseling is often described as *non-directive,* meaning that clients are helped to make personal decisions without undue influence by the counselor. This practice principle emerged from reproductive genetic counseling where couples face decisions about having children or continuing an affected pregnancy. It remains an important ethical principle for guiding clients through their reproductive choices. Clients are helped to make personally relevant and informed choices for themselves. Nonetheless non-directiveness is difficult to achieve since counselors have personal and professional biases and experiences that may be inadvertently expressed in how information is presented or emphasized in genetic counseling. While counselors may not intend to guide client decisions, it is reasonable to assume that genetic counseling influences them. Yet the majority of clients are capable of making their own decisions and can benefit from prenatal counseling by exploring their own beliefs, attitudes, and values related to their ability to parent a child affected with a particular condition. Genetic counseling that is client-centered focuses on meeting the needs of clients by working within the context of their sociocultural beliefs and lived experience. Even if a genetic counselor explicitly expresses her own beliefs during reproductive counseling, it is unlikely that a client will simply adopt them. However there are situations where conflicts in promoting personal reproductive choice do exist.

When a prenatal genetic counselor is employed by a commercial laboratory or prenatal testing center, there is more likely to be a potential conflict of interest. If the testing center promotes prenatal tests rather than promoting the choice of testing, then the counseling may emphasize the benefits of testing over the risks. There might be more frequent assumptions on behalf of the counselor that if the client was referred for prenatal testing, that the client is going to undergo testing rather than insuring that each client makes an informed and personal decision whether or not to undergo optional prenatal tests. Further, if the counselor's salary depends upon a certain number of tests being conducted, there is likely to be an even greater chance for persuasive prenatal genetic counseling.

In genetic counseling settings other than reproductive, non-directiveness has little relevance. In the common disease setting, for instance, making screening recommendations to promote health intends to be directive. Applying the notion of non-directiveness to genetic counseling in general has lead to a great deal of confusion in the literature (Kessler). In addition to directive health-related recommendations, communication in genetic counseling is often directive. Offering advice or making referrals may be also be construed as directive. The adoption of non-directiveness as a central tenet of genetic counseling has limited the use of (directive) therapeutic interventions that may be helpful to clients. Genetic counseling may be practiced in a more hesitant manner if counselors fear directing their clients' decisions when fully engaging with them may be more productive. Issues related to non-directiveness continue to be actively debated in the professional literature.

Client-Centered Practice

Interpretation and use of genetic information by clients depends somewhat on their personality traits and characteristics. Clients come from a variety of sociodemographic and ethnocultural backgrounds that shape their beliefs, values, and available resources. Clients also may belong to affected families who have experience with a condition under discussion. Others may not have had experience with it. These variables shape client needs, attitudes, and priorities. Genetic counseling necessitates assessment of these variables in order to tailor the information and counseling to meet client needs. A couple with two children affected with cystic fibrosis that faces a decision about prenatal testing with a subsequent pregnancy is expert on the disorder and its

impact on the family. A couple who is found to be at increased risk for having a child with cystic fibrosis based on carrier screening with no family history of the condition may have little idea of what having an affected child may mean for the child or themselves. Genetic counseling would differ in meeting the needs of these clients, even though at face value, each involves a fetus at 25 percent risk for being affected with the same condition, cystic fibrosis.

Since genetic conditions affect families, there may also be differences in how relatives view or use genetic information. Genetic counselors working with various family members have obligations to protect the privacy of individual clients and to support different decisions made within the same family. The offer to undergo predictive genetic testing, for instance, may result in some individuals who are interested and others who are not. Yet test results for one relative may reveal the at-risk status of another. So protecting personal testing decisions within families can be challenging. Genetic counseling aims to help relatives anticipate such consequences prior to undergoing testing. Rarely family members may choose not to reveal risk of a genetic condition to relatives. In this circumstance, genetic counselors may be persuasive in encouraging clients to notify their relatives so that each at-risk person may be informed and equipped to make his or her own decision about whether or not to undergo genetic testing. There is debate about the duty of genetics providers to warn at-risk relatives in situations where family members choose otherwise.

As more genetic discoveries emerge and genetics medicine moves into an era in which diagnoses are refined by genetic information, more tests are developed, and treatments tailored, all healthcare providers will need to understand some aspects of medical genetics. Nurses, primary care physicians, and even social workers and psychologists will be faced with helping clients to make decisions about using new genetic technologies. This sea change suggests a significant need for professional genetics education to prepare a variety of healthcare providers to care for clients in the future. Genetic counselors are important providers for helping to train others. In the meantime, it is important that clients who encounter new genetic technologies have access to appropriately trained and certified genetics providers. As genetic testing is increasingly utilized as a tool for medical management and not merely as a means to obtain risk information, there is likely to be less psychological turmoil for clients in making decisions about undergoing testing. However carrier testing or pre-symptomatic testing for serious, late-onset disorders without medical treatment will continue to elicit strong thoughts and feelings from clients. Certain genetic testing will continue to need to be accompanied by psychoeducational genetic counseling provided by well-trained clinicians to facilitate personal decision making. As the number and background of professionals involved in genetic testing expands, there is a greater potential threat to well-informed decision making. The maintenance of a high training and practice standard for genetic counseling is a priority in anticipating some of the consequences of the diffusion and proliferation of genetic testing.

Genetic counseling has evolved rapidly in its short history from the reproductive arena to pediatric and adult genetics clinics and more recently into common disease clinics. With this expansion, its goals have become more diverse and specific to the setting. As genetics medicine further emerges and new genetic tests are introduced, promoting informed choice about use of genetic tests will continue to necessitate pre-test genetic education and counseling. Ethical controversies related to duty to warn relatives, risks to the confidentiality of genetic information, and conflicts of interest related to commercial incentives for testing will expand and policies and even legislative protections will emerge.

GENETIC DISCRIMINATION

• • •

Genetic discrimination is the term commonly assigned to actions taken against or negative attitudes toward a person based on that person's possession of variations in the genome, or variations in the genome of his or her biological relatives. A component of stigmatization, genetic discrimination differentiates social treatment based on assumptions about the value of information suggested by a particular genetic configuration in predicting present and future health status (Condit, Parrott, and O'Grady). The details of one's genome are typically available through genetic tests (Burke). The nature of genetics is such that information derived from one person's genetic composition may implicate or be attributed to the biological siblings and/or descendants of that person. Genetic discrimination illustrates the danger of a misinterpretation—or oversimplification—of information suggested by some genes. Fear of genetic discrimination is often cited as a reason for avoidance of genetic testing services (Rothenberg and Terry).

Empirical evidence of genetic discrimination in contemporary society is somewhat slight (Nowlan). Early reports of genetic discrimination by adoption agencies have not been repeated (American Society of Human Genetics). Nevertheless, fears of genetic discrimination by employers and insurance companies continue to influence decisions regarding submission to genetic testing and participation in certain forms of genetic research. The result may negatively influence individuals' health (Rothenberg and Terry). Efforts to address genetic discrimination include legislation, industry self-restraint, and private action, each controversial for what it suggests about the ability to prevent forms of discrimination.

Genetic Information

Some variations in the genome have demonstrated value in predicting the health status of a person. Where a disease is monogenic, like Huntington's disease, its onset is foretold by the presence or absence of a mutation in a single gene (Guttmacher and Collins). The presence and location of single nucleotide polymorphisms (each commonly referred to as a "SNP," pronounced "snip"), may inform decisions in drug therapy by predicting an ability to metabolize a drug or a risk of toxicity (Guttmacher and Collins; Syvanen). In other instances, an enzyme or protein may yield similar information. Efforts to map the human genome with greater specificity, as well as efforts in pharmacogenomics, rely upon comparisons of the patterns of genetic variation in large numbers of people.

Media coverage and other efforts to relate complex concepts in genetics to a lay audience have revealed a tendency to oversimplify the relationship between one's genome and one's destiny. Specifically, the predictive value of genetic information is often overstated. Behavioral genetics, for example, remains in its infancy; few genetic mutations or polymorphisms are thought predictive of intelligence or cognitive ability. With the exception of monogenic diseases, which are relatively rare, the predictive relationship between the genome and disease is compromised by the relative lack of knowledge about the influence of environmental factors. The wide range of more common diseases is a function of interactions between the genome and such factors as diet, climate, and physical activity. Finally, a gap typically exists between knowledge of the discovery of a causal relationship attributable to a particular genetic variation and knowledge of a treatment for the condition at issue.

The result of this oversimplification is genetic determinism (Rothstein, 1999), alternatively termed "genetic reductionism" (Lee, Mountain, and Koenig) or "genetic essentialism" (Nelkin). The terms describe the phenomenon through which the importance of genetic factors is emphasized at the relative expense of environmental and social factors. Together, determinism and discrimination are elements of stigmatization (Condit, et al.). As explained by Celeste M. Condit, Roxanne L. Parrott, and Beth O'Grady in their 2000 article, discriminatory attitudes about genetics get much of their stigmatizing impact from excessively deterministic attitudes about genetics.

Insurance

Discrimination might manifest in several ways. The use of genetic information by insurers figures prominently in assessments of public attitudes and fears about genetic research and medicine. Theoretically, genetic tests obviate the need for the family medical history common in medical underwriting practices. Relatively few instances of discrimination by an insurance company have been reported, whether because discrimination is difficult to recognize or prove, or because the practice is not prevalent (Rothenberg and Terry).

Within the context of life insurance, the question is whether companies should either require genetic testing or have access to the results of genetic tests documented in medical records in deciding whether to underwrite a policy.

Insurance is characterized by a commercial transaction in which the company pays a benefit upon the death of the policyholder in exchange for a premium proportional to the mortality risk assumed by the insurance company (Cook; Nowlan). The fear is that a life insurer would decline to underwrite a policy for a person or family of persons who possess genetic variations that suggests early death. Insurance companies wish to avoid financial harm caused by adverse selection. Adverse selection results when persons who believe they are at a lower risk of illness or early death choose to purchase less insurance or leave the market, while persons who believe they are at higher risk purchase greater amounts of insurance. Ultimately, the money paid in premiums by persons of lower risk is no longer sufficient to cover the expense incurred by insuring persons of higher risk.

Medical underwriting is not as common in the context of medical or health insurance as compared to life insurance (Nowlan). Countries with a national health service extend resources to nearly all citizens without regard to health status; medical underwriting becomes relevant only in the small market for private health insurance. Nevertheless, fears are particularly pronounced in the United Kingdom, where—contrary to other countries, including the United States—life insurance is a requisite to the purchase of a home or other real estate (Cook).

The private health insurance market is much more prominent in the United States than in other countries, but is made available primarily through group plans subsidized by the employer in a voluntary arrangement (Rothstein, 2000). Medical underwriting is a greater possibility in the relatively small market of private individual policies, which can be very expensive.

Employment

Initial fears suggested that employers who had access to genetic information would refuse to hire persons with inherited characteristics that suggested greater use of health resources by either the employee or family members. Employers would try to control expenses on healthcare and perhaps absenteeism by pricing premiums in accordance with health status of the employee. Recent legislation in the United States prohibits employers from charging employees of higher risk a higher premium (*Health Insurance Portability and Accountability Act of 1996 (HIPAA)*). Cases of genetic discrimination primarily involve an employer's attempt to require genetic testing or access to the results of genetic tests already included as medical records as a prerequisite or condition of employment. While state and federal statutes regulate the employer's use of results from genetic testing, other statutes that impose upon the employer a duty to ensure worker safety partially restore access to such medical information (Rothstein).

Eugenics

The eugenics movement and other misguided attempts to translate science into government policy provide support for contemporary fears of stigmatization. Proponents of eugenics, a dominant scientific philosophy from the late nineteenth century through the mid-twentieth century, sought to improve the quality of the human race through social policy based on flawed theories about heritable characteristics (Galton and Galton). Agents of the government dissuaded persons perceived as mentally deficient or possessing an inherently criminal nature from reproducing, sometimes through laws mandating sterilization of groups of persons (Markel). Eugenic principles were consistent with social classification policies implemented in support of Nazi Germany, and contributed to the mass exterminations of persons.

With regard to the issue of *race,* many who cite concerns of genetic discrimination emphasize the dangers attendant to the racialization of disease or conflating social categories with genetic variations (Lee, et al.). Despite evidence that patterns of genetic variation are greater within racialized groups than between them, resistance to historical patterns of classifying persons by race is neither easy nor simple.

The association of disease with an identifiable human population is a dangerous and often unintended consequence of technology. In the later years of the twentieth century, efforts in the United States to implement policies to help persons afflicted with sickle-cell disease, a heritable disease, proved disastrous. A push for early diagnosis and treatment yielded several state laws that mandated screening African Americans for the disease. The years following the passage of these laws were marked by an increase in acts of discrimination by government, insurers, and employers against persons afflicted with the disease, as well as against persons who were merely carriers of the trait (Markel). The disease became associated with African-Americans in a way that illustrated the dangers and improvidence of conflating *race* with a particular genetic composition. The foregoing demonstrates the perils of premature and perhaps shortsighted policymaking.

At the beginning of the twenty-first century, there were reports of discord within the Jewish community regarding genetic testing (Schwartz, Rothenberg, Joseph, et al.). Following the identification of mutations in BRCA1 and BRCA2 that are associated with a higher risk of breast or ovarian cancer, many supported testing as critical to prevention and treatment of women who carry the mutation, while

others discouraged participation based on fear of stigmatization (American College of Medical Genetics). This reaction against genetic testing was based in part on a controversial history of research on Tay-Sachs disease. The knowledge gap between the ability to predict a condition and the ability to treat it created uncertainty and the opportunity for misinterpretation of existing information.

Fear vs. Fact

Some have observed that the greatest danger with respect to genetic discrimination stems from unsubstantiated fears of discrimination. Several studies document the effect of anxiety about the possibility of genetic discrimination on participation in genetic testing or screening procedures (Geer, Ropka, Cohn, et al.). Exaggerating the size of the problem promotes genetic determinism and feeds fears that inhibit participation in research and therapy.

The literature identifying the factors motivating an individual to participate in tests that yield genetic information useful in determining susceptibility to disease or illness reveal several themes. The desire to help a relative is commonly cited as a motivating factor (Applebaum-Shapiro, Peters, O'Connell, et al.). The relative paucity of empirical data as to the prevalence of discrimination does not influence public attitudes regarding a willingness to participate or fears of discrimination or stigmatization (Hall and Rich).

An individual's wish to avoid negative treatment based on deterministic attitudes can manifest in several ways. An individual may refuse to be tested for a particular trait even if necessary for diagnostic purposes. Alternatively, the person may opt to test anonymously or to pay for the test without filing an insurance claim—even if the test is covered—in an attempt to keep such information from the employer or medical insurer. For example, in the first years after the significance of the BRCA1 and BRCA2 mutations was announced and a predictive test made available, there emerged anecdotes in which persons took steps to conceal information from becoming a part of their medical records (Schwartz, et al.).

Social Policy

The power of the fear of genetic discrimination to direct behavior is central to debates regarding the need for curbs on such discrimination through social policy (Greely). The degree of restriction is often related to the degree of harm threatening economic and other values. In the United Kingdom, the strong relationship between life insurance, home ownership, and the effect of perceptions of danger on the national economy prompted a national investigation (Cook). At least partially to avoid more restrictive measures, the British life insurance industry declared a voluntary, qualified moratorium on policies. Some have suggested that industry self-restraint is preferable to overreaching or imprecise legislation (Nowlan). Critics contend that industry self-restraint can not serve as a sufficient deterrent to actions that could otherwise yield economic benefit.

Legislation plays a relatively more prominent role in policies regulating genetic discrimination in the United States. Absent a single, uniform statute at the federal level, the laws of individual states address genetic discrimination. The actions of employers and other entities are also subject to provisions within federal statutes that regulate the workplace and the marketplace (Pagnattaro). Legislation passed in the 1990s regulates the dissemination of medical records that could contain the results of genetic tests (*HIPAA*). Such regulation reflects the heightened value afforded privacy and confidentiality, particularly within the United States, in an era of advanced medical and informational technology.

Several scholars have criticized the use of legislation prohibiting genetic discrimination as premature and unnecessary government interference in a free market system (Epstein). Citing flaws in the legislative approaches to discrimination in other contexts, these scholars question the fairness of protecting the concealment of information that may have legitimate value. Others emphasize the absence of evidence of genetic discrimination by health or life insurance companies (Nowlan). To enact legislation on the basis of a problem that exists primarily through anecdotes, critics argue, is to validate fears that are unsubstantiated (Nowlan).

Still others praise legislation prohibiting genetic discrimination as an effective means of allaying the fears of the public (Greely). Legislation is a vehicle for establishing a shared consensus on the values underlying the matter. The cost of "symbolic" legislation, however, remains a matter for debate (Hellman).

Conclusion

More important than the prohibition of the actual behavior is the need to allay the concerns of persons acting on the basis of such fears. This is the challenge facing those who would shape public policy on the use of genetic information. Deterministic attitudes underlie fears of discrimination, as well as the actual discriminating conduct. The ability to surmise from one person's genetic information details about another will influence traditional notions of autonomy and even self-determination. The idea that stigmatization might follow from participation in genetic testing or other research

is an obstacle to the optimization of the benefits in health and resources that are increasingly available through advances in genetic technology.

GENETIC ENGINEERING, HUMAN

• • •

The development of recombinant DNA techniques in the 1970s enabled scientists to create genetically engineered organisms. In 1975 molecular biologists and geneticists held

a conference in Asilomar, California, to discuss the biosafety issues relating to the new technology as well as policies for regulation and oversight. In 1978 fertility specialists used in vitro fertilization (IVF) techniques to assist a British couple in conceiving Louise Brown, the world's first "test tube" baby. In the early 1980s researchers began using embryo-splitting technologies to produce desirable livestock clones for agriculture. By the end of the decade universities and biotechnology companies were manufacturing and patenting transgenic mice for use in drug testing and medical research.

During the course of those events many people expressed concern that these discoveries and innovations eventually would lead to human genetic engineering (HGE). In early discussions of HGE (circa 1965–1980) scientists, journalists, and scholars conjured up the familiar allegories of Mary Shelly's *Frankenstein* and Aldous Huxley's *Brave New World* to question the wisdom of pursuing the new technologies (Gaylin; Boone). Science fiction novels such as *Mutant 59* and *The Boys from Brazil* depicted the disastrous effects of genetic engineering experiments gone awry. The biotechnology critic Jeremy Rifkin (1983) warned of the Faustian bargain of genetic engineering and the dangers of meddling with nature. Theologians such as Paul Ramsey (1970) and bioethicists such as Leon Kass (1972) spoke about the dangers of "playing God" and disrupting family relationships. However, scientists, such as Joshua Lederberg (1966) and James Watson (1971) and philosophers such as Jonathan Glover (1984) and Joseph Fletcher (1965) embraced the possibilities of using HGE to advance scientific and social goals.

Two Key Distinctions and Four Basic Categories

While the public debate continued, scientists, clinicians, and scholars began to envision potential medical uses of HGE as they developed a framework for justifying the application of gene transfer technologies to human beings. Two key distinctions defined this framework: the somatic versus germline distinction and the therapy versus enhancement distinction (Walters; Anderson, 1985, 1989). Those distinctions implied four types of HGE:

Somatic gene therapy (SGT)
Somatic genetic enhancement (SGE)
Germline gene therapy (GLGT)
Germline genetic enhancement (GLGE)

Anderson (1989) and others argued that SGT could be justified on the grounds that it was morally similar to other types of medical treatments, such as pharmaceutical therapy and surgery. The goal of SGT is to transfer genes into human somatic cells to enable those cells to produce functional proteins in the appropriate quantities at the appropriate time. In 1990 the first SGT clinical trial involved an attempt to transfer normal adenosine deaminase (ADA) genes into patients with ADA deficiency, a disease of the imnune system caused by mutations that prevent the patient from producing sufficient quantities of ADA (Walters and Palmer). Because SGT targets somatic cells, it probably will not transmit genetic changes to future generations as a result of the fact that genetic inheritance in human beings occurs through germ cells. However, there is a slight chance that an SGT protocol will result in an accidental gene transfer to germ cells, and that chance increases as one performs the experiment earlier in human development. For example, SGT administered to a developing fetus entails a significant risk of accidental gene transfer to germ cells (Zanjani and Anderson).

The goal of GLGT, in contrast, is to transfer genes into human germ cells to prevent the development of a genetic disease in a child who has not yet been born. A GLGT protocol for ADA deficiency would attempt to transfer normal genes into the parents' gametes or a zygote so that the progeny would have the correct gene and therefore would not develop the disease. Because GLGT targets germ cells, it is likely to transmit genetic changes to future generations; therefore, it poses far greater risks than does SGT. According to many authors and organizations, SGT can be morally justified but GLGT cannot because it is too risky. Thus, many clinician-scientists who saw the promise of SGT attempted to draw a firm moral boundary between SGT and GLGT.

After the first SGT experiments began, many writers made the case for crossing the line between somatic therapy and germline therapy (Zimmerman; Berger and Gert; Munson and Davis). Those writers argued that some germline interventions are morally justifiable because they promote medical goals such as disease prevention and the relief of suffering. Most of the approximately 5,000 known genetic diseases cause disabilities, premature death, and suffering. Although couples often can use nongenetic methods such as prenatal genetic testing and preimplantation genetic testing to give birth to children without genetic diseases, for some diseases germline therapy offers the only hope of producing a healthy child who is genetically related to the couple. For example, if a male and a female are both homozygous for a recessive genetic disease such as cystic fibrosis (CF), the only way they can produce a healthy child is to use gene transfer techniques to create embryos with normal genes (Resnik and Langer).

Therapy versus Enhancement

Many of the writers, clinicians, and scientists who defended genetic therapy also had moral qualms about genetic enhancement. In genetic enhancement the goal of the intervention is not to treat or prevent a disease but to achieve another result, such as increased height, intelligence, disease resistance, or musical ability. Thus, according to many authors, there is a moral distinction between genetic therapy, which is morally acceptable, and genetic enhancement, which is morally unacceptable or questionable (Suzuki and Knudtson; Anderson, 1989; Berger and Gert). Until society achieves a moral consensus on genetic enhancement, HGE protocols should not attempt to enhance human beings genetically.

By making these two fundamental distinctions, SGT proponents were able to obtain public approval of and funding for SGT experiments and dispel some of the fears associated with HGE. Under this twofold classification, SGT experiments were ethical and should be conducted but others types of HGE experiments were unethical or at least ethically questionable and should not be conducted.

Whereas the somatic versus germline distinction has stood the test of time, the therapy versus enhancement distinction has been criticized (Juengst, 1997; Stock and Campbell; Parens; Resnik, 2000a). Some critics of the second distinction argue that many genetic *enhancements* would be morally acceptable. For example, some day it may be possible to transfer disease-resistance genes to human beings. If childhood immunizations, which enhance the human immune system in order to prevent disease, are morally acceptable, what is wrong with *genetic immunizations*? It also may be possible some day to manipulate genes that affect the aging process. If nongenetic means of prolonging life such as organ transplants are morally acceptable, what is wrong with genetic means of prolonging life?

Other critics question the cogency of the distinction because it is founded on the concepts of health and disease (Parens). Therapy is an intervention designed to treat or prevent disease; enhancement is an intervention that serves another purpose. However, how should one define health and disease? Several decades of reflection on these concepts have not solved the problem (Caplan). According to an influential approach, disease is an objective concept that is defined as a deviation from normal human functioning that causes suffering and places limitations on a person' s range of opportunities (Boorse; Buchanan et al.).

For example, CF is a disease because patients with CF do not breath normally. As a result, they have a variety of symptoms, such as shortness of breath and a persistent cough, which cause suffering and interfere with physical activity. CF patients also usually die many years before the normal human life span of seventy-plus years. Thus, a genetic intervention designed to treat or prevent CF is therapeutic.

However, this approach has some well-known problems and limitations. First, social and cultural factors play an important role in delineating the normal range of values that define disease. For example, dyslexia is recognized as a disease in developed nations because it interferes with reading, but it does not cause that problem in a nonliterate society. An adult in the United States who is shorter than four feet tall is regarded as having a disease—dwarfism—but the same adult living in an African pygmy tribe would be regarded as normal. Modern psychiatrists recognize depression as a mental illness, but it was regarded as a lifestyle or bad mood a hundred years ago.

Second, social and political values affect the range of opportunities in society and therefore have an impact on diseases; societies choose who will be disabled (Buchanan et al. 2000). For example, if a person has an allergy to cigarette smoke, he or she would have a difficult time breathing in a society in which smoking is permitted in public places. That person may become disabled, and his or her condition therefore would be a disease. However, that person would not have those difficulties is a society that bans smoking in public. The allergy would not prevent that person from working or participating in public activities. He or she therefore would not be disabled and would not have a disease.

Third, health usually is not defined as merely the opposite of disease. According to an influential definition of health, "Health is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity" (World Health Organization [WHO]). This definition implies that some enhancements of human functioning are necessary to promote health because health is understood not only as the absence of disease but as an ideal state of functioning and flourishing. Thus, immunizations that enhance the immune system promote health, as do exercise regimens that enhance human musculature and endurance.

As a result of these and other problems with the therapy versus enhancement distinction, several authors have argued that it does not mark any absolute moral or metaphysical boundaries. One cannot equate *therapy* with *morally acceptable* or *morally required,* and one cannot equate *enhancement* with *morally unacceptable* or *morally forbidden.* To determine the moral justifiability of a genetic intervention in a particular case, one must assess that intervention in light of the relevant facts as well as moral values and principles such

as autonomy, beneficence, and justice (Resnik and Langer). Some writers who criticize the distinction nevertheless maintain that it may be useful in setting an agenda for policy discussions or for raising moral warning flags (Buchanan et al.).

Inheritable Genetic Modifications

In the early debates about germline interventions most writers viewed GLGT and GLGE as methods for transferring genes to human germs cells such as sperm, ova, and zygotes or to human germ tissues such as the testes and ovaries. A human germline intervention would be similar to a genetic engineering experiment in a mammal in that it would attempt to transfer a gene into the DNA in the chromosomes in the cell nucleus. Writers on both sides of the GLGT debate agreed that random gene insertion would be an extremely risky procedure and that targeted gene replacement (TGR) would pose the fewest risks to progeny (Resnik, Steinkraus, and Langer).

Several important scientific and technical developments in the 1990s challenged this way of thinking about genetic interventions in the germline. In 1997 the experiment that produced Dolly, the world's first cloned sheep, demonstrated that nuclear transfer (NT) techniques could be applied to human beings (Pence). In this procedure one removes the nucleus from a zygote and transfers a nucleus from another egg or a somatic cell to the enucleated egg. The resulting embryo has a donor nucleus combined with the cytoplasm of the recipient. An NT procedure, like a GLGT procedure, produces inheritable genetic changes. However, an NT procedure does not attempt to modify human chromosomes. Since the early 1990s scientists and scholars around the world have had a vigorous debate about the ethical and social issues of human cloning (Kristol and Cohen). Several European countries, including Germany and France, have outlawed all human cloning. At the time of this writing the United States was considering a ban on human cloning, although no bill has been signed into law.

While the world was debating the ethics of NT, researchers conducted a more modest form of genetic manipulation in human beings: ooplasm transfer (OT). OT already has resulted in over thirty live births (Barritt et al.). In OT one infuses ooplasm (the cytoplasm from an egg) into a zygote. The resulting embryo has its original nucleus and a modified ooplasm containing ooplasm from the donor egg. OT also produces inheritable genetic changes because it modifies DNA that resides in the mitochondria: mitochondrial DNA (mtDNA). Because the mitochondria facilitate many important metabolic processes in cells, mtDNA plays an important role in cellular metabolism. Some metabolic disorders are caused by mutations in mtDNA. Less than 1 percent of human DNA consists of mtDNA; the majority of human DNA, nuclear DNA (nDNA), resides in the nucleus.

Although OT experiments and NT experiments do not appear to be as risky as experiments that manipulate human chromosomes, they are not risk-free because they can result in a mismatch between nDNA and mtDNA known as hetereoplasmy, which can affect the expression of both nDNA and mtDNA (Resnik and Langer; Templeton).

Artificial chromosomes pose an additional challenge to the earlier paradigm because they would not modify the chromosomes but would carry genes on a separate structure that would be segregated from the chromosomes (Stock and Campbell). One reason for developing artificial chromosomes is to avoid tampering with existing chromosomes. However, because an artificial chromosome could carry dozens of genes, it would transmit genetic changes to future generations.

As these developments unfolded, scholars discussed ethical and policy issues related to NT, OT, and artificial chromosomes (McGee; Bonnickson; Pence; Robertson, 1998; Stock and Campbell; Parens and Juengst; Davis). Some writers suggested that it would be useful to develop a typology for different interventions in the human germline to allow a distinction between various techniques, procedures, and methods (Richter and Baccheta; Resnik and Langer). For example, some techniques, such as TGR, attempt to modify the nDNA in human chromosomes. Other procedures, such as OT, attempt to change the composition of mtDNA. One could classify these procedures according to the degree of risk they entail, with OT being *low-risk* and TGR being *high-risk* (Resnik and Langer).

In light of the scientific, technical, and philosophical developments that occurred after the early discussions of germline interventions, in 2001 a working group convened by the American Association for the Advancement of Science proposed that people use the term *inheritable genetic modification* (IGM) instead of GLGT or GLGE because it provides a more accurate description of the techniques and methods that have been the subject of so much debate. According to the working group, IGM refers to "the technologies, techniques, and interventions that are capable of modifying the set of genes that a subject has available to transmit to his or her offspring" (Frankel and Chapman, p. 12). Under that definition, TGR, OT, NT, and the use of artificial chromosomes all would be classified as types of IGM. IGM could include methods that are used to treat or prevent diseases as well as methods intended to enhance human traits.

Arguments for and against IGM

There is not sufficient space in this entry for an in-depth discussion of the arguments for and against applying IGM procedures to human beings, and so the entry will provide only a quick summary of those arguments (for further discussion, see Resnik, Steinkraus, and Langer; Walters and Palmer; President' s Commission; Holtug).

ARGUMENTS FOR IGM. The following arguments have been made in favor of IGM.

1. IGM can benefit patients by preventing genetic diseases as well as the disability, pain, and suffering associated with those diseases (Zimmerman; Berger and Gert; Munson and Davis). IGM also can benefit patients who will enjoy the effects of enhancements of health, longevity, intelligence, and so on (Stock and Campbell; Glover; Silver).
2. IGM can benefit parents by enabling them to have healthy children who are genetically related to the parents (Zimmerman; Robertson, 1994).
3. IGM can benefit society by reducing the social and economic burdens of genetic disease. Society also can benefit from IGM if enhancements of human traits increase human knowledge, productivity, performance, aesthetic experience, and other social goals (Harris; Silver).
4. IGM can benefit the human gene pool by enabling society to promote "good" genes and weed out "bad" genes. For a critique of this argument, see Suzuki and Knudtson (1989).
5. Parents have a right to use IGM to prevent genetic diseases and promote the overall health and well-being of their children (Robertson, 1994).

ARGUMENTS AGAINST IGM. The following arguments have been made against IGM.

1. IGM can cause biological harms to patients that result from genetic defects caused by IGM procedures, such as underproduction or overproduction of important proteins, the production of a protein at the wrong time, and the production of nonfunctional proteins. Although some procedures, such as OT, are safer than other procedures, such as TGR, IGM entails many risks that scientists do not understand fully (Resnik and Langer). IGM also could cause psychological harms to patients, who may view themselves as products of their parents' desires or as mere commodities (Kass, 1985; Andrews).
2. IGM could cause harm to a mother who carries a genetically modified child. For example, IGM might carry an increased risk of preeclampsia or complications during labor and delivery.
3. IGM could harm future generations. Because some genetic defects may not manifest themselves until the second or third generation, it may be difficult to estimate the potential harm to future generations (Suzuki and Knudson).
4. IGM could harm the gene pool by reducing genetic diversity, which is important for the survival of the human species (Suzuki and Knudston). For a critique, see Resnik (2000b).
5. IGM could cause harms to society, such as the increased social and economic burden of caring for patients with genetic defects caused by IGM, increased discrimination and bias against racial and ethnic groups and people with disabilities, the breakdown of the traditional family and traditional methods of reproduction, the loss of respect for the value of human life as a result of treating children as commodities, and the loss of human diversity (Kass, 1985; Kitcher; Kimbrell; Parens and Asch; Andrews, 2000).
6. IGM could waste health-care resources that could be better spent elsewhere (Juengst, 1991).
7. IGM could violate the rights of children, including the right not to be harmed, the right to an open future, and the right not be the subject of an experiment (Kimbrell; Andrews, 2000; Davis; McGee; Kass, 1985; Resnik, Steinkraus, and Langer).
8. IGM subverts natural reproduction and the natural human form (Rifkin; Kass, 1985). See Resnik, Steinkraus, and Langer (1999) for a discussion of this argument.
9. IGM is a form of "playing God" because people do not have the wisdom or the authority to design themselves (Rifkin; Kimbrell; Ramsey). See Peters (1997) for a critique of this view.
10. IGM is the vain pursuit of human perfection (Kass, 1985). See McGee (1997) for a critique of this view.
11. IGM is nothing more than a modern version of the eugenics movement (Kevles). It will repeat all the errors of the Social Darwinists and the Nazis (Kass, 1985). See Buchanan et al. (2000) and Kitcher (1997) for a discussion of this view.
12. IGM will cause social injustice by increasing the gap between the genetic "haves" and the genetic "have-nots." See Buchanan et al. (2000) and Mehlman and Botkin (1998) for further discussion of this argument.

Policy History

Many governments, regulatory agencies, and international bodies have taken a dim view of IGM. In the United States the National Institutes of Health (NIH) formed the

Recombinant DNA Advisory Committee (RAC) in 1975 to regulate and oversee recombinant DNA experiments supported by NIH funds. The RAC has the authority to regulate NIH-sponsored human gene therapy experiments, including IGM experiments. The RAC will not consider proposals for germline alterations because those procedures do not involve attempts to treat individual patients but instead involve attempts to change the genes passed on to future generations (Recombinant DNA Advisory Committee 1995).

The U.S. Food and Drug Administration (FDA) has the authority to regulate human experiments supported by private funds in the United States. The FDA sets ethical standards for human experimentation related to the development of new drugs, biologics, and medical devices. If a company wants to obtain approval of and market an item governed by the FDA, that company must submit data to the FDA that conform to its ethical guidelines. The FDA has stated that it has the authority to regulate human gene therapy as well as human cloning (U.S. Food and Drug Administration 2002a, 2002b). Although the FDA has not published a statement about its authority to regulate IGM, it would appear to have the authority to regulate any IGM procedures that involve new biologics, which could include human embryos. However, an important loophole in the FDA's regulatory authority is the fact that the agency does not have the authority to regulate assisted reproduction per se; it can only regulate drugs, biologics, and medical devices used in assisted reproduction. There are no federal laws and few state laws pertaining to assisted reproduction (Annas). It is possible that fertility clinics could perform IGM procedures such as OT or even cloning without any government regulation or oversight unless new legislation is enacted (Frankel and Chapman).

Outside the United States the Council for the Organization of Medical Sciences (CIOMS), the World Health Organization (WHO), and the United Nations Educational, Scientific, and Cultural Organization (UNESCO) have stated that the safety and efficacy of germline therapy must be evaluated thoroughly before any procedure takes place (CIOMS, WHO, and UNESCO). The International Bioethics Committee (IBC), sponsored by UNESCO, issued a report on human gene therapy that opposed germline manipulation at present as well as all forms of genetic enhancement (International Bioethics Committee). A group of advisers to the European Commission issued a report in 1993 that concluded that germline gene therapy is not ethically acceptable at the present time (Group of Advisors). Several countries, including Denmark and Germany, have banned germline gene therapy (National Bioethics Advisory Committee).

In the United Kingdom the Human Fertilization and Embryology Authority (HFEA) regulates and oversees IVF and infertility clinics. In 1998 the Human Genetics Advisory Commission (HGAC) and HFEA released a consultation paper opposing germline manipulation as well as cloning for reproductive purposes (Human Genetics Advisory Commission/Human Fertilization and Embryology Authority).

Professional societies also have not embraced IGM. The Council for Responsible Genetics (CRG), a genetics watchdog group, has opposed human germline engineering since the 1990s (Council for Responsible Genetics). The American Medical Association (AMA) does not oppose germline gene therapy, but it holds that genetic interventions should be limited to SGT for the present time. The AMA endorses genetic therapy but opposes genetic enhancement (American Medical Association). The American Society for Reproduction Medicine (ASRM) has not taken an official position on IGM but has called for a moratorium on NT until ethical and safety issues can be resolved (American Society for Reproduction Medicine).

Conclusion

It is likely that societies will debate the ethical and legal aspects of IGM for many years. The field of biotechnology is advancing so rapidly that interventions that were merely conceivable at the end of the twentieth century are fast becoming a practical reality. It is to be hoped that people will develop effective and well-balanced laws and policies pertaining to IGM before the first genetically engineered baby is born.

GENETICS AND ENVIRONMENT IN HUMAN HEALTH

• • •

All living things interact with multiple environments, both physical and biological. With regard to the flourishing of plants and animals, environmental features such as temperature, humidity, sunlight, and altitude often set boundaries crucial to development. Biological interactions between living things frequently are another major factor in growth and survival, for example, where parasites and predators cause illness or injure plants and animals. So it is with human health and flourishing as well, where environmental hazards and infectious diseases account for the vast majority of illnesses resulting in death.

The publication of Rachel Carson's *Silent Spring* (1962) and the subsequent emergence of a worldwide environmental movement has raised social awareness of the dangers to human health posed by industrial chemicals. Of the several million chemicals listed by the American Chemical Society, about 75,000 are used as pesticides, cosmetics, pharmaceuticals, food additives, or industrial agents. Most new chemicals must be tested for potential toxicity to humans and other living things before they can be approved for sale. In the United States, the Food and Drug Administration (FDA) requires extensive animal and clinical testing of new drugs, vaccines, and approved drugs proposed for new uses, as well as animal testing for food additives and cosmetics. Under various pesticide laws, including the Toxic Substances Control Act of 1976, the U.S. Environmental Protection Agency (EPA) also requires toxicity testing of new chemicals before they are brought to market. In addition, the Occupational Safety and Health Administration, Consumer Product Safety Commission, Department of Agriculture, Department of Transportation, and their state and local counterparts, each have additional responsibilities regarding the control of chemical agents.

These regulatory policies have done much to improve environmental quality and protect humans from industrial hazards. Nonetheless, individuals do not bear the burdens of environmental risk equally and vary remarkably in their responses to chemical exposures and pharmaceuticals. Such variation may reflect differences in sex, age, nutrition, lifestyle decisions to smoke cigarettes or drink alcoholic beverages, recreational exposures to similar chemicals, concurrent occupational exposures, and use of protective gear or

medicines. In addition, variation in individual response may reflect inherited differences in a person's ability to metabolize specific chemicals, thus affecting individual risks of disease and other adverse effects.

The products of the Human Genome Project are allowing new investigations of these inherited differences that appear to make some individuals more vulnerable to specific environmental exposures or more susceptible to environmentally-induced diseases. The study of these inherited differences and their potential influence on individual response to environmental agents is the subject of the field of ecogenetics.

Ecogenetics: Individual Variation in Susceptibility to Environmental and Chemical Agents

Ecogenetics examines how genes and environmental factors interact with each other to affect human health and disease. Genes are sequences of DNA in humans' twenty-three pairs of chromosomes in each nucleated cell. Genes specify the sequence of proteins, which are the main effector molecules of cells, serving as enzymes (catalysts), structural molecules (like collagen), antibodies to fight off infections, and binders of oxygen or xenobiotics (including pharmaceuticals or chemicals in the environment). Environmental factors include social and familial environment, intrauterine environment, cigarette smoking, alcohol, other substance abuse, stress, and exposures to chemical, physical, and biological agents. Some environmental exposures such as ultraviolet light, X rays, and certain industrial chemicals cause damage to DNA (genetic mutations), which alter gene function as well as the structure and function of the protein specified by that gene. Although many such mutations appear to be of little consequence, some may lead to disease.

There are many examples of gene-environment interactions combining to affect human health. Body weight and obesity, for example, appear to be the result of food intake, energy expenditure, and various genetic determinants. For infectious diseases such as malaria and tuberculosis, genetic features appear to affect both individual susceptibility and the severity of the illness. Another example is response to pharmaceutical products, where some drugs with limited side effects (at usual doses in most individuals) may cause severe problems for persons with genes associated with decreased capacity to metabolize the drug. Without exposure to the drug, however, these genetic variants may be innocuous. For example, cytochrome P450 enzymes form a family of dozens of related enzymes with distinct and overlapping characteristics. One specific P450 enzyme, debrisoquine 4-hydroxylase, has been associated with marked variation in the metabolism of more than thirty drugs.

Biochemical and molecular techniques are being used to develop new genetic markers of host susceptibility to environmental and chemical agents. To cause poor health, many chemicals must be activated by enzymes to intermediates that attack DNA (as appears to be the case in many environmentally-induced cancers and birth defects). Other enzyme systems detoxify potentially toxic compounds, and variation in the genes that specify the sequence of enzymes involved in these biotransformation steps can result in people with similar exposures having very different disease risks.

An example of this type of gene-environment interaction affecting health outcomes is deficiency in the enzyme glutathione S-transferase (GST), which is believed to be an important predisposing factor in the development of some environmentally-induced cancers. About 45 percent of persons of European ancestry lack detectable activity of a particular form of GST. Several studies examining GST levels in lung tissue suggest that GST-deficient smokers are at higher risk of developing lung cancer, presumably because this enzyme detoxifies carcinogenic chemicals. Thus, GST-normal smokers are partially protected against lung cancer. In addition, high GST activity is an important protective factor against liver cancer resulting from exposure to aflatoxin (a toxin from fungi that grow on peanuts and corn).

An additional example of this type of ecogenetic phenomenon is provided by variation in the liver enzyme N-acetyl transferase (NAT), which has been associated with marked differences in blood levels of several drugs, including the anti-tuberculosis drug isoniazid (at standard doses). Roughly 50 percent of individuals of European or African ancestry have the slow acetylator phenotype (the form of the gene and enzyme with lower metabolic activity) associated with higher levels of still-active drug and a propensity to adverse effects. The same detoxification mechanism metabolizes several other chemicals, including the human bladder carcinogens beta-naphthylamine, benzidine, and 4-aminobiphenyl—all former mainstays of the dyestuff industry worldwide. People who are slow acetylators are at higher risk for bladder cancer, as expected from the hypothesis that they would be less able to detoxify these potent carcinogens by acetylation to inactive products. DNA probes are available to assay this kind of genetic variation in peripheral blood cells, rather than having to administer a test drug and measure metabolites in urine.

Gene-environment interactions also can be seen in many other kinds of diseases, not just cancers. For example, the common organophosphorus pesticide, parathion, is

converted to its toxic intermediate, paraoxon, by the P450 system and then inactivated by a circulating plasma enzyme, paraoxonase. About half of individuals of European descent have low paraoxonase activity. For similar exposures, people with lower activity of this enzyme are likely to be at higher risk for neurologic toxicity and take longer to recover. High blood cholesterol levels are related both to diet and to inherited variation in several genes affecting the proteins that carry fat (lipoproteins) and their cell receptors. Cholesterol- and fat-reducing diets and drugs can reduce coronary heart disease deaths and heart attacks; however, responses to diet and drugs appear to differ among people with different genetic causes of high levels of fat components in the blood. Chronic anemias due to iron deficiency are a major health problem throughout the world. Although iron can be supplied inexpensively by fortification of flour, a small percentage of individuals carry genes (for types of anemia called thalassemias or for an iron metabolism disorder known as hemochromatosis) that cause these individuals to absorb iron excessively. These people might be injured by additional dietary intake of iron.

Integrating Genetic and Environmental Information in Clinical Research

The risks posed by exposure to chemical and environmental agents are related to the level of exposure, the intrinsic potency of the agent, and the susceptibility of the person exposed. In general, the highest exposures are in patients receiving potent drugs or radiation as medical treatments and in workers manufacturing or cleaning up chemicals in various operations. Therefore, it is logical and efficient to investigate potential risks to human health in patients and in workers with known exposures to specific agents. Studies of risks to the general population from contamination of groundwater or from air pollution, consumer products, or hazardous waste sites are far more difficult to conduct because the levels of exposure are typically much lower and thus the likelihood of identifying adverse effects is significantly reduced. In addition, although chemical exposures may cause immediate toxicity to the skin, eyes, lungs, heart, liver, nervous system, reproductive organs, or other target sites in the body, some effects may be unrecognized at first, including mutations in specific genes that may eventually lead to cancer or birth defects. Repeated exposures at relatively low doses also may have cumulative toxic effects that are difficult to identify. The challenge of establishing that impairment of brain function can result from lead exposure, for example, illustrates the difficulty of assessing the role of chronic, low-level environmental exposures in disease.

These considerations highlight the importance of ecogenetic research combining careful exposure-assessment studies with investigations of genetic influences on disease. Such a multidisciplinary approach is being explored in a coordinated manner through the Environmental Genome Project (EGP), a research initiative supported by the National Institute of Environmental Health Sciences, a component of the National Institutes of Health. The goals of the EGP are to: (1) identify some of the more common genetic differences between individuals that appear to affect response to environmental hazards; (2) conduct epidemiological studies investigating the role of gene-environment interactions in the development of common diseases like asthma, cancer, and heart disease; and (3) promote the use of information regarding gene-environment interactions in public health initiatives.

The EGP will develop in several stages. In the first phase of the project, experts will identify a set of approximately 500 genes that appear to play a role in the development of environmentally-induced diseases. These will include xenobiotic metabolism and detoxification genes, DNA repair genes, signal transduction genes, and genes involved in oxidative processes. Having identified a set of genes that appear to be involved in environmental response, the second phase of the project will catalogue common genetic differences in these genes—differences that may affect the functioning of the associated enzymes. Finally, in the third phase of the EGP, researchers will study the biological implications of these genetic differences using functional assays and population-based studies of gene-environment interactions. Organizers of the project expect that the first two phases of the EGP will be completed in late 2004. The third phase of the project will require significantly more time to complete, however, and will involve numerous epidemiological studies conducted over the next ten to twenty years.

Since many of the genes believed to play an important role in how humans respond to environmental hazards appear to affect health only in the presence of specific environmental exposures, deciphering the relationships that exist between genetic variants and individual response has the potential to improve public health significantly. Identifying those persons most at risk, for example, and encouraging them to avoid those environmental hazards to which they are most susceptible, may help prevent or delay disease onset in large segments of the population without pharmacological interventions. In addition, projects like the EGP might eventually lead to:

1. more accurate estimates of disease risks;
2. targeted disease-prevention strategies or medical-monitoring programs to detect disease earlier;

3. pharmaceutical products with fewer adverse effects; and
4. a better understanding of biological mechanisms of disease.

A great deal of work will need to be done to elucidate specific genetic risk profiles for environmentally-induced diseases as we move into the era of genetic medicine. In the meantime, both the population-wide approach that emphasizes environmental measures and the genetic approach that aims to identify individuals at increased risk are likely to be advocated. It is certainly prudent, for example, that everyone follow a diet that avoids excess fat, cholesterol, and salt. At the same time, genetic tests may soon be able to identify those persons at highest risk of developing coronary heart disease and high blood pressure. Taken together, these two strategies may provide a powerful approach to encouraging individuals to change their diets and lifestyles in ways that promote good health.

Ethical Issues in Ecogenetics

Although ecogenetics is still in its infancy as a scientific field, a number of important ethical considerations can be anticipated and should be addressed before genetic tests are used to screen individuals or populations for inherited susceptibilities to chemical or environmental agents. For example, long before the development of molecular genetics, J.B.S. Haldane suggested in *Heredity and Politics* (1938) that it might be reasonable to exclude persons who are susceptible to potter's bronchitis (a common problem among British potters at the time) from work in that occupation. Since workplace exclusion, stigmatization, and discrimination can result from knowledge of genetic risk factors for disease, studies of gene-environment interactions raise a number of ethical and social issues of great importance.

How one defines the extent of an individual's risk, for example, is an issue deserving of attention. Susceptibility to one kind of chemical may not predict susceptibility to chemicals with unrelated metabolism or structure. Thus, no one should be branded as "hypersusceptible" to chemical exposures on the basis of being identified as vulnerable to a specific environmental hazard or chemical. Since much confusion often surrounds the interpretation of genetic information, with laypersons frequently overstating the predictive value of a test, educational programs that aim to improve public understanding of ecogenetic tests will be critical to the long-term success of this new field.

Another issue that will be important to clarify for the general public is that, even after a genetic risk factor has been identified and is well characterized, the cause of disease in a specific individual often will be unclear. The well-recognized interaction of cigarette smoking with workplace asbestos exposure in causing lung cancer reveals some of the scientific uncertainties and ethical problems associated with assignments of disease causation in individual cases. The mere fact that a person has a gene that predisposes him or her to a specific disease—and then goes on to develop that disease—does not establish that the genetic susceptibility was the cause of the disease. Other genetic or environmental factors, for example, may have contributed substantially to the outcome.

Another ethical consideration is that since genetic differences sometimes occur with markedly different frequencies across racial or ethnic groups, targeted genetic testing programs could place disproportional burdens on members of some racial or ethnic groups. Related to this is the problem of group stigmatization, where social disadvantage results from the general association of a susceptibility gene with a particular racial or ethnic group.

Although tests for genetic predispositions to chemical and environmental agents could lead to targeted preventive approaches and improved assessments of individual risk, it is important that the future availability of such techniques does not diminish the commitment to eliminate hazardous environmental exposures. For example, the ability to identify genetic sensitivities to toxins in the workplace may inadvertently shift the focus of risk-management efforts away from the improvement of unhealthy environmental conditions if employers find it less costly to dismiss genetically sensitive workers than to eliminate workplace hazards.

In addition, the potential *geneticization* of environmental disease may inappropriately place unreasonable expectations on those persons with known genetic sensitivities. Individuals known to be particularly susceptible to the harmful effects of a particular chemical agent, for example, may face social pressures to remove themselves from those environments in which that chemical is found (e.g., to move to a different neighborhood or change jobs). Ironically, if we are successful in reducing environmental exposures to levels sufficient to protect most of the population, genetic differences between individuals will account for a larger proportion of the remaining risk among those exposed. This possibility could foster more deterministic attitudes regarding the significance of genetic information, for example, resulting in research funding being diverted from traditional preventive strategies for improving public health to approaches stressing genetic causes of disease.

Lastly, while genetic markers of susceptibility are being developed for use in healthcare settings, it is important to be

mindful of the possibility that information about gene-environment interactions may be used in other contexts before those associations are well validated. In this regard, a recent Equal Employment Opportunity Commission (EEOC) claim brought forth against the Burlington Northern Santa Fe Railroad Company illustrates the potential for not-yet-validated associations to be used inappropriately. The EEOC dispute in question involved the railroad company testing workers for an alleged genetic predisposition to carpel tunnel syndrome. Although the extent to which the gene in question may be a predisposing factor in the development of carpel tunnel syndrome is largely unknown, that did not prevent the company from attempting to use this information in their efforts to avoid responsibility for workers' compensation claims. Whether other employers will adopt similar practices based on new ecogenetic information is a matter to watch carefully in the coming years.

GENETICS AND HUMAN BEHAVIOR

• • •

I. SCIENTIFIC AND RESEARCH ISSUES

Interest in the possible effects of genetic inheritance on human behavior is a perennial one, with its modern roots

dating back the writings of Sir Francis Galton in the late nineteenth century. The issue is often framed as a debate over "nature versus nurture." After the "rediscovery" of the work of Gregor Mendel (1822–1884) in the twentieth century, the issue came to be couched in terms of genes versus environments and their respective influences on the organism, while more recently the talk has been of DNA and its role in relation to other causal factors. Themes revolving around genetics and environment are especially contentious when behavioral and mental traits (and disorders) are brought into the picture. This has been the case for views about the self and responsibility, as well as in society in general, where the specter of eugenics is quickly raised. According to the Nobel Laureate Thorsten Wiesel, "Perhaps most disturbing to our sense of being free individuals, capable to a large degree of shaping our character and our minds, is the idea that our behavior, mental abilities, and mental health can be determined or destroyed by a segment of DNA." The inflammatory appearance in 1994 of *The Bell Curve* by social scientists Richard Herrnstein and Charles Murray, which argued IQ is substantially inherited and may differ among races for genetic reasons, represents a major example of this social contentiousness. Another highly fractious example revolved around the University of Maryland's project on genetics and criminal behavior, and especially the September 1995 conference. The conference was strongly criticized by groups opposed to any inquiries into genetics and crime, and some of these groups' representatives invaded the conference and had to be escorted away by the authorities (Wasserman and Wachbroit).

The academic discipline that studies the effect of genetics on human behavior is termed *behavior genetics* or *behavioral genetics.* In addition to studying humans, this discipline has a long history of examining the behaviors of simpler organisms, including the round worm (*C. elegans*), the fruit fly, (*Drosophila*), and the common mouse (*Mus*), as well as dogs, primates, and many other organisms. The organized discipline began to coalesce from a wide variety of disciplines in the 1960s with the appearance of the first textbook in the subject, *Human Genetics* by John Fuller and Robert Thompson. The disciplines contributing to behavioral (and psychiatric) genetics included biology (including genetics), psychology, statistics, zoology, medicine, and psychiatry. Especially significant was the psychology of *individual differences,* which perhaps provided the main themes of the new subject (see psychiatric geneticist Irving Gottesman's 2003 article for a brief but excellent historical introduction and references).

In the realm of behavioral disorders and genetics, the years since 1970 have seen a shift from the view of psychiatric disorders being primarily environmental (due to poor parenting, for example) to the contemporary view that amalgamates both genetic and what are called *nonshared* environmental influences as major causal determinants of mental disorders. This has not been a shift without controversy, and it reflects broader shifts in psychosocial studies of the contributions of nature and nurture (Reiss and Neiderhiser). Further, though psychology has paid increasing attention to behavioral genetics, cultural anthropology and sociology have been strongly resistant to any genetic approaches (Rowe and Jacobson).

Major Methods of Studying Genetic Influences

Traditional genetics, of the type investigated by Mendel and his followers, was able to identify genes that had large effects and often displayed typical patterns, such as those involving dominant, recessive, or sex-linked traits. Genes that affect human behaviors and exhibit such patterns are well-known, including Huntington's disease (caused by an autosomal dominant mutation) and phenylketonuria, or PKU (a recessive mutation). Symptoms of Huntington's disease's include degeneration of the nervous system, usually beginning in middle age and resulting in death. In this devastating disease, there is usually a gradual loss of intellectual ability and emotional control. The genetic pattern is that of a condition caused by a rare, single, dominant gene. Since affected people have one copy of the dominant disease gene and one copy of a recessive gene (for a "normal" nervous system), half of their offspring develop the disease. Huntington's never skips a generation. Since the gene is dominant, the person who inherits it will manifest the disease (if he or she lives long enough). If one full sibling has the condition, there is a fifty-fifty chance that any other sibling will also get the disease.

In contrast to dominant conditions, recessive conditions show a very different pattern of occurrence. *Recessive* means that both copies of the gene must be of the same form (the same allele) in order to show the condition. Two parents, neither of whom shows a trait, can have a child affected by a recessive trait (this happens if both parents are carriers of one copy of the recessive allele—the child thus has two copies, one from each parent, and manifests the condition). Recessive traits can skip generations because parents and their offspring can carry one copy of the recessive gene and not display the associated trait. In the population there are many recessive genes that cause various abnormal conditions. Each particular recessive allele may be rare, but since there are many of them, their combined impact on a population can be substantial.

Among humans, a classic example of recessive inheritance is the condition of phenylketonuria (PKU). Individuals with PKU usually are severely mentally impaired. Most never learn to talk; many have seizures and display temper tantrums. PKU is a form of severe mental retardation that is both genetic and treatable. It is genetic in that it is caused by a recessive genetic allele. Without two copies of that particular allele, a person will not develop the set of symptoms, including mental impairment, that is characteristic of PKU. However, scientific knowledge has led to a treatment. It was discovered that the recessive PKU gene prevents the normal metabolism of a substance that is common in food, making many normal foods toxic to the individual with two PKU alleles. A special diet that is low in the offending substance can prevent or minimize the nervous system damage that leads to the profound intellectual disabilities of untreated PKU individuals.

The example of PKU demonstrates that inherited (genetic) conditions can be treated—that knowledge of specific causation can result in effective treatment. This is an extremely important point both ethically and philosophically, because it is often misunderstood and misinterpreted.

Well over one hundred different genes are known for which relatively rare recessive alleles cause conditions that include severe mental impairment among their symptoms. The rapidly developing knowledge of basic genetic chemistry, from molecular genetics to biotechnology and the Human Genome Project, which produced a mapping of some 30,000 human genes early in the twenty-first century on April 15, 2003, holds out the hope that many more of these devastating genetic conditions may soon be treatable. As part of the Human Genome Project, genes for Huntington's disease and PKU have been identified and sequenced, though as yet no new therapies have been developed for these disorders.

In spite of these clear scientific successes related to Mendelian genetic-pattern disorders, many human traits—including normal traits, as well as somatic, behavioral, and psychiatric disorders—have *not* exhibited clear Mendelian patterns of inheritance. For those traits, an extension of Mendel's work to quantitative traits that was first developed by Sir Ronald Fisher, has been used extensively. Beginning in the 1990s, an additional, more molecular, set of techniques was developed to examine possible influences of genetics on human behavior. These two broad approaches to studying the influences of nature and nurture in psychiatry are termed *quantitative* (or *epidemiological*) and *molecular*. A brief summary of the two approaches is presented here, including some examples of their results and their problems (an overview of them can be found in Neiderhiser and in Schaffner [2001], and a systematic analysis is presented in *Behavioral Genetics* by Plomin et al.).

QUANTITATIVE METHODS. Quantitative, or epidemiological, methods are utilized to distinguish genetic and environmental contributions to quantitative traits or features of an organism, as well as to assess correlations and interactions between genetic and environmental factors that account for differences between individuals. These methods do not examine individual genes, but report on proportions of differences in traits due to heredity or environment, or to their interactions, broadly conceived. The methods include family, twin, and adoption studies. Adoption studies examine genetically related individuals in different familial environments, and thus can *prima facie* disentangle contributions of nature and nurture. Twin studies compare identical and fraternal twins, both within the same familial environment and (in adoption studies) in different familial circumstances.

Twin studies have been used extensively in psychiatry to indicate whether a disorder is genetic or environmentally influenced, and to what extent. Twin studies make several assumptions to analyze gathered data, including that the familial environment is the same for twins raised together but different for twins raised apart, an assumption called the *equal environments assumption.* Though critics of genetic influence often question this assumption empirical studies have confirmed it (Kendler et al.). The example of schizophrenia may help make some twin results clearer. Employing what are termed *concordance studies* of twins, Gottesman and his associates have reported over many years that the risk of developing schizophrenia if a twin or sibling has been diagnosed with the condition is about 45 percent for monozygotic (MZ) twins, 17 percent for dizygotic (DZ) twins, and 9 percent for siblings (Gottesman and Erlenmeyer-Kimling). This concordance pattern supports what is called a non-Mendelian polygenic (many genes) quantitative trait etiology for schizophrenia with a major environmental effect (> 50%), i.e., more than half of the differences in liability to schizophrenia among individuals is due to environmental factors. Twin studies can also be used to estimate the heritability of a trait or a disorder, which for schizophrenia is about 80 percent. *Heritability* is a technical term, one that is often confusing even to experts, and one which only loosely points toward the existence of underlying genetic factors influencing a trait. Investigators note that "it does *not* describe the quantitative contribution of genes to … any … phenotype of interest; it describes the quantitative contribution of genes to *interindividual differences* in a phenotype studied in a particular population" (Benjamin et al., p. 334). If there are no interindividual differences in a trait, then the

heritability of that trait is zero—leading to the paradoxical result that the heritability of a human having a brain is virtually zero. Heritability is also conditional on the environment in which the population is studied, and the heritability value can significantly change if the environment changes.

Keeping these caveats in mind, heritability estimates for many major psychiatric disorders appear to be in the 70 to 80 percent range, and personality studies indicate heritabilities of about 30 to 60 percent for traits such as emotional stability and extraversion, suggesting that these differences among humans are importantly genetically influenced. But even with a heritability of schizophrenia of about 80 percent, it is also wise to keep in mind that approximately 63 percent of all persons suffering from schizophrenia will have *neither first- nor second-degree* relatives diagnosed with schizophrenia, reinforcing the complex genetic-environmental patterns found in this disorder.

Twin studies were also the basis of a distinction between *shared* and *nonshared* environments. The meaning of environment in quantitative genetics is extremely broad, denoting everything that is not genetic (thus environment would include *in utero* effects). The shared environment comprises all the nongenetic factors that cause family members to be similar, and the nonshared environment is what makes family members different. Remarkably, quantitative genetics studies of normal personality factors, as well as of mental disorders, indicate that of all environmental factors, it is the *nonshared* ones that have the major effect. A meta-analysis of forty-three studies undertaken by psychologists Eric Turkheimer and Mary Waldron in 2000 indicated that though the nonshared environment is responsible for 50 percent of the total variation of behavioral outcomes, *identified and measured nonshared environmental factors* accounted for only 2 percent of the total variance. Turkheimer infers that these nonshared differences are nonsystematic and largely accidental, and thus have been, and will continue to be, very difficult to study (Turkheimer, 2000). This possibility had been considered in 1987 by Robert Plomin and Denise Daniels but dismissed as a "gloomy prospect"—though it looks more plausible.

Epidemiological investigations have also identified two important features of how genetic and environmental contributions work together. The first, genotype-environment *correlation* (GśE), represents possible effects of an individual's genetics on the environment (e.g., via that individual's evoking different responses or selecting environments). Such effects were found for both normal and pathological traits in the large Nonshared Environmental Adolescent Development (NEAD) study, described in detail in the 2000 book *The Relationship Code,* written by David Reiss and colleagues. Secondly, different genotypes have different sensitivities to environments, collectively called genotype×environmental *interaction* (G×E). Differential sensitivity is important in many genetic disorders, including the neurodevelopmental models of schizophrenia genetics and in a recent study on the cycle of violence in maltreated children (discussed later).

MOLECULAR METHODS. Classical quantitative or epidemiological studies can indicate the genetic contributions to psychiatric disorders at the population level, but they do not identify any specific genes or how genes might contribute (patho)physiologically to behavioral outcomes. According to psychiatric geneticist Peter McGuffin and his colleagues, "quantitative approaches can no longer be seen as ends in themselves," and the field must move to the study of specific genes, assisted by the completed draft versions of the human genome sequence (McGuffin et al., p. 1232). In point of fact, a review of the recent literature indicates that most research in behavioral genetics, and especially in psychiatric genetics, has taken a "molecular turn."

It is widely acknowledged that most genes playing etiological and/or pathophysiological roles in human behaviors, as well as in psychiatric disorders, will *not* be single locus genes of large effect following Mendelian patterns of the Huntington's and PKU type discussed earlier. The neurogeneticist Steven Hyman notes that mental disorders will typically be heterogeneous and have multiple contributing genes, and likely have different sets of overlapping genes affecting them. Mental disorders will thus be what are called *complex traits,* technically defined as conforming to *non*-Mendelian inheritance patterns.

There are two general methods that are widely used by molecular behavioral and molecular psychiatric geneticists in their search for genes related to mental disorders: (1) linkage analysis, and (2) alleleic association. Linkage analysis is the traditional approach to gene identification, but it only works well when genes have reasonably large effects, which does not appear to be the case in normal human behavior or in psychiatry. Allelic association studies are more sensitive, but they require "candidate genes" to examine familial data. An influential 1996 paper by statisticians Neil Risch and Kethleen Merikangas urged this strategy.

Studies in schizophrenia are again illustrative of these approaches, as are the Alzheimer's disease genetic studies reviewed later. Though there was an erroneous 1988 report of an autosomal dominant gene for schizophrenia on chromosome 5 that is seen as a false positive, evidence has been accumulating for genes or gene regions of small effect related to schizophrenia on many chromosomes, including 1q, 2, 3p, 5q, 6p, 8p, 11q, 13q, 20p, and 22q (Harrison and

Owen). Replication difficulties with these results in different populations of schizophrenics and their families have been a recurring problem, however.

Environmental Research and the Envirome

It is clear from epidemiological studies that more than half the variance of typical behavioral traits, as well as half of the liability for psychiatric disorders (including schizophrenia), is environmental. This has fueled major searches for various environmental causes. In schizophrenia, this work has been reviewed by Ming Tsuang and his colleagues, who note that the major environmental risk factors in schizophrenia are due to the nonshared environment. These include problems in pregnancy (e.g., pre-eclampsia) and obstetric complications, urban birth, winter birth, and maternal communicational deviance. Thus far, *identified* predisposing environmental factors have small values in comparison with genetic risk factors. Using a term coined in 1995 by James C. Anthony, Tsuang et al. have proposed that the entire *envirome* needs to be searched for extragenetic causes of disorders, including schizophrenia. These factors are believed to affect susceptible genotypes, involving G×E interactions.

Though evidence for susceptibility genes for major mental disorders continues to accumulate, there has been no strongly replicated result that might be used in diagnosis or in early detection and prevention interventions. Of all the *psychiatric* disorders that have been investigated to date by genetic strategies, only Alzheimer's disease (AD) provides both a classical Mendelian etiological picture and complex trait patterns, and thus can function as a concrete prototype for psychiatric genetics and for research on genetic influences on human behavior in general. There are three Mendelian forms of early-onset AD, due to dominant mutations in genes APP, PS1, and PS2. The strongly replicated APOE4 locus associated with late-onset Alzheimer's disease (LOAD), in contrast, is a *susceptibility gene,* neither necessary nor sufficient for the disease. The APOE4 and APOE2/3 alleleic forms also interact with other genes and with the environment. APOE alleles 2 and 3 appear to protect individuals with the APP mutation (Roses). Other susceptibility genes for LOAD continue to be investigated. a possible locus on chromosome 12 has been identified, and one was reported in 2000 on chromosome 9 (Pericak-Vance et al.; Roses).

Cognitive Abilities and Intelligence

Though there are more data about the inheritance of intelligence than about any other complex behavioral characteristic of humans, the word *intelligence* is viewed even by the proponents of IQ testing as misleading because it has too many different meanings. IQ researchers seem to prefer to use the expression "general cognitive ability," represented by the letter *g* (Jensen; Plomin, DeFries, et al., 2001). The notion of substantial genetic influences on individual variation in *g* or "intelligence" remains controversial even after almost a century of investigation.

Most investigators in behavioral genetics view the level of intellectual functioning (abstract reasoning, ability to perform complex cognitive tasks, score on tests of general intelligence, IQ) as a strongly heritable trait. In 1963, psychologists Nikki Erlenmeyer-Kimling and Lissy Jarvik summarized the literature dealing with correlations between the measured intelligence of various relatives. After eliminating studies based on specialized samples or employing unusual tests or statistics, they reviewed eighty-one investigations. Included were data from eight countries on four continents spanning more than two generations and containing over 30,000 correlational pairings. The overview that emerged from that mass of data was unequivocal. Intelligence appeared to be a quantitative polygenic trait; that is, a trait influenced by many genes, as are such physical characteristics as height and weight.

The results did not suggest that environmental factors were unimportant, but that genetic variation was quite important. The less sensitive trait of height (or weight) can be used to illustrate this distinction. It is well known that an individual's height can be influenced by nutrition, and inadequate diets during development can result in reduced height. The average height of whole populations has changed along with changes in public health and nutrition. Yet at the same time, individual differences in height (or weight) among the members of a population are strongly influenced by heredity. In general, taller people tend to have taller children across the population as a whole, and the relative height of different people is strongly influenced by their genes. This also appears to be the case with intelligence. The Erlenmeyer-Kimling and Jarvik survey data suggest that about 70 percent of the variation among individuals in measured intelligence is due to genetic differences. The remaining 30 percent of the variation is due to unspecified (and still unknown) environmental effects.

Two decades later, in 1981, Thomas Bouchard and Matt McGue at the University of Minnesota also compiled a summary of the world literature on intelligence correlations between relatives. They summarized 111 studies, 59 of which had been reported during the seventeen years since the Erlenmeyer-Kimling and Jarvik review. Bouchard and McGue summarized 526 familial correlations from 113,942 pairings. The general picture remained the same, with

roughly 70 percent of normal-range variation attributable to genetic differences and about 30 percent due to environmental effects.

However, researchers examining the behavioral genetics of cognitive ability estimate the heritability of *g* (or IQ) as substantially lower, about 30 to 35 percent. Statisticians Bernie Devlin, Michael Daniels, and Kathryn Roeder argue that the much of the difference between the high and low heritabilities can be accounted for by a substantial maternal environmental component. As in the height and weight example above, there is also a substantial general environmental component that increased IQ scores by about 30 points between 1950 and 2000. This is known as the Flynn effect (see Flynn).

Robert Plomin and colleagues have attempted to identify specific genes or gene regions, also known as quantitative trait loci (QTLs), that influence IQ. Though there has been one publication reporting an IQ-related gene (see Plomin, Hill, et al.), replication has not yet been forthcoming.

Much is known about the genetics of mental retardation and learning disabilities. The most common single causes of severe general learning disabilities are chromosomal anomalies (having too many or too few copies of one of the many genes that occur together on a chromosome). These genes may reside on additional chromosomes, for example trisomy 21 (an extra chromosome 21, or three instead of the normal two) is the cause of Down's syndrome, and the "fragile X" condition may by itself account for most, if not all, of the excess of males among people with severe learning disabilities (Plomin, DeFries, et al., 2001). A large number of rare single-gene mutations, many of them recessive, induce metabolic abnormalities that severely affect nervous system function and thus lead to mental retardation. Because the specific alleles involved are individually rare and recessive, such metabolic abnormalities can cause learning-disabled individuals to appear sporadically in otherwise unaffected families. The new field of molecular genetic technology holds a promise of future therapeutic regimens for many learning disabilities.

Personality Studies

Dimensions of personality tend to be familial (Benjamin et al.). Modern studies of twins and adoptees suggest that for adults, some major dimensions are influenced by differences in family environments, while some are not. For the dimension of extroversion, which encompasses such tendencies as sociability and impulsivity, genetic factors account for about 30 to 60 percent of the variation among adults, with about 50 percent of the variation being environmental in origin. But, surprisingly, none of the variation among adults appears to be related to environmental differences within families.

For neuroticism, which taps such traits as anxiousness (a characteristic state of anxiety), emotional instability, and anxious arousability (a tendency to react with anxiety to events), about 40 percent of the adult variation appears to be caused by genetic differences, and again none of the variation is from environmental differences that are shared by members of the same family. In contrast, social desirability, which measures a tendency to answer questions in socially approved ways and to want to appear accepted by and acceptable to society, does not show evidence of genetic causation. Essentially all of the measurable variation in social desirability appears to be environmental, with about 20 percent due to family environment.

Some authors, including Robert Plomin and colleagues, the authors of *Behavioral Genetics* (2001), suggest that because extroversion and neuroticism are general factors involved in many other personality scales or dimensions, most of the others also show moderate genetic variation. For example, a twin study involving eleven personality scales found genetic influence of various degrees for them all (Tellegen et al.). On average, across the eleven personality scales, 54 percent of the variation was attributable to genetic differences among the people, and 46 percent to environmental differences.

Tendencies toward affective (mood) disorders, including psychotic depression and bipolar disorder type I (manic depression), also are clearly influenced by genetics. A lack of familial co-occurrence has established the separateness of schizophrenia from the affective psychoses. Unipolar depression and bipolar affective disorder do co-occur, and there may be a genetically influenced major depressive syndrome distinct from manic depression. The affective disorders probably include a diversity of genetic conditions.

Other Traits

Although data are sparse for many traits, modern studies are revealing genetic involvement in many conditions of importance to society. Plomin and colleagues point out that, for males, the best single predictor of alcoholism is alcoholism in a first-degree biological relative. Alcoholism clearly runs in biological families. Severe alcoholism affects about 5 percent of males in the general population, but among male relatives of alcoholics the incidence is about 25 percent. The incidence remains about the same for adopted-away sons of male alcoholics. However, biological children of nonalcoholics

are not at increased risk for alcoholism when raised by alcoholic adoptive parents.

Behavioral and psychiatric geneticists have studied genetic influence on antisocial behavior and adult criminality. Studies tend to report that shared environment is more important as a cause in juveniles and that genetics plays more of a role in adults (Lyons et al.). These studies have been extremely contentious, however (Wasserman and Wachbroit). Since the early 1990s several molecular studies of genetics and violence have also emerged, two of which are cited here. In 1993 Hans Brünner and his group reported on a Dutch family with a missing gene on the X chromosome which governed the monoamine oxidase A (MAOA) enzyme, an enzyme that metabolizes some key neurotransmitters (Brünner et al.). The Dutch families' males exhibited an unusual number of antisocial behaviors of varied sorts (assaults, rape, arson, etc.). Males, lacking a second X chromosome, were more vulnerable to the effects of this mutation. The mutation was subsequently determined to be extremely rare, and behavioral geneticists largely lost interest in the MAOA gene. In August 2002, however, a major study involving about 1000 New Zealand families found that a less severe MAOA gene mutation had a significant effect on males' display of antisocial behaviors, including their being convicted for violent offenses (Caspi et al.). But the antisocial behaviors only appeared in those subjects (in as much as 85% of them) who had experienced abuse during childhood, indicating an important G × E interaction effect of gene with environment. This carefully designed study is yet to be replicated, but it has received widespread attention.

Both twin and adoption studies that indicate obesity is highly heritable, probably about 70 percent (Grilo and Pogue-Geile). In addition, a large adoption study of obesity among adults found that family environment by itself had no apparent effect—in adulthood, the body mass index of the adoptees showed a strong relationship to that of their biological parents, but there was no relationship between weight classification of adoptive parents and the adoptees. The relation between biological parent and adoptee weight extended across the spectrum, from very thin to very obese. Once again, cumulative effects of the rearing home environment were not important determinants of individual differences among adults (Stunkard et al.).

Philosophical and Theoretical Perspectives

Biologists, psychologists, and philosophers have engaged in high-level theorizing about the effects of genes on traits in general and on human behavior in particular. Perhaps the most vigorous and ongoing discussion has been generated by a variety of papers and books that can be loosely characterized as a "developmentalist challenge" to the separability of genetic and environmental contributions to an organism's features (Schaffner, 1998). Over the years, the biologist Richard Lewontin's views have been particularly influential in this regard. Similar views critical of an overemphasis of genetic influence on traits have been articulated by several other scholars (see *Cycles of Contingency* [2001], by Susan Oyama, Paul Griffiths, and Russell Gray, which presents a number of contributions to "developmental systems theory" [DST]). Thus far, DST has largely been directed at critiquing DNA priority in molecular developmental and evolutionary claims, and at recommending more epigenetic-driven research. It is conceivable that as DST develops further, it will be applied more specifically to the relation of nature and nurture in a number of psychiatric disorders.

Integrated Approaches

Some recent articles suggest that research integrating quantitative and molecular approaches with neuroscientific strategies will be the most fruitful way to provide a framework for genetic and environmental effects on organisms. Reiss and Neiderhiser recommend an "integrated" approach. In their 1991 book *Schizophrenia Genesis*, Irving Gottesman and Dorothea Wolfgram envision the future promise of neuroscience programs to assist progress in schizophrenia. The increasingly important neurodevelopmental perspective approach to schizophrenia has been championed by Tsuang and colleagues and implemented in recent papers from the Pittsburgh group (Mirnics et al.). In addition, a series of ethical issues have arisen in neuroscience that mirror many of those first generated by behavioral genetics, including issues of reduction, determinism, and responsibility. A new term, *neuroethics,* has been coined to describe these issues (Marcus).

The completion of the draft mapping of the human genome has led to a realization that the next stage of inquiry into examining human behavioral traits, and both somatic and mental disorders, will need to be very complex, involving functional genomics, proteomics (the study of proteins and their effects) (Pandey and Mann), and enviromics (Anthony). These will be difficult and complex projects that will also need to attend carefully to developmental issues, since most human diseases, including psychiatric disorders, probably represent the culmination of "lifelong interactions between our genome and the environment" (Peltonen and McKusick, p. 1228). Animal models will be helpful here, as will new technologies using DNA genetic chips, also known as *microarrays.*

Conclusion

There are diverse methodological approaches to studying the effects of genetics on human behavior and in relation to psychiatric disorders. The working out of the partitioning of genetic and environmental causes and their interactions at multiple levels of aggregation in complex systems, as humans are, will require many research programs extending over many years, hopefully producing a number of useful interim results such as those discussed above. These results, however, will not silence the continuing debates over the roles that genes and environments play in the complex choreography of organism development and behaviors.

II. PHILOSOPHICAL AND ETHICAL ISSUES

Behavioral genetics has been a focus of intense controversy both within and outside the field almost from its inception. Much of the controversy within the field involves conceptual and methodological issues such as the question: Do twin studies yield the most scientifically reliable conclusions about the degree to which genes shape behavior? Rather than address those issues, this entry examines some of the social and ethical issues that may arise as a result of what researchers in behavioral genetics claim to know regarding the role of genes in shaping human behavior. Special attention is given to what may be referred to as the promise or the threat of eugenics, depending on one's philosophic perspective, as that relates to developments in the field.

Historical Background

Eugenics is characterized by the devising of interventions aimed at improving the quality of the human genome. Those interventions can be either social behavioral or molecular. In *The Republic* Plato recommended using the power of the state to arrange marriages of the best with the best. A practical problem with that approach is that it is a very crude and haphazard way to improve the human genome. Philosophical and scientific thinking for roughly the next 2,000 years was locked into Platonic and Aristotelian premises, specifically the belief that the *nature* or *essence* of each living thing is eternal and immutable. However, the emergence of evolutionary theory from the work of Charles Darwin radically undermined that premise.

The *immutable* natures of all plants and animals in fact have been changing constantly (or perishing) in response to environmental forces over millions of years. In the nineteenth century emerging agricultural sciences showed was that such change need not be left to slow and chaotic natural forces; instead, the tools of science could be used to effect deliberately changes that suited various human needs. Darwin's cousin Sir Francis Galton took the next logical step and suggested that deliberate reproductive control could be applied to human beings as well. In 1883 he started using the term *eugenics* to describe those efforts.

In the early part of the twentieth century the eugenics movement was endorsed by many prominent scientists, intellectuals, and political leaders (Kevles), including Charles Eliot, the president of Harvard University. Still, the tools available for eugenic purposes remained crude and ethically problematic. It is one thing, morally speaking, to create social practices that would encourage the marriage of the best with the best; it is quite another to use the coercive powers of the state to sterilize individuals who are judged unfit to reproduce "their kind."

In the early twentieth century enthusiasm for eugenics might be said to have reached a peak in 1927 with the U.S.

Supreme Court decision *Buck v. Bell.* Oliver Wendell Holmes there upheld the constitutionality of state sterilization laws with the ringing words "Three generations of imbeciles is enough!" The rise of Nazism and the appropriation by the Nazis of the rhetoric of eugenics to justify their atrocities resulted in a tarnishing of the eugenics movement in the middle part of the century. To this day those unsavory connotations remain attached to the term *eugenics.*

The second half of the twentieth century saw the discovery of the DNA molecule by Francis Crick and James Watson, followed by the very rapid development of genetics as a science and the dissemination of genetic insights and techniques into other areas of science, such as behavioral genetics in psychology. That effort culminated in the mapping of the entire human genome, beginning in the 1990s to April 2003. One consequence of those scientific successes is that eugenics has regained a considerable degree of scientific and moral legitimacy.

A primary reason for the renewed legitimacy is the fact that molecular biology offers the promise of tools that can achieve with great precision whatever eugenic goals *we* might embrace. Furthermore, the emphasis by advocates of the *new eugenics* is on the voluntary use of those tools by individuals as opposed to their forcible imposition by the state. In addition, the emphasis of advocates for eugenics is not on improving the quality of *the* human genome. Instead, that emphasis is individually therapeutic, as in traditional medicine. The dominant goal is to improve the lifetime welfare of future possible children who otherwise would be faced with genetic deficiencies that would compromise the length and quality of their lives. However, there are critics of all forms of eugenics, whether new or old, whether aimed at eliminating debilitating medical conditions or enhancing desirable human traits such as intelligence (Rifkin; Kass).

Eugenics: Some Broad Moral and Political Issues

Who should be the *we* that would have the moral authority to determine eugenic goals? Should this be part of the authority and responsibility of the state, or should such decisions be left to autonomous individuals? If people chose to invest that authority in a liberal democratic state, would careful adherence to legitimate democratic processes be sufficient to guarantee the moral legitimacy of the eugenic policies that emerged from those processes? If conscientious adherence to such democratic processes were insufficient, what extrapolitical norms could justifiably be invoked for purposes of assessing those processes and policies critically? What would be the source of the moral authority of those norms?

Alternatively, if the coercive powers of the state were judged to be problematic, especially with regard to intimate and personal matters such as the genetic endowment of children, eugenic goals could be left to the choices of individuals and the private organizations that would provide the means necessary for achieving those goals, such as genetic testing and alternative means of reproduction. This would be what Philip Kitcher refers to critically as "laissez faire eugenics." If such eugenic outcomes were both privatized and uncoerced, would that guarantee the moral and political legitimacy of those outcomes? Troy Duster thinks not. Or would a state be correctly judged to be irresponsible for allowing any and all voluntary eugenic decisions to happen in an entirely unregulated fashion primarily because the best interests of future children would be at risk?

These questions are raised in the context of a liberal, pluralistic, secular, tolerant democratic state that seeks to maximize the scope of individual liberty as long as that liberty is not used to threaten the equally valuable rights and liberties of others or undermine important public interests. This type of state recognizes that there are many reasonable visions of what it means to live a good life and that consequently a state must refrain from using its coercive powers to impose a preferred vision of a good life on those who would not choose it for themselves (Rawls). It is a state that will not allow sectarian religious preferences to shape public policy, especially if a policy is needed to guide intimate life decisions. Thus, critical religious appeals to the language of "playing God" will have little legitimacy as rational support for public policies that might be aimed at outlawing "private eugenic efforts" by parents to shape the genetic endowment of their children (Peters; Evans).

Eugenics: Some Policy Issues

A state that did nothing to regulate any of the medical technologies that might be used to shape or choose the genetic endowment of future children might be regarded as irresponsible. After all, one version of the argument might go, how can a compassionate and responsible society allow children to be born with serious medical disorders, such as cystic fibrosis or Tay-Sachs disease, that would very adversely affect the length and quality of their lives when that society has the technology to prevent such harm? Alternatively, how can a compassionate and responsible society allow genetic and medical researchers to experiment with alterations in the genetic endowments of embryos if there is any risk of significant harm to the children who eventually would be born?

Both of these questions suggest a necessary and legitimate role for the state in regulating the development and use

of technologies that have a eugenic purpose. However, that leaves unspecified the norms that justifiably could be invoked in a liberal pluralistic society for purposes of shaping both the content and the purpose of those policies. For example, should a compassionate and responsible society use tax monies to underwrite basic research aimed at providing the capacity to shape the genetic endowment of future children? This society already spends billions of public dollars each year through the National Institutes of Health to address an enormous range of human health problems, many of which have genetic roots. Alternatively, the genetic research that people imagine necessarily would involve the destruction of numerous embryos that were only a few days old. That would violate the deep moral convictions of many people in the society who are concerned about protecting all human life from the moment of conception. Are their concerns sufficient to take such public funding off the table?

If the destruction of embryos is a legitimate societal concern, less offensive policy options are available for achieving eugenic goals. There could be public funding for eugenic education. This could take many forms, but the general idea is that future parents would know what options were available to them for shaping naturally or technologically the genetic endowment of their children. A society could encourage widespread and complex genetic testing long before marriage by underwriting the cost of that testing so that individuals would be motivated to refrain from having children altogether, refrain from having children with partners who were genetic mismatches, or refrain from reproducing except through the use of an alternative reproductive technology.

Utopian Eugenics

The policy options cited above would come under the rubric of *utopian eugenics,* a phrase introduced by Philip Kitcher. That phrase is intended to suggest the desirability of a society pursuing a range of eugenic goals within the constraints of a liberal pluralistic political framework. Broad public genetic education and public support for access to genetic testing would increase the capacity of individuals to make autonomous eugenic choices regarding their own children in the light of their deepest values. Such public support also would demonstrate responsible but noncoercive regard for the well-being of future children who otherwise would be vulnerable to the profoundly harmful vagaries of the genetic lottery.

The word *harm* merits special emphasis in understanding the thrust of utopian eugenics. Kitcher and others are morally and politically comfortable with eugenic policies aimed at giving parents tools for preventing substantial genetic harm to their future children. However, many people (Parens) are less comfortable with eugenic interventions aimed at enhancing the genetic endowment of future children. This raises two questions, one moral and the other conceptual: Is there a significant moral difference between genetic interventions aimed at minimizing genetic harm and genetic interventions aimed at enhancing traits? Can a sharp conceptual distinction be drawn between what are called genetic harms and what are called genetic enhancements? These questions are discussed and analyzed thoroughly, along with their practical implications, by Allen Buchanan and coauthors.

Behavioral Genetics and Eugenics: Distinctive Moral Concerns

The questions raised above might be characterized as generic questions about eugenics. The examples used have all been about physical diseases with strong genetic links. However, the actual history of the eugenics movement has largely involved what today would be labeled behavioral genetics. That is, what those advocates wanted eliminated from the human gene pool were genes associated with being feeble-minded, lazy, alcoholic, violent, inclined to criminality, and so on. This raises a host of other moral and political and philosophic issues that are much more perplexing than the issues listed above.

If an individual has a gene variant that will result in affliction with cystic fibrosis or Huntington's disease or an early-onset form of Alzheimer's disease, such disease processes are seen to be accidental afflictions of that individual's body. Those diseases do not alter people's fundamental nature as persons, as rational moral agents. However, if an individual is feeble-minded (or a genius), alcoholic, or inclined to criminality as a result of his or her genetic endowment, this seems to be integral to his or her nature as a person, as a choice-making creature. It also raises the troubling question of whether individuals with such genetic endowments can be held accountable for the behaviors that seem to flow from those endowments. The argument, stated very crudely, would be that people do not hold individuals responsible for having cystic fibrosis; consequently, those individuals should not be held responsible for their criminal behavior if that behavior is just another product of their genetic endowment.

Other troubling social consequences may be associated with behavioral genetics. Genes seem to "travel" in clusters: Family resemblances are a common social phenomenon. Those resemblances also show up among members of ethnic and racial groups. None of these observations are intrinsically troubling. However, if a particular racial or ethnic group is perceived socially to have many members who are

less intelligent, more violent, more prone to engage in criminal activity, and so on, and if those undesirable traits are believed to be genetically rooted, those social groups as a whole will be vulnerable to serious social stigmatization.

The practical argument is obvious: If members of *that group* cannot benefit from social investments in education, why waste resources on *them.* In this way the worst social prejudices can be given scientific and political legitimacy as well as insulation from moral criticism. That is, if individuals in the disfavored group are denied various social opportunities, those denials can be justified morally on the grounds that those individuals are genetically incapable of taking advantage of those opportunities. This issue has been the focus of a political firestorm that initially was generated by Arthur Jensen and then reignited by Charles Murray and Richard Herrnstein.

Behavioral Genetics: Key Elements of the Science

Moral judgments about personal responsibility for behavior or social discrimination must take into account relevant well-established scientific facts. Thus, it would be morally wrong to hold an individual who is completely in the grip of psychotic delusions responsible for his or her behavior in the same way one does with a person with normal rational capacities and moral sensibilities. At least two popular beliefs associated with genetics represent a gross distortion of the actual science and an equally gross distortion of related moral judgments.

The first belief is that people's fate is in their genes, that the genetic endowment of an individual is a *future diary* of that individual. In other words, people's behavior is at least very strongly determined by their genes. The second belief is that for any biological fact about people there is a *gene for* that biological fact. Thus, if scientists look hard enough, they eventually will find a *gene for* depression, a high IQ, aggression, criminality, being gay, and so on. A headline from *Time* magazine (Lemonick) is illustrative: "The Search for a Murder Gene."

What is referred to colloquially as *the* Huntington's gene would reinforce both of these popular misconceptions. That is, if an individual has inherited this gene, it is almost 100 percent certain that that person will have the disease (although there is considerable variation in the age at onset and the intensity of the disorder). That person is fated in a very strong sense. No personal behavior and no environmental variables can alter that fate. However, this picture of genetic determinism seems to have an extremely limited range of application. No human behavior of even minimal complexity seems to be genetically controlled in that simple a fashion (Ehrlich and Feldman; Beckwith and Alper; Ridley; Schaffner).

This entry does not address the philosophic issues and arguments associated with the free will–determinism debate or the debates in the philosophy of mind about whether mental events are nothing more than mechanistic brain states. However, a review of core scientific propositions that would be endorsed by a wide range of behavioral geneticists and a linking of those propositions with core scientific propositions in the neurocognitive sciences probably would provide a better basis for identifying and addressing related moral and political issues such as the question of the possibility of moral responsibility.

The Nature of Human Nature

Steven Pinker is the author of a provocative book titled *The Blank Slate: The Modern Denial of Human Nature.* There are three "myths" he intended to undermine in that book: (1) the belief that human beings are born as blank slates (from the philosopher John Locke) that are shaped completely by experience, (2) the belief in the ghost in the machine (from the philosopher Renée Descartes), which holds that the mind is a nonphysical entity that is connected mysteriously to people's physical bodies, and (3) the belief (from the philosopher Jean-Jacques Rousseau) that human beings are born as "noble savages," that they are born morally innocent and corrupted later by social institutions. Pinker contends that none of these beliefs can be supported by contemporary science.

Pinker argues that human beings have a nature at birth, that what is referred to as the mind is really the human brain, that the architecture of the brain is the product of eons of evolutionary development, that very complex interactions among many genes (as well as complex environmental factors) are ultimately responsible for that brain architecture, and that the detailed architecture of the brain varies from one individual to another as a result of the genetic variation and environmental influences that distinguish individuals. This genetic variation among individuals includes both cognitive and emotional differences.

Pinker is comfortable with the idea that from birth some individuals are more shy or more outgoing than others, more happy or more depressed, more inclined to be socially conformist or to engage in antisocial behavior, more inclined to be forgiving or to erupt in anger, and so on. For Pinker the same thing is true with respect to the display of intellectual abilities. He sees all these behavioral predispositions as ultimately being rooted in the genetic endowment of each individual; this is why he rejects the notion that humans at birth are noble savages or blank slates.

Some people consider the picture Pinker has painted excessively deterministic and mechanistic, both eviscerating any basis for moral responsibility for human behavior and reinforcing deep social prejudices against certain racial and ethnic groups. However, that conclusion is not warranted. What Pinker writes (p. 48) and what generally would be endorsed by behavioral geneticists is the following: "Most psychological traits are the product of many genes with small effects that are modulated by the presence of other genes, rather than the product of a single gene with a large effect that shows up come what may." He goes on to note that the effects of most genes are probabilistic and that the environment often modulates the effects of particular genes in complex ways. This is why identical twins do not live identical lives.

Behavioral Genetics and Eugenics: Contemporary Ethical Concerns

In 2002 in Great Britain the Nuffield Council on Bioethics addressed these issues and reached essentially the same conclusions. That is, the council sees no reason why research in behavioral genetics necessarily yields a fatalistic picture of human life in general or an undermining of the human capacity for moral judgment and moral responsibility. The genetic endowment of individuals establishes a range of behavioral options and predispositions related to personality, but the precise way in which those predispositions manifest themselves in a particular individual is a complex product of environmental chance and the deliberative capacities of that individual.

Those deliberative capacities can be influenced for better or worse by the formal and informal social learning opportunities offered in particular social contexts. For example, an individual may have a genetic endowment that predisposes him or her to react depressively to a range of disappointments and frustrations. However, an individual who is reflectively aware of those behavioral predispositions as a result of diligent parenting, sensitive friends, or personal reading may adopt a range of psychological and behavioral strategies that minimize the potentially damaging results of those depressive feelings. Alternatively, that reflective awareness might suggest taking medications aimed at altering the brain chemistry that sustains those feelings of depression. In either case what is illustrated is a responsible reaction to what might be described as innate features of one's personality. Kay Jamison's struggle with depression, as recounted in *An Unquiet Mind* (1995), is illustrative of these points.

If the picture sketched here is roughly correct and if the work of behavioral geneticists does not undermine people's capacity to be responsible moral agents, are any other moral issues raised by this research? The work of the Nuffield Council (2002) is helpful in responding to this question. The council points to two large concerns that potentially raise moral issues: medicalization and eugenics.

The term *medicalization* typically is used to express a specific criticism: that what once was regarded as a normal behavior or bodily state now is regarded as abnormal because there are medical interventions that give people control over that behavior or state. Some people are *just shy.* This is a fact about some individuals that is accepted routinely. However, if antidepressants such as Paxil can alleviate such behavioral dispositions and allow individuals to be more sociable (per social expectations), such individuals may no longer be accepted as shy persons. Instead, they may be *diagnosed* as shy and advised (expected) to seek appropriate medical help.

There is no simple response to this issue. One legitimate fear is that the range of social tolerance for personality types and traits will be narrowed excessively to the detriment of such individuals. That is, those individuals may be subjected to excessive social scrutiny and social pressure to conform to a narrow range of socially acceptable behavior. This seems contrary to the core values of a liberal society. However, in other cases medicalization of behavior that once was regarded as normal may be beneficial to both individual and social welfare. Attention deficit hyperactivity disorder (ADHD) illustrates this point. Children who are identified as having ADHD benefit greatly from drugs such as Ritalin. The practical moral problem is that the behavioral and diagnostic boundaries of this disorder are fuzzy and controversial, and this can lead to morally troubling problems of overdiagnosis and underdiagnosis.

The other concern raised by the Nuffield Council is the eugenics issue. Dean Hamer and coworkers announced in 1993 the discovery of "the gay gene." Hamer later retracted that claim, recognizing that the basis for the sexual orientation of individuals is much more complex than the workings of a single gene. However, his original claim helped establish in the public mind that there soon may be a genetic test for "being gay" that would allow potential parents in the future to use preimplantation genetic diagnosis (PGD) to weed out gay embryos. Similar beliefs suggest that in the future it will be possible to pick out or create through germline genetic engineering smarter or happier or nonviolent or nonalcoholic embryos. This refers back to the eugenics issues that were raised earlier in this entry.

Those issues may be addressed more thoughtfully by recalling a key scientific claim about behavioral genetics. These types of behavioral phenomena are only indirectly the

product of very complex interactions among many genes as well as environmental factors, all of which are very poorly understood. Nobody knows which genes, in what way, to what degree, and at what point in development yield the neural capacities that establish a range of intellectual abilities. This is true whether one's concerns are with happiness, aggressiveness, schizophrenia, or addiction (Hamer; Beckwith and Alper). Furthermore, if society's legitimate social goals include shaping human behavior in various ways, there also are available as tools a very large range of social practices and medical interventions.

Behavioral Genetics and Eugenics: Some Ethical Guidelines

The Nuffield Council on Bioethics) has suggested several criteria for assessing from a moral point of view eugenic interventions aimed at improving behavioral outcomes: effectiveness, safety, reversibility, and choice.

If researchers discover genes associated with intelligence, it is likely that any one of those genes will have only very small and uncertain effects on the intellectual potential of an embryo. Consequently, embryonic genetic intervention to improve intelligence appears to be an ineffective approach. IQ scores as measured by standardized tests increased twenty to thirty points during the twentieth century. Clearly, that improvement did not result from radical genetic changes.

Safety must be a critical moral consideration, especially if the individuals whose behavior is to be affected do not have the capacity to give consent, as would be true for children and embryos. Giving Paxil to a moderately shy child may be morally objectionable when researchers are not certain of the long-term effects of that drug and the behavior to be altered is only moderately dysfunctional. Gene therapy would be problematic on this criterion for children or adults because there has been little success and some serious bad outcomes. The risks of gene therapy may be reasonable if individuals are faced with a life-threatening disorder, but that is not the case when the goal is behavioral alteration.

Reversibility is the third criterion the Nuffield Council emphasizes. It is difficult to imagine that anyone would want to be less intelligent, less happy, vulnerable to addiction, or more prone to violence. However, if researchers engage in behaviorally oriented genetic alterations, they may overshoot the mark: An individual could end up experiencing feelings of happiness in socially inappropriate situations.

The Nuffield Council notes that physicians are very reluctant to do genetic testing of children for medical disorders to which a child might be vulnerable as an adult and for which there is no medical intervention. The council recommends similar reticence if genetic tests related to what might be described as presymptomatic personality disorders were developed.

For example, a child might seem as happy as any other child in the neighborhood, but parental concerns about a family history of depression might motivate them to pursue genetic testing of that child for depression. That testing would yield no obvious good for the child but could put the child at risk for stigmatization or a maladaptive response from the parents. In addition, such nonsymptomatic nontherapeutic genetic testing represents a violation of the privacy rights and autonomy rights of that child. Also, assuming that the test identified a genetic pattern associated with depression in the child's family, everything known today would suggest that this represented no more than increased susceptibility for that disorder, not certainty that it would express itself or that its expression would be severe.

There are considerations of justice and the protection of fair equality of opportunity that are relevant to this discussion. Some writers (Silver) fear that differences in wealth will permit the rich to purchase a superior genetic endowment, especially with regard to valued behavioral traits, for their children, establishing permanently superior genetic castes. However, this is a plausible concern only extremely far into the future, if ever.

Still, there are relevant considerations of justice in the present that are related to improving the genetic endowment of future children (Fleck). Genetic testing in vitro of eight-cell embryos, or preimplantation genetic diagnosis, permits the selection of embryos that are free of certain serious genetic defects. However, this intervention costs about $40,000 per successful pregnancy. It seems reasonable to ask whether such interventions should be publicly funded as a matter of social justice and perhaps as a matter of genetic social responsibility as well.

Conclusions

Relative to scientific understanding and technical capacities in the field of behavioral genetics, fears of behavioral eugenics are exaggerated. People have very little capacity, using the tools of molecular biology, to alter with confidence the genetic endowments of future children.

No emerging knowledge in the fields of behavioral genetics and developmental biology or the neurosciences would justify concluding in a global fashion that human beings can no longer be held morally responsible for their

behavior because their behavior has been determined in a mechanistic fashion by their genes (Wasserman).

However, as knowledge of the behavioral sciences becomes more refined and certain, society will be forced to make increasingly nuanced judgments about the capacity for responsible moral action by individuals whose genetic endowment includes significant susceptibility to aggression or depression or other socially or medically deviant behaviors. That is, society will have no right to advance global assertions of moral responsibility by all individuals in all circumstances. In some circumstances moral or legal responsibility for specific actions will be diminished or eviscerated as a result of biological facts beyond the control of the individual.

A liberal society should accord substantial respect for the procreative liberty of potential parents, including their right to determine the genetic endowments of their future children. However, a responsible liberal society will take seriously its obligations to protect those children from embryonic behavioral genetic experimentation that would threaten their future capacities for autonomy or the future interests generally valued by all human beings. No simple moral algorithm can indicate how such balances should be struck in making public policy.

GENETICS AND HUMAN SELF-UNDERSTANDING

• • •

Genetics on the simplest level is the name of a class of problems of organic chemistry: how to name and describe the structure and function of the DNA that forms the core structure within the nucleus of all living cells. The particles of the molecule are arranged in a structure called the double helix, and this doubled form traces the function of the molecule and the transmission of data between generations of organisms as each is copied for replication. Scientists have come to understand and believe that genes, the smallest unit within that molecular system, direct chemical reactions that create larger proteins that drive the processes necessary for cell growth and cell death. Much remains to be discovered about *how* this occurs, but *that* it occurs—that proteins direct biological processes, and that they in turn are directed by genetic or epigenetic activity—is largely a settled question.

Why then, does the idea of genetics excite such controversy? The problem lies in what one makes of this genetic narrative, and how the epistemic task of genetics implies fundamental ontological and moral assumptions. Hence, the meaning of *genetics* is only partially addressed as a problem of scientific definitions. It also queries some of the most profound of issues in philosophy (such as the meaning of identity), social theory (such as the meaning of justice), and theology (such as the balance between imaginative human actions and proper human duties).

Genetics as Science and as Ontology: A Simultaneous Debate in Bioethics

Bioethics as a field grew contemporaneously and concordantly with genetics; bioethics began with speculation about the meaning of gene research (Jonson). Nothing has concerned the field of bioethics, a field largely marked by concern for the unknowable and speculative future implications of activities in the biological sciences and medicine, more profoundly than genetics. Genetics is a metaphor and a medical hope. It is at once a final cure for diseases, a prophecy for illness and for abilities, and perhaps a harbinger of troubling injustice when used as definitive of moral status. Genetic knowledge in the late twentieth century became the central way to make meaning of the single most contentious and heavily freighted problem in human self understanding, that of origins and kinship and the way that birth circumstance was or was not determinate of fate. As philosophy and theology has much to say about kinship, fate, and family, bioethics has much to say about genetic knowledge of the same issues.

There is long history of moral advice directed toward genetic science, stressing the profound dangers attendant upon the kind of knowledge that genetics presents. Genetic knowledge represents a powerful and new understanding of how basic biological processes can be expected to unfold relative to older systems of human understanding as presented in religious or moral traditions, and genetic knowledge can be destabilizing to these systems. Since the relationship between present states of being and the unknown future had, up until the late nineteenth century, been in the purview of magic, philosophy, or religion, the unease surrounding genetic knowledge is understandable—fate, behavior, and character are powerful grounds of contention in any case. Yet by the first years of the twenty-first century, the relationship between the science of genetics and the critique of this science began to be shaped by its own dynamics as well. Genetic knowledge itself began to stand in for modern scientific knowledge, for scientism, and for instrumentality. Bioethicists found a belief in genetic causation vexing, perhaps reductionist; this critique became a stable feature of the literature of bioethics. It was a hallmark of the debate: Researchers would describe new discoveries in genetic science, and bioethicists would describe the attendant dangers. This can be illustrated well in the first (1995) edition of the *Encyclopedia of Bioethics,* in which researchers (Whitney, Anderson and Friedman) delineate, with clear enthusiasm, the emerging science of the mapping of the human genome—at that point just begun as a project, and philosophers, (Flew, Shweder, Juengst and Walters) raise the specter of Nazis, insurance company misuse of information, "playing God," and making "designer babies."

Nearly a decade has passed since that edition, five decades from the first discoveries that lead to modern DNA research (Watson, Crick, 1953, Franklin) and three decades from the Asilomar conference on recombinant genetic methodology, in which ethical issues took center stage in genetic research (Soll and Singer, 1973.).

Despite dramatic changes in the scientific knowledge base over the last several decades of the twentieth century, and despite an emerging praxis of medical and agricultural genetics, many of the identical concerns about hubris and

post-human futures are persistently raised in bioethical discussions of genetics, and little of the original choreography of the debate has altered. Why this might be the case, and why bioethicists might find genetic knowledge to be fraught with a particular sort of meaning, is the subject of this article.

Knowing and Meaning to Know

Genetic knowing long has implied a moral sense, a way in which we could come to know, utterly, and with certainty, our human selves. Thus genetic testing becomes the first issue of concern, and remains one of the most troubling ones. Genetic testing is where the process of differentiation begins, and is the most direct and immediate way that genetic knowledge inserts into the particular and individual lives of most members of society. Genetic testing leads to application as soon as it leaves the realm of the laboratory, and its rationale is only evident in application. If humans are constituted in particular and tangible physical ways, and if one comes to understand particular facts as expressing the very truth of one's being (things like gender, or size, or impulse regulation), then knowing more precisely or more clearly who one is implies that one might know more precisely what to do. One might, through knowing who one is more exactly, know the scope of possible actions. This could produce knowledge about how to live morally, how to construct the artifice of social order with compassion, wisdom, and insight. Further, the self might well be altered as humans alter other species. If humans can alter our species in the way that we can alter other parts of the natural world once thought immutable, the question emerges: how can we do so in a just and thoughtful manner?

One can argue at this juncture that it has always been the case that all science involves this sort of venture of self generation, and many have noted that genetic knowledge is a matter of more facts amassed, as opposed to a greater interpretive power (Jonson). In this argument, genetic knowledge is not unlike the new understanding of gametes that took place in the middle of the 1800s, a form of understanding of human reproduction that implicated theology as well as science. The shift from Aristotelian notions of the beginning of life to theories first developed when lenses could be ground and microscopes constructed allowed a democracy of meanings to be attached to reproduction. Large shifts in understanding occurred throughout the seventeenth, eighteenth, and nineteenth centuries. Darwinian explanations marked ontological revolutions as well as epistemic ones, disrupting and destabilizing fixed philosophical, social, and theological ways of understanding nature and moral location.

Maynard Olson argues that the understanding and interpretation of the double helix is another such leap in self understanding, and a prelude to even more potentially destabilizing—or potentially liberating—ways of organizing human societies. If humans' sense of ourselves as both free and freely choosing rests on a detachment from our bodily selves, it will be likely come to be seen as mistaken. We are, in this genomic age, as much shaped by this understanding of ourselves as genetically capacitated as we are by the understanding of ourselves as having souls and psyches.

Assembling Knowledge

Genetics suggests a set of ideas about the nature, goal, and purpose of human life. It suggests, then, a definition of the self relative to the human location in the phenomenological universe. Like all science, genetic science suggests a method—not only a set of facts, but a way of ordering, framing, and using the facts. Genetics—with the goal of understanding a large and complex phenomena, organism, or mechanism—seems to demand understanding, defining, and naming all the parts of the thing, knowing the smallest discreet part of the whole, and knowing how the activities of each part connect. Hence, the task is to define the parts list and the function of each part, as a way of describing the activities of the phenomena. What genetic science threatens are not only the ideal forms, but the relationships and activities of phenomena in the actual, moving, and existing world.

The search for atoms and wave particles in physics parallels the search for genes and chromosomes in biology. Genetics functions on the basic idea that pieces of the whole need to be fully understood, and that a reconstruction of both the structure and functional pathways of each event within the whole is critical to the organizing principle itself: Parts determine the whole. Further, like all knowledge, the fulcrum of genetics lies against the notion that naming and defining creates being and allows for possession: Names determine relationships. To name a thing is to define its identity, and hence to identify it as a thing that can be owned, exchanged, used, bought, and sold.

Finally, like all knowledge, genetics is also about power and control (of the unknowable future, of the unknowable body, and of the unknowable other). Genetics understands itself by disassembly, through the knowing and naming activity, done primarily by mapping in the lab and testing in the clinic. It is a critical Hellenistic notion that making is knowing and in the creation of a "working parts list" and a "manual," one can know the essence of the thing (Peters, 2002). The idea that having a parts list then assumes assembly is both what is intriguing and troubling about the meaning of genetics (Fleishacker). At the beginning of the

twenty-first century, the hopes for the next logical stage—reassembly—were merely theoretical, yet the prospect of manufacture seems inevitable and troubling to many critics.

The result of such reassembly—a commodity without human connection, named as a clone or as a designer baby—haunts the field, and this specter transforms the debates about genetic testing into something far larger. It becomes a debate in which knowing *which one am I?* becomes a kind of knowing *who could I be?* In this scenario, if one creates an object rather than a human person, one could have an unjust power over the production. Hence, genetic knowledge, testing, and even basic research stands in for the clinical results of the research at its farthest reach. Meaning and mythos overcome actual science, as ethicists and society look at the next stage. The sense of the power behind the discourse has driven both the enthusiasts of genetic science and the catastrophists.

The concerns about the meaning of genetic knowledge center around five topical areas: issues of identity; issues of relationships and kinship; issues of health/illness, ability/disability; and issues of justice. Identity is at the core of reflections on human meaning. Of all the answers to this question of identity, it is perhaps the emerging research and applications of genetic information that offer a definitive response. After the human genome has been fully charted, it will be possible to answer the identity question with a set of mathematical coordinates, an identity bar code that would be distinctly individual. Genetics is, among many other things, a way to name and to describe the processes that make one distinctive and particular. An understanding of how DNA shapes the self unfolds within older contextual ideas about identity. In the words of many that describe the genetic mapping projects, knowing and naming can help us "crack the code of Life," or "tell us who we are and why we behave the way we do," or "explain our traits." The genetic explanation—not the reductionist causality of one gene making one behavior—allows an understanding that genes, proteins, and the environment complexly and intricately signal one another and hence "write" the narrative of human action. If genes and proteins and signals allow for differing levels of biological products in our bodies, and if we react with pleasure, anxiety, or disease to these products, then the horizon of possibilities against which all action is taken is in part suggested by the limits of our creaturely, molecular selves.

The idea that inheritable characteristics determine family ties is an old notion, but the idea that membership in a class of people is similarly determined is an idea that gained ground only in the eighteenth century, when colonial expansion raised the problem of inclusion of others into categories of science. Membership, and hence moral status and social privilege, became linked not to narratives of place, dress, or speech, but rather to something more tangible: the phenotype of persons. This physicality of how one knew what was valid, the linking of truth with the observation of physical facticity, transformed both the science and the polity of modernity.

Identity is paradoxical for Americans. It is a country premised on the idea that who you were does not matter; who your parents were was not the determinant factor in this new land. For many, the radical change in heritage would be the interruption of centuries of closed familial possibilities, and the possibilities of shifting identity that urban and industrial concentrations required. Yet the mutable, spontaneous and creative re-imagining of the self has collided with another narrative, that of a deeply pre-organized and highly structured internal code, a code which, for better or for worse, is passed between generations. Hence, Americans hold two things in tension—that we are free of all previous and unchosen commitments, and that we are increasingly to be understood as having our fate scripted into our very cells.

The Remembrance of History

Paradoxically, what grounds concerns about the speculative future of science is the past—what is called "the shadow of history" (Juengst). Given the emergence of bioethics directly after the trials of the Nazi doctors at Nuremberg, it is not surprising that there is hardly any account of modern genetics that does not begin with a detailed account of the classic tragic and paradigmatic slippery slope of bioethics—the passage of Germany's most imminent scientists from physiologic metrics, to behavioral genetics, to eugenics, mass murder, and torture based on Aryan racial science. The death camps of the Shoah were particularly horrific in their painstaking record on the "science experiments" on the imprisoned Jewish, gypsy, and homosexual subjects, conducted under the rubric of exploring the question of human difference understood as racialized genetic difference.

In the United States, most intellectuals of the Progressive Era held the assumption that breeding was linked to human behavior in the straightforward way that it was linked to animal behavior. Few doubted Francis Galton's extrapolation of Darwin's understanding of hereditary traits, and the widespread acceptance of physical and mental characteristics as hereditary—and thus subject to social engineering—was a feature of arguments from sources as disparate as American socialists and industrialist Henry Ford (Kevles and Hood). The measuring and mapping of the human body was driven by a need to account for conditions of vast social difference, emerging class distinctions made newly apparent by the industrial revolution and colonialism,

and to justify such social inequalities with seemingly natural and logical categories (Duster; Gilman). Marking the physical differences between individuals and groups implied a ranking of worth and of deviance; it further implied that danger could be logically eliminated from a world cleansed and purified.

Genetics understood as eugenics could be used as the justifying modern ideology both to encourage "good" (i.e., healthy, large, white, socially obedient, Aryan) births, and to eliminate "sickly" or "weak" (mentally or physically disabled) births and people. While it is clear that the ideas of inheritance, family resemblance, and hereditary have ancient textual and historical power, this marriage of science and tradition clearly amplified the ideology. Hence, fears of the widespread misuse of genetics and its linkage to a "science out of control" were largely formulated in the period 1845 to 1945. This period, and the eugenic sterilizations that peaked in the 1920s and 1930s in the American context (finally ending only in 1973 with *Valerie N. v. State of California*), delineates the concern: since genetics was code for the worst excesses of state discrimination, is not the past inevitable prologue?

Issues of Justice

The idea of difference implies hierarchy. Genetic testing is conducted to find and define the metric of difference from an agreed-upon norm. Critics of genetic testing raise two problems: first, that the idea of testing can be used unfairly as a basis for allocation of scarce goods, such as admission to competitive institutions or privileged social locations (jobs, professional schools, university); second, the very idea of a norm is an invalid one, and one that creates and reifies social hierarchies that destabilize democracy.

One new bioethical argument has been raised by disability advocates. They argue that genetic tests are an imperfect way of understanding humanity. Genetic testing, which notes allelic variation, can point to difference but is not sensitive to how the differences will express in any one human body, nor any one human circumstance or exposure. Further, genetic testing can alert one to differences but cannot alter the genome of the person tested. Used in the context of a prenatal test, each parent must decide if the pregnancy should proceed or if the different genetic code and its attendant disease will create a child with a disability so profound that such a child would be better off having never lived. Then, argue advocates for the disabled, if such a child's life is considered too burdensome, will such a judgment be fatally linked to disabled persons already born? Since at this point only the person and not the genetic disease can be eliminated, will this have implications for the moral status of the disabled community?

A second troubling aspect of a widening use of genetic knowledge lies at the other end of the possible curve of genetic endowment and the notion of the normal. If researchers could intervene to alter disease-causing genes, might science not go further to enhance traits labeled as desirable? Justice issues arise not only in the classic distributive sense—wealthy individuals and classes of individuals will have a unique access to the first uses of enhancements—but also in the deeper sense that genetic science might disrupt the social compact by introducing such different abilities.

The final issue of justice asks a different genre of question: Will increased genetic knowledge and use of genetic information and interpretation allow for healthcare that is more or less just? There are at least two possible responses. First, as noted above, enhancement or differential access to genetics could deepen differences, particularly if such changes are heritable, allowing a persistent benefit across multiple generations. But the very quality of genetics that allows for wide applicability may well mean that genetic methods could be both widely available and less beholden. Chronic conditions that could be cured would mean that certain types of drug therapies would not be needed. Justice, argue Alan Buchanan, Daniel Brock, and Norman Daniels (2000), becomes a matter of making just choices rather than adjudicating and adjusting the unfairness of a genetic lottery. Many critical aspects of the problem of justice are not different in meaning from other types of sophisticated, highly technological medical interventions such as organ transplants, chemotherapy, or implantable cardioversion devices, which allow for similarly vast differences between persons, countries, and healthcare system membership. Genetic medicine can seem to be paradoxically more unjust precisely because it has the potential to become far more widespread in application, and because of its heritable character.

Issues of Relationships and Kinship

Linked to the issue of identity are the issues of family, kinship, and citizenship. Increasingly, genetic identity is used as a way of describing these sorts of relationships. Families in earlier historical periods defined the boundaries of love and relationship. With each new genetic advance from in vitro fertilization to cloning, the question is raised about whether bonds of love and family would be severed, and in some extreme accounts, the question of whether both genders would be needed at all, as genetic materials that

carry identity could be disaggregated and reassembled at will, without regard to family bonds.

Genetic science made significant progress in the years around the turn of the twenty-first century. The Human Genome Project, which provoked concern in many bioethicists, had been largely completed by 2003, and many more genetic tests are available and even commonplace in prediagnostic use. Further, the field of population genetics has emerged as a new force in medicine, anthropology, and popular culture via genealogy. Genes and genetic testing have become a feature not only of the clinical world, but of the world in which families search for roots to their past history. The search for roots has long been a part of establishing authenticity, and in the twentieth century this search for roots became a popular staple of fiction and culture, with genetic testing kits to find ancestry available through the Internet. For many groups, searches for genealogy were linked to the larger project in which cultures that had been destroyed or threatened were remembered and preserved. Such endeavors are not without scientific grounding: genetic science has noted for years that predictable mutation rates allow for dating when populations reached bottlenecks, encountered plagues, etc. The Y chromosome is slow to change, and single nucleotide polymorphisms (SNPs) can be noted and interpreted and used as markers in human populations. Since each male inherits one Y chromosome from his father, the Y SNP model haplotypes can be and have been used to trace genetic origins.

Specific populations that have attempted to confirm their narratives of origin with genetic testing include the Melungians and the Lemba.

The Melungians are a group of related families in loosely-linked communities in the mountains of Appalachia, called a *tri-racial isolate* by social scientists of the 1930s who wrote the first ethnographic studies to describe them. The Melungians, though, have embraced an origin story that they are really lost Turkish sailors; they have enlisted the resources of the University of Virginia's genetics department to further these claims, and are supported by the Turkish government.

The South African tribe of Bantus called the Lemba, like other tribes in Africa, has claimed ownership of a narrative of Jewish heritage. The Lemba observe a practice curiously distinct from surrounding Muslim or African native traditions: they observe Sabbath, they have menstrual rituals, and they have a particular priestly caste—the Bubas—that hold significantly more leadership. In the case of the Lemba, DNA mapping tests have been preformed, and the distinctive Cohen haplotype occurs in the same frequency as it does in Ashkenazi Jewish populations; this is very suggestive of a valid claim of Jewish origin.

The question raised by these cases involves the idea of identity: After the genetic tests are completed, will the facts of genetics trump the narratives of inclusion? Will the genetic information disrupt the story and weaken the claim of inclusion, or will it strengthen it?

Identity and Authenticity

This new use of genetic testing has raised a series of intriguing questions. If genetics is what makes one a "real" Native American or a "real" Jew, then is the DNA self the authentic self? Increasingly, DNA testing does establish criminal identity, parentage, and paternity. At stake in this discourse is how one defines and creates identity. In reflecting on this problem, the work of Charles Taylor is useful. Taylor notes that modernity threatens an authentic sense of identity in several ways.

For Taylor, the sense of self is diminished by "three malaises." First is an increasing individualism, the idea that the conscience and the consciousness of the self is shaped by our attachment to freedom understood as autonomy from hierarchy, order, and authority. The self is understood less as a person within a social structure but far more narrowly, and this may well "flatten and narrow our lives, making them poorer in meaning, and less concerned with others or society." Genetic knowledge, in this view, portends an ever greater threat in this direction—it is not just the individual person but her *genes* that seem to direct the will. Taylor's second malaise is the cluster of fears about the use of instrumental reason, technology, and efficiency as both explanatory and justifying. For Taylor, who understands the usefulness and libratory possibility of technology, the critique is still important; he argues that devices, technological solutions, and a cost-benefit strategy will also "flatten" the moral self. Taylor's final concern is that a focus on the value of an atomized self, in a technological world driven primarily by instrumental reason, produces a world with less active citizenship and a diminished moral sense. If one understands that the condition of the world is such that it stands in need of healing and repair, and that medical genetics might well play a critical role in understanding and addressing many disease states, then one can turn to Taylor: "We are embodied agents, living in dialogical conditions, inhabiting time in a specially human way, that is making sense of our lives as a story that connects the past from which we have come to our future projects. That means if we are to properly treat a human being, we have to respect this embodied, dialogical, temporal nature" (p. 106).

For Taylor, the struggle to find the meaning of the authentic self is never fully completed or realized. He is not thinking here primarily of the problem of phenome to genome, but his model allows reflection on a similar set of issues.

Genetic identity is vexed by a concern that science is leading toward a post-evolutionary state, understood by bioinformatics professor Pierre Baldi as the result of an evolution and relationality that could be entirely planned on our collective behalf. If genetic codes and hence knowledge of the gene-protein-phenotype relationship is finite, it all potentially can be known. "[S]ooner rather than later we will know all the letters and genes in the human genomes, all the protein families, as well as their structures and functions … in many ways we are reaching the end of our evolutionary odyssey … All the things that have been created and molded by evolution stand a chance of being seriously challenged" (Baldi, 2003). Baldi's thoughtful optimism may be premature, as others have argued for a more iterative ethics, one that worries step-by-step about the actual thing one can do in science, rather than the problems created by a speculative future scenario (Olsen). Yet meaning is made through one's sense of journey and direction as much as by one's attention to the drama. One understands and makes meaning of genetic knowledge through attention to the past, and to the future, as well as to the present.

Philosopher Bernard Williams considers the novel by Nigel Dennis called *Cards of Identity,* in which "an organization, called the 'Identity Club' engages in making people over, giving them a new past and a new character—a new identity." Williams notes that the key feature in the process was the choice of a new name. For Williams, what matters for identity is the relationship between the many, or the type, and the one, or the particular. Existence can be discontinuous, and identity is not to be confused with role. One's role or social identity is constructed, always shared: "[I]ndeed it is particularly important that it is shared and an insistence on such an identity, (say, Native American) is an insistence on the way that it is shared, by 'social processes'." Williams argues that such an identity, if embraced, is "an aid to living." Here, Williams notes that social identity is understood to be causative: "thought to explain or underlie a lot of the individual's activities, emotions, reactions and in general, life. And such an identity, particularly, if chosen is a search for a sort of a homecoming." Williams argues:

> It is also typical of such identities that they are not just analogous to the classifications of nature, but closely related to nature … they seek to affirm and *origin*.… it is typical in such cases that they have some sense that they are not just opting for one group among others, but … finding something that was there; or coming home—one kind of obedience to Nietzsche's splendid instruction "become what you are." In such a case, what I have come to lies outside my will, something that is given, although I must choose to take it up. (p. 10)

Identity is political, and it is, for Williams, linked to the project of the Enlightenment itself—a project of understanding and discovery of what was there all the time.

Life in the Imagined Future

Can one, with the human genome mapped, the "parts list" on ready file—not only for humans, but for an increasing range of our favorite or feared animals, plants, and viruses—go beyond the familiar critiques? What does genetic knowledge mean for us now, that we in fact have lived through the calamitous times so feared by critics in the 1990s? What does it mean to think genetically? Is it different than how a philosopher would think in 1955, 1925, 1825, or 1155? What part of this is knowing that human genes make a series of proteins that control pathways of more protein-protein chemical reactions, allowing this author to create and the reader to read these words and allowing them to be seen and stored by other proteins in the neurons? Does it become merely another metaphor, akin to, for example, the culturally ubiquitous metaphor of the body that is formed of clay by a Master Potter's hand? Or does, it, as was predicted in 1995, "make us rethink many of our moral concepts and theories."

In part, moral concepts and theories have been revised with the acquisition of genetic knowledge. Parents and physicians are willing to understand and act on behalf of an embryo on the basis of genetic information alone: they terminate, complete, or choose a particular pregnancy based on prenatal genetic diagnosis. Courts and police find completely credible the notion that samples of DNA at a crime scene can prove that a particular suspect was there and use this to arrest and convict one person, or to free others.

But remarkably, given the level of concern, moral concepts appear to be remarkably resilient. While it is true that new reproductive techniques did change the variety of ways that pregnancies could be begun, the years around the turn of the twenty-first century also saw significant increases in adoption, including interracial and international adoptions, and the evidence that genetic material mattered more than other familial bonds was conflicted. Some of the advanced reproductive technology stressed genetic ties, but others (as in the use of surrogate eggs from young women implanted in older women, or the use of sperm banks) stressed gestational or non-genetic bonds as increasingly important. The last half of the twentieth century was notable

both for a deepening sense of ourselves as driven by genetic coding, and for a deepening sense of fundamentalist religious fervor, spirituality, and attention to alternative medicine—quite an unexpected paradox. Genetic rhetoric in the period just after the mapping of the human genome, rather than accentuating perceived racialized divisions, steadily and officially proclaimed our unity as a remarkably coherent human species with highly conserved genetic similarities to other organisms. It has became commonplace to understand that genetic codes matter a great deal, at the same time that it has become commonplace to add that the complexities of environment and epigenetic factors, chaos theory, and randomness also play significant roles.

Conclusion

History, even very recent history, can be held to up to the prognostic ability of bioethicists who reflect on the future and predict its course. How has bioethics as a field done, in this way, against the unfolding of the knowledge only speculated about in the 1990s? To be sure, few if any of the predicted catastrophic or euphoric scenarios have occurred in any empirical way.

Is it prudent to have concerns about the potential consequences of genetic knowledge? To be sure. It has been fears and not faith that have driven the thoughtful design of many of bioethical regulations. Fearsome events may well await us, but the trends have not been in that direction, as a review of the world since the 1990s teaches. To the contrary, the importance of families has not waned, nor have kindred and kind been neglected. Children, as families have chosen to have fewer children overall, remain highly valued, and the bond between generations seems entirely unaffected at least by genetic testing, although there has been increased vigilance in all matters genetic. A deeper sense of faith in the ethical and moral integrity of research and in the core duties of medical science may well be in order.

By 2003, there were new laws, and far more robust ones, that protect privacy and insurance misuse; there also existed national oversight bodies in most industrialized countries, and bodies at the international, national, state, and non-governmental organization (NGO) levels, to regulate or at least publicly examine genetic policies and techniques. Bioethics centers and ethics debate in general flourished at the beginning of the twenty-first century, despite new and pivotal research in genetics taking center stage in many science policy debates. The President of the United States, George W. Bush, made human embryonic stem cells the subject of his first public address, and the U.S. Congress debated the science and ethics of genetic policies, especially cloning and genetic modification. The ethical discourse about meaning and agency moved from the academic margins to the center of the debate. Decades after James Watson, Francis Crick, Rosalind Franklin, and Linus Pauling moved the chemistry that enabled the basic theory of genetics towards the modern intellectual project of genetic sequencing, and decades after computational and structural biology coalesced this sequence into a credible account of how human persons develop, few would claim a victory for an unreflective position in the debates about the influence of nature versus nurture.

The human genome, our *nature,* is clearly understood as responsive and interactive with the environment, adaptive yet constrained. Few can credibly deny the reality of the genetic-protein explanation of the physical world. It is, for now, the best account of the phenomenological terrain, and it is the text and tool that facilitates the exploration of the details and the variable of our human selves. Will we reach unbreachable ethical boundaries in this terrain? Will the "moral harm" that might exist become too dangerous to contemplate, and will the existence of moral harms outweigh moral duties to simply know and name as much about the world as we can? Are there horizons beyond which we cannot venture, and entities we ought not to know, mysteries that allow humanity to exist? Or have we a human duty to our human curiosity? Can one argue for a duty to heal and in the pursuit of the goal of healing, allow for all knowledge, and all pursuit, no matter where it might lead? Such worrisome questions remain, despite both increased regulatory efforts and a series of gravely sobering and stochastic human events. An article such as this can only hope to highlight competing moral appeals as they emerge in the literature of bioethics and in the literature of science—it cannot hope to solve the quandaries, and humility in prognostication about our genetic future, for good or for ill, would be a wise and prudent path. Genetic knowledge places us in a position of unprecedented choices—not yet about our final telos, but in a very real way, in a position to understand both the gravity and the temptations of the road we travel there.

GENETICS AND RACIAL MINORITIES

• • •

Advances in genetic research such as the completion of the Human Genome Project (HGP) have significant implications for the health of members of racial minority groups. Research on human genetic variation is anticipated to increase biomedical understanding of disease etiology and affect social and cultural meanings of race. In this entry the ethical implications of genetic research for the health of members of racial minorities are discussed. Racial minorities are defined as groups that historically have been identified by race and as a result have limited access to resources and opportunities. This entry discusses the implications of advances in human genetics for the understanding of race and ethnicity and the impact of racial categories on research into human genetic variation. It addresses the effect of these implications on the national priority to decrease health disparities among racial groups in the United States. Discussion topics include genetic determinism and reification of race, the protection of research participants and informed consent, and the distribution of benefits from human genetic research and its implication for justice in regard to the health and well-being of members of racial minorities.

Human Migration, Genetic Diversity, and Race

Since its genesis in the sixteenth century, the concept of *race* as a biological *kind* has been a focal point of debate (Boxill). Controversy over the use of the term has emerged in regard to the values that have been attached to groups identified by race and the characteristics that have been attributed to them. Throughout the twentieth century scholars consistently challenged the validity of biological differences between populations that were linked to race. Scientific research consistently has revealed that more genetic variation exists within than between populations (Lewontin). Despite this finding, race has become increasingly salient in understanding disparities in the health status of population groups and continues to be an important factor in both biomedical research and clinical medicine.

Central to arguments over race is a lack of agreement on its definition. In a manner that often is implicit, biomedical researchers and clinicians use a potpourri of surrogate concepts, including skin color, hair type, national origin, and citizenship, to identify race. This situation is complicated by the common practice of relying on self-reports, which often are based on factors that have little to do with biology. In addition, racial categories change over time and tend to be context-dependent, as is illustrated by the history of U.S. Census racial and ethnic categories (Lee et al.). Since the insertion of the term *race* into scientific discourse, the definition of race has been a moving target, and this has contributed to confusion about its meaning and implications for biomedical research and clinical care.

In 1996 the American Association of Physical Anthropologists issued a statement that included the following assertion: "Pure races, in the sense of genetically homogenous populations, do not exist in the human species today, nor is there any evidence that they have ever existed in the past." Although it acknowledges that differences between individuals exist, the statement emphasizes that those differences are the result of hereditary factors and the effects of natural and social environments. Genetic differences between populations result from the effect of the history of human

migration and reproduction and consist of a gradient of varying frequencies of all inherited traits, including those that are environmentally malleable.

Critical to comprehending human genetic variation is an understanding of the meaning of population genetic structure, which is best understood as the pattern of genetic differences among genomes, the full sets of human genes found in the nucleus of each cell. These genes are arranged linearly on chromosomes and consist of strings of chemical units called nucleotides (Weiss). The genome interacts with the environment to produce phenotypes, or all observable traits of individual appearance and behavior. Patterns within the genome vary across a species, depending on the history of mating within that species. The patterns or genetic frequencies of human populations have been affected by mutation, migration, natural selection, and random genetic drift to varying extents. These forces have resulted in the genetic variation that exists among human populations. Genetic differences between global populations do not map neatly onto the racial categories that have emerged through sociohistorical processes. Instead, race, defined by discrete group boundaries, serves as a poor proxy for the continuum of human genetic variation.

Racial Categorization in Human Genetic Variation Research

The completion of the HGP has resulted in new and well-funded themes of scientific inquiry in medicine. A central goal of human genetic research is identifying the genetic and environmental causes of human disease. Recent advances such as high-throughput genomic sequencing technology have increased the efficiency of large-scale rapid genotyping and ushered in a new era of genetic epidemiological research. This research has focused on the identification of single-nucleotide polymorphisms (SNPs). As was discussed briefly above, the genome is specified by the four nucleotide "letters" A (adenine), C (cytosine), T (thymine), and G (guanine) that form patterns. SNP variation occurs when a single nucleotide, such as an A, replaces one of the other three nucleotide letters: C, G, or T. SNPs are believed to be associated with individual differences in susceptibility to disease; environmental insults such as bacteria, viruses, toxins, and chemicals; and drugs and other therapies.

The search for these genetic clues has led to efforts to map SNPs and use that information to identify the multiple genes associated with complex diseases such as cancer, diabetes, vascular disease, and some forms of mental illness. For most SNPs, all populations have all the possible genotypes for a SNP, but populations may differ in regard to the frequencies of individuals with each of the different genotypes.

Although the location of SNPs is believed to hold the key to identifying the genetic basis for the onset of disease and influencing responses to drug therapeutics, it has been posited that SNPs do not travel independently. Instead, SNPs are located in what has been identified as blocks of alleles that are inherited as units. The patterns of the SNP alleles in those blocks are called haplotypes. Studies show that most SNPs are in haplotype blocks that have been transmitted for many generations without recombination. Because each block has only a few common haplotypes, identifying haplotypes eliminates much of the tedious work of attempting to find single SNPs that are correlated meaningfully with disease. In effect, the task of locating frequently elusive needles in the enormous haystack of the human genome has been mitigated by the knowledge that these needles, or SNPs, tend to be located in groups. It is expected that the 10 million common SNPs will be reduced to 200,00 to 300,000 tag SNPs that will signal the location of regions that affect disease more readily through genome scans.

To create a genetic test that will screen for a disease in which the disease-causing gene already has been identified, scientists collect blood samples from a group of individuals affected by the disease and analyze their DNA for SNP patterns. Next, researchers compare those patterns to patterns obtained by analyzing the DNA from a group of individuals not affected by the disease. This type of comparison, which is called a disease gene association study, can detect differences between the SNP patterns of the two groups, indicating which pattern most likely is associated with the disease-causing gene. Eventually, SNP profiles that are characteristic of a variety of diseases will be established. As part of that effort an increasing amount of research has called for the DNA sampling of individuals identified with specific racial minority populations. The collection of DNA samples has resulted in the racial categorization of genetic material stored in governmental and commercial genetic databases.

Scientific Racism and Eugenics: Cautionary Tales

In considering the ethical implications of race in human genetics research, it is prudent to review the lessons learned from the history of scientific racism in medicine. In the United States and abroad scientific racism has resulted in the exploitation of racially identified populations in the name of scientific and medical progress. Although science often has been portrayed as *value-free,* scientific theories have been used to support beliefs in the inferiority of racialized populations. Historically, race began as a biological taxonomy by which humans were categorized according to phenotypic

differences such as skin color and facial features and by supposed personality traits. Despite general rejection of such definitions, scientific research is at times compromised by a priori assumptions that build on notions of race as biology.

The term *eugenics,* which was coined by Francis Galton early in the twentieth century, has been incorporated into various state-sponsored programs around the world (Galton). The most notorious of those programs was guided by the German program of *Rassenhygiene,* or "racial hygiene," that led ultimately to the Holocaust. In the early 1900s the eugenics program was promoted through scientific organizations such as the Society for Racial Hygiene and the Kaiser Wilhelm Institute for Anthropology, Human Genetics and Eugenics. Later, when incorporated into Nazi ideology after the rise of Adolph Hitler, the racial hygiene program led to a broad spectrum of egregious scientific experimentation and the eventual extermination of millions of Jews, Gypsies, homosexuals, and other individuals deemed undesirable by the Third Reich (Weigmann).

During that period of state-sponsored racism, other nations, such as Great Britain, Norway, and France, were adopting their own brands of eugenics policies. Eugenics gave scientific authority to social fears and lent respectability to racial doctrines. Powered by the prestige of science, it was coupled with modernizing national projects that promoted claims of social order as objective statements grounded in the laws of nature (Dikotter). Unfortunately, history provides several examples of how the marriage of scientific racism and national political agendas has led to the unfair treatment of socially and politically vulnerable racial minorities. In South America, for example, eugenic policies have been the key to a national revival in which indigenous concerns over racially diverse and socially disparate societies have led to race-based initiatives to regulate human reproduction. Brazil and Argentina have experienced the use of science in the name of forging "superior and cosmic national races" (Stepans).

Perhaps the longest single study involving the exploitation of human subjects in medical research was the Tuskegee Syphilis Study conducted by the U.S. Public Health Service. The study, which was called the Tuskegee Study of Untreated Syphilis in the Negro Male, began in 1932 and did not end until 1972. The study involved the recruitment of over 300 black men with syphilis who were told by researchers that they were being treated for "bad blood," a local term used to describe several ailments, including syphilis, anemia, and fatigue (Jones). Those men did not receive proper treatment even after penicillin became available as an effective therapy in 1943. In exchange for taking part in the study, the men received free medical examinations, free meals, and burial insurance. The Tuskegee Study caused a public outcry that led the assistant secretary for health and scientific affairs to appoint an Ad Hoc Advisory Panel that concluded that the Tuskegee Study was "ethically unjustified" (Brandt). It is a "powerful metaphor that has come to symbolize racism in medicine" (Gamble) and a cautionary tale about the vulnerability of racial minorities in biomedical research.

Ethical Issues of Identifying Race in Genetics

The development of genomic research technologies has the potential for a dramatic enhancement of biomedical prevention and treatment of disease. Efforts to identify genetic mutations associated with disease may yield significant findings that uncover important clues to the onset of common diseases. Critical to these endeavors is a growing need to understand human genetic variation. In the absence of cost-effective ubiquitous genotyping technology, researchers have tended to favor population-based sampling. Strategies of using racially identified populations in the mapping of genetic markers, however, should be viewed with due consideration of the potential ethical implications of such research. Of particular concern are the potential for stigmatization and discrimination, informed consent, and distributive justice.

REIFICATION OF RACE: STIGMATIZATION AND DISCRIMINATION. Historically, race, genetics, and disease have been linked inextricably, producing a calculus of risk. Sometimes these associations are accurate, and sometimes they reflect underlying social prejudice. One risk in medical research is that any racial or ethnic identifiers used in human genetic variation research will come to be reified as biological constructs, fostering a genetic essentialism. This essentialism could obscure the fluid nature of the *boundaries* between groups and the common genetic variation within all groups.

An example is sickle-cell anemia, an autosomal recessive disease that is caused by a point mutation in the hemoglobin beta gene (HBB). It is a condition that has been racialized as a "black disease" in the United States. However, closer scrutiny reveals that the incidence of sickle-cell anemia is associated with zones of high malaria incidence, because carriers of that gene have some degree of protection against malaria. The condition is the result of human migration and the interaction of genes with the environment. Its emergence as a racial disease is an artifact of U.S. history. If the source of slaves to the Americas had been Mediterranean regions, where the incidence of the disease is also appreciably high, rather than from Africa, sickle-cell disease might have become known as a southern European disease. The reification of race results in such conflations.

Stigma and discrimination are potentially harmful consequences that are associated with the reification of race and genetic essentialism, particularly if curative measures are not available. Insurance companies and managed-care organizations in particular have an economic stake in controlling the potential costs of "high-risk" clients (Knoppers). In addition, social prejudice could arise in the identification of correlations between genes and disease. Race may be treated as an independent variable in the calculus of risk and result in real social harms for individuals in regard to the anticipation that they will fall ill.

INFORMED CONSENT: PROTECTING POPULATIONS. Harm from race-based genetic research may extend beyond the individuals at risk for a particular disease if targeted genetic testing implicates socially identifiable groups. Increasing attention to the ethical implications of research on human genetic variation has resulted in a shift of emphasis from individuals to "groups." The question of who should "consent" to genomic research demands a discussion of who are the potential victims of research-related harms (Kass and Sugarman). Although the informed consent process focuses on individual participants in scientific studies, risks stemming from population-based research may affect those who are not direct participants but are implicated by their identification with particular groups (Wilcox et al.; Faden and Beauchamp).

Acknowledgment of such harms has fueled a growing debate over whether individuals alone are sufficient to consent to research participation or whether others who subscribe to or are ascribed membership in a racial group also should participate in this process as potential victims of research (Greely). Several scholars and policy makers have advocated "community consultation," arguing that internal review boards (IRBs) should implement new mechanisms that supplement individual consent with group permission (Weijer; Foster and Sharp; Clayton). Others have countered that giving groups the moral authority to bestow informed consent is conceptually flawed and logistically confusing (Juengst). In dispute are the assumptions that (1) there is a singular, self-evident social body that represents a particular individual human subject, (2) that social body has the moral authority to *speak* for all the members of a particular group, and (3) consultation with that social body absolves researchers of responsibility for prospective harms.

Population-based DNA sampling and the identification of racial minorities in research on human genetic variation have broadened the debate over informed consent. At issue are the responsibilities of researchers and clinicians for preventing future harms associated with knowledge that links race, disease, and genes and the need for the participation of research populations in the scientific process.

DISTRIBUTIVE JUSTICE: THE PROMISE OF PERSONALIZED MEDICINE. The decision to identify race in human genetic research may have important ramifications for the establishment of research priorities that could have implications for helping exacerbate or ameliorate health disparities between groups. An example of such research is the field of pharmacogenomics. It is well recognized that most drug therapies exhibit wide variability among individuals in terms of efficacy and toxicity. It has been estimated that over 100,000 patients die and 2.2 million are injured annually by adverse drug reactions (Lazarou et al.). For many medications differences in reactions are due in part to SNPs in gene-coding drug-metabolizing enzymes, drug transporters, and/or drug targets. The ultimate goal of such research is to develop "individualized" drug therapy that will reduce adverse side effects and provide cost-effective medicines (March et al.)

The adoption of pharmcogenomics has serious implications for the practice of clinical medicine. The population-based approach to the marketing of healthcare products raises the possibility that drug development will build on and strengthen notions of racial difference. Furthermore, *racial thinking* may have ramifications for the perceived beneficiaries of pharmacogenomics research in that racially identified consumer groups may unduly dictate the scientific development of therapeutics. This may lead to a racial segmentation of the market in which drugs are directed at groups in a way that will increase the economic health of the companies investing in therapeutics.

In the unlikely event that genotyping becomes so common that patients are able to identify themselves in terms of the multitude of SNPs involved in disease gene associations and drug metabolism, human genetic variation research will continue to use racially identified populations. Genetic research offers the potential for significant progress toward the mitigation of health disparities between populations in the United States. However, history serves as an important reminder that every leap in scientific advancement must be tempered by careful consideration of its ethical implications.

GENETIC TESTING AND SCREENING

• • •

I. REPRODUCTIVE GENETIC TESTING

Reproductive genetic testing comprises a set of techniques for sample collection and analysis, the aims of which are to detect fetal anomaly. This article will describe the most important of these techniques and consider their bioethical aspects. This will include both those reproductive genetic technologies that are used in established pregnancies and preimplantation genetic diagnosis, performed before the establishment of a uterine pregnancy.

Methods for Obtaining Samples for Prenatal Diagnosis

Amniocentesis is frequently used synonymously with the term *prenatal testing*. Amniocentesis is in fact merely a technique for removal, via a needle puncture of the uterus, of amniotic fluid from the sac which surrounds the fetus during pregnancy. This fluid contains fetal cells on which analyses can be performed. The usefulness of amniocentesis is tightly linked to expanding knowledge about genetics, the development of techniques of fetal analysis, and changing legal and social norms.

In 1955, it was first demonstrated that fluid could be removed from the amniotic sac, that fetal cells could then be cultured, and that the total number of chromosomes—including the sex chromosomes—could be ascertained—a process called karyotyping. The first use of karyotyping was to identify male fetuses of women who carried serious genetic conditions on their X chromosome. However, this was initially of limited usefulness as no information other than fetal sex was obtainable, the safety of the procedure needed further investigation, and pregnancy termination for fetal anomaly was not legal.

The later finding that a karyotype showing three rather than two copies of a chromosome (trisomy 21) was indicative of Down syndrome presented the possibility of much broader use for amniocentesis. Not only was Down syndrome an important cause of mental retardation, it was also predicted by a pregnant woman's increasing age rather than by her genetic history. When, in the mid-1970s, a large study demonstrated the safety of amniocentesis (NICHD National Registry for Amniocentesis Study Group) at approximately the same time that the Supreme Court decision in *Roe v. Wade* made abortion legal in the United States, the way was opened to the population-based use of this technique for women of advanced maternal age.

Serious maternal complications from amniocentesis are rare; the primary medical risk of amniocentesis is fetal loss from the procedure. For this reason, the age, at which amniocentesis is routinely offered, is driven by an equation that looks for equipoise between the risk of procedure-related miscarriage and the age-related risk of Down syndrome. It is worth noting that one can infer from this equation an equivalence between the negative outcome of a fetal death and birth of a child with a disability, an equivalence which, as discussed below, would be contested from various positions critical of prenatal testing. Nevertheless, as rates of procedure-related miscarriage have decreased—due primarily to the use of real-time ultrasound to guide the needle—the age at which women are routinely offered amniocentesis has also decreased. At the beginning of the twenty-first century, it is standard of care to offer amniocentesis to women over age thirty-five.

Although amniocentesis is most closely associated with trisomy 21, any chromosomal abnormality can be detected through karyotyping, and the sample of fluid obtained can be used to diagnose any fetal anomaly for which a cytogenetic, biochemical, or DNA test has been developed (e.g., Tay-Sachs, sickle cell anemia, Huntington's disease).

EARLY AMNIOCENTESIS AND CHORIONIC VILLUS SAMPLING. Amniocentesis is performed in the middle of the second trimester of pregnancy. By this time, pregnant women have often experienced *quickening* (perceived fetal movement) and the fetus is nearing the age of viability. These factors have led to a search for earlier modes of fetal sample collection, including first trimester ("early") amniocentesis and chorionic villus sampling (CVS).

Although there was initial enthusiasm for early amniocentesis performed in the eleventh through thirteenth weeks of pregnancy, recent data suggest that this procedure may pose significantly greater fetal risks than traditional amniocentesis, including high rates of pregnancy loss and risk of fetal malformations (e.g., club foot) (Bianchi, 2000). In addition, early amniocentesis is more technically difficult and thus more often will fail to obtain a fluid sample adequate for cell culture. Enthusiasm for the procedure has waned, although it is possible that future solutions to these problems will revitalize interest.

Rather, it is CVS that appears likely to become the procedure of choice for earlier fetal sample collection. The chorionic villi are precursors of the placenta and have proved a good source of fetal tissue. CVS can be performed safely as early as the tenth week of pregnancy, either transabdominally or transvaginally; the risks have been found to compare well with second trimester amniocentesis (Bianchi, 2000). In addition, the waiting period for results following CVS is shorter than in amniocentesis—three to eight rather than ten to fourteen days. Since there is considerable documented anxiety for parents waiting for prenatal test results, this represents a significant advantage.

MATERNAL SERUM FETAL CELL RECOVERY. Both CVS and amniocentesis are invasive techniques. They share disadvantages of potential fetal harm and are relatively costly to perform. Thus, there continues to be interest in finding a non-invasive, less expensive technique that could be used to gather a fetal sample early in pregnancy. There is only one such technique on the horizon in 2003—maternal serum fetal cell recovery.

It is known that a small number of fetal cells are sloughed off and cross into maternal blood circulation. After isolation from a maternal blood draw, these cells can then be used for any desired fetal analysis. However, fetal cells are numerically rare in maternal blood and their identification and isolation is difficult. In addition, the type of cell most amenable to detection and isolation is not ideal for chromosomal analysis (Holzgreve and Hahn). Nevertheless, work on this technique progresses and a prospective multicenter trial of this technique as a screen for chromosomal anomalies began in the mid-1990s (Bianchi, 2002). Early results were promising for chromosome analysis, but the future goal of fetal cell recovery remains broader than this: To be able to perform not only analysis of chromosomal abnormalities, but to capture the larger number of fetal cells needed for DNA techniques. This goal holds the promise of genetic analysis for any disorder of interest.

Screening Tests and Diagnostic Tests

The above techniques are used for diagnosis in high-risk women. But almost all pregnant women are offered a variety of other prenatal screening tests.

Although the distinction quickly becomes complicated, in its simplest form, screening tests are offered to a population of apparently healthy persons in order to find those few at increased risk. Ideally, screening tests are easy and inexpensive to perform and interpret, and do not entail risk for the person screened. Screening tests have high rates of initial positive results and thus a large percentage of people who have positive screening tests will prove not to have the screened-for problem on follow-up diagnostic testing.

In contrast, diagnostic tests are offered to individuals known to be at increased risk of a condition in order to answer the question, "Does this person have this disease?" Diagnostic tests are generally more complicated and expensive to perform and interpret, and may entail risk. They are expected to have higher standards of sensitivity and specificity: to do a much better job at identifying all and only cases of the disorder.

The screening and diagnostic testing regimens typically offered to pregnant woman and couples at the beginning of the twenty-first century are presented in Table 1. Each begins by asking a question that assigns the woman to a risk level. It is important to realize that each screening test has its own percentage of initial positive results; thus, each additional screen raises the risk for any individual woman of getting an initial positive result at some time during pregnancy. In addition, these tests are not all done at the same time in pregnancy. For example, an African-American woman, less than thirty-five years old, would be offered carrier testing for sickle cell disease in her first trimester and would also be offered multiple marker screening in her second trimester.

MSAFP and Multiple Marker Screening

While amniocentesis for Down syndrome is perhaps better known, the test which truly revolutionized prenatal diagnosis was maternal serum alpha fetoprotein (MSAFP) screening, which became the first screening test offered to all pregnant women solely for the purpose of discovering risk for a fetal anomaly.

MSAFP screening was developed to detect neural tube defects (NTDs) in the fetus. NTDs comprise a set of defects involving the development of the brain and spine and leading to varying degrees of physical and cognitive impairment, some of which are incompatible with life; they are among the most common of serious birth defects. Finding fetal NTDs is complicated by the fact that over 90 percent occur to women at no known risk, making it necessary to offer testing to the entire population of pregnant women to detect any reasonable percentage of fetal NTDs.

Alpha fetoprotein is a substance produced by the developing fetus and present in maternal blood during pregnancy. In the early 1970's, it was found that higher than normal levels of MSAFP correlated with increased risk of fetal NTDs. This suggested the possibility of an inexpensive, minimally invasive, screening modality for NTDs (Brock, Bolton, and Monaghan).

In the 1980's, researchers linked lower than normal levels of MSAFP to Down syndrome and other chromosomal abnormalities, thus expanding the utility of the test (Merkatz, Nitowsky, Macri, et al.). Early pilot projects demonstrating the feasibility of MSAFP testing increased enthusiasm for it as a prenatal screening test, and the screening became firmly established as standard of care in the United States when an American College of Obstetrics and Gynecology "Legal Alert" warned obstetrical providers that failure to offer the test might leave them open to liability in the case of a baby born with a detectable anomaly (ACOG, 1985).

However, one concern about using MSAFP to detect Down syndrome was that it had much lower sensitivity and specificity for chromosomal abnormalities that it did for NTDs. When it was found that the addition of other biochemical markers improved the ability of the screen to predict Down syndrome, these quickly became added to the analysis. Most providers perform multiple marker screening, with a *triple marker* screen including human chorionic gonadotrophin and unconjugated estriol being the most common. Since all these analytes are gathered from the same

TABLE 1

Current Screening Practices

Screening question	Answer	Next Step	Next Step	Next Step
What is your age?	>35	Referral for amniocentesis/CVS		
Is there any genetic disorder in your family?	Yes	Referral for carrirer testing **or** amniocentesis/CVS *(Depending on characteristics of the disorder and the mode of genetic transmission)*		
What is the race/ethnicity/country of origin of woman (and partner)?	African-American	Offered sickle cell carrier testing	If both partners are carriers, referral for amniocentesis/CVS	
	Ashkenazi-Jewish	Offered Tay-Sachs (and possibly an Ashkenazi-Jewish panel, including, e.g. Canavan disease) carrier testing	If both partners are carriers, referral for amniocentesis/CVS	
	Southeast Asian, Greek Southern Italian	Standard blood work-up looking for anemia may be used to suggest need for a next step	Offered alpha or beta thalassemia carrier testing	If both partners are carriers, referral for amniocentesis/CVS
	European-American	Offered cystic fibrosis carrier testing; some places may make this offer to ALL pregnant women	If both partners are carriers, referral for amniocentesis/CVS	
Are you beginning prenatal care <16 weeks of pregnancy	Yes	Offered multiple marker screening	If result is positive HIGH, referred for ultrasound If result is positive LOW, referred for amniocentesis	If result is inconclusive, referred for amniocentesis
		Suggested one-age screening protocol		
Are you beginning prenatal care in the first trimester?	Yes	Offered PAPP-A screening, adjusted by maternal age, and ultrasound to assess fetal nuchal translucency	If joint results are positive, referred for amniocentesis	

SOURCE: Author.

blood sample, the test has not changed from the point of view of the pregnant woman.

One important aspect of multiple marker screening is that it cannot be done until the fifteenth week of pregnancy, and most women are screened at sixteen weeks and above. This means that diagnostic work-up for a positive test is done toward the end of the second trimester, and a woman who wanted to terminate a pregnancy based on the results of a diagnostic test would be facing a late second trimester termination.

Suggestions for a One-Age Screening Protocol

Since the 1970s, maternal age has been used as a screen for offering amniocentesis to pregnant women, with biochemical screening offered to younger women since the late 1980s. However, there is debate about these guidelines (see, for example, Rosen, Kedar, Amiel, et al.; Haddow, Palomaki, Knight, et al.; Pauker and Pauker; Egan, Benn, Borgida, et al.; Dommergues, Audibert, Benattar, et al.). This controversy seems to be based largely on the trend toward women bearing children at later ages (from 1974 to 1997, the United States has seen a 2.7-fold increase in live births among women ages 35–49) (Egan, et al.). This age increase means a dramatic increase in the number of amniocenteses performed, with concomitant procedure-related losses and economic costs.

The most radical suggestion for changing the routine is to screen women of all ages in an identical manner (see last row of Table 1). The most promising of such approaches include ultrasound measurement of the thickness of subcutaneous edema in the neck of the fetus (fetal nuchal translucency) combined with new types of serum marker

screening (e.g., PAPP-A). When these techniques are performed in the first trimester of pregnancy, and the results are combined with the risk based on maternal age alone, this regimen is believed to have an 80 to 90 percent detection rate for trisomy 21 and other chromosomal abnormalities (Nicolaides, Heath, and Liao). Although fetal nuchal translucency screening has not been accepted as standard of care, the American College of Obstetrics and Gynecologists stated at the end of the twentieth century that it shows promise (1999).

The advantages of a single screening modality for women of all ages are that it would decrease the number of amniocenteses in older women and, with these more sensitive screening modalities, also increase the detection rate in younger women. (In terms of raw numbers, younger women have the greatest number of affected pregnancies.) Several sets of modeling data suggest that with this approach the overall detection rate would improve and the fetal loss rates would decrease (Rosen, Kedar, Amiel, et al.; Haddow, Palomaki, Knight, et al.; Dommergues, Audibert, Benattar, et al.). The disadvantage, however, would be that, since amniocentesis has a virtual 100 percent sensitivity, some fetuses with Down syndrome that would have been detected through universal screening of women over thirty-five would be missed, and some women over thirty-five would bear a child with Down syndrome who would not otherwise have done so. The ethical, and political, debates concern the fact that a medical service that was accepted as a right for pregnant women of a certain age would be withheld from those same women unless they had demonstrated risk. This may well appear to be an unacceptable form of sudden healthcare rationing to older pregnant women.

It is also worth noting that none of these one-age screening models refer to the detection of neural tube defects, but rather appear to exist in a separate universe of consideration and calculation. Thus, they would not solve the problem of multiple screenings and multiple chances for initial positive results and concomitant anxiety.

Prenatal Screening and the Experience of Pregnancy

The advent of MSAFP screening transformed the experience of pregnancy for the *low risk* woman—that is, the great majority of pregnancies. As is clear from Table 1, it is possible for a woman to go through a period of waiting for results of one test only to then begin all over again with testing for another condition. For example, a thirty-year old Southeast Asian woman might have a standard blood workup that revealed anemia, be offered thalassemia carrier testing along with her partner, and, when both proved to be carriers, be offered CVS; she might have a negative result and then, some weeks later, be offered multiple marker screening and receive a positive result; she might then choose to undergo amniocentesis. All of this could produce a healthy baby and a disastrously upsetting and expensive pregnancy. There appear to be no empirical data on the frequency of such experiences. However, variations on this theme are frequently reported by obstetric providers.

General Ethical Issues in Prenatal Diagnosis

In addition to the issues involved in one mode of screening or another, there are overarching ethical issues that concern the entire project of prenatal diagnosis. These involve contestations over the meaning, experience, and implications of these tests. Specifically, there is a lack of clarity about the centrality of pregnancy termination to an offer of prenatal testing; whether testing resolves or creates maternal anxiety; and the relationship of individual reproductive choices to societal effect. This latter includes the effects of prenatal testing on those with disability and, more broadly, the relationship between prenatal screening programs and eugenics. Related to the latter is a question about the effectiveness of individual autonomous choice as a safeguard against eugenic abuses related to prenatal testing. All these issues affect and are affected by the lack of a mechanism for rational deliberative decision-making in the United States about why and which prenatal tests are developed and offered.

PRENATAL TESTING AND ABORTION DECISION MAKING.

The performance of any medical test is predicated on a hypothesis of benefit which defines the way in which the results of the test will lead to actions that help prevent disease or ameliorate its burden. Implicitly, the person whose disease burden is being ameliorated is the person being tested. Although it is everyone's hope that identification of a fetus with a particular condition will lead to prevention or cure of that disease, this is very rarely true today and the only way to prevent the fetus being born with the condition is through termination of the pregnancy.

Religious objections. From the viewpoint of conservative religious positions that object to abortion under all circumstances, the link of prenatal testing and abortion is clear, and offering women this choice is deeply objectionable.

Cost benefit literature. There is another body of literature in which the centrality of abortion decision making to prenatal testing is quite clear—literature that assesses the effectiveness of testing programs by comparing the economic costs of prenatal testing to economic savings. The costs include such items as sample collection, analysis, and

results communication; savings include monies not spent on medical care for children who would have been born with disability but instead are not born. One of the major variables in the equation is the minimum number of women who need to choose termination in order for the screening program to be cost-effective, assuming that not all women who test positive will go on to end the pregnancy. Thus, the calculation both acknowledges the autonomous choice involved in prenatal screening programs in the United States and the need for those autonomous choices to lean, in sum, in the direction of pregnancy termination.

However, most literature that discusses the benefits of prenatal testing talks about the reassurance provided about the health of the fetus for the large majority of women—those who test negative—and the chance for women or couples who choose not to terminate to prepare emotionally for the birth of child with a disability. Generally stated last is the enhancement of *reproductive choice* in the case of a positive test result.

REASSURANCE AND ANXIETY. The issue of reassurance and, conversely, anxiety in relation to prenatal testing has received considerable attention. Women themselves often cite *reassurance* as a benefit of testing. Much empirical research has focused on the issue of anxiety for that group of women who receive an initial positive result. These data suggest that women's anxiety is raised following a positive result but that, in general, this anxiety is relieved by a negative result. Data suggest that for some women, however, the anxiety persists, along with difficulty believing their fetus is healthy.

Some feminist critics also suggest an irony in which the reassurance provided by testing may be necessary, in great part, due to anxiety raised by the testing itself. In general, these critics claim that the expansion of prenatal testing has radically changed the experience of pregnancy and that while the number of fetal anomalies has, of course, not increased, the perception of risk among pregnant women has increased greatly.

INFORMATION PROVISION. Another aspect of prenatal testing, sometimes cited by theoretical literature and pregnant women as an advantage for those unwilling to terminate a pregnancy, is the opportunity to have time to prepare emotionally for the birth of a child with a disability. However, there are no empirical data demonstrating that advance preparation actually has an effect on adjustment to the birth of a child with a disability. In addition, the majority of women who receive positive results do terminate their pregnancies. Data suggest that close to 90 percent of women terminate following a diagnosis of a chromosomal disorder such as trisomy 21; the rate of termination for NTDs is more variable, reflecting the greater variation in the severity of the detected anomaly (Cragan, Roberts, Edmonds, et al.).

Thus, the most obvious advantage of prenatal testing must remain the ability to terminate a pregnancy which would result in a child with a disability. This suggests that the bifurcated conversation in the United States about prenatal testing—in which cost effectiveness calculations make assumptions which are omitted or contradicted in the clinical literature and most patient education materials—may make it difficult to have a societal conversation about the larger effects of prenatal testing on society.

The Effects of Individual Reproductive Choices on Society

In addition to advantageous or deleterious effects on individual women and couples, concerns exist about the effects of prenatal testing on society.

THE DISABILITY CRITIQUE. The most forceful critique of prenatal testing is that made by disability theorists (Parens and Asch). Their most straightforward claim is that prenatal testing represents "search and destroy" missions against those who would be born with disability and is, simply, a eugenic program. A more subtle disability critique states that the choice to abort an otherwise desired fetus on the basis of one trait or characteristic sends the message that the lives of those with disability are not valuable and that the disability makes the child unacceptable (Asch and Geller); this has been termed the *expressivist argument.* Objections to the expressivist argument share a skepticism about the ability of individual acts to constitute a message. Objections to the disability critique in general often point to the increasing societal protections of individuals with disability that have co-occurred with the growth of prenatal testing.

THE LIMITS OF AUTONOMY. The argument that prenatal testing is not eugenic and not disvaluing of living individuals with disability rests largely on the way that testing programs protect the autonomy of women's or couple's decisions in regard to the use of testing and test results. A central ethical issue, therefore, concerns the actuality and the limits of such autonomy. Specifically: Are women or couples making autonomous decisions in regard to prenatal testing? Can the aggregate effect of autonomous choices be eugenic? And, if they can, how problematic is this?

Are prenatal testing decisions truly autonomous? Individual autonomy is a foundational principle in Western bioethics, and there is virtually universal agreement that

women and/or couples should make informed decisions about the use of testing and should not be coerced into pregnancy terminations following a positive prenatal test. The disagreement that exists, therefore, is about the possibility and actuality of such autonomy.

On a narrow level, there is concern that women do not understand the implications of an offer of prenatal testing; this has led to attempts to improve the informed consent process. Yet empirical research suggests that such attempts are only partly successful in the prenatal testing arena, as is true of informed consent in general. Empirical data suggest that, especially *low risk* women who are offered prenatal testing in a context of routine prenatal care, are likely to conflate prenatal testing for fetal anomalies with tests which can directly benefit themselves and their fetus (Press and Browner). It is possible that this misunderstanding is enabled by healthcare providers who are likely to find greater liability risk in the woman who refuses testing and has a baby born with a disability than one who does not fully understand the implications of prenatal screening and participates regardless; it may also reflect a reluctance on the part of both providers and pregnant women to discuss pregnancy termination. Some critics suggest, however, that some women would not have started down the prenatal testing path if they had truly understood the implications in terms of pregnancy termination; they argue that this may represent a compromise of their autonomy.

A broader concern is that the very existence of large-scale prenatal testing compromises the possibility of individual autonomous decision making. Feminist critics, among others, point out that prenatal screening has become routinized, with an offer of some sort of prenatal screening standard of care for all pregnant women. These critics assert that in this setting, not being screened, while a possible choice, becomes a marked one that requires justification to one's healthcare providers and one's peers. Concern has also been expressed that mothers who decide to forgo testing and give birth to a child with a disability will be blamed by society and even, perhaps, denied healthcare insurance for the child. There is little empirical support at this time for these latter claims.

Can the aggregate impact of autonomous choices be eugenic? Even if each choice to use prenatal testing and terminate a pregnancy is informed and autonomous, the net effect might be considered eugenic. And, in fact, there are those who do not consider this to be problematic. Thus, for example, some public health statements clearly cite the measure of success of screening for neural tube defects as the lowering of the number of children born with these defects. Some bioethicists also suggest that eugenics, premised on individual, autonomous choices, is not necessarily bad.

How Are Decisions About Prenatal Test Offers Made?

These positions would seem to require a clear social consensus of what changes in the gene pool would be *eu*-genic. Yet, at the turn of the twenty-first century there exists no body in the United States, as there is in other countries, that decides on the available panel of prenatal tests. Nor is there a forum for public discussion of this issue. Some tests stumble into becoming standard of care due to medico-legal concerns (e.g., MSAFP testing). At other times, decisions are made on an ad hoc bases. Thus, a strongly perceived need by obstetric providers for guidance about cystic fibrosis (CF) screening led to the convening of an National Institutes of Health (NIH) Consensus Development Conference. This group recommended the routine offer of CF carrier screening in pregnancy, but concerns that physicians were not prepared for this change in practice led to the creation of an ad hoc panel charged with creating recommended protocols for implementation (National Institutes of Health Consensus Development Conference). The existence of the panel has not calmed concerns that physicians are not ready to meet the challenge of offering a new population-based test.

As genes for Mendelian disorders and those that confer susceptibility to more common disorders are found in increasing numbers, the lack of any orderly process from gene discovery to test development and then to making that test available to the public becomes increasingly problematic. At this point, healthcare providers are the de facto gatekeepers, relying on recommendations from professional organizations, actions of insurance payers, patient demand, and their own consciences in making decisions about what tests to offer. As genetic knowledge increases, this will become an ever more pressing societal problem.

Preimplantation Genetic Diagnosis

If prenatal testing is about which children will not be born, preimplantation genetic diagnosis (PGD) can be said to be about which children will be born.

PGD began as an alternative to prenatal testing for fertile couples known to be at high risk of genetic disease. It comprises a series of highly technical steps. The scenario involves inducing superovulation in the woman to increase the number of eggs in one reproductive cycle, the harvesting of those eggs, and the creation of six to eight embryos by in-vitro fertilization (IVF). In the most common protocol, the resulting embryos are allowed to develop until they reach the eight- to twelve-cell stage, and then one or two cells are removed from each embryo for genetic analysis. Those embryos that carry the genetic defect are discarded. Depending on the number of unaffected embryos, some or all are

implanted. Which embryos are chosen and what happens to those that remain are issues of ethical contention.

Many issues raised by PGD are outside the scope of this article. However, two issues raised by PGD are also directly related to dilemmas discussed in the context of prenatal diagnosis: First, what is abortion? Second, how does one decide which babies will be born, and with what traits and/or diseases?

WHAT IS ABORTION? One of the advantages commonly cited for PGD is that it avoids the problem of abortion. This assumes a definition of abortion as the interruption of an established pregnancy. However, abortion can also be defined as "the arrested development of an embryo at a more or less early stage" (from the *Random House Dictionary of the English Language*), a definition which would include the discarding of embryos, affected or unaffected, within PGD. It would also appear that those individuals (and points of view) most uncomfortable with abortion in the prenatal setting would be most likely to endorse this broader definition of abortion and thus be unlikely to see PGD as a solution to the abortion issue.

WHICH BABIES WILL BE BORN? PGD involves an issue not raised by prenatal diagnosis—more embryos are produced by PGD than can be used. The existence of these "excess embryos" demands that criteria be found on which to predicate decisions about which children should be born. Although, in practical terms, these decisions are often made on the basis of simply finding sufficient unaffected embryos for implantation, the possibility of deciding which embryos to implant has provoked considerable discussion. For example, is it appropriate to base a decision about which of two unaffected embryos to implant based on the preference of the parents for a child of one sex rather than the other?

Some of the discussion of how to choose embryos for implantation has a proscriptive edge, such as the view that to bring to birth a child with any impairment, however slight, if it could have been avoided, is to harm the child; more categorical is the view that procreative beneficence demands the selection of the "best" children. The logical extreme of this latter position is suggested by the view that "the question is not which individuals have worthwhile lives, but which of two possible worlds would be better: a world where disabled individuals are brought to birth or a world where nondisabled individuals are brought to birth" (Bennett, p. 468).

Much of this sort of discussion belies a belief in the ability of genetic analysis to do things that are neither currently possible nor likely to be so in the future—for example, to isolate the embryo that will become the most intelligent child. Nevertheless, these openly eugenic views, which are not found in the literature on prenatal testing, would appear to be premised on the belief that abortion is not involved in PGD and that the choice involves a more acceptable *selection for* rather than *selection against.* However, such an assumption would likely not satisfy those who have the most concerns about abortion. And for those critics (see, for example, the feminist and disability critiques) whose concerns do not involve abortion, this discussion around PGD lays bare the eugenic thrust they see in all prenatal testing.

Conclusion

Discussions of both prenatal testing and preimplantation genetic diagnosis appear to assume that the continuing march of reproductive technology is inevitable. It is possible that the overriding issue in all of reproductive genetics is whether society will see the development and use of these techniques as matter for democratic deliberation and decision, or whether the implementation of new technologies will continue in the established piecemeal fashion, and ethical discussion will continue to be reactive.

II. NEWBORN GENETIC SCREENING

Throughout the United States, and in many other countries around the world, newborns are tested within the first few days to weeks of life for a varying array of metabolic disorders. Until recently, newborns were typically screened for only a handful of disorders, but recent technological advances and new knowledge about genetics have led to pressure for greatly expanded screening. At first glance, newborn screening might seem unremarkable. Much of medical practice is devoted to the early detection of disease to allow the delivery of effective interventions, and new developments are often received enthusiastically. But newborn screening programs have several features that individually and collectively pose particular ethical challenges.

All U.S. states require that newborns be screened, either prior to discharge or, if delivered outside a healthcare facility, within the first two to three days of life (AAP). Maryland, Wyoming, and, for some but not all tests, Georgia and Massachusetts require that parents give their permission for screening, though many states do permit parents to refuse screening (generally for religious reasons). This option may be difficult to exercise in practice, however, since few states require that parents even be told that screening is occurring, much less that they have a right to refuse. Thus, one of more remarkable aspects of newborn screening is that parents are not even nominally part of the decision-making process for their new infants (AAP; Paul; Clayton).

Those who argue against either notifying parents or seeking their permission reason that all children should be screened, and it would thus be a waste of money and effort to talk with parents (Cunningham). Proponents of mandatory screening argue that most parents would agree to screening, but that they might be unduly worried if they knew about the test (Cunningham). They assert further that parents who refuse would be harming their own children. These arguments raise two separate issues: (1) the justifiability of excluding parents, and (2) the characteristics of newborn screening programs (and the disorders they seek).

The Role of Parents

The role of parents in making healthcare decisions for their infants is addressed elsewhere in this encyclopedia. In general, parents are presumed to have a role to play in such decisions, which can be overridden only to avert serious harm. But clinicians cannot decide not to talk with parents simply because they think it would take too much time, would make parents worry, or that it would be a waste of

effort because parents usually agree to the clinician's recommendations anyway.

These principles suggest to the advocates of seeking parental permission that parents cannot justifiably be denied the opportunity to be informed about and participate in decisions about newborn screening. Most parents agree to screening, and informed parents are more likely to ensure that screening is performed, as well as to obtain any follow-up that may be required (Andrews). Even if parents refuse screening, it is unlikely that their children will come to harm, for the disorders sought in these programs are very rare.

Newborn Screening Programs

Universal newborn screening was first adopted for phenylketonuria (PKU), an inherited metabolic disorder that causes severe mental retardation unless treatment is started in the first few weeks of life (NAS). Children with this disease have few symptoms early on, but the metabolic abnormality can be detected in the first few days of life by testing either the urine or the blood. Thus, several factors converged to support the idea of early detection:

- The disease has a devastating outcome
- Treatment is highly effective in averting this outcome, but only if it is started early
- Affected children cannot be detected on the basis of symptoms in time to start effective treatment
- Screening reliably detects most affected children (NAS)

When clinicians were slow to adopt these tests in their clinical practice, in part because they were uncertain about the efficacy of treatment, advocates went to their legislators to get them to enact laws requiring PKU screening (AAP; Clayton; NAS).

In the two decades that followed the enactment of these initial laws, the diseases that were added to the testing panels generally had similar characteristics. Congenital hypothyroidism requires early treatment to prevent severe retardation, and it frequently is not detected clinically during the newborn period. The risk of overwhelming bacterial infection faced by young children with sickle-cell disease can be greatly reduced by giving prophylactic penicillin. Children with galactosemia are often critically ill by the time the condition is detected on the basis of their symptoms, an outcome that can be averted by using a formula that does not contain lactose (milk sugar). Typically, programs were expanded to these and other disorders in response to a combination of mounting medical evidence and political pressure by families and clinicians.

Pressure to expand the number of disorders being screened for expanded dramatically during the 1990s, largely as a result of the development of tandem mass spectrometry ("MS/MS") (AAP). This technology permits the detection of a large number of metabolic abnormalities on a single specimen of blood. Unfortunately, no treatment exists for many of the disorders detectable by MS/MS, which raises issues of whether to test for these abnormalities, and of what to tell families whose children may have one of the untreatable diseases.

Until recently, most state statutes focused on identifying affected children. Most state programs tried to ensure that these children were directed to appropriate sources of care, but few actually ensured the availability of needed medications and diets. Since children do not have universal access to healthcare, some children received no treatment, and some parents suffered job lock. Increasingly, states, practitioners, and clinicians have begun to work together to develop systems to ensure the delivery of care for these children (AAP), a laudable goal which is threatened by the increasing pressure to privatize newborn screening.

The Problem of False Positives

Screening tests are assessed according to their sensitivity (the percentage of affected individuals detected) and their specificity (the percentage of unaffected individuals who are correctly excluded from further testing). The actual number of people who receive inaccurate initial screening results depends in large part on the frequency of the disease in the population. The more common the disease, the more likely it is that a person who receives a positive (abnormal) test result will actually be affected. (The rhetoric of screening and testing is confusing in that "positive" test results almost always mean that something is wrong.) As the disease becomes less frequent, the proportion of initial results that turn out to be "false positives" increases. Suppose a disease has an incidence of 1 in 10,000 and a population of 100,000 people is tested with a screening test that has a sensitivity of 90 percent (so that 9 out of 10 affected people will test positive) and a specificity of 99 percent (so that 99 out of 100 unaffected people will test negative). The results overall would be as follows:

	Test positive	**Test negative**
Affected	9 "true positive"	1 "false negative"
Unaffected	999 "false positive"	98,991 "true negative"

Put another way, for every person who was truly affected (and tested positive), 100 people who did not have the disease would also (falsely) test positive. In addition, nine people who did have the disease would test negative. While

most people who get false positive test results are ultimately reassured by further testing, some may continue to be worried. Affected children who are missed in these programs may face substantial delays in diagnosis if clinicians reason that the child could not have the disorder because it would have been identified in the newborn period.

The disorders sought in newborn screening programs typically are quite rare, usually having frequencies in the 1-in-5,000 to 1-in-15,000 range. Some of the diseases that are being added being to newborn screening panels are as rare as 1 in 100,000. Without denying the benefits that can come to affected children who are detected in these programs, it is important to acknowledge the possible harms that may befall the many children who inevitably receive falsely abnormal results. The newborn period is a particularly vulnerable time. Parents are just beginning to know and bond with their infants. Bad news, even if incorrect, can interfere with the formation of this central relationship and lead parents to view their new infants as medically fragile. One study revealed that almost 10 percent of parents whose infants received initial false-positive screening results for cystic fibrosis were still worried a year later that their children were affected or otherwise sickly.

Thus, the trend has been to increase the disorders for which newborns are screened, including some for which the benefits of early invention are unclear or may be absent, all the while causing a growing number of infants to receive false-positive test results, which will cause some of them harm.

The Implications of These Disorders

Most of the disorders sought by newborn screening are inherited, usually as autosomal recessive disorders. If parents have a child with one of these diseases, they have a one in four chance in each subsequent pregnancy of having another affected child. Children with such a disease can have affected children themselves if they have children with partners who have one or two copies of the same mutated gene. Some screening protocols, such as those for sickle-cell disease and cystic fibrosis, also detect carriers (children who have a single copy of a mutated gene). While these children do not have the disease, the presence of a mutated gene signals an increased risk of having a truly affected child, both for them and for their parents. From an ethical perspective, it seems obvious that parents should be told about all of these implications, but this sort of communication often does not occur.

One of the more difficult ethical questions is whether parents should be encouraged to alter their future reproductive plans in order to decrease the costs of disease to society. The general consensus is that decisions about having children are to be made by the prospective parents according to their own values, and that genetic counseling is to be nondirective (Andrews, Fullerton, Holtzman, et al.).

Another complex issue is whether decreasing the number of affected children born, whether as a result of state intervention or even of independent decisions by prospective parents, should be seen as an additional goal or benefit of newborn screening. Some governmental officials have made this argument, even calculating the decreased healthcare expenditures that follow from the birth of fewer affected children in their efforts to calculate the cost efficacy of newborn screening (Cunningham). Others, including advocates of disability rights and opponents of prenatal diagnosis, find these arguments distasteful and potentially coercive (Asch).

Unintended Consequences

Untreated women with PKU are profoundly retarded and rarely have children. As a result of the successful implementation of newborn screening and treatment for PKU, however, many affected females are now in their reproductive years, have intelligence in the normal range, and can and do become pregnant. Unless these women adhere to the highly restrictive and burdensome PKU diet prior to conception and throughout their pregnancy, their children will be born with severe brain injury.

These children typically do not have PKU themselves because their fathers are not likely to be carriers since those mutations are not common. The injuries they suffer during pregnancy result instead from the high levels of phenylalanine that exist in their mothers' blood when they eat a normal diet, levels which are particularly toxic to the developing brain. The irony then is that improving the lives of women with PKU creates a high level of risk to the children they may bear. Clearly, these women need to be educated about the importance of adhering to the proper diet prior to and during pregnancy. The ethical dilemma is whether it is ever appropriate, and if so, how, to bring pressure to bear to lead these women to either follow this onerous diet or avoid childbearing altogether (Robertson and Schulman).

Newborn Screening Samples as DNA Databanks

Birth is the only time of life when the government collects blood from virtually everyone. Some states discard these samples within a few months after birth, while others retain them indefinitely. In the past it was not possible to extract

much information from these samples because most metabolites deteriorate quickly, but recent advances, particularly in DNA testing, have created new possibilities. Newborn samples can be used for DNA identification, for further investigation when a child subsequently becomes sick, or for research, for which they may be particularly attractive as a true population sample. However, all these uses are secondary to the purpose for which they were initially collected—to detect children with diseases that urgently require treatment.

The appropriateness of using these samples for these other purposes raises many of the questions that attend any use of stored tissue samples for research, including: (1) whether it is necessary to ask the donor (or in this case the parent) for permission; (2) when, if ever, it is appropriate to inform individuals of their personal results; and (3) what sort of review needs to occur before these samples can be used. The fact that these samples are typically obtained without parental knowledge or permission makes these issues that much more urgent, particularly in a society that is so deeply concerned about issues of genetic privacy. It would be rather ironic if a system of universal DNA identification were developed as a by-product of newborn screening rather than as a result of an explicit policy decision.

Conclusion

The particular ethical issues posed by newborn screening arise because these programs are required and run by the government, typically do not involve parents in decision making, often implicate reproductive decision making, and can provide samples for a growing number of secondary uses. These unique factors suggest that parents should have a greater role to play in these programs, and that these programs should remain narrowly focused on detecting diseases for which treatment is urgently needed to avert serious sequelae.

III. POPULATION SCREENING

One of the sequelae of the Human Genome Project has been a resurgence of interest in using clinical genetic testing tools

at the population level to promote public health goals (Khoury, 1996; Coughlin). This resurgence raises a number of bioethical issues for public health policy-makers and the health professionals involved in delivering genetic services: questions about the limits of public health authority in this domain, the justice of population-based genetic interventions, the social costs of such screening, and the ethical allegiances of the clinicians involved. In this entry, these issues will be reviewed through the lens of one problem that seems to animate all the rest: the problem of defining *prevention* for the purposes of a *public health genetics.*

Background

Mass genetic screening programs have a relatively long history amongst modern genetic services, starting with the screening of newborns for prophylactic therapy against metabolic disorders in the 1960s and continuing into adult carrier testing programs for recessive genetic diseases such as Tay-Sachs (Kaback; Blitzer and McDowell), sickle cell disease (Bowman; Duster), and the thalassemias (Angastiniotis, Kyriakidou, Hadjiminas) in specific at-risk populations in the 1970s. The early adult screening programs shared two features that warranted, and garnered, significant attention within bioethics and health policy (National Academy of Sciences; President's Commission). First, they targeted specific socially-defined populations, which raised issues of group-specific stigmatization and discrimination (Kenan and Schmidt; Markel). Second, the information about carrier status the screens provided was primarily useful for reproductive rather than therapeutic decision-making, raising issues of parental autonomy, paternalism and procreative choice (Juengst, 1988; Thompson et. al).

The 1980s witnessed a second wave of adult genetic screening programs, aimed at detecting pregnant women at risk for delivering children with genetic birth defects and chromosomal abnormalities (Cunningham and Kizer; Haddow, Palomaki, Knight). These programs are intended to have universal application within populations, and have been routinized into the obstetrical care of pregnant women in many countries, raising issues of voluntariness and informed consent (Press and Browner; Marteau). They have also provoked an outspoken reaction from the community of people with disabilities, who argue that such programs work against attempts to reform social attitudes about disability (Parens and Asch).

Today, these three *traditional* forms of population genetic screening—newborn screening, risk-group carrier testing, and pregnancy screening—continue to make up the vast bulk of population genetic screening activities that are funded and evaluated as state public health initiatives. At the same time, the disease targets of these screening efforts have changed, as public health programs see rationales for shifting specific tests from one form of testing to another. Thus, many states have added sickle cell testing to their universal newborn screening panels (Olney), and calls have been made for universal screening of pregnant women for maternal PKU (Kaye, et. al) and fetal hemoglobinopathies (Cuckle). Moreover, genetic tests originally reserved for clinical use in families at risk for diseases such as cystic fibrosis or fragile-X syndrome have also begun to be used as population screens, both as part of newborn screening panels and prenatal testing programs (Caskey; Cuckle). In all such shifts, the tests have moved in the direction of earlier and more universal screening.

The new wave of interest in *public health genetics* generated by advances in genomic science focuses on tests that would have universal application within multi-ethnic populations, like pregnancy testing, but, like newborn screening, would measure the tested individuals' personal risk for disease, with an eye toward prophylactic action. Moreover, in addition to screening for signs of rare *genetic diseases,* like all the traditional forms of screening, the emphasis is on the detection of molecular markers that confer statistically increased risks for more complex, and more common, chronic diseases of adulthood, like coronary artery disease, cancer, or diabetes (Khoury, Burke, Thompson).

The discussion of using these new tests as public health tools has been dominated by questions of feasibility and utility (Omenn, Holtzman). As one review concludes:

> Several issues must be addressed, however, before such tests can be recommended for population-based prevention programs. These issues include the adequacy of the scientific evidence, the balance of risks and benefits, the need for counseling and informed consent, and the costs and resources required. Ongoing assessment of the screening program and quality assurance of laboratory testing are also needed. (Burke et al., p. 201)

These concerns mirror those expressed in the literature on using predictive genetic risk assessments as a part of medical care in clinical settings (Geller, et. al.). The use of these same tests as population screening tools would place them in the larger context of the existing population genetic screening programs, however, and it is in that context that they become most bioethically challenging. As these tests become integrated into the shifting mix of existing *population-based prevention programs,* they expose fundamental questions about the goals of the enterprise that have not been so apparent in the past. What should population-based genetic

screening strive to accomplish, and by what criteria should one measure success?

Phenotypic and Genotypic Prevention

The ubiquitous answer to these questions in the literature of public health genetics is *the prevention of disease,* a classic public health goal. This goal is operationalized as the reduction over time in measures of the morbidity and mortality caused by the target disease within the screened population. To flesh out the kinds of interventions that should be counted in those measures, most authors appeal to the public health field's traditional lexically-ordered scheme of primary, secondary and tertiary *levels of prevention,* and attempt to categorize population genetic screening tests accordingly. Thus, for example, one public health guidance document states:

> Primary prevention genetic services are services intended to prevent a birth defect, genetic disorder, or disease before it occurs. Genetic counseling is a form of primary prevention. Genetic counseling provides couples with information about their pregnancy, and reproductive risks and pregnancy options. Secondary prevention genetic services are services intended to prevent the unfavorable sequelae of an existing disorder or genotype. Newborn screening is a classic example of secondary prevention. Tertiary prevention genetic services are services aimed at ameliorating the unfavorable consequences of existing disorders, through enabling services such as parent-to-parent support and empowerment. (Kaye et al.)

Using this scheme provides a logic for shifting tests into the newborn, prenatal and preconception stages, because traditionally "primary prevention" has been considered the ultimate goal of public health interventions.

Unfortunately, this scheme also introduces an important equivocation into public health discourse between two different ways in which genetic screening might be thought to be *preventive*: genetic screening as a technique for preventing the expression of a genetic disease in an individual and genetic screening as a technique for preventing the intergenerational transmission of disease genes. For convenience, the first kind of prevention may be called *phenotypic prevention,* since its goal is to prevent the manifestation of a particular clinical phenotype. Similarly, the second sort of prevention may be called *genotypic prevention,* (or *genoprevention*) because its goal is to prevent the birth of people with particular genotypes. Equivocating between these two senses of prevention in discussions of population screening results in the attribution of genotypic preventive goals to public health genetics. That, in turn, generates the deeper questions of public authority, social justice, and professional allegiance that animate bioethical concern in this area.

Phenotypic Prevention

The dominant rhetoric of contemporary public health genetics stresses phenotypic forms of prevention as the primary goal of population genetic screening (Coughlin). This is not surprising. Phenotypic prevention is a straightforward medical pursuit that few would criticize: it is designed to further the health interests of individual patients by allowing them to avoid foreseeable medical problems. Almost all public health efforts outside of population genetic screening employ this concept of prevention, and even within public health genetics there are typical phenotypic prevention efforts at each of the three *levels of prevention* (Holtzman).

The concept of phenotypic prevention rests on several assumptions, however, which are worth unpacking. First, phenotypic prevention assumes that there are people who survive the intervention to benefit from having their foreseeable health problems forestalled. Thus, for example, proposals to *prevent* occupational disease by firing all susceptible employees instead of cleaning up the workplace seem inherently wrong-headed. Second, it assumes that diseases are best defined at the level of the actual health problems that they occasion for individual people, rather than in terms of their preclinical etiology. Otherwise, preclinical interventions like dietary changes would be directly curative, not prophylactic. Third, it assumes that diseases are distinct from the people they burden, so that it becomes appropriate to use metaphors of external defense to describe the beneficiaries, as *vulnerable* to *attack* by disease without the *protection* of prevention.

Along with these assumptions, the concept of phenotypic prevention enjoys a high degree of moral authority as an imperative for medicine and society. In fact, the promise of phenotypic preventive measures to "protect the helpless from harm" has been compelling enough in our society to allow both primary and secondary forms of phenotypic prevention to become established in effectively mandatory programs as a matter of public policy (President's Commission).

Of course, if primary prevention is the prevention of the onset of a genetic disease in an at-risk patient, then most of the preconception, preimplantation, and prenatal genetic screening interventions usually classified as *primary prevention strategies* cannot, in fact, qualify for that status. Neither pre-implantation embryo screening nor selective termination can serve to prevent the onset of a heritable disease in

affected patients. At most, they are capable of preventing cases of a disease within a family (or a population), by allowing parents (or a society) to avoid the birth of at-risk individuals.

This conceptual confusion does lead to some cognitive dissonance in the literature. The Centers for Disease Control and Prevention, for example, illustrates the concept of *primary prevention* in genetics by listing "medical and community-based interventions focused on carrier detection and premarital counseling as ell as on prenatal diagnosis and pregnancy termination," but then adds the confusing parenthetical remark that "(This last may not be considered primary prevention)" (Khoury et al., 1997, p. 1718). It is also telling that one can find carrier screening, intrauterine diagnosis and selective termination classified in the literature as an example of primary prevention (Kaye, et. al.), secondary prevention (Wertz, Fletcher, and Berg), and even tertiary prevention (Porter)! Clearer thinkers: Holtzman (1989) sets carrier screening, amniocentesis and selective termination outside of preventive medicine's traditional trichotomy, by labeling them as a form of genetic disease *avoidance.* Similarly, the editor of the journal Community Genetics declares that:

> Calling termination of pregnancy after prenatal diagnosis "prevention" is a perversion of terminology. I suggest that we should use the term "reproductive choice." By analogy with prevention, one might define different levels of reproductive choice. Primary reproductive choice would then consist of actions to avoid conception of affected offspring, while secondary reproductive choice would bar implantation or birth of affected embryos and fetuses. (ten Kate, p. 87)

In fact, when they incorporate reproductive genetic screening programs into their menu of preventive interventions, public health geneticists have been forced to slip between two very different senses of *prevention.* They have conflated screening to prevent the phenotypic expression of a genotype in a particular patient (*phenotypic prevention*) with screening to prevent the birth of individuals with a particular genotype (*genotypic prevention*). These two visions of screening reflect quite distinct concepts of disease prevention, with different histories within healthcare, different philosophical assumptions, and different degrees of moral authority.

Genotypic Prevention

Genotypic prevention is a pursuit that is much more controversial than phenotypic prevention. That is understandable, for several reasons:

First, it is often hard to know what ends genotypic preventive measures are intended to serve. Genotypic preventive measures are usually described as a way of furthering the procreative interests of prospective parents, by allowing them to avoid the birth of individuals with foreseeable health problems (like AID following adult carrier testing for cystic fibrosis mutations, or selective termination following intrauterine diagnosis of Down's syndrome).

At the same time, these same interventions are often evaluated in terms of the economic and public health interests of society, according to their ability to reduce the incidence of genetic disease in a population. Thus, the famous "success stories" of genetic screening (like the Mediterranean carrier screening programs for beta-thalassemia, or Tay-Sachs screening in the Ashkenazi-American population) most often counted as successful in terms of these societal criteria (Rao, et. al.; Blitzer and McDowell). In those stories, in fact, the commitment to channeling screening efforts through the individual's voluntary reproductive choices is itself portrayed as simply a savvy strategy for achieving the profession's underlying goal of reducing society's healthcare costs (Caskey; Palomaki; Chappele, et. al.).

Secondly, whether geno-prevention is pursued in the cause of family planning or the public health (or both), it must make two sets of related assumptions. First, it assumes that the diseases it prevents are best understood at the level of the genotype, rather than through the pathophysiology of their expression, just as AIDS is understood in terms of its causal HIV infection rather than the infection's clinical sequelae. Understanding genetic disease through the lens of the germ theory in this way means that the language of "molecular disease," and "DNA-based diagnosis" seems apt, and it makes sense to contrast preventing the vertical transmission of pathogenic disease genes with palliative or symptomatic interventions like low phenylalanine diets.

Second, proponents of geno-preventive efforts must assume important personal (or social) value judgments about the burden of the cases of disease being prevented. Genes are not, like germs, external infectious agents that can be kept (or cleaned) out of a living person's body. Instead, genotypic prevention has to involve avoiding the birth of individuals conceived with the pathological genotype. The beneficiaries of such an intervention cannot be the individuals whose births are avoided: if the genotypic transmission has been successfully prevented, there can be no such individuals.

That means that to justify geno-prevention someone (parents or society) must make the judgment that the burden of coping with cases of a disease outweighs any other value that individuals with a given genotype might bring to a

family or community, and warrants action to exclude individuals with those mutations from the lives of the wild type.

Finally, genotypic prevention already has a bad track record as a social and professional goal. Genotypic prevention has been accepted before as a societal imperative, on the coat-tails of the public health movement's successes with the primary prevention of infectious disease (Allen). The "Eugenics Movement" of the first half of the twentieth century is remembered primarily for the discriminatory immigration restrictions and coercive sterilization laws it produced (Reilly), and the ease with which it was appropriated to support genocide (Muller-Hill). The horrific consequences of ranking genotypic preventive goals over individual interests still effectively undermine any claims to moral authority it might make.

Unfortunately, as its controversial features already suggest, to the extent that population genetic screening becomes associated with a professional allegiance to genotypic prevention, it inherits all the history, assumptions and moral liability of that concept, and the prospects for a well-reasoned public assessment of its merits dim considerably.

Against this background, the professional confusion over the true goals of contemporary genotypic prevention services and the fact that all geno-preventive services require the judgment that some genotypes are predictably burdensome enough to others to outweigh any other potential their bearers might have, makes it easy for critics of new approaches to genotypic prevention to remind the public of the excesses of the historical eugenics movement, and label any new efforts accordingly, with powerful political effect (Hubbard).

Moreover, inviting external political challenges is not the only trouble that endorsing genotypic prevention would create for public health genetics. it would also create substantive philosophical tensions within the field which could threaten the ethical integrity of the field. Since genotypic prevention is also unnecessary as a rationale genetic screening and counseling services, some argue that it is time for public health authorities to explicitly eschew this old eugenic legacy as a professional goal.

Ethical and Social Implications

As a professional ethical matter, accepting genotypic prevention as a proper goal of public health genetics has chilling implications. Expanding the geneticist's preventive goals of genetic medicine to include reducing the incidence of pathological genotypes broadens their responsibilities beyond their presenting patients to the next generation's aggregate population. Since the latter will always be a bigger group, its preventive health needs will always be greater by at least some scores (e.g., disease care costs), and therefore, for some, more compelling. This makes it very easy for genetic medicine to elevate what began as a serendipitous "by-product" of its services—the reduction of disease burden and cost to society—to a central position within its mission, without even noticing when it does so.

Again, such criteria do have a long history in applied human genetics, as basic ingredients in the various programs of "negative eugenics" this century has witnessed. They even continue to be explicitly used by some genetic services programs seeking to justify their public support in economic terms (Chappele, et al; Cuckle). As a result, there is no need to guess at the internal dangers that adopting such ideals would pose for the professional ethics of genetic medicine: the experiment has already been conducted. Experience shows that there are at least four important hazards for the profession:

1. First, the field would have to decide where within the spectrum of human genetic variation to define the pathological genotypes it would seek to prevent (Juengst, 1988). Most of the proponents of preventive genetic screening programs skirt this problem by stipulating that they are only talking about "severe congenital abnormalities" that produce "serious handicaps." (Cuckle). These caveats address this line-drawing problem in a time-honored way, by appealing to common sense notions of severity. In doing so, the proponents of geno-preventive germ-line intervention are following the footsteps of authors like Dr. Nathan Fasten, when he wrote in 1935 that:

> Here one must pause to comment that it is difficult to define clearly the standards of desirability or the standards of perfection in the human family. Even so, most normal persons would agree that the hopeless cases of physical and mental defectives, those that are incapable of care for themselves, particularly where it is certain that such defects are the results of hereditary factors, are no asset to society and should be eliminated as quickly as possible. (p. 354)

So far, Dr. Fasten appears to be anticipating the modern argument. However, Dr. Fasten's own list of what "most normal persons" should include in the class of "hopeless cases" is telling:

> Here are included the feeble-minded, the insane, the paupers, the confirmed criminals, and the grave sex offenders. This group, in general, is a tremendous burden on society. Genetic evidence has been accumulating to reveal that most of these defects are due to heredity. Social workers also

> have discovered that from this stock the largest percentage of the dependent individuals originate. Geneticists and social workers, therefore, believe that nothing but good can come from efforts in the direction of the rapid elimination of this branch of society. (p. 355)

Of course, it would be unfair and anachronistic to insinuate that the contemporary advocates of genetic screening subscribe to eugenic ideologies like Fasten's: they clearly do not. The point in resurrecting him is simply to illustrate that it is often hard to know, in the thick of things, how much one's professional assessments of pathology are influenced by larger cultural ideologies and social values.

If genetic medicine is to prevent its practitioners from being lured away into other social agendas, it still must address the challenge of defining its domain. As the intensity of the debates over the prenatal sex selection as a professional practice already demonstrates (Warren), drawing these boundaries will involve just as difficult a set of value judgments as attempts to use genetic technologies to *enhance* specific human traits. As Dr. Fasten reminds us, without more operational definitions, rhetorical appeals to "severity" and the intuitions of the "reasonable person" will not help brighten any of the lines that will need to be drawn across the spectrum of human traits as genetic medicine's power matures.

2. Moreover, it is increasingly clear that preventing the birth of a particular "pathological" genotype will not always mean preventing a clinical health problem. The more we learn about human genetics at the molecular level, the more complicated the story becomes. One increasingly prominent feature of that story over the last few years has been the deterioration of the theory of specific causation within genetics (Strohman). Not only are most health problems "polygenic" to some degree, but even the traditional "single gene disorders" are turning out to be molecularly heterogeneous (Holtzman). As the number and variety of different specific mutations that can all cause the same disease increases, so does the challenge of detecting and correcting them all in a patient. Worse yet, the causal complexity works in both ways: even the paradigmatic examples of clean Mendelian "singe gene" disorders, like "recessive" cystic fibrosis and "dominant" Huntington's disease are turning out to be multifactoral enough that carrying one of their (multiple) pathognomic genotypes no longer guarantees that one will experience a problematic clinical syndrome (cf. Tsui; Benjamin).

In other words, genotypes are not turning out to function very well as germs. The complexity of their expression as health problems undermines the confidence with which a clinician can predict the occurrence of severe health problems from a DNA diagnosis. Since genotypic prevention is conceptually committed to a deterministic etiology of specific causation, geno-preventive measures risk making (and acting on) both false negative and false positive prognoses. This means that they also risk intervening unnecessarily in cases that the environmental forces of expression and penetrance would have naturally mitigated.

3. Thirdly, as a consequence of its deterministic assumptions, genotypic prevention cannot help stigmatizing genotypes, and (since they are inseparable) the people whom they mark, as undesirable or pathological in themselves (Markel, Parens, and Asch). This kind of reductionism, reducing personal identities to disvalued health problems and disvalued health problems to one stigmatizing sign, is at the root of much of the social discrimination that people with disabilities must already overcome (Fine and Asch). To have public health authorities endorse genotypic prevention as a goal can only exacerbate these challenges, because it provides a medical sanction for exclusionary attitudes.(Saxton; Kaplan; Faden). The concern is that, if a given genotype carries such a disvalue for health professionals, it would not seem unreasonable for the public to chastise those who avoid screening as "irresponsible reproducers" and hold them accountable for their recklessness by denying them opportunities or services, like medical care for affected offspring (Thompson, et. al).

4. Finally, the ways in which genotypic preventive goals tend to overshadow individual interests also endangers the therapeutic relationship within genetic medicine. To the extent that genetic services programs are evaluated in terms of their success to reducing the incidence of particular genotypes, genetic service providers will inevitably have an stake in seeing that their clients make the "right" reproductive decisions: i.e., decisions not to bear children at risk for genetic disease. This is a pressure that is already creating tension within medical genetics, as the field attempts to accommodate itself to healthcare delivery systems that are managed with societal healthcare costs in mind. For example, there has been a lively debate in the British medical literature about how genetic services should interpret the societal expectation that they will "pay their own way" within the national health budget (Chappelle; Clarke). Genotypic prevention, in other words, imports a professional goal that encourages practitioners to influence the reproductive decisions their clients make, despite their professed respect for the reproductive autonomy of those they serve.

Fortunately, all of these professional ethical risks—the subordination of professional integrity to social ideology,

the inappropriate reliance on simplistic science, the professional disvaluing of human minorities, and the willingness to invade the sphere of reproductive privacy on behalf of society's economic interests—are dangers which human geneticists have succumbed to and overcome before (Kevles; Allen). Moreover, they are also the dangers in response to which the contemporary *client-centered* professional ethic of medical genetics has largely been shaped. In contemplating the future of germ-line gene therapy, it may be helpful to recall how this existing moral tradition handles the question of genotypic prevention, and consider its relevance for public health genetics. Doing so shows that genotypic prevention is not only a dangerous goal for genetic medicine to espouse, it is also completely unnecessary.

The Existing Tradition

One of the reasons it is easy to slip between the phenotypic and genotypic senses of *prevention* in discussing genetic medicine's goals is that the desire to bear children free from specific genetic diseases can and often does provide a rationale for prospective parents' interest in the specialty's services. But that does not pose a professional ethical problem for clinical geneticists: whether the intervention is genetic counseling, adult carrier screening, intrauterine diagnosis, preimplantation screening, providers of genetic services can help parents achieve their geno-preventive goal in good conscience, because it falls within the sphere of reproductive choices which parents are free to make in a tolerant society. Even the sharpest critics of genotypic prevention as a professional and public policy will agree that individual decisions about these interventions are inseparable enough from core personal values and beliefs to warrant the same respect we give to other fundamental freedoms (of religion, for example)(Saxton; Fine and Asch).

However, it is not necessary to conflate the *patients'* goals with the *professional* goals of genetic medicine in order to display respect for reproductive autonomy. In doing so, advocates of increased screening blur a distinction that clinical geneticists providing more traditional genetic service have worked hard to clarify: the distinction between the profession's mission in providing its services and the personal interests of their clients (Botkin).

Clinical geneticists argue that their professional goals in offering reproductive genetic testing and counseling services have little to do with the content of the autonomous reproductive choices that their clients make. Their mission is to treat a special class of reproductive health problems their clients face as prospective parents: *the reproductive planning problems posed by their risk of having a child with a genetic disease* (NSGC; Bartels). The advocates of this ethos assert that "the fundamental value of genetic screening and counseling is their ability to enhance the opportunities for individuals to obtain information about their personal health and child-bearing risks and to make autonomous and noncoerced choices based on that information," not the elimination of genetic disease (President's Commission). From this perspective, the geneticists' goals are not so much "preventive" as directly therapeutic: the reproductive planning problems they address are already fulminant when their clients engage their services, and their treatment consists of giving them the information, counseling, and options they need to address their problems in terms of their own values and beliefs (Kessler).

This approach to defining the mission of reproductive clinical genetics has several important features for our purposes. The first is its emphasis on the practitioner's primary professional obligations to his or her presenting clients—usually prospective parents—rather than with the next generation. Thus, practitioners are warned that:

> Counselors may find themselves pulled by an allegiance to the unborn child—whose well-being is, after all, the ultimate object of their concern as well as the motivating interest of the parents. As understandable as this concern may be, in the end it must give way to the duty owed to the counselee—the parents (Capron, p. 334).

Secondly, since in practice *reproductive health* largely boils down to the ability to fulfill one's procreative ambitions, the geneticists' treatment goals can only really be accomplished within the context of their patients' own life plans and beliefs. Because the content and consequences of the reproductive decisions that the geneticist helps facilitate reflect personal moral judgments made within the sphere of the patients' procreative liberty, they are understood to be beyond the geneticists' professional domain of concern. As a consequence, geneticists are expected to be strictly *nondirective* in the counseling they provide, and to help their clients to make their own value judgments about the relative burden of the disease their children may inherit. The practical result of this orientation is a strongly client-centered ethos that, historically, anticipated the rise of *patient autonomy* in the ethics of other medical specialties by twenty years.

In part, this tradition has historical roots in the reaction of postwar medical geneticists to the excesses of their eugenic predecessors. However, it also reflects an important strategy for dealing with the predictive and moral uncertainties of the reproductive decisions that geneticists' help their clients make (Juengst, 1989). The tradition is often inaccurately

accused of prescribing "value-neutrality" and criticized accordingly (Caplan), but it would be more accurate to label it as "value-sensitive," since it instructs clinical geneticists to discern and work with their clients' values, rather than be blind to them.

The consequence of this client-centered, non-directive ethos is that genetic medicine has no need to adopt geno-preventive goals in order to explain or justify the interventions it performs on behalf of its clients. In fact, it is free to repudiate "public policy intended to change the genetic makeup of the populations" (Council of Regional Genetics Networks), and thereby to distance itself from the liabilities that the geno-preventive concept brings to the profession. One recent statement of this ethos is worth citing at length, because of the ways it clearly displays its roots in the field's concern with the hazards of espousing geno-preventive goals for their services:

> Reproductive genetic services must ultimately serve personal—not public—interests, in improving the overall reproductive lives of women. Whatever societal gains might be realized through the eugenic use of reproductive genetic services should be heavily outweighed by the personal needs of women and their families. The ideals of self-determination in family matters and respect for individual differences, ideal that lie behind the client-centered view of reproductive genetic services, are jeopardized whenever the primary goal of these services becomes the prevention of the birth of individuals with a disorder or a disability. To the extent that voluntary reproductive genetic services are evaluated even indirectly in eugenic terms, societal pressures have the potential to threaten the important interests of individual women and their families. (Thomson et al., p. 1161)

Of course, there are still plenty of ethical tensions within this model of genetic medicine (e.g. cf. Bartels). For example, as more can be done to address the phenotypic problems associated with fetal genotypes identified through genetic testing, it becomes harder to interpret prenatal testing as solely aimed at addressing a parental reproductive health problem. In these cases, the fetus emerges as a *presenting patient* for the medical geneticist, with its own claims to professional allegiance. Similarly, to the extent to which the profession fails to distinquish between their commitment to a non-directive counseling style and their professional obligation to establish the limits of their services, concerns about a laissez faire, commercialized, "consumer eugenics" will remain. Genetic medicine also has to grapple with the fact that, unless the profession is willing to use genotypic preventive measures of success, it may find its reproductive testing and counseling services excluded from cost-conscious healthcare coverage plans as relative luxuries.

Moreover, despite its prominence in the rhetoric of the field, it is also true that this client-centered ethos does not command universal allegiance amongst human geneticists: in fact, 59% of geneticists surveyed do still endorse the "reduction in the number of carriers of genetic disorders" as a professional goal for their field (Wertz and Fletcher). Nevertheless, on the whole, rejecting genotypic prevention in favor of focusing on the interests of the presenting patient serves its advocates well in clinical genetics. By keeping the specialty's loyalties with the particular patients at hand, and its professional prescriptions within the context of those patients' own values and goals, it inoculates the field against infection by the dangerous agendas of negative eugenics.

The bad news for proponents of population genetic screening, of course, is that returning to the client-centered ethos of medical genetics does mean that they will have to forego their appeals to genotypic prevention in making their case. Whether or not genetic screening has any promise for "purifying the human gene pool" should remain totally irrelevant to its acceptance as a public health tool. Given the political, professional and social dangers of going down the eugenic road, any short-term benefits of doing so could carry a very heavy price for all concerned.

Conclusion

Genetic medicine is quickly leaving the stage in its history when it only has information and solace to provide its patients. As it becomes increasingly incorporated into public health, it will be important not to forget the moral tradition that sustains it. Affirming the traditional commitment of geneticists to the physical health and reproductive autonomy of their clients and patients means relinquishing genotypic prevention as a formal goal for the profession. In contemporary political argot, public health genetics should continue to be an empowering, not an exclusionary science: it should continue to be about helping living people address their individual health problems, and not about protecting the *gene pool* or society from those people, as some form of expensive pollution. Speaking clearly about the place of *prevention* in public health genetics is one way the pioneers of the new era can reaffirm this fundamental conviction.

IV. PUBLIC HEALTH CONTEXT

Genetic testing and screening programs have long been part of public health programs in the United States. For decades public health authorities have recommended the screening of newborns for specific genetic (and nongenetic) conditions through genetic tests that use blood samples from infants. Neonatal genetic testing and screening increasingly are becoming part of public health practice in the modern genetic revolution. Genetic testing and screening in the delivery of health services and for occupational purposes (Shulte and DeBord) are becoming more common despite legal impediments.

The proliferation of genetic testing and screening in the interests of protecting public health may help improve health outcomes on a population basis, but it simultaneously raises significant legal, social, and ethical concerns. When should genetic tests be allowed without informed consent? Should genetic screening be allowed for every condition for which a reliable and accurate test is available? When should genetic screening programs be mandatory (required) or voluntary (optional)? How can public health authorities or others acquire, use, or disclose sensitive genetic test results? These and other ethical issues are discussed in this entry in the context of the classic debate between individual rights and the goal of protecting the public's health.

Genetic Testing and Screening: Similarities and Distinctions

Though often used interchangeably, genetic testing and screening are different concepts. *Genetic testing* refers to medical procedures that determine the presence or absence of a genetic disease, condition, or marker in individual patients (Gostin). Genetic tests involve an examination of chromosomes, DNA molecules, or gene products (such as proteins) to find evidence of certain mutated sequences.

Genetic tests can (1) confirm a diagnosis for a symptomatic individual, (2) assist with presymptomatic diagnosis (e.g., Huntington's disease) or assessment of the risk of development of adult-onset disorders (e.g., Alzheimer's disease), (3) identify carriers of one copy of a gene for a disease in which two copies are needed for the disease to be expressed, and (4) aid in prenatal diagnosis and newborn screening. Hundreds of genetic tests are available to predict diseases in individuals and the population (Secretary's Advisory Committee on Genetic Testing [SAGCT]). Many others are being developed.

Despite their great potential, technical limitations to genetic tests can inhibit the prediction of disease in individuals. A genetic test may not be able to identify every mutation of a gene (which can have mutations in several places along its base pairs) and thus may not indicate an abnormality. Different mutations in a gene have different effects. The cystic fibrosis gene, for instance, has 800 potential mutations with varied effects on health (SACGT). In addition, genetic tests do not measure the complex interactions between genes and environment that contribute to the onset of almost all diseases. As a result, a genetic test is limited in its ability to gauge an individual's susceptibility to causes of mortality such as heart disease accurately.

Screening entails the systematic application of a test to a defined population (Gostin). *Genetic screening* refers to programs designed to identify persons in a subpopulation whose genotypes suggest that they or their offspring are at higher risk for a genetic disease or condition. In many cases this requires the administration of genetic tests, as defined above. Thus, whereas genetic tests are used to reveal specific propensities among individuals, genetic screening programs help identify rates of genetic diseases or conditions among subpopulations and sometimes can uncover previously unknown or unrecognized conditions. The nature and scope of genetic screening programs vary. Some screening programs are mandatory: Persons must participate in a screening program unless they opt out (where allowed) for religious, philosophical, or other reasons. Most screening programs, however, are voluntary. Persons may choose to participate (opt in) but do not have to.

There are many examples of genetic screening for public health purposes. Women may be screened for genetically related breast cancers. Persons may participate in prenatal genetic screening programs to determine genetic disorders in embryos before implantation. Obstetricians may advise pregnant women in higher-risk groups about specific genetic tests. Fetal karyotyping, for example, can suggest an increased likelihood of carrying a fetus with Down's syndrome among older women. Screenings for conditions such as Tay-Sachs disease and cystic fibrosis are available. Perhaps the most prominent example of genetic screening among a subpopulation is the long-standing public health practice of screening newborns for genetic conditions. Most states require the screening of infants for treatable genetic disorders, particularly phenylketonuria (PKU), subject to refusal on religious or philosophical grounds (New York State Task Force on Life and the Law). Some statutes deem newborn screening voluntary, although in practice it almost always is done in the interest of protecting an infant's health.

Genetics and Public Health

Genetic testing and screening further public health goals of preventing and treating diseases in the population in many ways. Because many diseases and conditions result from interaction among genes, behavior, and environment, understanding the role genes play in contributing to diseases clarifies the ways in which environmental and behavioral influences may lead to the onset of diseases. With this knowledge public health professionals can shape their assessment, policy development, and assurance techniques more effectively. Public health professionals can promote the use of genetic tests and services when inexpensive and effective treatments are available to advance the collective health of the population. An example mentioned involves newborn screening programs, which are expanding in scope as new genetic causes and treatments of disorders are discovered.

Genetic testing and screening for multifactoral conditions such as cancer may allow susceptible persons to change their behaviors and environment, thus improving public health. Public health officials may be best equipped to conduct population research to evaluate the clinical validity and utility of genetic testing and screening. Also, those officials can play a substantial role in the dissemination of information to medical professionals and the public about the role of genetics in health (Gostin, Hodge, and Calvo).

The use of genetic tests and screening for public health purposes, however, can be problematic. Genetic tests that have high rates of inaccuracy can lead to low predictive values when they are incorporated into a genetic screening program. Significant numbers of tests results that are false positive (healthy persons are wrongly determined to be affected by a genetic disease or condition) and false negative (persons who are affected go undetected) can follow. Experience with genetic screening for sickle-cell anemia among African-Americans in the 1970s demonstrated the potential discrimination that may follow a public health screening program (New York State Task Force on Life and the Law). Beyond obvious individual harms, genetic screening programs that are not scientifically sound or justifiable on societal grounds have little utility in public health. With

limited resources for preventive public health measures, genetic screening programs that produce small yields (the number of newly recognized cases derived from the screening) as a result of inaccurate testing or other failures can compromise public health goals. Stated simply, poorly administered or poorly designed genetic screening programs that use inaccurate tests or insufficiently target at-risk populations negatively affect individuals and result in minimal or no improvement in public health.

Ethical Concerns

Ethical issues pervade any public health strategy involving genetic tests or screening. This section examines some of the key ethical issues concerning individual informed consent, the design and application of genetic screening and testing, and privacy and discrimination. These and other issues are explored in the context of the sometimes divergent views of public health and individual ethical theories discussed below.

BIOETHICS AND PUBLIC HEALTH ETHICS. Ethical questions arising from genetic testing and screening in the context of public health require an understanding of the differing perspectives of individual and public health ethics. Principles of bioethics largely have an individualistic focus. Persons as individuals are entitled to autonomy, are owed fair and equitable treatment, and must not be harmed intentionally. These rights inhere in each person and, consequently, are owed to each person. Principles of public health ethics do not abandon this individualistic approach. Protection of individual rights is critical in public health practice that increasingly stresses an ethic of voluntarism.

In contrast, public health is focused on the health of communities. Protecting the health of communities sometimes may require individuals to act or contribute to the larger community goals. For example, screening infants for genetic diseases requires parents to allow their children's blood to be tested. The resulting infringement on individual autonomy and decision making under this scenario may be minimal, but the impact on public health can be extraordinary. Public health authorities suggest that this infringement is completely justifiable under a public health ethical framework that envisions individuals as members of society with certain communal goals.

Many bioethicists often perceive a conflict between individual ethical rights and duties and public health ethics. Public health programs and efforts seemingly interfere with individual decision making, bodily integrity, and other protected interests. Ideally, public health programs incorporate the ethical rights of individuals to promote individual participation, which is essential to accomplishing many communal health goals. Sometimes it is not possible to respect the ethical interests of individuals and accomplish legitimate public health goals. For example, it is problematic to allow persons to deny public health authorities access to their diagnoses of genetic disease, which the authorities need to conduct effective surveillance. The individual's claim of a breach of privacy rights under principles of autonomy could trump the community's goal of monitoring disease among the population. Public health ethics suggests that persons participate in public health measures even when some infringement of their individual rights may follow. This analysis provides an appropriate framework for considering the ethical issues discussed below.

INDIVIDUAL INFORMED CONSENT. Principles of autonomy strongly support the individual's right to informed consent before genetic testing or screening. Many law and policy makers, particularly at the state level, have passed legislation or created administrative regulations in the last decade that require specific, written informed consent (sometimes including genetic counseling). Before the administration of a test patients are entitled to explanations of the nature and scope of the information to be gathered, the meaning of positive test results, the underlying disease or condition, and any risks involved in the testing or activities that follow a positive result. Through advance informed consent it is hoped that patients can weigh the benefits of genetic testing against the risks. However, problems in understanding the complexities of genetic science and uncertainties in the meaning of positive test results can limit the value of informed consent (Press and Clayton).

Should genetic tests ever be allowed without informed consent? Public health officials may justify mandatory newborn screening programs without parental consent by reference to utilitarianism and corresponding legal principles that authorize the state to protect children. However, at least in regard to autonomous individuals, there is little justification to mandate genetic testing or screening without informed consent.

WHEN SHOULD GENETIC SCREENING BE PERFORMED? Although genetic screening may be enhanced through the use of accurate tests, there are other key considerations, including determining (1) the at-risk population to be targeted for screening, (2) the method or methods of screening, whether mandatory (required) or voluntary (optional), (3) the persons who have access to the screening program (Lin-Fu and Lloyd-Puryear), (4) whether there is an effective and affordable treatment for the condition being screened, (5) the corresponding benefits to individuals of screening in

cases in which treatment is lacking, and (6) whether the screening program is well tailored to accomplish the underlying public health goals.

Each of these criteria underlying the implementation of a genetic screening program is critical. If the screening program targets too large a group and is thus over-inclusive, persons may unjustifiably be asked or required to participate without any individual or public health benefit. If the screening is mandatory, individual autonomy can be breached unfairly. In cases in which persons lack access to testing services, they are unfairly left out of a public health program designed to improve communal health. If there is no effective treatment for a genetic condition, is there a valid reason to screen anyone for it? Many public health officials would suggest that there is not.

PRIVACY AND DISCRIMINATION. Many persons view their genetic information as highly sensitive and take affirmative measures to protect the privacy of that information. According to Georgetown University's Health Privacy Project (2001), over 15 percent of people engage in privacy-protective behaviors (e.g., withholding information, providing inaccurate information, doctor hopping, or avoiding care) to shield themselves from misuse of their health information. Individuals are concerned about the privacy of their genetic data because breaches can lead to invidious discrimination against an individual or group (Hodge and Harris) by insurers, employers, government agencies, and other societal members. Health, life, and disability insurers may attempt to use genetic test results to limit or deny coverage. Employers may reject applicants for positions or advancement on the basis of their genetic flaws (Gostin, Hodge, and Calvo).

Complicating the privacy claims of individuals, however, are the legitimate claims of others who have a right to know about another person's genetic profile. Spouses, offspring, and close family members may claim a right to obtain knowledge of an individual's genetic test results. State courts in Florida and New Jersey have suggested that healthcare workers may be obligated to share the results of genetic tests with blood relatives of their patients in certain circumstances. Right-to-know claims may further principles of beneficence but can impinge on the privacy rights of individuals participating in public health genetic screening programs.

GENETIC EXCEPTIONALISM. Individual privacy and antidiscrimination concerns relating to genetic testing have led many states to adopt genetic-specific privacy and antidiscrimination laws that are intended to protect persons from wrongful acquisition, use, or disclosure of individually identifiable genetic data. These laws treat genetic information differently from other medical or personally identifiable information and typically establish heightened protections (Gostin and Hodge). Within the context of public health uses of genetic testing or screening programs the trend toward genetic exceptionalism presents its own ethical and practical concerns.

Genetic exceptionalism suggests that genetic information is unique. Many people believe that genetic information is different from other health data for several reasons. Foremost among those reasons is its predictive nature. Unlike most other medical records, which describe an individual's past or current health condition, genetic tests can identify (with varying degrees of confidence) the increased risk of future disease in otherwise healthy individuals. Other qualities add to the perception that genetic information is different. It remains largely stable throughout life. Genetic footprints are remarkably identifiable. Genetic conditions are inherited, and this means that genetic information necessarily reveals information about an individual's current family members and future offspring. Finally, although genetic tests are limited in their capabilities, genetic information can transcend health status to reveal predispositions and personal characteristics (Gostin, Hodge, and Calvo).

There are drawbacks to treating genetic information differently. Strict protection of autonomy, privacy, and equal treatment of people with genetic conditions may threaten the accomplishment of communal goods, including public health surveillance. As scientists discover more medical conditions that are gene-based, it will become increasingly difficult to distinguish genetic data from other medical data. Genetic information is part of the continuum of an individual's medical record and cannot be separated from those data easily. Some privacy advocates argue that genetic information is more sensitive than other health information because it can provide significantly more personal information about an individual's existing and future medical conditions. However, *nongenetic* electronic health records also may provide many personal details. Electronic health records include private demographic, financial, and family history information as well as a patient's social, behavioral, and environmental factors (Gostin and Hodge).

Genetic-specific statutes may be considered unfair because they treat people who are facing the same social risks differently on the basis of the biological cause of their otherwise identical health conditions. Why, for example, should medical information about a woman who has developed breast cancer of genetic origin (e.g., BRACA 1 or 2) be given greater protection than information about a woman who has developed breast cancer because of environmental or behavioral factors such as smoking (Rothstein)?

On a practical level, treating genetic diseases as distinct from other medical diseases or conditions may enhance the stigma of genetic testing and screening programs even as lawmakers attempt to remove their stigmatizing effects. This can create public fears and misapprehension about genetics that may discourage individuals from seeking testing or participating in screening programs and may thwart future scientific progress.

Conclusion

The public health benefits of genetic testing and screening support their existing and future uses in the population, yet the underlying risks to individuals and populations require caution and awareness. Ethical issues related to the administration of testing and screening with informed consent, the privacy rights of individuals, and concerns about discrimination cannot be resolved easily. Balancing individual rights with the community's interests in promoting public health requires an understanding of the sometimes divergent positions of bioethics and public health ethics. Exceptionalizing protection of individual rights that are based on distinctions of genetic tests or information from other health data is difficult. Ultimately, choices about the use of genetic tests and the administration of genetic screening in the population must be made collectively in the interests of promoting improvements in public health.

V. PREDICTIVE GENETIC TESTING

In June 2000 international leaders of the Human Genome Project (HGP) confirmed that the rough draft of the human genome had been completed a year ahead of schedule. In February 2001 special issues of *Science* and *Nature* published the working draft sequence and analysis. A complete, high-quality DNA reference sequence was announced in April 2003, two years earlier than the originally projected completion date. Although a major goal of the HGP is to provide tools to treat, cure, and ultimately prevent genetic disease, the immediate outcome has been a surge in the number of genetic tests that can be used to determine an individual's risk for developing an ever-increasing number of genetic diseases.

The ability to provide currently healthy individuals with DNA-based risk assessments for diseases that will manifest in the future, especially in the absence of effective treatment for those diseases, presents challenges for those at

risk, health professionals, and society. This entry explores some of those challenges, concentrating on tests that can detect mutations associated with adult-onset disorders.

Available Tests

The beginning of the era of genetic prediction can be dated to 1983, when Huntington's disease (HD) became the first disease to be mapped to a previously unknown genetic location through the use of restriction enzymes that cleave deoxyribonucleic acid (DNA) at sequence-specific sites (Gusella et al.). Huntington's disease is a late-onset autosomal dominant neuropsychiatric disorder. The child of an affected parent has a 50 percent chance of inheriting the genetic mutation that causes HD. Disease onset usually occurs in the fourth decade of life and is marked by a movement disorder, alterations in mood, and cognitive decline. There is no treatment or cure.

Inherited variations of these DNA sequences, which also are known as restriction fragment length polymorphisms (RFLPs), can be used as genetic markers to map diseases on chromosomes and to trace the inheritance of diseases in families. The discovery of these markers represented a significant advance in HD research. Not only did the markers provide a possible clue for finding the HD gene and understanding the mechanism by which the gene causes brain cells to die, this discovery meant that predictive testing for some individuals at risk for HD was possible through the use of a technique called linkage. Linkage testing requires the collection and analysis of blood samples from affected and elderly unaffected relatives of the at-risk individual who asks for testing to trace the pattern of inheritance of the HD gene in a specific family. Linkage testing is labor-intensive and expensive and can result in erroneous conclusions caused by incorrectly attributed paternity, misdiagnosis, and the distance between the gene and the markers used for testing. The discovery of the HD gene in 1993 (Huntington's Disease Collaborative Research Group) made testing more accurate, less expensive, faster, and possible for every person at risk for HD.

Since that time new discoveries in molecular genetics have shifted the focus from relatively rare single-gene disorders such as HD to common adult-onset disorders that cause substantial morbidity and mortality. Examples include the identification of mutations in the BRCA1 and BRCA2 genes as causes of susceptibility to breast and ovarian cancers (Miki et al.; Wooster et al.), the discovery of multiple genetic mutations associated with the risk of colorectal cancer (Laken et al.; Lynch and Lynch), the reported association between the APOE e4 allele and late-onset Alzheimer disease (Strittmatter et al.), associations between factor V Leiden and thromboembolic disease (Hille et al.; Ridker et al.; Simioni et al.), and the identification of the HFE gene for hereditary hemochromatosis (Beutler et al.; Edwards et al.). In the second decade of the twenty-first century it has been predicted that genetic tests will be available for diabetes, asthma, dyslexia, attention deficit hyperactivity disorder, obesity, and schizophrenia. These discoveries point to the potential use of genetic tests for population screening in adult populations and an increasing role in public health for genetic testing.

Evaluating New Tests

The National Institutes of Health–Department of Education–Department of Energy (NIH–DOE) Task Force on Genetic Testing stated in 1998 that any proposed initiation of population-based genetic screening requires careful attention to the parameters of both analytical and clinical validity. For DNA-based tests analytical validity requires establishing that a test will be positive when a particular sequence is present (analytical sensitivity) and establishing the probability that that test will be negative when the sequence is absent (analytical specificity). Clinical validity involves establishing measures of clinical performance, including the probability that the test will be positive in people with the disease (clinical sensitivity), the probability that the test will be negative in people without the disease (clinical specificity), and the positive and negative predictive value (PV) of the test. The positive PV is the probability that people with a positive test eventually will get the disease. The negative PV is the probability that people with negative test results will not get the disease.

Two features of most of the genetic diseases discussed as candidates for population-wide screening also affect the clinical validity of any test designed to screen for those diseases. The first is heterogeneity, or the fact that the same genetic disease may result from the presence of any of several different variants of the same gene (an example would be cystic fibrosis, with over 900 mutations found in the CF gene) or of different genes (such as the genes for breast cancer BRCA1 and BRCA2). The second is penetrance, the probability that disease will appear when the disease-related genotype is present. Both heterogeneity and penetrance may differ in different populations, causing difficulties in the interpretation of test results. The final Report of the Task Force on Genetic Testing stated that "clinical use of a genetic test must be based on evidence that the gene being examined is associated with the disease in question, that the test itself has analytical and clinical validity, and that the test results will be useful to the people being tested" (Task Force on Genetic Testing).

From a public health perspective the value of implementing these tests on a population-wide basis will depend to a large extent on whether early treatment of diseases discovered through screening improves the prognosis (Burke et al.). That can be determined only through randomized clinical trials, an expensive process for the array of tests likely to be developed in the near future. However, experience with hormone replacement therapy (HRT) for healthy postmenopausal women in which HRT was found to cause more health problems than a placebo (Writing Group for the Women's Health Initiative Investigators) and a widely used knee surgery technique for osteoarthritis that was found to be ineffective (Moseley et al.) suggests that such trials may be a necessary component of any proposed large-scale screening effort.

Critics of this approach say that the prospective studies necessary to gather this type of information can take years. If widespread use of a test is withheld until the positive predictive value is determined fully and the risks and benefits of testing are known clearly, manufacturers and laboratories could be inhibited from developing tests, and consequently, people will be denied the benefits of being tested. Even without an effective treatment these benefits might include a reduction in uncertainty, the ability to avoid the conception or birth of a child carrying the disease-causing mutation, escape from frequent monitoring for signs of disease or prophylactic surgery, and freedom from concerns about employment or insurance discrimination.

In the absence of a consensus on the public health benefits of widespread screening, tests continue to be developed and in some cases marketed directly to physicians and consumers. For example, in June 2002 Myriad Genetics, based in Salt Lake City, Utah, announced that it would market genetic tests for familial cancers to the general public despite the fact that those tests were appropriate only for a very small percentage of the population. This practice has been the subject of some controversy (Holtzman and Watson), especially in cases in which predictive tests have become available without adequate assessment of their positive predictive value or benefits and risks. Without this information it is difficult for providers or consumers to make thoughtful and fully informed decisions about whether to offer or to use the tests. In another case a test based on the association of the APOE e4 allele with late-onset Alzheimer's disease was marketed directly to physicians just months after the first paper about that association was published. The genetics community decried this development, asserting that the actual interpretation of those associational data for any single individual could not be determined and that any test result based on it would be misleading if not worthless. The public outcry was so great that the test was withdrawn from the market in a matter of months.

The Testing Process

Requests for testing can arise from a variety of circumstances and for a number of reasons. For example, although genetic test results can be used to guide individual healthcare and reproductive decisions, genetic testing often is sought to fulfill familial, domestic, or vocational responsibilities (Burgess and d'Agincourt-Canning). For this reason healthcare professionals must be adept at presenting and discussing the potential ramifications of testing in light of the at-risk individual's reason for requesting testing. Genetics practice also calls for pretest and posttest counseling and formal informed consent procedures to ensure that people deciding whether to undergo genetic testing are informed about the risks and potential harms, benefits, and limitations of the test, as well as alternatives and treatment options (National Advisory Council for Human Genome Research; Holtzman and Watson).

At the beginning of the twenty-first century, the volume of genetic testing was not great and the vast majority of testing occurred in genetic centers or in consultation with highly trained geneticists and genetics counselors. As the number of tests increases, the demand for testing may outstrip the capacity of genetics-trained individuals to respond. This scenario suggests that it is likely that more and more testing decisions will be made by physicians with little formal training or experience in genetics. Some question the ability of physicians to perform this function and continue to recommend referrals to health professionals with specific training in genetics to ensure proper counseling, informed consent, and correct interpretation of test results (Giardello et al.).

A related issue is the fear that physicians will be more likely to take a directive approach to decisions about testing. This approach is antithetical to the concept of the value-neutral nondirective counseling that is a main tenet of all genetic counseling. Historically, this commitment to nondirective counseling can be understood as a moral stance designed to disassociate modern genetics from the eugenics movements of the first half of the twentieth century, which often advocated forced sterilization for individuals deemed to be genetically abnormal (Paul).

Philosophically, nondirective counseling also reflects the centrality of respect for autonomy (the right to self-determination or self-governance) in modern bioethics. Because decisions about genetic testing often involve reproduction and/or an individual's most personal desires and fears, the genetics community has adopted the view that the

role of the genetics professional is to help an individual make a decision about testing that is consistent with that person's most strongly held values. Genetic counselors in training are taught specifically not to let their own opinions and attitudes influence the information that is given to people or recommendations for a course of action.

The Decision to Be Tested

The process of genetic testing can challenge traditional concepts of autonomy and privacy. The desire to be tested on the part of one individual can place pressure on other family members if their cooperation is required for the test to be done. In testing for familial cancers, for example, it is often necessary for a family member who is already affected to be tested first to identify the specific disease-associated mutation in the family. If the affected family member refuses to cooperate, that refusal can frustrate the desire of other family members to learn about their risk. This need to identify an index case also makes it difficult for an individual who wishes to be tested to keep that decision private.

Some authors have advanced the concept of *relational responsibility* as playing a key role in decisions regarding testing (Burgess and d'Agincourt-Canning). This ethical concept emphasizes that decisions about genetic testing occur within complex social relationships that are embedded in and shaped by notions of responsibility to specific others. Thus, although testing guidelines often emphasize that the decision whether to undergo genetic testing should be solely that of the individual for his or her own purposes and free from coercion by a spouse or another family member, research suggests that in reality people often make decisions about testing on the basis of the wishes and desires of others, primarily close family members, about whom they care deeply. Rosamund Rhodes has taken the notion of relational responsibility further, arguing that individuals have a moral duty to pursue genetic information about themselves, especially in cases in which that information has ramifications for others, such as spouses or children (Rhodes).

Ordering Tests

Once the decision has been made to pursue testing, tests for relatively common disorders usually are obtained from commercial laboratories (GeneTest). Blood is drawn and mailed to the laboratory, and the test results are conveyed back to the healthcare professional who ordered the test. That person then has the responsibility of conveying the results, usually in person, to the individual who has been tested. Genetic tests for rare disorders sometimes are available only from laboratories in academic medical centers that have a particular interest in the disease in question. Those laboratories may not have satisfied the ongoing quality and proficiency assessments required of commercial laboratories, thus raising questions about the reliability of testing obtained from this source.

Sharing Genetic Information

When a test has been performed and a result has been obtained, other considerations come into play. Perhaps the most vexing is whether and when a person has a moral duty to share genetic information. Genetic test results for a specific individual also reveal information about that person's relatives. Parents and children share half their genes, as do siblings. If a woman learns that she carries a gene associated with breast cancer, does she have a responsibility to share that information with her sister? Many writers agree that that responsibility exists, with Dorothy Wertz and colleagues suggesting that at the level of the person genetic information, although individual, should "be shared among family members" as a form of shared familial property (Wertz et al.). Indeed, most people, once they are aware of the implications of genetic information for other family members, willingly share the information with those for whom it is especially relevant.

However, what if a woman with a breast cancer mutation does not wish to share that information? May her physician breach her confidentiality and warn her sister? Several groups have addressed this issue in depth (President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research; Andrews et al.). Guidelines published by the American Society of Human Genetics Social Issues Subcommittee on Familial Disclosure in 1998 state that the legal and ethical norm of patient confidentiality should be respected, with breaches of confidentiality permitted only in exceptional cases. Those exceptions are (1) when attempts to encourage disclosure by the patient have failed, when the harm is highly likely to occur and is serious and foreseeable, when the at-risk relative or relatives are identifiable, and when the disease is preventable/treatable or medically accepted standards indicate that early monitoring will reduce the genetic risk and (2) when the harm that may result from failure to disclose outweighs the harm that may result from disclosure (Knoppers et al.). At least one author has argued that knowledge about the risk for conceiving a child with a deleterious gene does not pose the type of serious, imminent harm that generally would require disclosure (Andrews).

In regard to the issue of disclosure Ruth Macklin suggests the institution of a patient "Miranda" warning so that before genetic testing occurs, a patient would be warned

about the circumstances that would result in the disclosure of genetic information to other family members regardless of the patient's intentions to disclose (Macklin).

Two court decisions appear to indicate an increasing trend toward disclosure. In *Pate v. Threkel,* Florida, 1995, a physician was held to a duty to warn patients of the familial implications of a genetic disease. In *Safer v. Estate of Pack,* New Jersey, 1996, the court held that a physician has a duty to warn relatives known to be at risk for a genetic disorder regardless of potential conflicts between the duty to warn and the obligations of confidentiality. The courts have not yet addressed a physician's obligation to disclose information concerning individuals whose occupations may place the lives of others in danger, such as pilots and air traffic controllers.

The completion of the Human Genome Project will result in a proliferation of genetic tests for a wide variety of disorders. Some public health advocates argue for a broader role for population-based testing, whereas critics believe that further work needs to be done to understand the value of testing on a widespread basis. Concerns exist about the ability of consumers and physicians to make informed decisions about whether to use genetic tests and are exacerbated by a growing trend on the part of commercial laboratories to market the tests directly to consumers. Once a test has been ordered and the results have been obtained, questions remain about the duties of both individuals and healthcare professionals regarding disclosure of test results.

VI. PEDIATRIC GENETIC TESTING

DNA-based clinical testing is available for over 900 genetic diseases, and research-based testing is offered for hundreds of others. Such testing can aid in making diagnoses, assessing recurrence risks, and providing accurate prognoses. Often genetic testing is initiated prior to the onset of symptoms. This type of testing is known as pre-symptomatic or predictive genetic testing, and is typically offered for adult-onset diseases such as Huntington's chorea or certain types of cancer. Huntington's chorea, or Huntington's disease, is a progressive, fatal, neurological condition that affects movements and memory. Individuals who carry the gene for Huntington's disease usually begin showing symptoms around age 40, though this can vary dramatically between individuals and families. The types of cancer that can be associated with inherited DNA mutations include breast cancer, ovarian cancer, and certain types of colon cancer.

Though DNA-based clinical testing has become a part of routine management for numerous diseases, it presents a unique set of circumstances that separate it from other types of testing. Since a number of genetic mutations are inherited from parents, testing either children or parents will often reveal increased risk for other family members. In the cases of autosomal dominant conditions such as Huntington's disease or Hereditary Breast and Ovarian Cancer syndrome, an affected parent has a 50 percent chance of passing on the defective gene to his or her child.

There are a number of ethical issues associated with the use of pre-symptomatic testing for adult-onset disorders. One important area of discussion focuses on whether genetic testing for these diseases should be initiated in children. Several professional organizations, including the American Academy of Pediatrics and the American Society for Human Genetics, have formal positions stating that children under the age of eighteen years should not undergo genetic testing for adult-onset disorders. The American Society for Human Genetics states: "if medical or psychological benefits of a genetic test will not accrue until adulthood, as in the case of … adult-onset diseases, genetic testing generally should be deferred" (American College of Medical Genetics, pp. 1233–1241), and the World Federation of Neurology Research Group on Huntington's Chorea explicitly recommends not testing any minors.

These policies are driven by the argument that since these are adult-onset disorders for which there is no treatment or medical intervention during childhood, there is no medical benefit to testing. Additionally, children are unable to understand the complexities involved in the testing and therefore cannot provide informed consent. Testing these children, then, potentially could be seen as harmful, as it takes away their right not to know their genetic status.

Proponents of genetic testing in children argue that there are situations when the benefits of testing, either medical or emotional, outweigh the potential harms. This article will explore these arguments in detail, and present a proposal for appropriate use for predictive tests in children.

Pre-symptomatic genetic testing for adult-onset disorders typically involves a detailed informed consent process. This process can include discussions of the natural course of the disease, prognosis, risks to other family members, and treatment options. Some informed consent processes, such as the one outlined by the Huntington's Disease Society of

America, require a psychiatric assessment to determine how test results will be viewed, and what potential reactions might occur. This process can be lengthy and challenging for an adult, and would not be possible for a child. The question, then, is raised as to whether parents can consent for the pre-symptomatic genetic testing for children.

Medical decision making for adults is largely guided by respect for persons and autonomy, whereas in pediatrics it is guided by beneficence. With regards to adult medicine, medical decisions made by competent adults who have undergone an appropriate informed consent process are typically respected. In a pediatric setting, the parents traditionally have had the responsibility of medical decision making, where a competent adult is challenged to make decisions not for his or her own care, but for the child's. This is based on the assumptions that parents are typically interested in maintaining their children's best interests and safety; parents are in a position to know what those best interests are by virtue of knowing their children better than anyone else; parents usually must deal with the financial, emotional, and practical aspects of such decisions; and Western society typically has strived to maintain privacy and parental control within a family unit whenever possible. In other words, the autonomy of parents traditionally is respected as long as it supports the benefit of the child; the challenge then becomes balancing the rights of the children with the rights of parents.

Can Predictive Genetic Testing be Harmful?

There are some situations where the desires of the parent, regardless of how well meaning, may not be in the best interest of the child. In the case of pre-symptomatic genetic testing, a parent often has a need to know what the genetic status of a child is, but that information may or may not be beneficial to the child, and even could be harmful. The purpose of an informed consent process for pre-symptomatic testing is to enable individuals to make decisions about whether they want this information, and to consider how it might affect how they live their lives. A child who has undergone genetic testing will never have the option not to know the results of that information. A positive test result in a child may result in potentially serious psychosocial affects on relationships, family, school performance, and self-concept. This is particularly true if the child has watched a great deal of suffering on the part of the parent. A negative test result can lead to survivor guilt or feelings of being ostracized from affected family members. Many adults choose not to undergo testing due to the psychological burden of incorporating a test result into their lives and futures, and opponents of predictive genetic testing in children feel that children should be offered that same freedom from knowledge.

Personal experience can also interfere with a child's ability to understand the complexities of a positive result, or the reassurance of a negative result. For example, a positive DNA test for the genes associated with Breast and Ovarian Cancer syndrome confers a lifetime risk of developing breast or ovarian cancer of approximately 50 to 80 percent, not 100 percent. Conversely, a negative test result for this child reveals that her risk of breast cancer is not zero, but rather that of the general population, which is approximately 10 percent. A child who has watched her mother die from breast cancer may view this positive result as a prediction of her future and a death sentence, instead of indicating an increased risk. This is a heavy burden to place on a child who is already struggling with the loss of a parent.

The nature of genetic material presents an additional challenge to testing individuals of any age, but these issues can be magnified when dealing with children. By definition, genetic testing often reveals information about other family members, and healthcare providers should consider prior to testing how that information will be addressed. Specifically, genetic testing can reveal cases of non-paternity that can have an adverse affect on the relationship between parent and child.

Can Predictive Genetic Testing be Beneficial?

There are potential benefits to pre-symptomatic genetic testing in children. From a parental standpoint, knowing the genetic status can help parents plan financially and emotionally for their child's future. A positive result may mean long-term care issues that can be offset by advanced financial planning. A parent who is afflicted with a genetic disease may seek comfort in knowing that he or she did not pass on the defective gene to a child, even if symptoms of that disease are years away. In the cases of Huntington's disease and certain types of cancer, an affected parent may not survive long enough for their child to reach adulthood, meaning the parent may die not knowing if their child will suffer a similar fate.

The child herself may be comforted by a negative result. There is a strong argument for the emotional benefit of being able to tell a child who is afraid of the disease of a parent that he or she is unlikely to develop the same disease. This is particularly true in an adolescent, who may have been able to identify his or her own risk through research, even if this information was never discussed at home or with a medical practitioner.

In addition, there are potential medical benefits to be considered. In the case of familial adenomatous polyposis (FAP), a familial colon cancer syndrome, colon cancer has been reported in children as young as ten years of age. Approximately 75 percent of those individuals carrying a DNA mutation associated with FAP will develop precancerous polyps before age twenty. In families where this disease has been identified, children of affected parents have a 50 percent chance of having inherited the mutation. For these children, a positive test result would mean a much more rigorous medical course, involving annual colonoscopies to monitor the development of polyps, and most likely a prophylactic colectomy in the future, both measures that could save lives. A negative test result would spare these children from such invasive screening, and reveal their lifetime risk of colon cancer to be that of the general population.

Though it is generally understood that children do not possess the competence to make medical decisions, the situation is less clear for adolescents. Obviously there is no perfect age that competence can be assumed, nor is there a minimum age at which it can be specified as absent. There are adolescents who are capable of engaging in the informed consent process and making medical decisions for themselves. One would hope that, when possible, the decisions of the parent would encompass conversation with the child or adolescent and involve the minor to whatever degree is appropriate for maturity, interest, and responsibility.

The Rule of Earliest Onset

One proposal for determining the appropriate use of predictive tests is the "rule of earliest onset." Simply put, the rule states that "genetic testing should be permitted no earlier than the age of first possible onset of disease" (Kodish, p. 391). This guideline allows for the possibility that medical benefit may outweigh potential harms. Employing this basic rule provides several advantages. First, predictive testing is limited to those children for whom there is a potential medical benefit. Though this does not eliminate the possibility that decisions to test will be fueled by additional motivations, it ensures that benefit to the child will be present. Secondly, by delaying testing until an age when symptoms may occur, one maximizes the likelihood that the now older child can participate in the decision-making process. Finally, it is a family-specific guideline for testing that accounts for variation in the age of onset. For example, even though the majority of Huntington's disease occurs in adults, approximately 10 percent of cases are juvenile. In these families, the disease is typically transmitted through a father whose own disease had an earlier than expected presentation. If predictive testing for a child is being considered, and the history reveals that in this particular family the father is the affected individual and his symptoms developed in his twenties, then the rule of earliest onset for this family would suggest testing an adolescent.

Conclusions

Predictive genetic testing in a pediatric setting is complicated by the complexity of the information, the fact that testing decisions are being made by someone other than the person being tested, and the potential impact of the test results. Traditionally it has been thought that predictive genetic testing should not be offered to children under the age of eighteen, and many professional policies have been developed in support of this.

These policies are based on the assumption that "medical or psychological benefits of a genetic test will not accrue until adulthood." This article has discussed situations where there is arguably either a medical or emotional benefit to the child that would warrant testing, and presented a proposal for the use of predictive genetic testing in pediatrics.

GRIEF AND BEREAVEMENT

• • •

The term *grief* can be defined as a type of stress reaction, a highly personal and subjective response that an individual makes to a real, perceived, or anticipated loss. Grief reactions may occur in any loss situation, whether the loss is physical or tangible, such as a death, significant injury, or loss of property; or symbolic and intangible such as the loss of a dream. The intensity of grief will vary, depending on many variables such as the meaning of a loss to the individual experiencing it. It should be recognized that loss does not inevitably create grief. Some individuals may be so disassociated from the loss object that they experience little or no grief, or their response may be characterized by intense denial.

This definition of acute grief distinguishes it from other terms such as *bereavement* or *mourning.* Bereavement refers to an objective state of loss. If one experiences a loss, one is bereaved. Bereavement refers to the fact of loss, whereas grief is the subjective response to that state of loss. Mourning has had two interrelated meanings within the field. On one hand, it has been used to describe the intrapsychic process through which a grieving individual gradually adapts to the loss, a process that has also been referred to as "grieving" or "grief work." The term has also been used to refer to the social aspect of grief, the norms and patterned behaviors and rituals through which an individual is recognized as bereaved and socially expresses grief. For example, in the United States, wearing black, sending flowers, and attending funerals are common illustrations of appropriate mourning behaviors.

Paradigms of Grief

Grief was first empirically described in 1944 by Eric Lindemann, a psychiatrist who studied survivors of the Coconut Grove Fire, a 1942 Boston fire that swept through a nightclub, killing many. Lindemann described grief as a syndrome that was "remarkably uniform" and included a common range of physical symptoms, such as tightness of throat, shortness of breath, and other pain, as well as emotional and other responses. It should be recognized that Lindemann's research was based on a sample of primarily young survivors of sudden and traumatic loss.

This medical model of grief was continued most clearly in the work of George Engel (1961). Engel believed that grief could be described as a disease, one having a clear onset in a circumstance of loss; a predictable course that includes an initial state of shock; a developing awareness of loss characterized by physical, affective, cognitive, psychological, and behavioral symptoms; and a prolonged period of gradual recovery, with the possibility that this recovery may be complicated by other variables. He noted that other disease processes also are influenced by psychological and social variables. Even the fact that grief is universal and rarely requires treatment, Engel argued, is not unlike other diseases. Engel also noted that whether or not a disease requires medical treatment or is even recognized as a disease is a social convention. Epilepsy, alcoholism, and many forms of mental illness are recognized as diseases but were not at other times in human history or in other cultures.

Another paradigm that attempts to offer insight into the nature of acute grief is the psychological trauma model. This model, based on the work of the Austrian neurologist Sigmund Freud (1917), views grief as a response to the psychological trauma brought on by the loss of a love object. Acute grief is a normal defense against the trauma of loss. To Freud, grief is a crisis, but one that will likely improve over time and that generally does not require psychiatric intervention.

Perhaps one of the more influential models to account for acute grief is the attachment model developed by John Bowlby (1980). This approach emphasizes that attachment, or bonding, is a functional survival mechanism, an instinct found in many of the higher animals. Given the prolonged periods of infancy and dependency, attachment is necessary for the survival of the species. When the object of that attachment is missing, certain behaviors arise that are instinctual responses to that loss. These behaviors, including crying, searching, and clinging, were seen by Bowlby as biologically based responses that seek to restore the lost bond and maintain the attachment. When these bonds are permanently severed, as in death, these behaviors continue until the bond is divested of emotional meaning and significance. These behaviors also serve a secondary purpose. By expressing distress, they engage the care, support, and protection of the larger social unit. This psychobiological model sees grief as a natural, instinctual response to a loss, a response that continues until the bond is restored or the grieving person detaches and divests of the bond.

These early approaches continue to influence understandings of grief, though more contemporary models emphasize that grief is a natural response to major transitions in life and that bonds between the grieving individual and the lost object continue, albeit in different forms, after the loss (Klass, Silverman, and Nickman). In addition, more recent approaches emphasize that a significant loss may shatter assumptions, causing grieving individuals to reconstruct their sense of self, their spirituality, and their relationship to others and the world at large. While this may be a painful process, it also may be a catalyst for growth.

Manifestations of Grief

Individuals can experience acute grief in varied ways. Physical reactions are common. These includes a range of physical responses such as headaches, other aches and pains, tightness, dizziness, exhaustion, menstrual irregularities, sexual impotency, breathlessness, tremors and shakes, and oversensitivity to noise.

Bereaved individuals, particularly widows, do have a higher rate of mortality in the first year of loss (Osterweis, Solomon, and Green). There may be many reasons for this—the stress of bereavement, the change in lifestyle that accompanies a loss, and the fact that many chronic diseases have lifestyle factors that can be shared by both partners. It is important that a physician monitor any physical responses to loss.

There are affective manifestations of grief as well. Individuals may experience a range of emotions such as anger, guilt, helplessness, sadness, shock, numbing, yearning, jealousy, and self-blame. Some bereaved persons experience a sense of relief or even a feeling of emancipation. This, however, can be followed by a sense of guilt. As in any emotional crisis, even contradictory feelings, such as sadness and relief, can be experienced simultaneously.

There can be cognitive manifestations of grief. Included here is a sense of depersonalization in which nothing seems real. There can be a sense of disbelief and confusion, an inability to concentrate or focus. Bereaved individuals can be preoccupied with images or memories of the loss. These cognitive manifestations can affect functioning at work, school, or home. Many persons also report experiences in which they dream of the deceased or have a sense of the person's presence, even sense-based experiences of the other.

Grief has spiritual manifestations. Individuals may struggle to find meaning and to reestablish a sense of identity and order in their world. They may be angry at God or struggle with their faith.

Behavioral manifestations of grief can also vary. These behavioral manifestations can include crying, withdrawal, avoiding or seeking reminders of the loss, searching behaviors, over activity, and changes in relationships with others.

The reactions of persons to loss are highly individual and influenced by a number of factors. These include the unique meaning of the loss, the strength and nature of the attachment, the circumstances surrounding the loss such as the presence of other crises, reactions and experiences of earlier loss, the temperament and adaptive abilities of the individual, the presence and support of family and other informal and formal support systems, cultural and spiritual beliefs and practices, and general health and lifestyle practices of the grieving individuals.

The Course of Grief

There have been a number of approaches to understanding the process or course of acute grief. Earlier approaches tended to see grief as proceeding in stages or phases. Colin Murray Parkes (1972), for example, described four stages of grief: shock, angry pining, depression and despair, and detachment. Recent approaches have emphasized that grief does not follow a predictable and linear course, stressing instead that it often proceeds in a roller-coaster-like pattern, full of ups and downs, times when the grief reactions are more or less intense. Some of these more intense periods are predictable—holidays, anniversaries, or other significant days—but other times may have no recognizable trigger.

More recent approaches have emphasized that grief involves a series of tasks or processes. J. William Worden

(1992) described four tasks to grief: recognizing the reality of the loss, dealing with expressed and latent feelings, living in a world without the deceased, and relocating the deceased in one's life. Therese A. Rando (1993) suggested that grieving individuals need to complete six "R" processes: recognize the loss, react to the separation, recollect and reexperience the deceased and the relationship, relinquish the old attachments to the deceased and the old assumptive world, readjust to the new world without forgetting the old, and reinvest. (While the language of both Worden and Rando is specific to death-related loss, their models can be adapted to other losses as well.) These and other similar models reaffirm the very individual nature of grief, acknowledging that these tasks or processes are not necessarily linear and that any given individual may have difficulty with one or more processes or tasks.

The critical point to remember is that the course of grief is not linear. Nor is there any inherent timetable to grief. Grief reactions can persist for considerable time, gradually losing intensity after the first few years. Recent research as well emphasizes that one does not "get over the loss." Rather, over time, the pain lessens, and the grief becomes less disabling as individuals function at levels comparable to (and sometimes better than) preloss levels. Bonds and attachments to the lost object continue, however, and periods of intense grief can occur years after the loss (Klass, Silverman, and Nickman). For example, the birth of a grandchild can trigger an experience of grief in a widow who wished to share this event with her deceased spouse.

Help and Grief

Persons experiencing acute grief can help themselves in a number of ways. Because grief is a form of stress, lifestyle management including adequate sleep and diet, as well as other techniques for stress reduction, can be helpful. Bibliotherapy or the use of self-help books can often validate or normalize grief reactions, suggest ways of adaptation, and offer hope. Self-help and support groups can offer similar assistance as well as social support from others who have experienced loss. Others may benefit from counselors, particularly if their health suffers or their grief becomes highly disabling, impairing functioning at work, school, or home, or if they harbor destructive thoughts toward self or others. Parkes (1980) particularly stressed the value of grief counseling when other support is not forthcoming.

Pharmacological interventions also may be helpful particularly when the grief is disabling, that is, severely compromising the individual's health or ability to function. Such interventions should be focused on particular conditions, such as anxiety or depression, that are precipitated or exacerbated by the bereavement. Pharmacological interventions should be accompanied by psychotherapy.

Most individuals seem to ameliorate grief in that, over time, they can remember the loss without the intense reactions experienced earlier. Nevertheless, anywhere from 20 to 33 percent seem to experience more complicated grief reactions (Rando).

Complicated Grief

While models of complicated grief vary (Rando; Worden), complicated grief reactions generally involve intensifications and exaggerations of the earlier described responses to grief that effectively impair the individual's ability to function. Complicated grief can also be evident in masked reactions—that is, the grief is masked by another problem such as substance abuse.

One factor that can complicate grief is disenfranchisement. The term *disenfranchised grief* refers to a grief that results when a loss is not socially sanctioned, publicly acknowledged, or openly mourned. Grief may be disenfranchised because a loss is not recognized (e.g., the loss of an animal companion), a relationship is not recognized (e.g., a friend or therapist), the griever is not acknowledged (e.g., a very young child or a person with developmental disabilities), the death evokes shame or censure (e.g., an execution), or the way the person expresses grief is considered inappropriate or unacceptable. In such cases, the person has experienced a loss, but has "no right to grieve," no expectation of public acknowledgement or support (Doka, 1989, 2002).

Ethical Issues in Grief

Ethical issues in grief may emerge from three sources. First are general issues for counselors. Grieving persons can be highly vulnerable. Counselors have to have personal integrity and follow the ethical standards of their profession, including maintaining confidentiality, preventing harm to the client or others, assuring competence, and upholding standards of professional behavior. Counselors should familiarize themselves with their respective codes of ethics. They may wish to review as well the Code of Ethics of the Association for Death Education and Counseling.

In addition to the normal standards of professional conduct, counselors should be aware of two other ethic-related issues that might arise in grief counseling. Ethical issues within the course of the medical treatment of the deceased person may affect responses to grief. For example, a person who decided to terminate treatment may struggle with that issue within the grief process. In similar ways,

ethical decisions made after the death—such as the disposition of the remains or inheritance—may also be reviewed in the grieving process. For example, the deceased may make requests regarding the disposition of remains or property that families may be reluctant to follow. Such situations can exacerbate grief—intensifying guilt or anger and causing conflicts that lessen mutual support and add concurrent stresses.

H

HARM

• • •

Harm is a central concept both in the practice of medicine and in ethics. Hence, it is no surprise that in bioethics harm plays a prominent role. The proper goal of medicine is to prevent, alleviate, or eliminate harm to patients that result from disease or injury. Moreover, some medical interventions themselves have a serious potential to cause additional (iatrogenic) harm—for instance, pharmacological side effects or even death from surgery.

General prohibitions against inflicting harm on others supposedly belong to the principles of any moral code, and an attitude of non-malevolence (taking care that others do not suffer harm) is widely regarded as a core virtue and as a decisive source of moral motivation. Beyond this, bioethics is concerned with harm-related judgments, obligations, prohibitions, and problems. The harm at stake is most often harm to patients. Such debates as those about professional duties toward patients, about matters of resource allocation, or about the limits of patient self-determination all deal in part with actual or potential suffering, dysfunction, pain, or death of patients. Some problems, however, relate to potential harm to third parties. For example, HIV-positive patients risk infecting uninformed sexual partners and pregnant women who consume drugs risk harm to their unborn children. Other ethical questions deal with harm to health professionals themselves—when, for instance, a physician faces treating a contagious patient under substantial personal risk. And finally, various arguments in bioethics address the possibility of long-term social harm resulting from certain permissive practices (the so-called slippery slope argument). For example, critics of prenatal selection against severe genetic diseases predict shrinking social solidarity with the handicapped and with their justified claims to social support.

While its central role in bioethics thus cannot be disputed, *harm* remains a vague and contested concept that in and of itself does not provide much moral guidance. What counts as harm varies greatly, as do the scope and relative importance of the prescriptions not to inflict, to prevent, or to remove harm.

Conceptual Questions

An instance of harm may be assessed with reference to kind, degree, and duration. Risk assessment, not considered here, also includes the probability of harm's occurrence. According to the *Oxford English Dictionary,* harm is "evil (physical or otherwise) as done to or suffered by some person or thing; hurt, injury, damage, mischief." As far as harm is relevant to moral deliberation, however, this broad concept must be restricted.

First, harm should be understood as person- (or animal-) regarding, that is, as consisting of events or states of affairs that are negative for someone—as expressed in Joel Feinberg's definition of harms as "setbacks to interest" (p. 31). As long as the sticky question of what counts as interests remains open, this concept of harm is still neutral to various ethical positions. Problems start with determining who counts as a bearer of interests; for instance, do embryos (as potential persons), the deceased or permanently unconscious (as former persons), or animals bear interests? These issues, although obviously important for evaluating abortion, transplantation, decisions to end treatment, or animal protection, will not be pursued here.

Secondly, ethics in general ethics and bioethics in particular have to restrict their focus on those instances of harm that are in some way or other linked to human action. It would not make sense to morally deliberate about ineluctable evils, deplorable though they may be. Rather, harm is ethically relevant only if it occurs or persists in consequence to human agency, be it by action or omission, from intention or negligence, but not from unavoidable ignorance. Thus, what counts as harm with relevance to bioethics is context-relative: harm is contingent upon professional knowledge and medico-technical progress.

Thirdly, bioethics, reflecting both ordinary moral and non-moral language usage, commonly differentiates between harm on the one hand and mere loss or lack of benefit on the other. Harm is not simply conceptually complementary to benefit (interest satisfaction), but it also represents a significant disservice to its *victim.* Along the scale of interest satisfaction, there are numerous positions of submaximal satisfaction (disbenefits) that it seems inappropriate to call *harms.* There is thus an asymmetry between harm and benefit in the sense that harm pertains exclusively to the basics of well-being. It may be wrong to prevent someone from obtaining a luxury good, but nevertheless, its consequence does not qualify as harm. Another argument elucidating this asymmetry emphasizes that harm has or leads to distinct phenomenal qualities of bodily or psychological painfulness and suffering, which is by no means true for all instances of lacking benefit (e.g., Noddings). Moreover, pity for someone's experience of harm is a motivation distinct from other forms of benevolence (e.g., Sidgwick).

Not to inflict, to prevent, or to remove harm usually takes moral precedence over providing those benefits the lack of which does not count as harm. Such asymmetry between harm and benefit has been traditionally acknowledged (e.g., by John Stuart Mill), but a more systematic focus on harm is a rather recent development of applied ethics, with its eye to more concrete moral rules (a notable exception being Jeremy Bentham's 1789 taxonomy of "pains" by sources, kinds, and circumstances). The improvement of people's well-being being a more or less central goal of any moral code, concrete efforts must first focus on the most important obstacles to well-being, that is, on existing or potential harm.

Understanding harm as a significant setback to someone's interests already implies that usually it ought to be avoided. In this sense harm is a weak normative concept, carrying a presumption of evaluative negativity. However, not every infliction or non-prevention of harm to another person is, all things considered, necessarily wrong, and in just this sense harm is not a strong normative concept. For instance, not to treat a particular patient in a tragic triage situation may be a deplorable but ethically-justified decision. Likewise, foregoing life-saving surgery on a competent patient because he autonomously decided against it, by no means "wrongs" him, in the sense of violating legitimate moral claims (Feinberg). Where harming thus does not necessarily mean wronging, the same is, of course, also true the other way round. One ought not conflate people's legitimate claims to justice or self-determination with those of not being harmed. Less clear cut is the distinction between harms and *offenses,* where the latter cause unpleasant, though not harmful, mental states. In the context of medicine, patients might be frustrated, shocked or irritated by inefficient hospital structures or by physicians who behave rudely. Whether such states of offendedness turn into proper harm seems to be but a matter of degree and duration.

Harm and Harm-Referring Duties in Bioethics

Assessing harm and distinguishing it from offenses, minor hurts, or non-harmful instances of lacking benefit requires an analysis of harm's nature and of how to determine its significance. Particularly in the context of healthcare, many instances of harm and potential harm to patients are widely uncontested, namely: severe lack of functioning resulting from bodily or mental disease, enduring pain, substantial suffering, gross disfigurement, or premature death. Another, easily neglected category of possible harm in the context of medical practice is of a psychosocial nature: for example, patients may experience absorbing anxiety, mistrust, alienation, helplessness, loss of self-control, loneliness, or annoyance due to structural and human deficits. In particular, the work of feminist ethicists (e.g., Noddings; Warren) and physician-ethicists (e.g., Cassell; Pellegrino and Thomasma) has created a new awareness of widely neglected kinds of harm to patients that occur in daily medical practice and that can largely be reduced or avoided when caregivers are humane and sympathetic. Even beyond the individual patient-caregiver relationship, general loss of trust in contemporary biomedical institutions and practices, in researchers and clinicians seems to be a prevalent and deeply troubling problem (O'Neill).

Finally, harm may occur as a setback to patients' higher-level "critical interests" in living a life they consider good (Dworkin). Notably, decisions about one's time and manner of dying are likely to relate to such highly personal, critical interests. Focusing on these issues would involve yet another conceptual enlargement of (modern) medical harm.

All of these states or events are setbacks to individuals' interests in basic well-being, and thus univocally considered harmful. In principle, they can be relevant to bioethics

whenever they potentially occur or persist as a consequence of intentional behavior, where behavior must be understood in a broad sense. Hence, ethically-relevant harm can result from both omission and commission, from individual or collective acts, from a patient's own decision or from someone else's.

Harm can be intended, merely foreseen, or accepted as a lesser evil when compared to the consequences of all available alternatives, and it can be intended with regard to an identified or to a statistical addressee. Take a patient's premature death, to illustrate the broad variance of agents and victims and of causal and intentional modes under which ethically relevant-harm can occur in medicine. This premature death could, for instance, be the consequence of: a physician's decision to stop life-saving treatment, a negligently wrong treatment, an unfortunate research intervention, the patient's own decision against further treatment, a rationing policy, or a negligent infection from undisclosed sexually transmittable disease.

To emphasize it once more: it seems hard to find even one bioethical problem that does not somehow involve aspects of harm to patients or, less frequently, to health professionals or third parties. In all these matters, however, dissent arises when it comes to the comparative evaluation of a particular harm's negativity; in setting standards for professional, social, or personal responsibilities for people's health, and corresponding duties; and in the assessment of distinguishing harm from mere lack of benefit in healthcare.

With regard to duties, some scholars in ethics formulate a distinct duty of nonmaleficence, expressing a prohibition on actions with foreseeable harmful effects. Others, however, include this prohibition as part of a duty of beneficence. This, and whether such obligation is construed as a prohibition on causing net harm to someone (such that, say, shooting a murderer to save the lives of his three victims would not count as maleficent), or on harming itself (the shooting would be maleficent, though perhaps justified), is a question of terminological and classificatory preference. The duty of nonmaleficence is still indeterminate under any of these descriptions, not only because they reintroduce the problems of harm assessment but also because they are silent about permissible limits and trade-offs.

Recognizing a distinct principle of nonmaleficence is fairly common in medical (in contrast to general) ethics. It is meant to guide actions by caregivers in those situations that are most likely to produce harm. However, depending on both formal tailoring of concepts and on normative perspectives, there exist formal and substantial differences among bioethical perspectives in what is understood as nonmaleficence. Tom Beauchamp and James Childress, for instance, turn to the four duties of beneficence originally distinguished by William Frankena in 1973. Frankena's classification of duties is based on a distinction between harm and benefit and on the action's causal mode:

1. not to inflict harm;
2. to prevent harm;
3. to remove harm; and
4. to promote good.

Beauchamp and Childress modify Frankena by subsuming the first duty under nonmaleficence and leaving the last three duties under beneficence. Their distinction between the two duties of nonmaleficence and beneficence thus corresponds to the difference between negative and positive duties (i.e., duties of omission versus duties of commission), again depending on aspects of causality. Beauchamp and Childress do not, however, take this classification as such to be normatively decisive; rather, they intend to capture ordinary language usage, mirroring the empirical fact that noninfliction of harm often is achievable at lower cost to the agent than is obeying positive duties. It is in this generalized sense that the obligation of nonmaleficence frequently has priority over beneficence.

Along these lines, Allen Buchanan and Dan Brock have suggested that appeals to nonmaleficence in medicine be understood as specific reminders: in Hippocratic times, not to forget that some treatments were only burdensome and not beneficial; in contemporary times, to correct "for professional biases toward over-treatment of non-communicating patients in conditions of great risk or profound uncertainty" (Buchanan and Brock, p. 256). These reminders pay attention to medicine's increasing potential not only to benefit patients but also to inflict iatrogenic harm upon them (Sharpe and Faden).

The duty of nonmaleficence may conflict with the autonomy of patients who request treatment that physicians consider harmful (e.g., unjustified surgery, futile chemotherapy, or drugs). With an eye to precisely this conflict, H. Tristram Engelhardt, Jr., understands the duty of nonmaleficence as a justification to limit patients' self-determination.

Problems with Harm in Medicine

As to the more precise nature of harm and to the scope of harm-related duties, bioethics inherits some of the controversies of general ethical theory. A crucial question is to what extent there are objective criteria for identifying and evaluating harm. If such criteria could be found, this might, for

example, justify a physician's overriding a patient's own "harmful" preferences. Or, such criteria could be adduced in surrogate decision making for noncommunicating patients, as well as in matters of allocative justice (where it becomes crucial to evaluate medical interventions in terms of their comparative tendencies to avoid or alleviate net harm).

The issue of determining criteria is linked to the objectivity/subjectivity debate concerning people's well-being and ability to live a good life (see Griffin), and the setbacks to these. With most experts agreeing that there is an irreducible plurality of harms, the subjectivist view takes harm to be a significant setback only to actual wants or desires, possibly after procedural safeguards have been met. Here, for instance, a patient's death due to intentional non-resuscitation would be harmful only if the patient, when informed and asked, would opt for treatment. In the objectivist view, harm is a significant setback also to interests that are want-independent, but related to ideals of a good life. Here, death due to non-resuscitation could be harmful to a patient, regardless of whether he or she wants it.

The fundamental distinction between "want regard" and "ideal regard" (as a difference between subjective versus objective concepts of interest) was introduced by Brian Barry in political philosophy. In that area, lack of autonomy in forming one's wants is less obviously a danger than it is in medicine, where patients can so easily be ill informed, manipulated, or otherwise incompetent when forming their preferences. Therefore, at least certain procedural safeguards—such as standards of informed consent—are not inconsistent with "want regard" in medicine. Other safeguards, like elevating standards for patient competence to a level commensurate with the expected harm that would result from acting in accordance with patient choice (e.g., Buchanan and Brock), arguably cross over into "ideal regard." In any case, there is room for hybrid positions between the extremes of pure want regard and ideal regard. Consider forcing a Jehovah's Witness to be transfused with blood. Justifying this by reference to the patient's presumed objective interest in the preservation of his life falls under ideal regard. Arguing that the patient would want the transfusion if she were not bound to her irrational belief system puts harm assessment by want regard under some ideal-regarding constraint.

A common argument in favor of taking harm as an objective concept stresses the broad consensus in what "rational persons desire to avoid for themselves" (Culver and Gert, p. 70). Reference to the obvious consensus about the desirability of avoiding disease, disability, pain, premature death, and suffering, presupposed in daily medical work, is familiar from the debate over concepts of disease (Culver and Gert). To concur on this point does not imply acknowledging universal standards for all sorts of harm. Rather, pain, disability, and premature death are seen as universal harms simply in being setbacks to very basic interests, the satisfaction of which is instrumental to practically all conceptions of a good life. It would, of course, not come as a surprise to find this true for many kinds of harm, in contrast to mere lack of benefits.

Even more serious problems with defining medical harm hinge on the need to compare two instances of harm, such as those from alternative treatment courses or from alternative resource distributions. Such ranking judgments are needed on kinds of harm (for example, pain versus addiction; premature death versus disfigurement; disease versus a restricted lifestyle) and on how much, when, and for how long harm is to be accepted, and for what purpose. At least implicit comparative evaluations of risks of harm and benefit are involved in virtually any treatment decision or medical indication (Veatch). Here, more fundamental disagreement starts: Some authors emphasize the great variability in comparative harm assessment, pointing to its relatedness to the context of each patient's irreducibly personal or parochial conception of a good life (e.g., Engelhardt; Veatch). This position has nurtured so-called autonomy-centered bioethics, which considers the assessment of harms and benefits to be the patients' business only. In contrast to this position, other scholars want to keep at least some objective ground for evaluations: medical interventions should, according to them, be determined futile not by patients, but by professional standards whenever they appear to be disproportionately harmful and thus "not reasonable" (Brody); or these scholars see interpersonal variability in ranking harm—though it exists—as not predominant and therefore not ruling out a beneficence-centered bioethics.

Other fundamental problems relate to the legitimate scope and relative importance of the obligations to prevent or to remove harm. First, some such actions, although morally laudable, are not required of the agent because they pose undue burdens or risks for him. For example, a therapist need not risk his own death in treating a violent patient. But how far do these agent prerogatives go? And how are they determined and justified? Secondly, harm preventing or removing actions sometimes ought to give way to other overriding duties (e.g., the duty to remove still greater harm from another or to respect patient self-determination). However, there are many different views as to what counts as overriding duty. Between the two extremes—understanding nonmaleficence as the trivially indeterminate principle "avoid harm (whatever that is) unless it is outweighed" or having as many specified duties as there are different normative theories—attempts have been

made to give a more specific meaning to nonmaleficence without leaving the middle ground of broader consensus.

How to Handle Pluralist Harm Assessment

Undeniably, different people have very different notions of what *medical harm* would be for themselves or for others. Autonomy-centered bioethics has seen its task as spelling out procedures to foster a "morality of mutual respect" (Engelhardt) and patients' self-determination. This approach leads to particular concern for informed consent, policies for advance directives, substituted judgment, and so on. A contrasting approach urges that instead of inviting radical individualism in assessing medical harm, we redetermine medicine's substantive goals. Daniel Callahan, for example, argues that such individualism results in net harm to all by consuming too many resources for marginal benefits and setting wrong priorities in our lives. Stressing the importance of expectations and cultural presumptions in determining what individuals view as harm, Callahan hopes to find arguments acceptable to the whole of society—in favor, for instance, of decreasing individual expectations for life-prolonging treatment in old age.

Other authors concur that individualistic harm assessment is the wrong paradigm for medicine: "Moral atomism" is viewed as impoverishing medical practice socially and morally, that is, as giving up grounds on which a sense of community and good decision making should develop (Pellegrino and Thomasma). Others see "moral atomism" as leading to a waste of physicians' power to assist patients in pursuing their goals (Brody, p. 50), or as leading to paralysis in crucial policy questions, such as how to determine the best treatment interests of incompetent patients (Emanuel). Ezekiel Emanuel opts for communitarian healthcare settings, where groups of patients and physicians shape medicine according to their shared assessment of harms and benefits; others are confident that the consensus on harm in the context of medicine is substantial (Pellegrino and Thomasma; Cassell; Brody). They see the main problem in "the view that the physician respects autonomy by taking a negative, hands-off stance" (Brody, p. 50), which they argue ought to be given up in favor of assisting patients, in a critical and trustworthy manner, to assess harms and benefits.

Prominent Controversies on Medical Harm

A prohibition on killing is often taken to be the most important negative duty of nonmaleficence, death being a major harm for most people. Generally, the same is true for the medical context, with the contested exception of assistance in dying. Proponents of active voluntary euthanasia for terminally-ill patients are not only prepared to give priority to patient self-determination in these situations, but would not even consider the resulting death a harm and its intentional provision maleficent—rather to the contrary. Controversies over these issues across many cultures result from different views on the allegedly harmful or benefiting nature of a patient's death from assistance—be it by active killing, by withholding or withdrawing life support, assisted suicide, or indirect euthanasia. Those who insist on normative differences between these various forms of assistance often give normative weight to the involved causal or intentional differences. A prominent instance of such an argumentation is the controversial Roman Catholic doctrine of double effect, according to which, for example, indirect euthanasia can be justified in spite of the death that may result, since the latter is not intended but merely foreseen as a by-product of beneficent painkilling. Other opponents of aid in dying argue with the social harm than could be expected from one or several of these practices once, established as legitimate option for the terminally ill (the slippery slope argument).

Yet another debate centering on the concept of harm-concerns cases of sexually-active patients who carry a sexually-transmittable virus (e.g., HIV) and refuse to inform their partners. Legal prescriptions aside, bioethicists are divided as to whether the treating physician, who cannot convince his patient to the contrary, has a duty to inform those at risk. Obviously the obligation to prevent harm to others conflicts with the professional obligation to confidentiality; violating confidentiality might also lessen the general trust in physicians' patient advocacy.

The heated controversies on prenatal diagnosis, gene therapy, and wrongful birth and wrongful life issues focus on possible harm to future children or their parents, but also on those who are living with genetic handicaps. Once again, bioethicists dissent on what to identify as harm, how to evaluate its negativity, and how to balance related duties against other ethical obligations.

In summary, there is a remarkable tension between harm's undisputed importance in bioethics and the numerous different ways in which it comes to be conceptualized and evaluated, thus mirroring the plurality of existing ethical approaches.

HARMFUL SUBSTANCES, LEGAL CONTROL OF

• • •

At the beginning of the twenty-first century, opium, its constituent morphine, and the derivative heroin were viewed with fear and suspicion. As both popular and professional attitudes in the United States turned against drug use in the United States around 1980, physicians began to fear prescribing potentially addictive analgesics, and likewise, patients began to fear taking them. This attitude contrasts sharply with that of one of the leading American physicians in the mid-nineteenth century, George Wood, of the University of Pennsylvania, who wrote in 1868 that opium produces "an exaltation of our better mental qualities, a warmer glow of benevolence, a disposition to do great things, but nobly and beneficently, a higher devotional spirit, and withal a stronger self-reliance, and consciousness of power" (Vol. 1, p. 712).

Clearly, the ethical position a person takes regarding the availability of a drug is affected profoundly by whether that person believes that the drug is risky in any amount or that reasonable doses of the drug are a boon to humankind. These two positions have alternately influenced experts and the public since at least the eighteenth century in English-speaking countries. In times when one of these attitudes has held sway, the opposite ethical position has been dismissed as wrongheaded and refuted both morally and scientifically.

Attitudes toward Alcohol

Alcohol, a drug with a long history of easy availability and widespread consumption in the West, provides instructive

examples of these dramatic shifts of opinion and their impact on ethical positions. The history of fermented beverages such as beer and wine goes back millennia, and distilled spirits began to be produced by about 1300 in Europe. For centuries afterward, nearly pure alcohol was produced in small amounts, and extraordinary characteristics were attributed to it. *Aqua vitae,* as certain distilled alcohol products were termed, was said to prolong life. In its qualities it approached the quintessence, or fifth element (along with earth, air, fire, and water). The "spirit" derived from distillation, according to John French, a seventeenth-century English physician, had wonderful "vertues … for there is no disease, whether inward or outward, that can withstand it" (p. 132).

In England, new scientific data challenged the old beliefs during the "gin epidemic" of the eighteenth century. For the first half of the century a battle raged between the populace—especially in London, where gin was cheaper than an equal volume of beer —and some religious and secular leaders who were appalled by the spiraling number of public drunks, "weak, feeble, and distempered children" (Plant, p. 9), and deaths attributed to the massive and cheap consumption of distilled spirits. Hogarth's print *Gin Lane* of 1751 captures the social destruction resulting from a substance that once had been thought of as an unadulterated good.

The new view of distilled spirits was incorporated into voluntaristic plans for self-improvement, most notably the religious movement led by John Wesley. In his attempt to revitalize the Church of England and establish a strict morality of behavior, Wesley argued for a distinction between fermented spirits and distilled spirits. He described distilled spirits as "a certain, tho' a slow poison," although he conceded that they might have medicinal uses (Wesley, p. xix). Eventually Wesley's Methodism moved, especially in the United States under the guidance of Wesley's chosen missionary, Francis Asbury, to a rejection of alcohol in any form.

In addition to moral objections, in the United States criticism of alcohol was based upon social and medical observations. Benjamin Rush, perhaps the most distinguished American physician of his time, launched an attack on alcohol that was based on his experiences as a physician in the War of Independence. Rush countered the popular notion that distilled spirits were a healthy means of invigorating soldiers and field workers, and a stimulant to intellectual activity. However, like Wesley, he focused on spirits, not on all forms of alcohol. His pamphlet *An Inquiry into the Effects of Ardent Spirits upon the Human Body and Mind,* written in the 1780s (reprinted in Musto, 2002a, p. 27), was distributed by the thousands throughout the nation and was still being reprinted and distributed four decades later.

TEMPERANCE MOVEMENTS. Later reformers, most notably Lyman Beecher in his monumental *Six Sermons on Intemperance* (reprinted in Musto, 2002a, p. 44), which first appeared in 1826 (reprinted 1828), adopted a more extreme attitude, condemning not only distilled spirits but all alcoholic beverages. Moderation was no longer recommended as an ideal; instead, it was presented as a dangerous delusion that would draw many people into alcohol abuse. Alcohol itself, Beecher argued, not the amount or type consumed, was an evil.

Thus, the United States experienced a positive attitude toward alcohol consumption in the eighteenth century, followed by a reversal dominated by the image of alcohol as a fundamentally evil substance that led to widespread prohibition in the 1850s. That first peak of prohibition faded under the resentment of the public, the difficulty of enforcement, and the monumental distraction of the Civil War. Later in the nineteenth century, opposition to alcohol revived, centering on the burgeoning urban saloon, a center of political and moral corruption, and a symbol of the rising fear of recent immigrants crowding into the cities. This anti-alcohol campaign was even more successful than the previous crusade, achieving by 1920 a total legal prohibition of alcohol except for sacramental, industrial, and medicinal uses.

AFTER PROHIBITION. After 1933, the year of the repeal of the Eighteenth Amendment, the backlash against Prohibition made advocacy of alcohol control an object of ridicule until about 1980; then another change in attitude toward alcohol—perhaps the beginning of a third temperance movement— once again put the issue of the damaging social consequences of alcohol in the forefront of public concern. In 1984 the federal government established a national drinking age of twenty-one, and since 1989, all containers for beverage alcohol manufactured for sale in the United States have been required by federal law to bear a government label warning against the dangers of alcohol. Since the 1980s state drunk-driving laws have been made much more punitive. Per capita consumption of alcohol, which hit a third historical peak in 1980, has been in a gradual decline since that time.

Attitudes toward Other Drugs

The image of alcohol did not wax and wane in isolation from the public's perception of drugs such as morphine, heroin, and cocaine, although the peaks of their favorable and

unfavorable public images did not coincide precisely with those of alcohol. The use of cocaine rose rapidly after its introduction into the United States in the mid-1880s. Not until the Harrison Act of 1914 did the federal government prohibit the sale of cocaine without a prescription. A similar restriction on alcohol, National Prohibition, was enacted five years later, and by the mid-1920s the federal government had moved to eliminate heroin completely as a legally obtainable substance (Musto, 2002b).

When one reviews the history of drugs and alcohol in the United States, it is apparent that the ethical debate and extent of control have been related to the healthy or poisonous image of those powerful substances. Interestingly, neither extreme was buried by the victory of the contrary position. The ascendancy of one point of view seems to have created the conditions for the gradual emergence of the opposite attitude. A further point worth noting is that in the campaign against drugs and alcohol, the American practice has been to condemn them as being without any but the most limited value as medicine, and to hedge any exemption with tight restrictions. The periods of favorable and unfavorable attitudes are rather lengthy compared with the human life span, and so each tends to be seen as the settled opinion of science and society, and the presence or absence of controls seems to be based on what appear to be established premises.

The Control of Drugs and Alcohol

The control of drugs and alcohol involves both practical and philosophical considerations. Practically, a nation or locality has a limited array of controls, and those controls usually depend on the compliance of the public.

EFFECT OF LICENSING AND TAXATION. During the English gin epidemic, Parliament was limited to using a variety of license fees and taxes, which were not always easily enforced, to curb the production of gin. Success in the campaign did not begin to be acknowledged by observers until after 1750, by which time, presumably, the baleful effects of gin and the prolonged campaign against it by reformers had changed public attitudes toward that form of alcohol.

Control of opiates and cocaine initially took a different turn because, by the late nineteenth century, the licensing of physicians and pharmacists had become widespread in the United States. As a result, the first form of control over those drugs, after a period of free access, consisted of making them available by prescription only, although commonly a small amount would be permitted in an over-the-counter remedy. To alert the public, the Pure Food and Drug Act of 1906 required that the amount of drugs in a remedy be included on the label.

During the Progressive Era (approximately 1890–1920), reformers worked to give the central government more power, so that the benefit of uniform national laws could be applied to problems such as tainted meat, adulterated medicines, the destruction of forests, and drug abuse. With regard to drug abuse, the knotty constitutional problem was addressed by basing the Harrison Act of 1914, which was meant to regulate the distribution of opiates and cocaine, on the federal power to tax. Each transaction, from importation to retail purchase, had to be recorded, and a small tax had to be paid. Evasion of that law would be punished as a violation of the tax statutes. The restriction on maintenance doses of opiates for addicts was effected through Treasury Department regulations that were promulgated to carry out the Harrison Act. That part of the regulation was overturned by the U.S. Supreme Court in 1916 as a violation of states' rights, but it was effectively reinstated on another basis by the Court in 1919 during a peak of concern over drug addiction and in the face of the impending prohibition of alcohol.

The impact of alcohol prohibition on the severity of other drug laws illustrates a common factor in the control of drugs that might be called the *hydraulic model,* which implies that repression of one drug shifts use to another substance. This analysis encourages a blanket control of drugs and is especially popular at times when it is believed that abuse of a particular drug is a sign of an "addictive personality" (as in the late twentieth century) or the affliction of "inebriety" (late nineteenth century). These diagnoses suggest that the afflicted individual is pressured to use alcohol and drugs, and that if one substance is not available, he or she will switch to another.

EFFECTIVENESS OF DRUG CONTROL MEASURES. The question of "availability" raises the controversial issue of the effectiveness of control measures. Do laws against drugs accomplish much more than raising the price of drugs? Can prescription controls or international interdiction reduce the supply of drugs? Can prohibition reduce the supply of alcohol? The answers to these questions are elusive, but one can say that in general the reduction in drug and alcohol use that accompanied the restrictions in the United States beginning with World War I (and ending with the start of a second drug epidemic in the 1960s) occurred during a period of extraordinary antagonism toward drugs. Drugs came under progressively more severe laws, with the exception of alcohol, whose prohibition was repealed in 1933.

Confidence in legal control was reinforced by the obvious decline in drug use, and alcohol consumption fell from 1.7 U.S. gallons per capita in 1910, to about 0.6 gallons between 1920 and 1930, and did not return to the 1910 level until the mid-1960s (Rorabaugh, p. 232). Anti-drug legislation became increasingly severe, even after Prohibition was repealed in 1933, including mandatory minimum sentences and, in 1956, federal enactment of the death penalty as an option in some cases of drug trafficking.

To understand the doubts concerning legal sanctions in the late-twentieth-century drug "epidemic," it is necessary to compare the two drug epidemics. During the first wave of drug use, laws did not exist until the public's fear demanded them. The more recent wave of drug use found the most severe drug laws in effect at a time when a favorable attitude toward drug use was spreading across many sectors of American life. The apparent weakness in the enforcement of these laws, their clash with a new attitude among experts and the public, and the failure to recall the earlier experience with drugs led to ridicule and comfortable evasion of the law. A renewed harmony between anti-drug attitudes and anti-drug laws followed in the 1980s and later.

In the 1930s, at the end of the epidemic that peaked at about the time of World War I, the United States, after requiring general anti-drug and anti-alcohol education through state laws, adopted a policy of silence regarding drugs. When silence was not possible, exaggeration was instituted to complement the increasing severity of the drug laws. That policy may account for the loss of public memory of that early "epidemic"; the style of calling any drug use fraught with extreme danger (for the purpose of discouraging experimentation) contributed to the lack of balanced knowledge about drugs that characterized both adults and youth in the 1960s. The ultimate effect of the policy was to undercut the credibility of official statements on drug use.

In addition to the issue of changes in attitudes toward drugs and the practical problem of what control mechanisms exist, there is the broader question of control philosophy. Should drugs be controlled at all? Should the state try to protect citizens from their own desire to use drugs? Is drug control a law-enforcement problem, a public-health task, or a moral or religious issue? For Beecher (1828), alcohol had to be controlled because, whereas drunkenness ruined health and family life, it also impaired the individual's ability to hear and respond to God's message of salvation. Alcohol produced temporal death and eternal damnation.

Beecher's British contemporary John Stuart Mill rejected American prohibition laws and similar restrictions on the buyers of alcohol as an unjustified interference with liberty. Mill was particularly harsh on actions designed to protect individuals from themselves. To questions of policy he applied this prime principal: "Over himself, over his own body and mind, the individual is sovereign" (p. 11).

The debate between law-enforcement and public-health approaches to drug and alcohol abuse is particularly sensitive to public attitudes toward the nature of the drugs themselves. In an era of drug toleration, public-health methods and medical treatment in general are advocated and practiced. The concern is not so much with a drug itself as with the bad effects that it may have on an unwise or excessive user. As the attitude turns against the use of drugs in any amount, frustration and anger support police action, arrests, and punishments for violations of a strict rejection of drug use that leaves no room for *recreational* drug use.

The War against Drugs

The nature of the American drug experience changed quickly in the mid-1960s. The use of illegal drugs, which had existed at the fringes of society for more than three decades, moved to the center of youth culture. The drugs of choice were cannabis and other psychedelics, such as LSD. Advocates claimed that using those substances gave a person an experience of ultimate reality, a kind of insight that saints had achieved only after lengthy meditation and asceticism. Aldous Huxley gave an early cachet to psychedelic use with two accounts, *The Doors of Perception* (1954) and *Heaven and Hell* (1956), based on his use of mescaline. Huxley believed, however, that such experiences were best confined to an intellectual elite. In the 1960s Timothy Leary expanded that concept in the 1960s to include everyone. "Turn on, tune in, and drop out" was his advice to America. A striking example of faith in the drug revolution was Charles Reich's *The Greening of America* (1970), which saw marijuana as the "truth serum" that would create a new consciousness and a new society.

Passage of the Drug Control Amendments of 1965—an early response to the use of psychedelics, stimulants such as amphetamine, and sleeping medications such as barbiturates—was intended to restrict licit pharmaceutical production. Legal production of amphetamines was reduced from 100,000 pounds annually to less than 1,000 pounds by 1990. By 2002 the amount had risen to 20,000 pounds, largely as a result of the use of amphetamines in treating hyperactive children. The basis of anti-drug laws beginning in 1965 was shifted from the taxing power of the federal government to the Interstate Commerce Clause, a precedent that would be followed in the future.

Another significant element in the 1965 law was the creation, within the U.S. Food and Drug Administration, of

the Bureau of Drug Abuse Control (BDAC), which would have as its targets all dangerous drugs except the opiates, cocaine, and marijuana; those traditional substances continued to be the province of the U.S. Treasury's Bureau of Narcotics. Then, because separating out the turfs of the two control agencies proved difficult, they were merged in 1968 as the Bureau of Narcotics and Dangerous Drugs (BNDD) and moved from the U.S. Treasury Department and the U.S. Department of Health, Education, and Welfare Department to the U.S. Department of Justice.

The Nixon administration (1969–1974) confronted growing public alarm over rising drug use among youth and, in response, created the basic element of the war on drugs that continues to the present (Musto and Korsmeyer). One of the Nixon administration's major goals was to reduce crime. Persuaded by the successful record of methadone treatment in the District of Columbia that indicated adopting such treatment could lower crime rates, Nixon gradually came to favor the use of methadone as a substitute for the illegal opiates used by addicts. The fact that Nixon, who was known to have a visceral antagonism to drug use, would initiate a national policy of substituting a legal addiction for an illegal one surprised many people.

Out of the Nixon era came the first "drug czar"; the first federal strategy (1972) that attempted to coordinate all federal anti-drug efforts; the creation of the Drug Enforcement Administration (DEA), the successor to the BNDD and the Office of Drug Abuse Law Enforcement (a temporary effort by the federal government to affect local drug dealers); and the National Institute on Drug Abuse (NIDA).

Under Nixon the budget to fight drugs rose to heights never before attained in the federal government; thousands of additional BNDD and DEA agents were trained and were placed internationally as well as nationally. Nevertheless, throughout the Nixon era the American people grew more tolerant of the use of drugs, particularly cannabis. Public opinion did not turn against drugs until about 1980, at the end of Jimmy Carter's presidency. The 1970 Drug Abuse Prevention and Control Act reflected a liberalization of the drug laws through the elimination of mandatory minimum sentences and a provision for clearing the record of an individual convicted of personal possession of cannabis. Although Nixon would seek a resumption of mandatory minimum sentences in 1974, as his administration was collapsing, that punishment was not resurrected until the Anti- Drug Abuse Acts of 1986 and 1988.

Perhaps the most alarming change in drug use habits in the 1970s and 1980s was the use of "crack" cocaine, a method that allows the user to inhale cocaine fumes and results in an intense brain response. The deaths of prominent sports figures from cocaine use crystallized public opinion against drugs and led Congress and a series of presidents to wage a war on drugs that was unprecedented in American history. Drug law convictions crowded prisons and caused a backlash to the anti-drug campaign.

Decriminalization

In the era of increased drug use that started about 1965, an attack on prohibitory laws began with criticism of the extraordinarily long sentences meted out to persons who possessed small amounts of marijuana. By 1970 the federal law had been softened and advocates of legalizing marijuana were organized. With the rise in cocaine and heroin use, many people called for legalizing or "decriminalizing" those drugs on the grounds that their dangers had been exaggerated. In 1972 the term *decriminalization* was proposed in the first report of the U.S. Commission on Marihuana and Drug Abuse as a compromise between arresting persons with small amounts of marijuana for personal use, and allowing a free market in marijuana. Decriminalization would allow use while still permitting a national policy warning against the drug and maintaining legal sanctions against those who produced and distributed large amounts of the plant.

Libertarians, such as the economist Milton Friedman, added a philosophy of freedom from state interference in private acts, such as drug use, to the debate over controls. Although the public has been increasingly opposed to drug use (reflected also in reduced consumption of tobacco and alcohol) and in favor of strict anti-drug laws since about 1980, analyses questioning the campaign against drugs have continued (Friedman).

Opposition to the "war against drugs" has centered on two themes: interdiction of drugs from foreign nations and domestic enforcement of stricter anti-drug laws. Critics have argued that interdiction has not affected the availability of drugs, especially cocaine, the chief target of the U.S. Coast Guard and the other "uniformed" services as well as the U.S. Drug Enforcement Administration. With regard to domestic policy, application of harsh criminal penalties to drug offenders is condemned as a source of prison crowding that does little or nothing to reduce crime or hard-core drug use.

A recent suggestion offered by those opposed to overreliance on the criminal justice approach is "harm reduction," a phrase that attempts to describe Dutch drug policy. The Netherlands is noted for allowing personal use of drugs, providing sterile needles to drug injectors, and generally tolerating drug availability. The expectation is that in the long run this policy will allow more users to survive and experience a life less dominated by, or free from, drug use.

Criticism of any policy that would appear to encourage or facilitate drug use has been severe. Arguments against legalization include the observation that laws pressure users into treatment, the symbolic importance of an anti-drug policy, and the fear that drug use would increase if drugs were easily available and inexpensive.

Conclusion

The history of drug and alcohol control illustrates the slowly shifting assumptions societies make regarding those powerful substances. At the extreme of each attitude the good or evil nature of drugs seems so obvious that contrary notions are rejected with dispatch. Consequently, the ethical debate is deeply influenced by these alterations in attitude. These contrary positions also make an indefinitely sustainable drug policy difficult to frame.

HAZARDOUS WASTES AND TOXIC SUBSTANCES

• • •

Developed nations such as the United States annually use more than 60,000 hazardous chemicals in their agricultural

and manufacturing processes. Because at least 10,000 are introduced each year, often we know very little about their effects. When we began massive use of such chemicals, we did not know that by the 1970s human breast milk would become more contaminated with toxins than any allowable manufactured foods. We did not realize that measurable amounts of DDT would appear in the polar ice caps. We did not suspect that by 2000 Silicon Valley would have more Superfund sites, twenty-nine, than any other single U.S. location—all because of toxic wastes from manufacturing high-tech products such as disk drives and semiconductors. We did not realize that, because of their long lifetimes, many hazardous chemicals would be able to migrate from their present waste sites and would threaten persons living thousands of years in the future. On the whole, we have assumed that dangerous chemicals are *innocent until proved guilty.* Because we do very little sophisticated epidemiological testing and rarely take account of food-chain and synergistic effects, thousands of chemicals have become both important to our agricultural and manufacturing processes and ubiquitous in our environment. Hence, it is often difficult to prove that any one chemical is responsible for specific harms, even when we know that it is theoretically able to cause many *statistical casualties.*

Hazardous wastes, byproducts of manufacturing, scientific, medical, and agricultural processes, have at least one of four characteristics: ignitability, corrosivity, reactivity, or toxicity (Wagner). Hazardous substances become wastes only when they have outlived their economic life. They include solvents, electroplating substances, pesticides such as dioxin, and radioactive wastes. Toxic substances, a subset of hazardous substances, have the characteristic of toxicity: the ability to cause serious injury, illness, or death.

Many persons became aware of the threat of hazardous wastes and toxic substances when American scientist Rachel Carson (1907–1964) wrote *Silent Spring* (1962), one of the earliest warnings of the dangers of pesticides, or when Michael Brown wrote his spellbinding account of hundreds of cancers, genetic damage, and birth defects near Love Canal, New York, and other waste sites in 1980. Indeed, hazardous-waste management has become one of the most serious environmental problems facing the world. In the United States alone, more than 5 billion pounds of toxic chemicals are released each year into air, water, and land. Approximately 80 percent of hazardous waste has been dumped into thousands of landfills, ponds, and pits throughout the world, from Love Canal in New York, to Mellery in Belgium, to North-Rhine in Germany. It has polluted air, wells, surface water, and groundwater. It has destroyed species, habitats, and ecosystems. It also has caused fires, explosions, direct-contact poisoning, and numerous cases of cancer, genetic harms, neurological disorders, and birth defects.

Surprisingly, one-quarter of the mercury and nearly one-half of all dioxin released into the American environment is from the healthcare industry. The mercury comes from blood temperature gauges and batteries, for example, while the dioxin comes from burning chlorinated plastics, like the PVC tubing used in kidney dialysis. Both mercury and dioxin are emitted by hospital incineration, and each patient-day is responsible for 9 kilograms of solid waste. Much of the dioxin emitted is from biochemical waste, 60 percent of which is not handled adequately.

In part to protect workers and the public from the dangers associated with hazardous substances, the U.S. Congress passed laws such as the 1954 Atomic Energy Act; the 1975 Hazardous Materials Transportation Act; the 1976 Resource Conservation and Recovery Act (RCRA); the 1976 Toxic Substances Control Act (TSCA); the 1977 Clean Water Act; the 1977 Clean Air Act; and the 1980 Comprehensive Environmental Response, Compensation, and Liability Act known as CERCLA or Superfund (Dominguez and Bartlett). These laws include provisions that require monitoring pollutants, reporting spills, preparing manifests describing particular wastes, and special packaging for transporting specific types of hazardous materials. The Clean Air Act regulates smelter emissions, for instance, and the Clean Water Act regulates mining-caused water pollution (Young). RCRA was passed to fill a statutory void left by the Clean Air Act and the Clean Water Act, which require removal of hazardous materials from air and water but leave the question of the ultimate deposition of hazardous waste unanswered. Although RCRA addresses the handling of such waste at current and future facilities, it does not deal with closed or abandoned sites. CERCLA focuses on hazardous-waste contamination when sites or spills have been abandoned; through penalties and taxes on hazardous substances, CERCLA provides for cleaning up abandoned sites.

Despite laws that govern dangerous substances, and despite the fact that 50,000 environmental assessments are prepared annually in the U.S., many to evaluate waste sites under the 1969 National Environmental Policy Act, hazardous wastes remain a major problem. One reason is that well-financed industrial waste polluters can dominate underfunded government regulators. Another reason is that the North American Free Trade Agreement (NAFTA) has allowed more U.S. waste to go to countries such as Mexico. The U.S.-to-Mexico waste flow doubled, for example, from 1994 to 1999, and yet Mexico has only one licensed

hazardous waste facility. A third factor is that the use of toxic substances and the management of hazardous wastes raise ethical issues that have not been adequately addressed by existing regulations. These issues include siting, rights of future generations, workers's rights, free and informed consent, compensation, due process, appropriate ethical behavior under conditions of uncertainty, where to place the burden of proof regarding alleged waste harms, and workers's and the public's right to know.

Equity Issues

Those who can afford to avoid hazardous wastes and toxic substances typically do so. Those who cannot are usually poor or otherwise disadvantaged. For this reason, public and workplace exposure to such hazards raises questions of intergenerational, geographical, and occupational equity. Intergenerational-equity problems deal with imposing risks and costs of hazardous wastes and toxic substances on future persons. Geographical-equity issues have to do with where and how to site waste dumps or facilities using toxic substances. Occupational-equity problems focus on whether to maximize the safety of the public or of the people who work with hazardous materials because we often cannot protect both groups at once. For example, effective decontamination and safety assurance at waste sites typically require more worker exposure to toxins but reduce public risk. Using mechanical or nonhuman decontamination and safety procedures, however, is safer for workers but usually increases public risk because such procedures are less effective than those controlled closely by people (see Kasperson).

Intergenerational equity requires us to ask whether we ought to mortgage the future by imposing our debts of buried (or stored) hazardous wastes on subsequent generations. Current plans for future U.S. government storage of high-level radioactive waste, for example, require the steel canisters to resist corrosion for as little as 300 years. Nevertheless, the U.S. Department of Energy admits that the waste will remain dangerous for longer than 10,000 years. Government experts agree that, at best, they can merely limit the radioactivity that reaches the environment, and that there is no doubt that the repository will leak over the course of the next 10,000 years (Shrader-Frechette, 1993). To saddle our descendants with the medical and financial debts of such waste, much of which is extremely long-lived, is questionable at best: We have received most of the benefits from the use of industrial and agricultural processes that create hazardous wastes, whereas future persons will bear most of the risks and costs. This risk/cost-benefit asymmetry suggests that, without good reasons or compensating benefits, future generations ought not be saddled with debts of their ancestors. Moreover, any alleged economies associated with storage of hazardous waste are, in large part, questionable because of the practice of discounting future costs (such as deaths) at some rate of x percent per year. For example, at a discount rate of 10 percent, effects on people's welfare twenty years from now count only for one-tenth of what effects on people's welfare count for now. Or, more graphically, with a discount rate of 5 percent, 1 billion deaths in 400 years count the same as one death next year. A number of moral philosophers, such as Derek Parfit, have argued that use of a discount rate is unethical, because the moral importance of future events, like the death of a person, does not decline at some x percent per year.

Another issue related to intergenerational equity is what sort of criteria might justify irreversible damage to the environment, such as that caused by deep-well storage of high-level nuclear waste. On the one hand, irreversible management schemes for nuclear waste, because they are premised on the nonretrievability of the waste, theoretically impose fewer management burdens on later generations, but they also preempt future choices about how to deal with the hazards. On the other hand, schemes that are reversible allow for wider choices for future generations, but they also impose greater management burdens. If we cannot do both, is it ethically desirable to maximize future freedom or to minimize future burdens? The technical problems associated with storing long-lived hazardous waste for centuries are forcing us to take a great gamble that our descendants will not breach the waste repositories through war, terrorism, or drilling for minerals; that groundwater will not leach out and transport toxins; and that subsequent ice sheets, faulting, seismic activity, and geological folding will not uncover the wastes.

Using and storing toxins also raises questions of environmental justice, that is, spatial or geographical equity in the risk distributiuon (Shrader-Frechette, 2002). One such issue is whether it is fair to impose a higher risk (of being harmed by seepage from a hazardous-waste dump, for example) on persons just because they live in a certain spot. Or, is it ethical for people in one area to receive the benefits of products created by using toxic substances, while people in another area bear the health risks associated a hazardous-waste dump? How does one site hazardous facilities equitably, and how does one transport toxic substances safely (see English)?

Questions about the equity of risk distribution are central to the issue of managing toxic substances because thousands of persons—such as the 1984 victims of the Union Carbide toxic leak in Bhopal, India—have already died as a consequence of exposure to hazardous substances.

Current trade agreements also allow much hazardous waste of developed nations to be shipped to developing ones. Economic comparisons of alternative chemical technologies and different waste sites typically ignore the externalities (or social costs) such as the inequitable distribution of health hazards benefits associated with them. Geographical and intergenerational inequities are typically *external* to the benefit-cost schemes used as the basis for public policy. Consequently, decision makers almost always ignore them (Shrader-Frechette, 2002).

The most serious problems of geographical equity in the distribution of risks associated with dangerous substances arise because developed nations often ship their toxic chemicals and hazardous wastes to developing countries. One-third of U.S. pesticide exports, for example, are products that are banned for use in the United States. These exports are annually responsible for 40,000 pesticide-related deaths, mainly in developing nations (Shrader-Frechette, 1991). Likewise, the United Nations estimates that as much as 20 percent of the hazardous waste produced in developed nations is sent to other countries where health and safety standards are virtually nonexistent. The Organization of African Unity has pleaded with member states to stop such traffic, but corruption and crime have kept the waste transport going (Moyers). Indeed, exporting toxic substances and hazardous wastes may be the current version of the infant-formula problem. During the last three decades of the twentieth century, U.S. and multinational corporations have profited by exporting infant formula to developing nations and by encouraging young mothers not to nurse their children. They have been able to do so only by extremely coercive sales tactics and by misleading persons in developing countries about the relative merits and dangers of the exports.

Some of the greatest risks associated with toxic substances and hazardous wastes, whether in developed or developing nations, are borne by workers. One of the main questions of occupational equity is whether it is just to impose higher health burdens on workers in exchange for wages. Is it fair to allow persons to trade their health and safety for money? This question is particularly troublesome in the United States, because many other countries—such as the Scandinavian nations, Germany, and the former Soviet Union—have standards for occupational exposure to risks from toxins that are just as stringent as standards for public exposure. The United States, however, follows the alleged *compensating wage differential* (CWD) of Scot economist Adam Smith (1723–1790), presupposing that wages compensate workers for increased occupational exposures to toxic substances. As a consequence, U.S. regulators argue that, in exchange for facing higher risks than the public faces from toxic substances, workers receive higher wages that compensate them for their burden. Other countries do not accept the economic theory underlying the CWD and argue for equal health standards, for making public and worker exposure norms the same (Shrader-Frechette, 1991).

Consent and Right to Know

One reason critics question the theory underlying the CWD is its presupposition that, by virtue of accepting certain jobs, workers exposed to serious hazards give free, informed consent to the risks. Yet, from an ethical point of view, those most able to give free, informed consent—those who are well educated and who have many job opportunities—are usually unwilling to do so. Those least able to give genuine consent to a risky workplace or neighborhood—because of their lack of education or information and their financial constraints—are often willing to give allegedly informed consent.

The 1986 U.S. Right-to-Know Act requires owners or operators of sites using hazardous materials to notify the Emergency Response Commission in their state that toxins are present at a facility. However, at least three factors suggest that this law may fail to ensure full conditions for the free, informed consent of persons likely to be harmed by some hazardous substance. First, owners or operators (rather than a neutral third party) provide the information about the hazard. Often those responsible for toxic substances and hazardous wastes do not inform workers and the public of the risks they face, even after company physicians have documented serious health problems. Employers in the chemical industry, for example, frequently spend money on genetic screening to exclude susceptible persons from the workplace rather than to monitor their health on the job (Draper). Second, the existence, location, and operational procedures of dangerous facilities are likely things to which citizens and workers have not given free, informed consent in the first place. Third, mining is not included among the industries required to report their toxic emissions to state and federal regulators. For example, Utah's Bingham Canyon Copper Mine, owned by Kennecott Copper, ranks fourth in the nation in total toxic releases, yet it and other mining companies do not report their releases (Young).

Sociological data reveal that, as education and income rise, people are less willing to accept either work in hazardous facilities or risky jobs; those who do so tend to be poorly educated or financially strapped. The data also show that the alleged CWD does not operate for poor, unskilled, minority, or nonunionized workers. Yet these are precisely the people most likely to have risky jobs, such as handling nuclear wastes. In other words, the very persons *least* able to

give free, informed consent to occupational risks are precisely those who *most* often work in risky jobs (Shrader-Frechette, 1993).

At the international level, a similar situation occurs. The persons and nations least able to give free informed consent to the location of facilities for using or storing toxic substances are typically those who most often bear such risks. Hazardous wastes shipped abroad, for example, are usually sent to countries that will take them at the cheapest rate, and these tend to be developing nations that are often ill informed about the risks involved. In 1989, the United Nations passed a resolution requiring any country receiving hazardous waste to give consent before it is sent. Because socioeconomic conditions and corruption often militate against the exercise of free informed consent, however, it is questionable whether the U.N. resolution will have much effect (Shrader-Frechette, 1991).

Industrial offers of financial benefits—for storing hazardous waste in a developing nation or in an economically depressed community—create a coercive context in which requirements for free informed consent are unlikely to be met. Likewise, high wages for desperate workers who agree to take risky jobs may jeopardize their legitimate consent. In such contexts, we must admit either that our classical ethical theory of free informed consent is wrong or that our laws and regulations fail to provide an ethical framework in which those most affected by hazardous substances can give free informed consent to the risk.

Given the many consent-related problems relevant to risk from hazardous substances, a crucial issue is: Who should give consent? Liberty and grass-roots self-determination require local control of whether a hazardous facility is sited in a particular area. Yet, equality of consideration for people in all regions and minimizing overall risk often require federal control. Should a particular community be able to veto the location of a hazardous facility, even though that site may be the best in the country and may provide the most equal protection of all people? Or should the national government have the right to impose such risks on a local community, even against the wishes of that group?

On the one hand, federal jurisdiction is more likely to protect the environment, to avoid the tragedy of the commons, to gain national economies of scale, and to avoid regional favoritism. Federal jurisdiction is also more likely to provide compensation for victims of spillovers from another locale and to facilitate the politics of sacrifice by imposing equal burdens on all. On the other hand, local jurisdiction is more likely to promote diversity, to offer a more flexible vehicle for experimenting with waste regulations, and to enhance citizen autonomy and liberty. Local jurisdiction also is likely to encourage cooperation through participation in decision making, to discourage some kinds of inequitable federal policies, and to help avoid many violations of rights.

Compensation

Current U.S. laws do not typically provide for full exercise of due-process rights by those who may have been harmed by toxins or hazardous wastes. Many of the companies that handle dangerous substances do not have either full insurance for their pollution risk or adequate funds to cover their liability themselves. RCRA and CERCLA, however, require such companies both to show that they are capable of paying at least some of the damages resulting from their activities and to clean up their sites. Because enforcement of liability and coverage provisions of these laws is difficult, many hazardous-waste industries often operate outside the law. Furthermore, most insurers have withdrawn from the pollution market, claiming that providing such coverage carries the risk of payments for claims that would bankrupt them.

Just as insurers fear potentially large liability claims in cases involving hazardous-waste substances, so do members of the public. For example, in 1987 when the U.S. Congress chose Yucca Mountain, Nevada, as the likely site for the world's first permanent facility for high-level nuclear waste, local residents and the state asked for unlimited, strict-liability coverage for any nuclear-waste accident or incident. The U.S. Department of Energy's response to the citizens, based on the 1957 Price-Anderson Act, was that the government would allow the waste facility to bear only limited liability. Consequently, the U.S. nuclear program, including radioactive-waste management, has operated under a government-imposed limit for liability coverage. This limit, designed to protect the nuclear-waste industry from bankruptcy caused by accidents, is less than 3 percent of the government-calculated costs of the April 1986 Chernobyl nuclear catastrophe, and Chernobyl was not a worst-case accident (see Shrader-Frechette, 1993).

Limits on government or industry liability for hazardous-waste and toxic-substance incidents are problematic for several reasons. First, liability is a well-known incentive for appropriate, safe behavior. Second, refusal to accept full and strict liability suggests that hazardous- and radioactive-waste sites are not as safe as the government maintains they are. Third, if government officials may legally limit due-process right then, in the case of an accident at a hazardous-waste facility, the main financial burdens will be borne inequitably by accident victims rather than by the perpetrators of the hazard. Fourth, because much less is known about the dangers from hazardous wastes and toxic substances than about more ordinary risks, full liability seems a reasonable

requirement. And finally, the safety record of hazardous facilities, in the past, has not been good. Every state and every nation in the world have extensive, long-term pollution from toxins. Even in the United States, the government has been one of the worst offenders. A congressional report has argued that cleaning up the hazardous and radioactive wastes at government weapons facilities would cost more than $300 billion (U.S. Congress; Shrader-Frechette, 1993). Such problems argue for citizens's rights to full liability.

Uncertainty, Human Error, and the Burden of Proof

Inadequate compensation for victims of toxins, inequitable distribution of the risks associated with hazardous wastes, and the uncertainties and potential harm associated with such substances provide powerful arguments for reducing or eliminating exposure to them. To decrease exposures and to move *beyond dumping,* however, we must have market incentives for reducing the volume of toxic substances and hazardous wastes (Piasecki; Higgins). To reduce the volume of these threats, we must know exactly what effects they cause, and we must make risk imposers accountable for their behavior. Ensuring accountability is not easy. Adequate tests for medical responses to low-level chemical exposures require samples of thousands of persons, because so many toxic substances produce health effects synergistically, because there are many uncertainties about actual exposure to hazardous substances, because the effects of such exposure often are unknown (Ashford and Miller), and because phenotypical characteristics among individuals often vary by a factor of 200. All four variables cause extreme differences in humans's responses to toxins.

Uncertainties about exposure and about the consequences of exposure to hazardous substances are compounded by the fact that the industries that produce toxic substances and hazardous wastes—and that profit from them—usually perform the required tests to determine toxicity and health effects. Pesticide-registration decisions (about allowing use of the chemicals) in the West, for example, are tied to a risk-benefit standard that combines scientific and economic evidence. Because industry does most or all of the testing, and because environmental and health groups are forced to show that the dangers outweigh the economic benefits of a particular pesticide, there is much uncertainty about the real hazards actually faced by workers and consumers. As a consequence, virtually no groups want toxic substances or hazardous wastes used or stored near them. Hence the protest: *Not in my backyard*—NIMBY.

NIMBY responses also arise as a consequence of public mistrust of human institutions for controlling hazardous wastes and toxic chemicals. All dangerous technologies are unavoidably dependent upon fragile, sometimes short-lived, human institutions and human capabilities. Faulty technology, after all, did not cause the injuries and deaths at Three Mile Island, Bhopal, Love Canal, or Chernobyl. Human error did. Human error and misconduct also may be the insoluble problem with using toxic substances and managing hazardous wastes. According to risk assessors, 60 percent to 80 percent of industrial accidents are due to human mismanagement or corruption (Shrader-Frechette, 1993). For example, at the nation's largest incinerator for hazardous wastes, run by Chemical Waste Management, Inc., in Chicago, a 1992 grand jury found evidence of criminal conduct, including deliberate mislabeling of many barrels of hazardous waste. They also discovered deliberate disconnection of pollution-monitoring devices. More generally, corruption in the waste-disposal industry has been rampant in the United States ever since the 1940s, when the Mafia won control of the carting business through Local 813 of the International Brotherhood of Teamsters. In the mid-1990s, three Mafia families still dominated hazardous-waste disposal and illegal dumping: the Gambino, Lucchese, and Genovese/Tiere crime groups (see Szasz). Given the potential for human error and corruption, citizens are frequently skeptical regarding whether hazardous and toxic substances will be handled safely, with little threat to workers or to the public.

Because of scientific unknowns and uncertainties about human behavior and corruption, several moral philosophers have argued that potentially catastrophic situations—involving hazardous wastes and toxic substances—require ethically conservative behavior (Cranor; Shrader-Frechette, 1991; Ashford and Miller). Such situations often require one to choose a *maximin* decision rule to avoid situations with the greatest potential for harm, as John Rawls (1971) has argued. Ethical conservatism, in a situation of uncertainty, also may require society to place the burden of proof—regarding risk or harm—on the manufacturers, users, and disposers of hazardous substances, rather than on their potential victims. This, in turn, may mean that we will need to reform our laws governing so-called *toxic torts* (Cranor).

Given the longevity and the catastrophic potential of many toxic substances and hazardous wastes, we may need to reevaluate the human and environmental price we have paid for our economic progress. Although our society may not be able to avoid use of certain toxic substances and disposal of some hazardous waste, it is clear that we need to maximize the equity with which we distribute the risks associated with such threats. We also need to guarantee, so far as possible, that potential victims of toxins are informed about the risks they face and that they freely consent to

avoidable risk impositions. Finally, we ought to ensure that those put at risk from toxic substances and hazardous wastes are compensated, so far as possible, for harm done to them. Because of numerous uncertainties about their effects, and because of the catastrophic potential and the longevity of many hazardous materials, our behavior regarding them ought to be ethically conservative.

HEALING

• • •

Health and Wholeness

Healing is an action whose goal is the restoration of health. The English word *health* literally means *wholeness* and *to heal* means *to make whole.* Ancient Greek had two words generally translated as "health": *hygieia,* meaning "a well way of living," and *euexia,* meaning "good habit of body." Leon Kass (1985) notes that the English and both Greek words for health are totally unrelated to all the words for disease, illness, and sickness. This is also true for German, Latin, and Hebrew. In addition, the Greek terms for health, unlike the English, are unrelated to all the verbs for healing. Health for the ancient Greeks was a state or condition unrelated to, and prior to, both illness and healers. The English emphasis on wholeness, Kass also notes, is comparatively static and structural, implying a whole distinct from all else and complete in itself and connoting self-sufficiency and independence. The Greek terms, in contrast, stress the functioning of the whole, and not only its working but its working well. Kass sums up this Greek understanding of health by defining it as a natural as opposed to a moral norm that reveals itself in activity as a standard of bodily excellence or fitness. It is the well-working of the organism as a whole, an activity of the living body in accordance with its specific excellences.

The work of healing in Western culture is the proper activity of the profession of medicine. Howard Brody (1987) calls medicine a craft in which scientific knowledge is applied to particular patients for the purpose of "a right and good healing action," employing the now-classic phrase of Edmund Pellegrino (1982). Unlike the Greek, the English language sets up a relationship between medicine, whose business is healing, and health that is problematic. Kass states the problem this way: Health and only health is the doctor's proper business; but health, understood as well-working wholeness, is not the business only of doctors.

HEALTH AS EQUILIBRIUM. A less formal starting point than Kass's from which to examine the relationship between health and medicine is Pellegrino's definition of health as a state of accommodation, defined in different terms by each person. We feel healthy, he says, when we have found an equilibrium between our already-experienced shortcomings and our aspirations and have adjusted our goals to the gap between them. This means that health cannot be understood apart from a person's life history, or to use José Ortega y Gasset's phrase, one's "personal project" (p. 45). Healing, according to this definition of health, occurs when a new equilibrium is found between one's hopes and one's failures that can be incorporated into one's personal project. As such, healing must be based on an authentic perception of the experience of illness in the particular person.

THE CONTEXT OF HEALING. It follows that for an action of someone who professes to heal to be a right and good healing action, it must be situated in the context of a personal history so as to restore the direction of a personal project. This requires that a dialogue be established between healer and patient whose goal is the creation of a common ground of meaning shared by the healer and the patient. How extensive that common ground must be to constitute a right and good healing action is open to question. In taking a medical history, physicians have traditionally tended to restrict the province of illness to the *facts of diseases,* leaving unexplored the *fact of illness*—that is, the physical, psychological, and moral vulnerability the patient suffers in the attack on his or her very being that Pellegrino calls "the ontological assault of illness" (1982). However, this concentration on facts and diseases does not result from simple, unreflective traditionalism. Rather, it has enabled the profession of medicine to set very definite limits to the boundaries of healing and thereby to maintain control over the responsibilities that physicians take upon themselves as healers.

THE BOUNDARIES OF HEALING. The attempt by physicians such as Pellegrino to enlarge the boundaries of what counts as healing has often produced frustration and anger. For example, Franz J. Ingelfinger, in a classic editorial in the *New England Journal of Medicine,* rebukes those who would expand medical treatment to include families, not just individuals: "The curious idea is abroad that the doctor should be a factotum of health. By some singularity of reasoning, his role as healer is disparaged, and the words 'care, not cure' are becoming as tiresome as 'death with dignity'" (p. 565). He continues by lamenting that if the doctor is insensitive to the "multiple environmental conditions that threaten our mental and physical selves, he is regarded as failing the holistic image that many—both

lay and medical—wish to impose on the physician" (p. 565). Ingelfinger concludes by asserting that the physician's primary concern, in spite of utopian claims to the contrary, should be sickness, not overall health; medicine should concentrate on "scientifically accurate diagnosis and treatment."

THE NATURE OF HEALING. The resistance of physicians such as Ingelfinger to what they regard as an unwarranted expansion of their role in society signals a fundamental disagreement within Western society about the nature of healing. Holistic approaches to medicine challenge traditional assumptions about who can be called a healer, what the goal of healing should be, and, most important, who can say what constitutes a right and good healing action: the healer or the one to be healed. Those who take positions like Ingelfinger's insist that only those who engage in "scientifically accurate diagnosis and treatment" deserve to be called healers, that healing aims at the cure of disease, and that the healer's profession alone can determine what constitutes a right and good healing action.

Those who disagree with these assumptions often attack their opponents as simply *uncaring.* Victor Kestenbaum, however, argues that the point of departure and method, not the lack of feeling, is the real issue. By distinguishing between caring and curing and limiting medicine to the latter, Ingelfinger and his colleagues take as normative the physician's perception of illness, shaped by the method of science, and then seek to derive global professional obligations from it. Thus they cut the phenomenon of illness to fit a prior conception of role and discourse. Pellegrino, Kestenbaum notes by way of contrast, starts with illness as experienced by the patient and derives professional obligations from the distinctly human dimensions of being ill and in distress. The responsibilities of the healer follow from the complexity and scope of the phenomenon of illness, not from the self-declared duties of the profession.

The Healing Profession

In the 1950s Pedro Laín Entralgo observed that "the curative activity of the physician is always determined by the reality of the human being towards which it is directed, that is, by the 'personal' conditions of the disease and of the patient" (p. xv). Pellegrino believes that this accommodation to the reality of the patient follows from the promise that the medical profession, in the person of the physician, makes to the patient: "The promise of help that shapes the nature of every healing act and defines the requirements for successful healing—even when cure is not possible" (p. 160). But, Pellegrino notes, considerable confusion exists between doctor and patient about what healing means. Physicians, he says, often fail to comprehend what the patient understands by the promise of healing; patients often fail to understand what the physician thinks he or she is promising. Physicians, in response, are moving toward a restricted sense of promise, emphasizing technical competence, whereas patients expect not only competence but compassionate help as well. The wider the gap between professional promises and lay expectations, the more difficult becomes the collaboration between physician and patient to discover the equilibrium that constitutes genuine healing. As the gap increases, Pellegrino also notes, patients will be more tempted to seek alternatives to the "medical model" and lose the benefits of scientific competence.

COMPETENCE AND COMPASSION. Healing requires, Pellegrino insists, both competence (in scientifically accurate diagnosis and treatment) and compassion (the capacity to enter into the experience of illness with the patient). Competence is a necessary but not sufficient condition of healing. Healing "must be shaped at every step by the purposes of the healing acts—by the good of the person who is ill—his bodily good, of course, but also his concept of health, his value system, and his sense of the kind and quality of life he thinks is worthwhile" (p. 161). Pellegrino sums this up by declaring that the physician therefore has the obligation to protect the moral agency of the patient, to enhance it even in the face of the special vulnerabilities of being ill.

This protection of the moral agency of the patient lies at the heart of compassion; it is essential to the performance of a right and good healing action. Healing thus requires that the conversation between physician and patient encompass more than what can be accommodated by scientifically accurate medical language. As Jay Katz has observed, despite the quantity of words overflowing patients' medical charts, the world shared by doctor and patient is often one of profound silence, offering not the humaneness of shared understanding but the humaneness of services silently rendered (Katz).

The Silent World of Medicine

Yet modern scientific medicine owes its success to silence of a sort, a disbelief in words that Laín Entralgo traces to two tenets of the Hippocratic school of medicine. First, the latter rejected the use of words as a therapeutic tool; medicinal remedies were preferred to exorcism, which relied on the curative power of "fine words used in the manner of charms" (Laín Entralgo, p. 47). In addition, Hippocratic physicians

trusted the patient's symptoms to reveal the causes of disease and dismissed the patient's own words about the source of his or her condition as unreliable opinion.

THE CLINICAL GAZE. Michel Foucault (1973), in his discussion of the antecedents of modern medicine, discovers a similar kind of silence in the "clinical gaze," a reorganization of medical perception that took place in the eighteenth century. Disease ceased to be perceived as an alien force inserted into the body and subject to the words of exorcism; instead, disease was the body itself, become diseased. Healing became the task of deciphering corporal space, a work of seeing instead of speaking. The model physician is Hippocrates, who applied himself only to observation, despising all preconceived systems that might bias the observer. This clinical gaze flourishes only in the relative silence of theories, imaginings, and whatever serves as an obstacle to the sensible immediate. In addition, when physicians question the patient, they question only what they can see—the body become diseased—and only in the language proposed by the body. All other languages, including that spoken by the patient, must fall silent before the absolute silence of observation. Within this double silence, Foucault says, things seen can be heard at last, and heard solely by the virtue of the fact that they are seen. It is in this sense that "the clinical gaze has the paradoxical ability to hear a language as soon as it perceives a spectacle" (p. 108).

The conversation that emerges from this double silence is an interior dialogue that the observer has with him- or herself, not a dialogue with the object of gaze. In the context of the physician-patient encounter, the language describing what the physician has seen gives structure to the encounter, not any language the patient might speak. The profundity of this silence derives from its absoluteness: Not only must the patient keep quiet about theories and imaginings that might relate to his or her illness, absolutely nothing the patient says can have any significance for the physician because no language can exist that has priority over the language of observation. This muting of the patient's own voice gives rise to what Foucault calls "the great myth of a pure Gaze that would be pure Language: a speaking eye" (p. 114). What it sees, it gathers and organizes; and as it sees, and sees more clearly, it speaks and teaches. The speaking eye becomes "the servant of things and the master of truth" (p. 115).

THE LANGUAGE OF CURING. Secretiveness, or what Foucault terms "esotericism," arises from this model for the physician-patient relationship because, as Foucault observes, one sees the visible (the true) only because one knows the language. Unlike Molière's physicians, who spoke Latin merely in order not to be understood, Foucault's clinicians speak openly about that which anyone can see but only they can understand, because through the language of clinical description they have the means to see and hear at the same time, having access to a language that masters the visible. At this point, the earlier epistemological silence (Foucault's "double silence") that results from a constriction of perception changes into the silence of which Jay Katz speaks, a silence made even more baffling and profound by having as its vehicle a multitude of words that make every pretense of being understandable.

In effect, this model of medical perception insists that healing cannot be spoken or even thought of apart from the language of curing, that is, scientifically accurate diagnosis and treatment. This clinical perception and its promise of truth tend to overshadow all other claims to truth, reducing the promise to help those who suffer illness to the promise to be scientifically competent. Attempting to expand that visual horizon—particularly in the direction of the perspective of the patient—risks introducing an unacceptable noise into the silence of the medical clinic, an unwelcome and meaningless distraction from the work of curing.

Healing and Cultural Reality

Healing, of course, is a much broader cultural phenomenon than that encompassed by Western scientific medicine. Admittedly, the success of Western medicine at curing has helped justify its claim to be the model for healing in the world today. Yet, as Eric Cassell notes, "the success of medicine has created a strain: the doctor sees his role as the curer of disease and 'forgets' his role as healer of the sick, and patients wander disabled but without a culturally acceptable mantle of disease with which to clothe the nakedness of their pain" (Cassell, 1976, p. 51). This strain also appears in the way patients perceive their physicians. Western culture has conferred upon doctors the role of the care of the sick; but although doctors' role as the curers of disease is clear, their role as healers remains obscure. The latter role, Cassell adds, depends less on their ability to provide a scientifically accurate explanation of their patient's illness than to provide an explanation consistent with the culture of the patient. The reality that counts is cultural reality, and the system used by the healer or doctor need be accurate only in terms of the culture in which it is being used, for it serves to explain illness. The importance of the healer's explanation, Cassell insists, cannot be overemphasized.

THE HEALING RELATIONSHIP. As Cassell sees it, the healer's knowledge, imparted to the patient, helps move the world of

illness from the unknown to the rational world. This knowledge allows the patient to "work on" the illness and to make an essential link between conscious process and body process that, Cassell says, marks the "educated" patient. Such healing is not cognitive alone. In addition to educating the patient, healers also play an active physical part in providing a link between symbolic reason and the body: They use their hands. Cassell calls this the "tenderness phenomenon," as important as education in the process of healing. He associates this phenomenon with parenting, and, in this sense, healers serve as parents. In addition to other aspects of the parental role, we transfer to them the right to lay hands on us, to be tender to us, and to pass through our territorial defenses.

The connectedness that underlies the tenderness phenomenon works in both directions. Healer and sufferer become exquisitely sensitive to one another; each can sense the feelings of the other. If healers can accept that the feelings they have can come from the patient, they can use their own feelings in the presence of the patient to provide a vital link with the patient's interior emotional state that is otherwise closed to the clinical observer. Cassell emphasizes that the ability of healers to establish this connectedness with the patient is not an exception to the role of healer but is rather an integral part of the healing function. It shatters the silence of which Katz writes, and substitutes for clinical detachment the "constant will of one trying to recognize" (Brody, 1992, p. 263).

Establishing this connectedness does not make of the healer a great person but does place both healer and patient in the presence of a deep human mystery that is greater than both of them. It is to be present at a creation that Elaine Scarry likens to the rediscovery of language: "Physical pain is not only itself resistant to language but also actively destroys language, deconstructing it into the pre-language of cries and groans. To hear those cries is to witness the shattering of language. Conversely, to be present when the person in pain rediscovers speech and so regains his powers of self-objectification is almost to be present at the birth, or rebirth, of language" (p. 172).

Explanation, education, and connectedness form the core of Cassell's understanding of the healing relationship. The problem with the scientific explanation of illness is not that it is incorrect, since, as Cassell notes, "we know that it need not be correct, since for most of the history of medicine it has not been correct" (1976, p. 128). Put differently, the virtue of scientifically accurate diagnosis and treatment does not lie in its correctness. The fact that it seems correct does not entitle it to stand as the only and sufficient explanation of illness. Although science has been empowered by Western culture to dictate diagnosis and disease categories, Cassell notes that it has little or nothing to say about sick persons, their behavior, patient-healer communication, and so on. "If the whole point of the clinical encounter is to decide what is the right and the good thing to do for a specific patient, then traditional medical theory is sorely lacking" (1991, p. 6).

The Power of the Healer

Although he recognizes the limitations of traditional medical theory, Cassell does not intend to belittle or dismiss the role that the scientific explanation of disease has in Western culture or the promise it holds for the world. He wishes, in fact, to acknowledge its power: "The therapeutic power of the doctor-patient relationship grows in importance as the technology of cure becomes more powerful" (1991, p. 69). Yet, unfortunately, even as the importance of the relationship between doctor and patient grows under the stimulus of technology, so does the isolation of the patient, who becomes lost in a maze of tests, procedures, and treatment teams. To disregard this relationship only adds insult to the injury inflicted by isolation. "It has been one of the most basic errors of the modern era in medicine to believe that patients cured of their diseases—cancer removed, coronary arteries opened, infection resolved, walking again, talking again, or back home again—are also healed; are whole again" (1991, p. 69). What has been forgotten, he says, is that technology itself has no power—humans acquire power by employing the technology.

The importance of power in the therapeutic relationship has been explored at length by Howard Brody (1992). He analyzes the healer's power in three components: Aesculapian, charismatic, and social. The healer acquires Aesculapian power by virtue of training in the craft of healing. The power is impersonal, transferable to any other healer of comparable skill and experience. Charismatic power is founded on the healer's personal qualities and character and cannot be readily transferred. It is independent of the disciplinary knowledge and skill belonging to Aesculapian power. Social power arises from the social status of the healer within a particular society. It derives its authority in part from the implied contract between the healing profession and society that empowers the profession to determine truth in regard to illness.

The power to heal involves a complex interplay among all three kinds of power; it is a mistake, Brody notes, to limit the power of healing to Aesculapian power alone. Any discussion of what constitutes a right and good healing action must entail an exploration of the proper use of the other forms of power that the healer possesses. These forms of power risk what Brody calls "the dark side of the force."

This is "a lust, half childish, half sadistic, to use whatever power we might have to victimize others less powerful, and to enjoy it—to glory in the fact that they and not we are the victims, and to escape for a moment into the fantasy that since we can avoid their victimhood through our power, we are invulnerable and need never again feel fear" (Brody, 1992, p. 21).

THE VIRTUE OF COMPASSION. Healers can find the antidote to the dark side of the force by acknowledging the feelings of vulnerability and weakness that arise in them as they face the patient. They can do this only if they are open to the experience of being ill and in distress. To do this effectively, Brody says, healers need more than to be told they have an obligation to be open; they need to develop the virtue of compassion, an internalized habit of character that becomes an instinctive attitude of openness and vulnerability.

A major irony in the healer-patient relationship emerges here. To be compassionate in response to the suffering of the patient is itself a powerful act of healing. In showing compassion, the healer empowers the patient in a way that merely curing disease cannot. Curing disease eliminates a threat to bodily function and integrity; alleviating suffering, without which healing is a mere charade, restores the sufferer's connections with humanity and the ability to make sense of his or her own life. Yet, Brody says, this act of empowerment is possible only to the extent that the healer is willing to adopt a position of relative powerlessness, to acknowledge that the patient's suffering has incredible power over her or him and that it is impossible to remain unchanged in the face of it.

SHARED POWER. Western medical training urges compassion as a duty of the profession but at the same time warns, "Don't get too involved." Brody interprets this warning as a form of false reassurance that the power to heal does not entail the felt powerlessness of compassion. This denial of the power that the patient's suffering has over the physician is a rejection of the concept of shared power, which Brody states is the essential element in the ethical use of power. This denial also betrays a fundamental misperception of power as a zero sum game, that is, the belief that anything that increases the power of the patient within the healing relationship must necessarily decrease the healing power of the physician.

This *competitive* notion of power conforms to the type of moral reasoning that Carol Gilligan discovered among non-minority males in North American culture. The dominant male culture emphasizes the importance of finding the rules that govern a relationship and then selecting courses of action in keeping with the rules, even if such devotion to rules means sacrificing someone's interests to the considerations of abstract justice (Gilligan). She counters with a type of moral reasoning common to the women she studied: They tend to focus on the nuances of personal relationships and seek solutions that protect the interests of all affected parties and that avoid bringing harm to anyone.

RESTRUCTURING THE POWER OF HEALING. Following the lead of Gilligan, other voices have appealed to an understanding of moral relationships from the perspective of women, such as Nel Noddings (1984), whose work on caring has influenced nursing ethics (Bishop and Scudder); and Virginia Warren (1989), who applies a feminist point of view to the conduct of medical ethics itself. Although these critics represent a wide range of opinion on the means to be used and even on the foundational reasons for doing so, most of them would agree with Susan Sherwin that there is a need to develop conceptual models for restructuring the power associated with healing and to clarify how "excessive dependence can be reduced, how caring can be offered without paternalism, and how health services can be obtained within a context worthy of trust" (p. 93). Sherwin notes with approval that, for many mainstream medical ethicists, compassion is frequently claimed to be more compelling than justice, a tendency she finds especially common in the contribution of physicians to medical ethics.

If this need for compassion is admitted, the significant question then becomes, What can allow a physician to experience the powerful suffering of a patient in a way that encourages the physician to share power and therefore to become not only a curer but also a healer? What is needed is a way for healers, and physicians in particular, to experience the felt reality of shared power without seeing it as a betrayal of their Aesculapian power, no matter how evident in this process its limitations may appear to become.

THE LIMITS OF AESCULAPIAN POWER. The strategy employed by many patient advocacy groups of leaving physicians' Aesculapian power undisturbed while severely restricting their social and charismatic power avoids the issue by ceding to physicians their chosen territory. Such an approach abandons the project of power sharing and attempts to render the healer-patient relationship "doctor-proof" by segregating Aesculapian power from the other forms of power. This strategy errs because it assumes that "we can wring morally acceptable actions out of any physician no matter how good or bad his motives if only we have the right rules for him to follow" (Brody, 1992, p. 55). As feminist critics have noted, this strategy endorses the *masculine* assumption that solving moral problems means discovering the right rules while leaving intact the existing power

relationships. It cannot succeed because, as Brody points out, it mistakenly presumes that the healer's power comes in two neatly differentiated categories: power that helps fight illness, and power that can be used to violate patient's rights. But no such easy distinction is possible because the same powers can be easily redirected for good or ill.

The realization of shared power can take place only if those who profess to heal acknowledge responsibility for all the forms of power they possess. They must be reassured that owning up to their charismatic and social power does not imply that their Aesculapian power is fraudulent, although it may require them to admit that something like the placebo effect is present in almost every healing encounter (1992). For physicians to profess to heal requires the realization that their Aesculapian power, despite the warrant of its scientific accomplishments, is limited in both its scope and effectiveness. Curing does not ensure healing, and healing is possible even if there cannot be cure; nor is every human ill subject to cure. Such an admission, however, does not exempt those who profess to heal from attending to the needs of the poor, the oppressed, or those victimized by war, prejudice, and despotism. It only reminds them that their social and charismatic powers alone have authority in these difficult areas.

AESTHETIC DISTANCE. Compassion, lest it degenerate into codependency, does need to maintain a certain strength and thus a certain distance from the plight of the sufferer. Brody characterizes this distance as aesthetic rather than emotional; it resembles the reader's approach to a work of fiction (1992). To regard the suffering patient as a text, attended to at an aesthetic distance, still permits and even encourages intense emotional involvement. In reading the text presented by the sufferer, the healer must maintain in his or her imagination that separate vantage point from which the experience of the sufferer can be reinterpreted and reconnected to the broader context of culture and society.

Healing and Community

Healing reconnects the sufferer both to the self and to the world. The final and perhaps least appreciated aspect of healing is the need for this reconnection to take place in the context of a community, a need as real for the healer as it is for the sufferer. Healing requires from the healer a commitment over time to become a person capable of compassion and therefore of healing, who has the deep knowledge of how to fuse power and powerlessness, strength and vulnerability. This openness to vulnerability required of healers is more than a simple disposition to the notion of vulnerability. As Brody notes, there is a difference between being "disposed" to something and striving over time to become something. It is the latter that is the mark of virtue.

In cultivating compassion as a professional virtue, healers must be willing to be formed by a compassionate community, "confident that they will receive empathic compassion and support from each other as they attend to the sufferings of their patients" (Brody, 1992, p. 267). In this arena, Brody ruefully notes, implicit issues of power have most stood in the way of the profession's reform. The self-imposed image of the physician as a powerful, scientific, objective individual, he says, works against the development of any effective peer support system. But it also cripples the physician's ability to be present to those in pain, which, as Stanley Hauerwas notes (1985), should be the goal of medical training.

For Hauerwas, "the physician's basic pledge is not to cure, but to share through being present to the one in pain" (p. 220). This pledge is difficult to carry out on a day-to-day basis. No individual has the resources to see so much pain without that pain hardening him or her. Pain, as Scarry notes, is destructive of human community; hence the prime directive of the healer to be present to those in pain carries with it an embodied threat to the ability to continue to be a healer. She or he must not only be formed as a healer by a compassionate community, but must also be continually sustained and nurtured by such a community—the kind of community, Hauerwas notes, that the Christian church claims to be.

There is a rich and varied tradition of healing not only within the Christian church but also in virtually every religious tradition. In fact, the role of healer in early societies encompassed not only the people's health but their entire welfare, including their spiritual welfare. The specialization that has accompanied modern civilization, however, makes discussion of the relationship between healing and religious belief problematic in that it is no longer clear who is priest, who is healer, and whose authority should predominate. The relation of medicine to particular religious traditions (Numbers and Amundsen) and the relevance of theological ideas, particularly that of covenant, to medical ethics (May) have opened up areas of fruitful exploration for both medicine and religion. But it may be well to concentrate, as Hauerwas does, not on these theoretical relationships but on the practical relation between communities, between those who practice religion and those who practice healing.

It is in this sense, Hauerwas says, that those who profess to heal need religion—not to provide miracles when there is a failure to cure, not even to supply a foundation for their moral commitments, but rather as a source of the habits and practices necessary to sustain them over the long haul as they

care for those in pain. There needs to be a body of people who have learned the skills of presence to keep the world of the ill from becoming a separate world, both for the sake of the ill and for those who care for them. "Only a community that is pledged not to fear the stranger (and illness always makes us a stranger to ourselves and others) can welcome the continued presence of the ill in our midst" (Hauerwas, p. 223).

In the final analysis, healing is a communal action whose goal is the restoration not only of physical and mental wholeness to those who suffer illness but also of their integrity as persons, that is, as beings-in-relation to themselves and to other persons. It is a communal action in two senses: It reaches out to those isolated by illness to reconnect them to the human family; and it is sustainable only within a community that practices compassion as a virtue. The future of the healing professions everywhere depends as much on this nurture as on technical competence and the wise use of material resources. Those who profess to heal must know that no one is fully healed until all are healed.

HEALTH AND DISEASE

• • •

I. HISTORY OF THE CONCEPTS

Health and disease are among the fundamental experiences of human life. The concepts that people in various cultures have used in an attempt to understand and respond to those experiences have to do with the way humans relate to nature and culture. The concepts of health and disease have far-reaching consequences for diagnosis and therapy, the attitude and behavior of physicians, how patients deal with disease, social attitudes and structures, the shape of moral choices, and the cultural significance of sickness and wellness behaviors.

Health and disease are not merely medical terms; they are also vital themes in art, philosophy, theology, sociology, and psychology. In fact, these very disciplines remind medicine again and again of its distinctly *anthropological* character, in the sense that medicine deals with the nature and destiny of humans. Neither medicine nor the concepts of health and disease with which it deals can be properly understood by using the starkly contrasting categories of natural sciences and human sciences as a framework. Just as medicine cannot be reduced to either of the two, so it is also necessary to connect nature and culture in order to understand health and disease.

A universally valid definition of health has been as hard to formulate as a universally valid definition of disease. Health and disease are physical, social, psychological, and spiritual phenomena that can be represented in concepts that are both descriptive and normative (the latter meaning based on norms), although these two sorts of concepts have not always been clearly distinguished in the historical development of these ideas. Humans not only determine what will be regarded as health and disease; at the same time they also interpret these experiences and decide how to respond to them.

Concepts of disease and health are especially important because they influence the manner and goal of medical treatment. Thus a mechanical or technologically structured understanding of disease (which views the human as a defective machine) requires a mechanical or technologically structured therapy (regarded as repair) and therapeutic relationship (a relationship of technician to defective machine). More personal or holistic concepts urge corresponding types of therapy and healer–patient relationships.

Contemporary medicine increasingly faces the task not only of overcoming sickness but also of preserving health. Prevention and rehabilitation play increasingly important roles alongside curative therapies. Treatment is understood to include attentive caring and support. Chronic suffering and death place different demands on the doctor–patient relationship than do acute illnesses. In light of such developments, concepts of health and disease require new definitions. A historical retrospective may assist in arriving at those definitions.

This entry does not attempt to offer a thorough cross-cultural analysis of concepts of health and disease; rather, it presents essential dimensions and changes in these concepts in the general course of history, their relationships with sociocultural backgrounds, and their practical and ethical consequences (Diepgen, Gruber, and Schadewaldt; Riese; Rothschuh; Schipperges, Seidler, and Unschuld; Temkin). A consideration of these historical developments can stimulate new reflections and initiatives, but history differs from any theoretical system. History has its own rules and logic. A progressionist explanation of the gradual development of notions of health and disease is inadequate. There are continuities and discontinuities, progress and regress, even within a single event or movement. This complex nature of history in general characterizes the history of medicine and specifically the history of the concepts of health and disease.

Health and disease suggest a variety of meanings from psychological, social, and spiritual perspectives. The word *illness* in the English language refers to the subjective or personal side of disease, whereas *disease* refers to the medical conception of pathological abnormality. It is possible for a person to feel ill without having a disease, and conversely, to

have a disease without feeling ill. The term *sickness* transcends both of these concepts by focusing on social consequences. The concept of the *sick role* corresponds to the social nature of disease. The way in which societies vary in their interpretations of physical and mental disorders and in their treatment of and symbolic reactions to them reflects the cultural dimension of disease.

Nonetheless, some basic categories will be useful in the following discussion. One category is the explanation of disease, illness, and sickness. From a physical perspective, the different approaches of the past attribute disease to either liquid or solid components of the body or to the relationship between the body and the soul. Other distinctions refer to whether diseases should be regarded as existing entities (the ontological notion of disease) or as phenomena affecting individual persons in a variety of ways (the symptomatic notion of disease); and whether and to what extent the constitution and disposition of the individual (endogenous factors) and/or external (exogenous) factors play a significant role in determining health and disease.

A second category concerns response to disease, illness, and sickness. These responses have frequently been shaped by the explanation of disease, illness, and sickness. These two categories evolved into the science and clinical practice of medicine.

Primitive Peoples

There is no life without disease and pain; their ubiquitous nature is demonstrated by history. The skeletons of the first humans (500,000 B.C.E.) display bone disturbances and fractures. It is difficult to offer accurate descriptions of the health and disease of historically primitive peoples, because claims must depend on limited and problematic archaeological, paleopathological, and written sources (Clements).

At the dawn of human history, medicine had a magicomystical, demonic-religious character. Exogenous factors such as spirits, spells, and gods were considered responsible for disease. Personified living entities, spirits, took over a healthy body and made off with the soul of the person or allowed foreign elements to invade the body. Spirits, dead or living, could exercise fateful effects, acting out of revenge for breaches of taboos. Disease, directly related to sin and wrongdoing, represented not only an individual but also a social destiny. What befell one person befell the whole family, group, or tribe.

The diagnostic and healing powers of the healer or priest-doctor were supernatural. The healer had to be able to recognize which forces were at work in any given case. He did this by reading the stars or by drawing meaning from minerals, plants, and animals. Amulets and magic spells, oracles, atonement and confession, exorcism, bloodletting, and ceremonies of purification functioned as both preventive measures and cures. The whole community took part in the healing process; even pets were brought into it. Primitive peoples exhibited great cleanliness for the sake of prevention and strictly observed their cultural taboos.

There are remnants of these primitive notions of disease in today's lay language. For example, in English slang menstruation is sometimes called "the curse"; the German word for lumbago, *Hexenschuss,* means witch's wound. To what extent one can observe these assumptions about sickness and health, and the social structures that correspond to them, among the primitive peoples of today is hard to say. Modern civilization and medicine have left their impact in every part of the world. Primitive peoples, too, change over time.

Ancient Cultures

Precursors to medical systems and theories of disease were found in the ancient cultures of Mesopotamia and Egypt between the fourth millennium B.C.E. and the first, which established connections between concepts of nature and religion, on the one hand, and views of sickness and health on the other. Parallels between Chinese, Tibetan, Indian, and Greek perceptions of sickness and health indicate that these cultures may have derived these ideas from the same sources. Ancient American cultures also shared similar perceptions.

For these cultures health and disease were physical as well as religious phenomena. Sickness was still associated with sin, even as empirical interpretation of health and disease began to spread. Egyptian papyri (2000–1500 B.C.E.), for example, describe the courses of various diseases and categorize them according to regions of the body. The papyri list causes, symptoms, and prognoses, as well as empirical interventions. Putrefaction within the body in the form of spoiled material (*materia peccans*) caused sickness; these substances had to be removed if the patient were to be cured. The Greek historian Herodotus (fifth century B.C.E.) describes monthly purifications in Egypt.

Dietetic, medicinal, and surgical interventions were used, and much attention was given to public health. The medicine of ancient cultures combined religious ritual with empirical treatment. The Babylonian code of Hammurabi (d. 1750 B.C.E.) contained the first list of surgical fees and penalties in the case of failure; each varied according to the social status of the patient.

The explanatory dimensions of medicine, such as symptomology, nosology (the classification of diseases), diagnosis, and etiology (the study of the causes of diseases), as well as clinical dimensions such as prognosis, therapy, and prevention, began to establish themselves in these centuries. The traditional healer became the professional doctor; specialization developed. In this era, empirical observation, causal explanation, magic, and faith coexisted in medical theory and practice.

Greece and Rome

More extensive and reliable historical sources exist for ancient Greece and Rome. The ancient Greeks (500 B.C.E.) explained health and disease cosmologically and anthropologically, that is, in close relation to nature in general and to human nature in particular. Medicine sought not only to cure disease but also to maintain health. The pre-Socratic philosophers, who were the physicians of this time, developed a universal model of health, whose outlines can be found in the medical texts of Hippocrates (c. 460–c. 377 B.C.E.) and other physicians of the Corpus Hippocraticum (400 B.C.E.–200 C.E.). These pre-Socratic physicians must be distinguished from magicoreligious healers, who still existed at that time (Kudlien).

The great physician Galen (129–c. 199 C.E.) elaborated a model of health and disease as a structure of elements, qualities, humors, organs, temperaments, times of day, and times of year (Schöner). Health was understood in this perspective to be a condition of harmony or balance (*isonomia*) among these basic components that make up both nature in general and the individual body. Disease, on the other hand, was regarded as discordance, or the inappropriate dominance (*monarchia*) of one of the basic components. Disease in the perspective of humoral (pathology determined by bodily fluids) was interpreted as the disproportion (*dyscrasia*) of bodily fluids or humors: phlegm, blood, and yellow and black bile. Solidistic pathology traced disease to disturbances among the solid components of the body (shape, consistency, distance, etc.). The pneumapathological (spirit) approach attributed disease to a failed relationship between body and soul. Health (*eucrasia*) was characterized by equilibrium in the body.

Dietetics was considered of primary importance to the therapeutic process, followed by medication and lastly by surgery, a hierarchy exactly opposite to the prevailing Western approach of today. In the ancient perspective, dietetics involved much more than a health-conscious regulation of food and drink. Rather, it entailed a broad concept of how one should live a healthy life. Dietetics was concerned with six aspects of life that, although natural, did not regulate themselves, as did such physiological functions as respiration and digestion. Because they required human manipulation, these six aspects of life were called "non-natural" (*sex res non naturales*). These areas included how humans deal with:

1. air and light;
2. food and drink;
3. sleep;
4. motion and rest;
5. secretions; and
6. passions of the mind (Rather).

According to Galen, and in contrast to contemporary views, health and sickness were not the only states of existence. Rather, there was a third condition, an intermediate state of *neutrality* that existed between health and sickness: Medicine was therefore conceived as the science of health, sickness, and neutrality. In this notion of medicine, the overcoming of sickness was secondary to the preservation of good health or to aiding patients in living with impediments and handicaps. Galen said that because health precedes illness both in time and in esteem, one should try first to preserve health and only second to cure the illness as far as possible.

Philosophy and medicine mutually influenced one another in antiquity, although Hippocrates is said to have separated medicine from philosophy. Health and disease are not only empirical descriptions. They always have philosophical implications and practical effects. The Greek philosopher Plato (c. 428–c. 348 B.C.E.) defined medicine as the theory of health, and in the perspective of his ethical concept of health, he legitimized the active euthanasia of the physically handicapped and the mentally ill. Plato and his student Aristotle (384–322 B.C.E.) developed a typology of three physicians with corresponding types of relationships with the patient. The *slave doctor* commands, and the patient has to obey. The *doctor for freemen* explains the treatment to the patient and the patient's family. Doctors understood to be *medically educated laymen* signified individuals who take responsibility for their own health, sickness, and death.

While abortion and active euthanasia were forbidden as therapeutic acts for the Hippocratic physician, the Stoics justified these practices in situations in which the patient had lost or was in danger of losing moral autonomy and rational awareness. Harmony of the mind was placed above health and disease, above wealth and poverty. For the Stoic philosopher Seneca (c. 4 B.C.E.–65 C.E.), disease meant physical pain (*dolor corporis*), the suspension of joy (*intermissio voluptatum*), and the fear of death (*metus mortis*)—implying that disease combines physical, psychological, social, and mental dimensions. While being persecuted by the Roman

emperor Nero, Seneca ended his own life through active euthanasia with the help of his friend and doctor Statius Annaeus.

The Middle Ages

The Christian Middle Ages (500–1300) interpreted health and sickness in a theological perspective. Cosmological (or natural) and anthropological (or human) approaches were subordinated to, without being supplanted by, the supernatural notion of transcendence. Christian beliefs and natural causes for health and disease were not mutually exclusive. Sicknesses could be described simultaneously as physical entities and as acts of God's intervention. The Christian, Arabic, and Jewish traditions all viewed health or *quality of life* as the outcome of a good relationship with God.

Medicine consisted of theory and practice, each of which was further divided. Medical practice consisted of dietetics, medicaments (therapeutic substances), and surgery. Galen's humoral pathology prevailed throughout the Middle Ages, and dietetics in antiquity's broad sense of the term continued to function as the most important form of treatment. The emphasis on spirituality did not run counter to medical aid and health education. As the vessel of the soul, the body warranted careful attention.

During the Middle Ages, a variety of specific health rules (*Regimina sanitatis*) were developed for people of various ages, occupations, and classes, as well as for both sexes. One famous example, the *Regimen Sanitatis Salernitanum* from the thirteenth century, has survived in various medical customs and was published in all major European languages.

According to the medieval Christian viewpoint, the figure of Christ as healer (*Christus medicus*) stood behind every doctor, and behind every patient was the figure of the suffering Christ. Health, disease, and healing gained their meaning from this perspective. These concepts were related intimately to the idea of salvation history (eschatology), seen as a progression of the world starting with its establishment in paradise (*constitutio*), through its earthly existence (*destitutio*), and finally to resurrection (*restitutio*).

These concepts also had their practical consequences, manifested in biographies and other documents of arts and literature. Each transition from health to sickness and from sickness to health represented this eschatological process on an individual level. Even though sickness, suffering, and death had salvific significance or were essential traits of human life, they were fought with dietetics and medical therapy. But they were also to be accepted, because earthly life is different from paradise. In this regard, Saint Augustine (354–430) remarked that people have to say "yes" to some forms of pain but are not forced to love them.

The Greco-Roman link between health, beauty, and morality was abandoned during the Middle Ages. Every sick, suffering, or handicapped individual had the right to receive medical treatment. Hospitals, first founded during the Middle Ages, were open to all suffering and helpless people, based on Jesus' words: "I was sick, and you cared for me" (Matthew 25: 26). At the same time, however, the Bible was used to justify excluding lepers from society.

The classical and Christian concept of the seven cardinal virtues (prudence, temperance, fortitude, justice, faith, hope, and love) applied to healthy people as well as to the sick, doctors, and the community. Suicide and euthanasia were regarded as sins because they were deliberate attempts to shorten life. Therefore the ancient Hippocratic oath was continuously accepted in this epoch. The art of dying (*ars moriendi*) was considered a central part of the art of living (*ars vivendi*). Sickness could be traced to inherited sin, personal guilt, demonic possession, or a test from God. Job of the Old Testament represented a classic example of the latter.

In contrast to present-day attitudes, health was also viewed as negative in the moral and religious sense ("corrupting health": *sanitas perniciosa*) and sickness as positive ("a healing sickness": *infirmitas salubris*). Coping with illness was believed to manifest a person's fortitude; furthermore, a life without physical or psychical damage or pain was thought to produce a false image of earthly life and the human condition. A contemporary biographer, writing about the constant illness of the saintly German abbess Hildegard of Bingen (1098–1179), who was also a prominent naturalist and physician, said that her whole life could be compared to a "precious dying."

The Modern Era

With the coming of the modern era at the time of the Renaissance, which began in the fourteenth century, an emphasis on this world, nature, and the individual replaced the medieval focus on the hereafter. The secularization of paradise—or the hope of realizing beauty, youth, and health in an earthly life—has influenced human thought and action and the course of medicine up to the present. Empirical observation, causal explanation, and rational therapy became the ideals of education, research, and practice in medicine. Nevertheless, magic, astrology, and alchemy continued to play a role in medicine for quite some time.

At the transition from the Middle Ages to the modern era, the German physician and philosopher Paracelsus

(1493–1541) designed an all-encompassing system of medicine. Along with philosophy, astronomy, and alchemy, ethics acquired a fundamental role. Paracelsus replaced the ancient humoral pathology with three rudiments from alchemy: salt, mercury, and sulfur. Dominance of one of these biochemical components over the others led to different types of diseases. Disturbances in the spiritual principle also led to disease. According to Paracelsus, the general factors that contributed to disease belonged to nature as well as culture: (1) cosmic influences (*ens astorum*); (2) material influences (*ens veneni*); and (3) individual constitution (*ens naturale*), spirit (*ens spirituale*), and God (*ens Dei*). Paracelsus's concept of disease is ontological or essentialistic: Disease is a "thing," which he compared with a parasite, a separate organism. This notion contrasts with the Hippocratic concept, which explained sickness as an individual, symptomatic phenomenon.

The utopian writings of the English statesman Thomas More (1478–1535), the English philosopher Francis Bacon (1561–1626), and the Italian philosopher Tommaso Campanella (1568–1639) include basic categories for determining health and disease as well as guiding principles for eugenic public health policies. Their concepts justified suicide and euthanasia—but only under the condition that it be done freely (at the decision of the individual). During the Renaissance the different types of euthanasia, still relevant in the discussions of the subject today, were already established. Not everyone supported active euthanasia as a social reaction to sickness. The German theologian Johann Valentin Andreae (1586–1654), unlike More and Bacon, expressly rejected euthanasia in his 1619 work *Christianopolis.* He stated that "reason commands that human society should be more gently disposed toward those who have been less kindly treated by nature" (p. 274).

The philosophy of the French mathematician René Descartes (1596–1650), with its mechanical model of health and disease, became highly important for the concepts of disease and therapy. According to Descartes, the body is a perfect clockwork mechanism set in motion by God to function mechanically. The soul, also divinely created, acts independently from the body. This dualistic system of body (*res extensa*) and soul (*res cogitans*) was widely accepted in medicine and produced a mechanistic view of physiology, still accepted in the present, that also existed in lay interpretations of health and disease. Scientific explanation concerned the discovery of the fixed rules of mechanistic structures and their processes. Clinical medicine concerned the detection of damaged structure, malfunction, and departure from these rules, and the restoration of proper anatomic structures and physiology.

During the Enlightenment (eighteenth century), the real beginnings of a public health movement began to take shape. The German philosopher Gottfried Wilhelm Leibniz (1646–1716) made numerous recommendations for public health. The American statesman and philosopher Benjamin Franklin (1706–1790) formulated a characteristic phrase of the time: "Health is wealth." The German physician Johann Peter Frank (1745–1821) and the French philosopher Jean-Jacques Rousseau (1712–1778) represented the opposition between state policies and individual agendas. According to Rousseau, civilization and the state had ruined human health in its natural state. Frank, in contrast, believed that social reforms lead to progress. Several books were published primarily on prevention and rehabilitation. The German physician Christoph Wilhelm Hufeland (1762–1836), author of the widely distributed *Makrobiotik* (1797), manifested again the relationship between concepts of health, disease and therapy —especially as normative categories— with the social attitudes and reactions. He believed that physicians should not be allowed to engage in active euthanasia, pointing out that physicians who start to decide which sick persons are worthy of living become "the most dangerous people in the state."

The concepts of health and disease vacillate between anatomy and physiology. The definitions of disease and health of the Scottish physician John Brown (1735–1788) received great recognition in the medicine, philosophy, and literature of his time. His 1780 work *Elementa Medicinae* defined health and disease in terms of the relationship of opposing forces within a person: of organic excitability and external and internal stimuli, resulting in an excited or irritated condition of the organism. According to Brown, disease is the result of overstimulation (*sthenie*) or insufficient stimulation (*asthenie*). Health, on the other hand, is characterized by equilibrium between the capacity to be stimulated and internal and external stimuli. Treatment, therefore, functioned either to strengthen or subdue stimuli. Bloodletting and diet calmed a condition of overstimulation, whereas ether, camphor, and opium had the opposite effect. Equally important for the further progress of medicine was the anatomical foundation of pathology by the Italian physician Giovanni Battista Morgagni (1682–1771) with his fundamental work *De sedibus et causis morborum* (On the seats and causes of disease), published in 1761.

Romanticism and idealism, around 1800, introduced interpretations of health, disease, and death that are of general importance and transcend substantially the limits of medicine (Leibbrand). These three states were regarded as dialectically connected with one another and interpreted as the main stages of the genesis of Spirit out of nature, a

Hegelian theme (von Engelhardt). According to the German poet Friedrich von Hardenberg (1772–1801), who wrote under the pseudonym Novalis, there is always disease in health and health in disease; illness or sickness is given a central value: "Medicine should be an elementary science of every cultivated person" (Novalis, p. 474). Illness can be an experience or medium of personal growth. The personhood of the patient becomes a central claim: "Human being = person; that is the point of unity," (Heinroth, p. 158) categorically announced the german physician Johann Heinroth (1773–1843). The German philosopher Joseph Schelling (1775–1854) held that health is the harmonious relationship of the basic organic functions of sensibility, irritability, and reproduction. The German philosopher Georg Hegel (1770–1831) argued that life would be impossible without disease, that each organism contains the "germ of death" from birth, and that all therapy presupposes that disease is not a total loss of health but rather a conflict within physical or psychical forces. Only through disease and death of the individual does the universal and eternal world of the spirit come into being. "Above this death of Nature, from this dead husk, proceeds a more beautiful Nature, proceeds Spirit" (Hegel, p. 443).

MEDICINE AND THE NATURAL SCIENCES. Medicine in the remainder of the nineteenth century followed the model of the natural sciences and not that of natural philosophy and philosophical anthropology of the romantic-idealistic era. This increasingly self-conscious scientific medicine concentrated on curing disease and neglected the maintenance of good health. It also neglected the contributions of the arts, literature, and theology. The patient became more and more an object. The patient's subjectivity or personality was disregarded, and the history of the patient was reduced to the history of the disease. Anatomy and physiology were connected; the cell replaced tissue as the center of attention. Experimentation, statistics, and causal thinking became the basis for medical research. A Cartesian concern for mechanistic structure and function according to discernible rules became paramount.

The German pathologist Rudolf Virchow's (1821–1902) definition of disease was widely accepted: "Disease begins at that moment when the regulatory system of the body is not sufficient to overcome a disturbance. It is not life under abnormal circumstances, nor the disturbance as such which produces a disease, rather the disease begins with the insufficiency of regulatory mechanism" (p. 193). According to Virchow, the body's regulatory ability varied from person to person. The healthy body is capable of bringing an abnormal situation back into equilibrium. Disease was an observable phenomenon in the living body, caused by internal and external factors. The cell became the basis of disease, and—using a political metaphor—it deserves recognition, along with blood and nerves, as the "third estate." The infection of cells, and thus the body, by external infectious agents became the dominant explanation of disease. The clinical response was to eradicate the infection.

In the nineteenth century, dietetics lost its broader or anthropological meaning and came to refer simply to the intake of food and drink. Thus a 2,000-year-old tradition, already limited in the eighteenth century, reached its end. Nevertheless, the tradition of dietetics survived longer in the area of hygiene than in pathology. Scientific medicine in its modern form considered heredity, psychical, and social factors relatively unimportant to the etiology of disease. Infection was the decisive explanatory factor; therapeutic results from the period substantiated this theory. Thus, the development of concepts of health and disease and of clinical responses to them was synergistic, a historical process that continues into the present.

At the beginning of the twentieth century, constitutional pathology and anthropological medicine began to counteract the one-sided approach of infectious disease modules of medicine. Medicine recovered the importance of the individual and social circumstances in health and disease—constitutional pathology on the physical level, anthropological medicine on the psychical or mental level. Human beings were conceived as participating in nature as well as in culture. The German physician Viktor von Weizsäcker (1886–1957) reintroduced in his anthropological medicine "the person as subject," in regard to the patient, the doctor, and science.

In medicine as well as in biology, the concept of finality (*causa finalis*) regained attention; diseases not only have a physical cause (*causa efficiens*) but also manifest a sense of meaning. The controversy between monocausal thinking (*causalism*) and multifactorial thinking (*conditionalism*) influenced medicine during those decades around 1900 and is still lively: Can disease be deduced from one cause, or is it necessary to take different causes of different areas of reality into consideration? The concept of cause not only has consequences for the theory of disease origin and disease process but also affects medical therapy, prevention, and rehabilitation, all of which in turn shape the individual and social situation of the sick person.

Philosophers and theologians, as well as writers and artists, hoping to give people assistance that the natural sciences and medicine were unable to provide, continued to produce valuable interpretations of health and disease that took the spiritual or cultural nature of human experience into account, calling into question the established normative

equation of health as positive and disease as negative. The French writer Marcel Proust (1871–1922) stated that humankind owes its major cultural accomplishments to sick and suffering people: "They alone founded religions and created masterpieces" (p. 405). Increasingly, arts and literature have been acknowledged as being helpful in coping with disease, pain, and death.

The German philosopher Martin Heidegger (1889–1976) claimed that he wrote his analysis of death in *Being and Time* (1927) especially for doctors; in this work, Heidegger emphasized that only the human beings have the consciousness of death and of their own death. The German physician and philosopher Karl Jaspers (1883–1969) defined disease and health in the perspective of his philosophical position. Neurosis being "a failure in the marginal situations (*Grenzsituationen*) of life," he visualized the goal of its therapy "as a self-realisation or as a self-transformation of the individual through the marginal situation, in which he is revealed to himself and affirms himself in the world as it is" (p. 275). Jaspers contended that psychiatry shared two major methodologies: that of "explanation," which characterizes the natural sciences (disease), and that of "understanding," which is typical of the human sciences (illness). The ethical and practical consequence of his concept of disease in the objective, subjective, and cultural sense is outlined in his concept of the existential communication between the physician and the patient. Existential communication combines the subjective and cultural dimensions in an ethical perspective.

In the twentieth century, psychology and sociology expanded the scientific understanding of health and disease, emphasizing the difference between *disease* as objective and physical, and *illness* and *sickness* as subjective and social. According to this general perspective, contemporary people associate disease with the following interpretations: challenge, enemy, punishment, weakness, relief, strategy, loss or damage, and value (Lipowski). Medicine concentrates on weakness, loss, and damage, that is, the physical components of this model.

In the sociological perspective the role of the sick person is characterized by:

1. freedom from daily duties,
2. freedom from the responsibility for the sick condition,
3. the obligation to want to become well again, and
4. the obligation to seek medical help (Parsons; Schaefer).

Descriptive and normative aspects permeate this sociological definition of the role of the sick person. Disease is not only described in its social causes and consequences; demands and expectations are formulated. Subsequent studies have revealed further processes of different levels (age, sex, socioeconomic state, type of disease, etc.) of defining a person as sick. Also important are the differentiation between "bad" and "ill," or criminal behavior and sickness, and the negative or stigmatizing consequences of diagnostic acts.

The 1947 World Health Organization (WHO) definition of health—"a state of complete physical, mental, and social wellbeing and not merely the absence of disease or infirmity"—has to be interpreted in its social and political context and purposes. These included attempts to justify international involvement in the internal affairs of countries. It is another matter whether medicine can offer explanations and therapies to achieve *complete,* multifunctional wellbeing, the definition of which includes social and spiritual as well as medical aspects. The WHO definition was used as the starting point for intense bioethical debates on the moral and political responsibilities of the international community in regard to healthcare—especially for corresponding projects in developing countries. But this definition, taken generally, is limited in its sharp contrast between health and disease and its exaggerated estimation of health. With good reason, health can also be regarded as the ability to bear injury, handicaps, and the anticipation of death, and to successfully integrate these abilities into one's life. Integration is the capacity to cope with death; death is a part of life and not only its contrary or end.

Conclusion

The history of concepts of health and disease is the history of concepts that explain and direct response to disease, illness, sickness, and health. These concepts are deeply rooted in physical and psychical experiences and have medical and social consequences. The importance of scientific explanations, with their roots in Cartesian medicine and developments in the nineteenth century, is obvious. Of equal importance, perhaps, are attempts to counterbalance an excessive emphasis on scientific medicine with anthropologic, social, ethical, and political dimensions of the concepts of health and disease. After all, for much of its history medicine has not been confined solely to disease but also took responsibility for health. Therapy in the past meant more than just curing; it also meant prevention or preservation of health and assistance in chronic disease and in dying. Disease was interpreted as a disturbance of the organism, the sick person, and his or her social situation. Furthermore, medicine did not have sole domain over health and disease; a multitude of important interpretations originated from the

arts, theology, and philosophy. In this holistic perspective, people of the present also expect medical and social aid.

Sickness and health, in their natural and cultural breadth, remind medicine of its fundamentally scientific and humanistic nature. Health and disease are concerned with life and death and are closely connected to the physical, social, psychic, and spiritual nature of humans.

Today, disease and health are conceived as more closely connected (Canguilhem; Engel). The transitions and parallels are seen more strongly, and the interplay of the body, soul, spirit, and environment is more carefully observed. Attention is shifting from infectious diseases to chronic illness and death, though the experience of acquired immunodeficiency syndrome (AIDS) and other diseases prove the continuity of those events. The emergence of molecular medicine, with its reliance on genetic concepts of health and disease, may lead to a reintegration of the scientific and humanistic dimensions of the concepts of health and disease. The global scientific and economic limitations of medicine have made the concepts of health and disease a central topic in theory as well as in practice, for science as well as for everyday life.

Developing countries have special problems to overcome that stem from their own cultural changes and from their reception of Western medicine. The Western world must be critical of its own normative position in regard to these developing countries as in regard to its own concept of life. Disease should not be understood merely as a limitation or a loss, but also as a challenge. Coping with illness can manifest courage and compassion; meeting this challenge strengthens self-confidence, causes social reform, and enriches the world of culture.

II. SOCIOLOGICAL PERSPECTIVES

The sociology of health and disease has two distinct traditions, each with somewhat different implications for the field of bioethics. The first tradition is socioepidemiologic in nature, which is to say it focuses on understanding how the distribution of death and illness is influenced by such factors as age, gender, race, and social class. The second tradition is oriented to the doctor-patient relationship and is concerned with the meanings of illness for patients and practitioners, and with how these meanings reflect the nature of power and authority in society.

The Social Epidemiology of Illness

ORIGINS. Sociological perspectives on health and disease can be traced to the French sociologist Emile Durkheim's classic treatise, *Suicide* (1951). In this work, Durkheim examined the impact on the suicide rate of such variables as residence (urban or rural), marital status, and religious affiliation. Durkheim's basic assumption was that if suicide were purely an individual phenomenon, these variables would have no impact on group rates. Using public health statistics, Durkheim determined that the suicide rate was higher among urban dwellers than among those who lived in rural areas, that the rate of the unmarried exceeded that of the married, and that of Protestants exceeded that of Catholics. He theorized that social ties linking individuals to society inhibit suicidal impulses, while the absence of such ties does not. Much subsequent socioepidemiology of illness echoes Durkheim's findings that those with a greater stake in society fare better than those with a lesser stake.

Since Durkheim published this work, sociologists have dedicated themselves to showing that who becomes ill is not just a matter of individual constitutions, but is heavily influenced by the standard variables of sociological explanation; namely gender, race, and class. While the proposition that one's social position predicts one's health status is generally accepted, attention is also now being paid to the pathways that explain this phenomenon. Bruce Link and Jo Phelan, for example, argue that individually based risk factors need to be contextualized in order to consider what puts people at risk, and that social factors, such as socioeconomic status, are fundamental causes of disease because their association with disease remains constant even when intervening factors change.

GENDER. Despite their greater life expectancies, women report more morbidity and utilize health services more frequently than do men (Verbrugge). Explanations advanced for the higher rates of illness among women include less satisfying social and economic roles; greater stress; more cultural permission for reporting discomfort; and biological differences.

CLASS. The relationship between class and mortality and morbidity is well documented. At all age levels in the United States, there is an inverse relationship between morbidity and social class (Syme and Berkman). This means that as class standing increases, the prevalence of illness decreases, and vice versa. Similar relationships have been demonstrated for other countries in the industrialized West. There is also evidence that the association between socioeconomic status (SES) and health exists at all levels of the SES hierarchy (Adler, et al.). It has been argued that socioeconomic status is a key factor in the creation of disparities in health, and that the reduction of health disparities will rely on addressing the components of SES, particularly income, education, and occupation (Adler and Newman).

Although the link between social class and the prevalence of illness is not disputed, the reasons for it are. A number of explanations have been advanced to account for this relationship, including lack of access to healthcare resources; lifestyle (there is an inverse relationship between obesity, as well as tobacco and alcohol consumption, and social class); and increased exposure to economic and social stress. Work has been indicted as a causal factor in the relationship between social class and heart disease (Siegrist, et al.; Marmot and Theorell). Lower-class jobs provide less autonomy, more constraint, and less opportunity for expression than middle-class occupations. In addition, the causal direction of the link between class and illness has been questioned, with some analysts suggesting that since the less well are unable to compete in the economic system, they have their class standing lowered as a result. This is known as the *downward drift hypothesis.* There is some evidence to suggest that inequality itself, independent of income, is

detrimental to health, and not only to those who have fewer resources but also to those with higher SES (Kawachi and Kennedy).

RACE. Race is another variable that affects mortality and morbidity. Vincente Navarro argues that once class is taken into account, differentials between whites and blacks disappear. This may be so, but at a pragmatic level there is a very real association of health status with urban poverty and race. This association accounts for morbidity and mortality associated with violence, infant mortality, and HIV infection associated with intravenous drug use and prostitution. The problems of the urban poor in gaining access to healthcare services have also been well documented. Compliance with treatment regimens is also an issue for inner-city populations, with the most common explanation being the cultural distance between providers and patients.

STRESS AND DISADVANTAGE. Stress has been used as a variable to explain relationships among gender, social class, race, and illness. While the "fundamental cause" concept (Link and Phelan) attempts to expand the causal pathways studied between SES and health, the "stress theory" specifies one particular aspect of the relationship between social position and health. Persons of lower SES experience more stressful environments, such as economic strain and insecure employment (Brunner), and these stressors influence susceptibility to disease by impacting (among other things) the nervous and immune systems. Stress seems to better account for variations in rates of mental, rather than physical, illness (Lin and Ensel). Despite the widespread agreement on how to measure it, there is confusion about what *stress* is. There is also widespread agreement that social supports and networks buffer stress, but there is some confusion about how (Kessler, et al.). Moreover, stress does not have an equal impact on men and women. Marriage, for example, buffers stress better for men than for women.

ELIMINATING HEALTH DISPARITIES. Having demonstrated that health disparities often follow the contours of social disadvantage, a great deal of work has been focused on how to specify the causal pathways of this disadvantage, with the goal of eliminating disparities in health. This has led to disagreement about what the causal pathways to health differentials are, and about the ways in which efforts to reduce disparities can reach the intended beneficiaries without widening the very gap they are intended to close. Medical innovations and public-policy interventions to reduce disparities are often introduced and carried out in a context of inequality (Mechanic), and it has been argued that targeting facets of socioeconomic status, such as a living wage, may go furthest in reducing health disparities (Link and Phelan; Adler and Newman).

Social Epidemiology and Bioethics

The social epidemiology of illness demonstrates that sickness does not fall equally upon rich and poor, men and women, or upon black and white. Distributional inequities are more than simple political and economic problems—they have an ethical dimension as well.

Bioethicists need to pay greater attention to issues of justice and equity at a political level; that is, to the ethical dimensions of political decisions. As the allocation of scarce resources becomes a public issue of greater salience, the underserved will need advocates. The championing of individual patient rights that marked bedside bioethics in its formative years needs to be extended to the class of uninsured and underinsured patients as healthcare grows in importance on the national political agenda.

As its scope of inquiry expands, bioethics may have the opportunity to play a greater role in policy making. However, there is a danger here as well. So long as bioethics is focused on the bedside, both the subject matter and the texts appropriate to it are limited. Once the links between class, race, gender, and illness are illuminated, the boundaries of bioethics become murky. The doctor-patient relationship may be fraught with moral complexity, but it is a rather neatly defined, bounded whole. This is not so for the entire distributive system of society.

The Social Construction of Illness

The second tradition in the sociology of illness is less concerned with the distribution of illness by race, class, and gender, and more concerned with the social meanings attached to illness. It is more concerned with the roles of provider and patient, and with what these roles say about the distribution of power and authority in society. The social epidemiological tradition is involved in the analysis of large data sets (such as national samples) to determine statistical correlations between health status and social traits such as gender, class, and race. The social-constructionist approach is more likely to involve firsthand observation of behavior in a limited number of settings. These observations of behavior provide a basis for drawing conclusions about the nature of healthcare more generally. Favored themes in the social-constructionist approach include the management of uncertainty, the difficulties of lay-professional communication, and the use and misuse of professional authority.

THE SICK ROLE. Sociological speculation about the nature of the doctor-patient relationship begins with Talcott Parsons's discussion of the "sick role" (1951). Although Parsons's unique insight is so commonplace today that we do not appreciate its originality, he was among the first to focus on the doctor-patient dyad as a role relationship with a set of reciprocal rights, duties, and obligations.

Parsons begins with a discussion of the basic social situation in which patients and physicians find themselves. Patients are: (1) not to blame for their condition, (2) powerless, and (3) technically incompetent. Physicians' existential position is one beset with uncertainty about what ails the patient and how best to treat it. In addition, they are unable to cure many of the ills of patients, and there are difficulties with access to both patients' bodies and the intimate details of their lives.

Each role consists of four interlocking imperatives that grow out of the social assumptions made about each actor. The sick patient is granted a temporary exemption from normal social responsibilities. In exchange for this exemption, the patient must seek technically competent help, must be motivated to get well, and must comply with treatment regimens. The passivity of the patient stems from what has been called the "power asymmetry," which Parsons says characterizes the relation of doctor and patient. The only positive action Parsons ascribes to the patient is to seek help. By making this a role obligation, Parsons ignores the complexities of help-seeking behaviors. Such complexities include the recognition of a condition as *illness,* of the cultural and economic barriers to access, and of the nature of lay networks. In addition, with his stricture on technically competent help, Parsons invalidates any and all alternatives to allopathic medicine.

Physicians, according to Parsons, occupy roles whose demands are dictated by their existential situation. First, physicians achieve their roles by mastering basic areas of knowledge. Some physicians are smarter than others, and some know more, but all have completed the same core medical curriculum. Parsons calls this "universal achievement." Second, physicians limit their ministrations to areas of competence. They are expert in areas of health and illness, and their advice is limited to these areas. Parsons identifies this as "functional specificity." The limits of functional specificity have widened as the links between lifestyle, stress, and illness have been documented. Nonetheless, there are limits. Physicians maintain an attitude of affective neutrality. Renee Fox and Harold Lief identify this as "detached concern." Physicians are involved with the problems of their patients, but not so involved as to interfere with rational decision-making. Finally, physicians act from a stance that Parsons identifies as "collective neutrality." The physician is not guided by self-interest or the profit motive. Rather, physicians' actions are guided by altruism, by what will restore health, whatever the sacrifice or cost to the physician, patient, or collectivity.

Parsons's analysis describes normative patterns rather than empirical occurrences. His physicians live in a world in which they share values with patients and always act in the best interests of the patient. They also act as agents of social control. The physician provides legitimate excuses from work, directs treatment, and controls access to healing resources. Tension may arise because the interests of the social system and of the patient may not coincide.

THE SOCIAL CONSTRUCTION OF ILLNESS. Parsons's "sick role" is the first sociological theory to recognize that the experience of illness is determined by social factors. Many sociologists accept Parsons's basic insights but differ with him on how the experience of illness is shaped by values and beliefs that are implicit, tacit, unexamined, and variable across cultural groupings. Conflict theorists, for example, emphasize that society is made up of competing groups with different values, rather than, as Parsons argued, cooperating groups with shared values (Freidson). For these sociologists, the physician's role as a fiduciary whose actions express the interests of patients is disputed; the physician is seen instead as a *moral entrepreneur* who cloaks self-interest or the interests of his or her social class in a neutral scientific language.

Conflict, or *labeling,* theorists share with Parsons the understanding that physicians act as agents of social control but they differ about who benefits from these gatekeeping activities and what the consequences of these activities are. For Parsons, the physician's actions certifying illness serve the entire society by promoting an environment in which the individual designated as *sick* can later return to productive social and economic roles. There are no long-term consequences to the labeling of individuals.

Labeling theorists contend that labeling is used by the dominant classes to protect their interests, suppress the less fortunate, and reinforce established hierarchies (Becker; Freidson). Casting an individual in the sick role stigmatizes him or her and spoils life chances (Goffman; Scheff). Susan Sontag has argued that the vocabulary of illness leads those who are sick to blame themselves. Those who are vulnerable to labeling engage in a variety of social strategies to avoid it. Peter Conrad and Joseph Schneider have described how those with epilepsy, for example, attempt to stay "in the closet" with their condition rather than suffer the discrimination that attends candor.

Much of the work of labeling theorists depends on the contention that the locus of social control in the modern state has shifted. Conrad and Schneider observe that explanations of deviance now rely on "madness" instead of "badness." The dominant agents of social control are no longer clergy, but physicians. Social problems become medicalized, and the targets of therapeutic activity are more likely than not to be the socially disadvantaged. Jane Mercer, for example, found that the label *mentally retarded* was significantly more likely to be applied to members of minority populations.

In labeling theory a key variable of interest is social power. Labels are used to depress the social chances of the disadvantaged are also manipulated to aid the powerful. New categories of pathology emerge that create opportunities for healthcare professionals who use newly discovered syndromes to expand their power, while the social and structural conditions that generate problems remain, or become, invisible. For example, Stephen Pfohl views the discovery of the "battered-child syndrome" as a boon to pediatric radiologists and other pediatric professionals. The beating of children is not new, however, but its treatment as a medical problem is novel. Entire diagnostic classification systems may be viewed this way. Joel Kovel has criticized the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (DSM-III; now replaced by the DSM-IV), the official diagnostic system of mental health professionals, for hiding social and political meanings in apparently neutral language. The purpose of the DSM, in this view, is to enable the psychiatric profession to control the institutions of mental health.

Individuals may actively seek some labels and avoid others. Tsunetsugu Munkata points out that in Japan the label *neurasthenia* is widely adopted to avoid the stigmatizing term *schizophrenia,* while Peter Conrad has shown how both parents and school professionals embrace the label of *hyperkinesis* to describe unruly children. Parents accepted the label because it absolved them of blame for their children's conditions; school officials accepted the term because it offered an individual-level explanation for restive behavior, allowing them to overlook deficiencies in school organization. Many illness designations signify entities whose precise, objective markers of disease are unclear. Sufferers, however, seek the legitimation of the disease label. Suffering is a powerful determinant of self-labeling, as the proper label serves to excuse and explain behavior that would otherwise be unacceptable. The early labeling theorists concentrated on labeling as a top-down phenomenon, stressing the repressive features of labels while ignoring the benefits some labels conferred.

The fact that the powerful resist—as well as discover, create, or construct—disease classification should also not be overlooked. Phil Brown and Edward Mikkelsen describe how the inherently conservative bias of epidemiological methods that depend on population-based measures retarded the identification of an environmentally generated cancer cluster in Woburn, Massachusetts. In another case, scientific medicine and organized mining interests retarded the recognition of "black lung" as an occupational disease (Smith). Both cases illustrate how the alliance of organized science with corporate interests can burden and delay successful efforts to discover or construct disease or the cause of disease.

Social Construction and Bioethics

Two key points of contention distinguish Parsons's theory of the sick role from labeling theory. The first is whether physicians have patients' interests reliably at heart. Parsons, in claiming that physicians have a "collectivity orientation," signals his confidence that they do. For labeling theorists, however, claims of altruism are utilized to cloak self-interest. This difference in attitude is very apparent in the writing from each orientation on the role uncertainty plays in medicine. From a Parsonsian orientation, uncertainty is a problem to be overcome and a psychological burden to physicians (Fox, 1959). From a labeling orientation, uncertainty is a ploy that physicians magnify in order to control patients (Davis).

The second key difference between Parsons and the labeling theorists concerns patient autonomy. For Parsons, the only autonomous decision made by the patient is the one to seek care. After that, patients simply, and appropriately, follow the doctor's orders. Since the physician has the patient's best interest in mind, there is no reason for the patient to balk or to question. For labeling theorists, there is no reason for the patient to follow medical regimes without question, since there is no guarantee that the physician has the patient's best interest in mind.

Informed consent is based on the principles of autonomy and self-determination. Sociological description of the doctor-patient relationship, whether from Parsons or from the labeling theorists, illuminates the absence of autonomy and self-determination. Sociologists differ on the necessity and value of such principles.

The earliest sociological studies of death and dying (those of Barney Glaser and Anselm Strauss, published in 1965) described the extent to which autonomy and self-determination were missing in the doctor-patient relationship. Physicians operated in what Glaser and Strauss called a

"closed awareness context." Physicians knew of fatal conditions but routinely did not pass this information on to patients, and they often colluded with family members to keep this information from patients. These practices were rationalized as kinder than being candid.

Because of informed consent, a veritable revolution occurred in the doctor-patient relationship. Candor replaced evasion. With informed consent, patients are more than ever the masters of their own treatment. The paternalism that marked Parsons's description of the doctor-patient relationship has given way to a more egalitarian, more formally contractual, relationship. While there is much to celebrate in these changes, something may have been lost. There are costs involved with a fuller patient autonomy. Under the banner of autonomy, physicians may hide behind their role as technical experts and leave weighty matters to patients. There are also new possibilities for the psychological abandonment of patients.

III. ANTHROPOLOGICAL PERSPECTIVES

Medical anthropologists focus on people's life worlds (the subjective experience or phenomenology of sickness and healing), their cultural systems of meaning (e.g., ideas about what causes disease and how it is diagnosed), and the material conditions in which experiences and beliefs are situated (e.g., local disease ecology). Medical anthropologists attempt to understand and describe the medical beliefs and practices of people whose cultures and life worlds are often very different from their own. They routinely are confronted with the problem of translating unfamiliar meanings and experiences into familiar (Western) terms and concepts without taking them out of context or subordinating them to Western assumptions about sickness, health, efficacy, autonomy, and the like (Lock and Gordon; Kleinman, 1988; Gaines).

The anthropological perspective makes it possible to examine and clarify bioethical issues from multiple cultural points of view. The current debate over the bioethics of organ harvesting—the surgical removal of transplantable body parts such as the heart, liver, and kidneys—illustrates why it is important to have a clear understanding of cultural points of view. For transplantation to succeed, organs must be removed either (1) from a living donor in cases in which the organ is not vital to the donor's survival (e.g., a single kidney) or (2) immediately after a donor's death, before the organs have begun to decompose.

In most Western societies the line between life and death in the context of organ harvesting is identified with brain death, the irreversible loss of higher brain functions. The decision to identify death with brain death is consistent with Western cultural notions: Selfhood is identified with the mind, and the mind is by convention situated in the brain. This arrangement has the practical advantage of leaving a working heart in a harvestable body, facilitating the collection of transplantable organs. Japanese culture, in contrast, recognizes a different relationship between selfhood and the body: The self is not identified with a single body region. From this perspective a brain-dead body with a functioning heart has not crossed the line from life to death and is not yet a harvestable resource (Lock, 2002). Clearly, cultural definitions of selfhood and personhood have a profound impact on people's responses to bioethical issues.

Orientations to the Body

The history of medical anthropology is to a large extent a history of scrutinizing and challenging Western assumptions about sickness, beginning with the distinction between biomedicine and traditional medicine. (Most medical anthropologists prefer the term *biomedicine* to the alternative terminology: *scientific, modern,* and *Western* medicine. For an explanation see Leslie.) At first glance the distinction appears to be a commonsense way to classify different kinds of medical systems; in practice it rests on a set of problematic assumptions.

First, it implies that *traditional* medical systems have something fundamental in common, whereas in reality so-called traditional systems are highly diverse in both their medical theories and their practices and share little as a category other than being different from biomedicine (Leslie

and Young). Second, juxtaposing traditional medical systems with biomedicine implies that biomedicine is a monolithic system, beyond the reach of culture. However, social scientists have demonstrated significant variation in biomedical notions, technologies, and clinical practices both within communities and across cultures (Brodwin, 2000; Hahn and Gaines; Lindenbaum and Lock; Lock, 1993; Lock, Young, and Cambrosio). Third, comparing biomedicine to other medical systems also sets biomedicine as the standard of medical care because it is based on scientific principles; this conveys the idea that other medical systems are not as *real* or therapeutically effective.

A more useful way to compare medical systems across cultures is to start with the question, How do the beliefs and practices of a medical system orient healers and patients to their bodies? An answer from the Western perspective might be that because the body is the site of the pain and suffering associated with sickness, the body must be the focus of attention for patients and healers everywhere. In reality, medical systems are not equally interested in the body. Rather, those systems and their perspectives are distributed along a continuum that includes the biomedical perspective among many others.

At one end of the continuum are systems whose orientation to the body can be called externalizing in that their diagnostic and therapeutic ideas and techniques direct people's attention away from the sufferer's body. In those systems the medical gaze looks outward, scanning networks of people and beings (e.g., ancestral spirits, possession spirits, demons) for morally significant encounters and events involving the sick person or that person's close relatives. The diagnostic goal is to construct a useful etiology, that is, a string of circumstances and events that lead to the onset of suffering and distress and identify the ultimate source of the sickness. The therapist's goal in those systems is to insert himself or herself into the patient's sickness narrative and, once there, persuade or coerce the pathogenic agents to stop afflicting the patient. The classic account of diagnosis and treatment in an externalizing system is E. E. Evans-Pritchard's *Witchcraft, Oracles, and Magic among the Azande* (1937).

A sick person's body is a site of discomfort and distress, and in this sense sickness is the same all along the continuum. At the externalizing end, however, the patient's bodily experiences and transformations are mute. Typically, the body is a black box in that although people may have names for certain body parts and organs, they can posit no functions or systemic connections for them. Pain, suffering, and the visible transformations that accompany sickness and disease signify only themselves; they reveal nothing about processes and events that biomedicine recognizes are taking place inside. Although practitioners may give patients medicaments to take, those medicines are characteristically anodynes or substances that are intended to make the patient more comfortable while the actual cure is being pursued elsewhere. In short, in externalizing systems medical meanings and experiences are created and connected by discrete socio-logics rather than by a universal bio-logic (Lock and Gordon).

Anthropologists describe three broad types of therapeutic strategies that operate in externalizing medical belief systems: agonistic strategies, in which the goal is to eliminate or neutralize pathogenic agents; initiatory strategies, in which the goal is to bring the patient and the pathogenic agent into a permanent and manageable relationship (Boddy); and strategies of persuasion, in which the goal is to persuade the pathogenic agent through offerings or appeals to cease afflicting the patient (Lewis). Beyond these generalizations, externalizing systems are highly heterogeneous.

Biomedicine is at the opposite end of the continuum, among the internalizing systems, in which diagnosis and therapy orient patients and healers toward the body. Here sickness coincides with the limits of the body, and the goal of diagnosis and therapy is to get inside the body, to take control of its internal parts and processes. Circumstances and events outside the body are interesting only to the degree to which they lead to inferences about pathological processes taking place inside. It is in these systems that one finds theories of pathophysiology, the grammars that enable people to read bodily changes symptomatically.

Medical Efficacy

Common sense inclines people to suppose that because internalizing systems are able to read embodied symptoms, they are more empirical and realistic than externalizing systems are. Ethnographic research, however, indicates that all medical systems, externalizing as well as internalizing, are generally empirical and realistic. That is, they are capable of routinely producing self-vindicating outcomes, evidence that demonstrates their efficacy.

Medical efficacy can be demonstrated by two different kinds of results. First, efficacy is sometimes a capacity for producing hoped-for results, such as the amelioration of pain or the remission of symptoms. In practice it is not difficult for externalizing and internalizing systems to produce hoped-for results in light of the fact that the majority of medical problems consist of either (1) transient or recurrent symptoms that are perceived as being discrete disorders or (2) self-limiting diseases, episodes that end in either spontaneous remissions or death. In these circumstances medical practices acquire a reputation for hoped-for efficacy when

three conditions are met: An intervention routine occurs between onset and outcome, remissions predominate over deaths and other unwanted outcomes, and superior alternative interventions are absent or inaccessible.

Second, efficacy can take the form of producing expected results. This occurs when practices and procedures are able to produce evidence that affirms the line of reasoning and the underlying assumptions that persuade patients and practitioners to select particular interventions. Expected results can be produced without also producing hoped-for results. Thus there is the grim joke that the operation succeeded but the patient died: The patient's body, once opened up, reveals a pathology that affirms the correctness of the assumptions and choices that have led from diagnosis to surgery, but the intervention is unsuccessful because of circumstances beyond the clinician's control. All medical systems, whether internalizing or externalizing, appear capable of distinguishing between hoped-for results and expected results.

In addition, serious sickness is a source of distressing feelings that are only incidentally connected to the pain and suffering of a sick person. Medical practices may have the effect of reducing such distress by connecting sickness events to local systems of moral and cosmological meaning. This power to give meaning to and impose moral order on chaotic and threatening events may be sufficient to perpetuate certain medical practices even when those practices have no great reputation for producing cures. Those practices sometimes are called healing rituals by anthropologists.

The Mind-Body Problem

One of the current debates in biomedicine surrounds the mind-body problem, which has arisen from the observation that sickness is simultaneously an objective phenomenon and a subjective phenomenon. In the language of the social sciences the objective (or bodily) component is called *disease,* and refers to abnormalities and dysfunctions in organs and organ systems. The subjective component is called *illness,* and refers to the patient's unique and holistic experience of either disease-related distress or certain other socially disvalued states, such as psychogenic mental disorders, that conventionally are bracketed together with diseases. Disease can occur in the absence of illness, as in the case of undiagnosed and asymptomatic hypertension, and illness can occur without disease, as in adjustment disorder and somatization disorder.

Anthropologists have critiqued the mind-body distinction in two ways. The first critique calls for a reconceptualization of the relationship between mind and body. The argument is that people need to free themselves from the objective-subjective comparison and take account of the continuous interaction between mind and body: the capacity of the mind to affect bodily states positively and negatively, the mind's predilection for using bodily states as idioms of distress, and so on (see Csordas).

The second and more radical critique refers back to anthropology's task of translating unfamiliar meanings and experiences into intelligible concepts without subordinating them to Western assumptions about sickness, healing, and agency. Both Western culture and biomedicine assume the existence of a mind situated in the brain. In practice, the mind is one of the Western ways of talking about the self: the body's seat of consciousness, the subject of its experiences, the initiator of the body's purposeful actions, the repository of its memories, and the locus of moral agency. To anthropologists the Western mind/self is a cultural artifact; it exists because people have practices that make it exist in the same way that possession spirits exist in the Sudanese *zar* cult. Indeed, there are many cultures and systems of medicine that are *mindless* in the sense that they have no corresponding network of mental and moral meanings, and they constitute people and experiences in fundamentally different ways. Thus, the mind-body distinction has been criticized not because there is a need for more effective concepts for connecting psyche (mind) to soma (body) but because the notion of mind itself and the practices through which that notion emerges subordinate non-Western cultures and realities to a distinctively Western ontology (Good and Kleinman; Kleinman, 1988).

Patterns of Resort

The idea that in any community an individual's medical behavior is congruent with a unitary set of meanings concerning sickness and its causes, diagnosis, and treatment is an obstacle to translating medical realities between cultures. Anthropologists make a series of distinctions between medical traditions, sectors, and systems so that they compare cultural norms of medical behavior:

1. A medical tradition is a set of practices and technologies organized around historically situated ideas about etiology, symptomatology, and treatment. Biomedicine, Ayurvedic medicine, and the zar cult are examples of medical traditions. Traditions are simultaneously vocabularies for interpreting the world and plans of action and technologies for producing facts that confirm their interpretations of the world.
2. The actual forms a tradition takes in a specific community make up its medical sector. A particular medical tradition can be put into action in various ways. It can be used to justify a range of practices,

technologies, and routines, and it can be adapted to a variety of institutional settings. For example, in many less developed countries the biomedical tradition is practiced in four sectors: licensed professionals (physicians, nurses, etc.), fee-for-service injectionists (who inject clients with substances from the biomedical pharmacopeia), pharmacists (who can diagnose symptoms as well as prescribe treatments), and domestic settings (where the biomedical tradition is employed mainly to diagnose problems). Although the four sectors share a single tradition, they include different sets of options. In the first sector clinicians monopolize diagnosis and treatment choices and decide which etiologies will be tested and confirmed and which sets of cultural meanings and socioeconomic implications will be realized through these practices. Injectionists and pharmacists represent patron-dominated sectors of biomedicine in the sense that patients or members of their families make their diagnoses before consulting the practitioner. Practitioners may be asked for alternative diagnoses, but the ultimate decision is the patient's.

3. A medical system is equivalent to the collection of traditions and sectors that are available to the people in a particular community. Medical beliefs and practices are useful to patients and their families because those people know how to incorporate them into patterns of resort. These are the paths that people create in the course of actual sickness episodes as they navigate their way from one medical sector to another, picking and choosing from among their options.

The ethnographic literature suggests two main patterns of resort. In the first the patient or a surrogate simultaneously consults alternative traditions. People have various motives for following this strategy. In some cases patients believe that the effects of multiple interventions are cumulative; in other cases they are unsure which, if any, of the available traditions will provide an effective cure. In some communities, notably in southern Asia, the simultaneous pattern of resort reflects a therapeutic division of labor. Biomedicine is prized for its quick effects against causal agents such as microbes and its ability to treat symptoms such as high fevers. The Ayurvedic tradition is valued for its ability to counter the perceived side effects of biomedicines, especially antibiotics, and its ability to restore an equilibrium among the body's organs and humors, that is, the state synonymous with health. The alternative strategy consists of a sequential pattern of resort in which the individual exhausts the resources of a tradition or sector before moving on to an alternative tradition in the medical system (Young, 1983).

The paths that individuals follow through their medical systems are determined by a variety of factors. For example, patients who want to avoid stigmatizing etiologies (ones that would contaminate or spoil an individual's social identity) or diagnoses with a poor prognosis are likely to compare the range of diagnoses and etiologies that belong to the various traditions in their medical system and then start off with the tradition that offers the most favorable outcomes. The choice may be influenced by cost-benefit calculations. That is, a practitioner's or sector's economic and geographic accessibility are weighed against the perceived seriousness of the patient's sickness and the value of the patient to his or her family (Nichter).

Implications for Bioethics

Why is it important for bioethics to understand that health, illness, and disease are socially shaped, culturally constructed, and historically situated? Basically, those ethnomedical beliefs and values inform people's health-related behavior. More specifically, culture shapes the ways in which people make decisions in the context of morally charged healthcare situations. Culture also shapes the kinds of ethical situations that can arise in a particular healthcare or healing setting and the frameworks for understanding and models for responding to those ethical dilemmas. Anthropology's cross-cultural or comparative perspective, combined with ethnographic methodological approaches, helps people (1) recognize that moral norms vary cross-culturally and (2) challenge tacitly held cultural assumptions in biomedicine and bioethics about what counts as human, self and other, normal and abnormal, life and death, right and wrong, and other key moral concepts (Marshall and Koenig, 1996, 2001; Haimes).

Anthropological investigation into contemporary debates about bioethics raises new questions, provides insights into the ways in which people experience ethical issues, and broadens the scope of inquiry. Anthropological research on genetics, for example, shows that women's decisions to undergo prenatal genetic testing are informed by cultural definitions of risk, perceived acceptable forms of disability, and social dynamics between women and genetics counselors (Browner et al.; Rapp). These factors may come as a surprise to bioethicists, who may expect attitudes toward abortion to take a primary role in women's prenatal decisions. With regard to examining the genetic basis of medical conditions such as Alzheimer's disease and sickle-cell anemia among African Americans, anthropologists have been at the forefront in pointing out the problems with using the term *race.* For instance, using that term risks perpetuating essentialism about clinical phenomena. They also have identified how notions of heredity hinge on cultural ideas of kinship

and the implications of genetics research for defining claims to group identity (Koenig and Silverberg; Brodwin, 2002; Gordon; Wailoo, 1997).

The ability to explicitly recognize the cultural basis of bioethical constructs, such as the concept of autonomy, can help bioethics scholars rethink the premises of moral arguments. Furthermore, by recognizing that medical systems maintain their own logic, bioethicists and biomedical practitioners are more likely to attempt to understand patients rather than label them as irrational or incompetent. Patients' perceived levels of competency—from both legal and ethical perspectives—can affect their involvement in medical decision making.

As an example one might consider the case in which a Mien mother from Laos brings her daughter to a pediatrician for her four-month immunizations (Crigger). The pediatrician observes a number of burns on the child's stomach and considers whether to call the Department of Child and Family Services, thinking that the mother has abused her child. The burns actually were the result of a healing ritual designed to ameliorate the child's symptoms that were identified as meaningful to Mien culture. Understanding that the burns are a result of a therapeutic regimen can help the pediatrician realize that the mother was not abusive or neglectful; instead, she was attentive to improving the health of her child (Brown and Jameton). In contrast, one might consider the physician's attempt to pierce skin with a needle as unnecessarily harmful even though it is intended to improve health. Different cultures have different conceptions of what therapeutic interventions constitute acceptable harms or risks and benefits. This case illuminates how culturally shaped ethical notions of risk and benefit are. With a cultural perspective in mind bioethicists can reconstruct arguments regarding risk-benefit ratios. Biomedical healthcare practitioners who recognize these cultural dynamics can better provide not just culturally competent care but also high-quality care.

Conclusion

A community's medical beliefs do not correspond to a homogeneous set of meanings. Both in complex societies and in *traditional* and *tribal* societies individuals are drawn by sickness into multiple and often contradictory systems of meanings and action. The appearance of unity and homogeneity within a specificcommunity is not accidental, however. Usually it is an expression of power, of the capacity of one segment of the community—its medical experts, political leaders, moral authorities, and others—to define and control which of the alternative sets of medical meanings will be carried over into public discourse. In this sense power is the ability to convince people that the socially dominant meanings of sickness are also the authentic meanings (Young, 1982).

IV. PHILOSOPHICAL PERSPECTIVES

Concepts of health and disease—as well as of sickness, wellness, deformity, disability, dysfunction, and disfigurement—direct social energies. They inform medicine and healthcare policy regarding what is wholesome, what is to be avoided, and what is to be treated—all else being equal. Concepts of health and disease either directly or indirectly describe, evaluate, and explain reality and help to assign social roles. Decisions about the meaning and scope of concepts of health and disease profoundly influence the character of healthcare. For example, if alcoholism, homosexuality, menopause, or aging are considered diseases, then medical treatment, resources, and research will be focused on treating them. These concepts therefore become the focus of public-policy debates, and they may conceal value judgments that should be treated more explicitly as bioethical issues.

Diseases and sicknesses are usually distinguished from sins, crimes, and social problems in that they are not directly under the control of the will and are explainable, predictable, and (usually) treatable by an appeal to somatic or psychological laws, generalizations, and associations. Pains that are directly under one's own control or that of others (e.g., the pain from standing on one's own foot), difficulties of a moral sort (e.g., being blameworthy), problems of a spiritual sort (e.g., refusing to repent for one's transgressions), or legal disabilities (e.g., being a convicted felon) are thus contrasted with states of disease or illness. This contrast discloses a boundary between disparate human practices (e.g., blaming the immoral, convicting felons, exorcising demons, treating diseases), and the criteria used to distinguish between any of these practices will vary from culture to culture and shift within the history of a particular culture. In addition, the line between medical and other problems is, in part, a function of the competencies of those making the judgment. Diseases and illnesses are what medicine treats.

Illnesses and diseases are generally identified because they involve a failure of function, a pain that is considered

abnormal (compare the pain of teething with that of migraine [King]), a deformity, or the threat of premature death. Insofar as judgments regarding proper function, normal pain, correct human form, and normal span of life can be made without reference to culture-dependent values, concepts of disease will not depend on social norms of proper human function. The same can be said with regard to concepts of health. Though much is said regarding healthcare, health, and wellness, one may question whether such notions can be understood only in positive terms. The positive concepts of health must be understood in relation to the absence of particular dysfunctions, pains, or deformities, and there may be numerous concepts of human well-being and exemplary function (Boorse,1975). It is also difficult to provide a positive account of health and well-being that will not include concepts of economic, political, and social health. For example, the World Health Organization's 1958 definition of health as a "state of complete physical, mental, and social well-being" (WHO, p. 459) has been criticized for being too broad and ill defined to guide the formation of health policy (Callahan). The philosophical literature, aside from addressing these difficulties with concepts of health, has focused mainly on concepts of disease and illness.

Philosophical concerns regarding concepts of health and disease can be organized under six questions:

1. Are disease entities to be discovered or are they and their classifications instrumental constructs that are created to achieve certain ends?
2. How do explanatory models shape the boundaries between health and disease and determine the meaning of disease?
3. What values shape concepts of health and disease, and to what extent are these culturally determined?
4. Is the definition of mental disease and health different from that of somatic (or physical) disease and health?
5. Do concepts of animal disease function in the same way as concepts of human disease?
6. How can concepts of health and disease be used for overt political and social ends?

The *ens morbi*

The history of medicine is replete with talk of clinical findings constituting an *ens morbi* (disease entity). Disease entities have been conceived of as metaphysical entities, clinical entities, pathological entities, etiological entities, and genetic entities. These ways of considering diseases generated a significant dispute in the nineteenth century between those who held that disease entities (and the classifications within which they are understood) identify realities in the world and those who held that disease classifications are at best distinctions imposed on reality to achieve certain goals (e.g., of diagnosis, therapy, and prognosis). The first were termed *ontologists,* while those who took a more conventionalist, instrumentalist, or nominalist position were termed *physiologists.* This distinction appears to have been articulated in 1828 by Françlois-Joseph-Victor Broussais (1772–1838), who denounced ontological accounts of disease (1821). Carl Wunderlich (1815–1877), Ernst von Romberg (1865–1933), Alasdair MacIntyre, Samuel Gorovitz, and others have, in various ways, taken positions in sympathy with Broussais.

Ontological theories have held that disease terms or classifications name things in the world. Though Broussais had directed his criticisms against clinical classifications, disease ontologists can be taken to include any who perceived diseases as entities, including metaphysical views advanced by individuals such as Paracelsus (1493–1541), who held that diseases are specific entities that arise outside the body.

Disease entities have also been understood as clinical realities, or as recurring constellations of findings. Thomas Sydenham (1624–1689), in classifying disease entities, construed them as enduring types and patterns of symptoms: "Nature in the production of disease is uniform and consistent; so much so, that for the same disease in different persons the symptoms are for the most part the same; and the selfsame phenomena that you would observe in the sickness of a Socrates you would observe in the sickness of a simpleton" (p. 15). It is within such a view of disease that one can speak of a person having a typical case of typhoid. Such language expresses the view that there is a central identity for a disease that is its essence, or *type.* One can therefore classify diseases by type, as well as speak of instances of a disease as approximating a *typical* case. Within this understanding, one can also talk of typical cases as rare: "One rarely sees a typical case of secondary syphilis." Patients embody clinical realities where *typical* means the full and complete expression of a disease, or an ideal type, but not necessarily its usual expression. It was against this genre of account that Broussais spoke.

Etiological accounts, like metaphysical views, focused on the cause of the disease as the disease entity, but regarded disease entities as empirical, and usually infectious, agents. Rudolf Virchow (1821–1902) characterized this view as "ontological in an outspoken manner" (p. 192). Virchow considered this understanding of disease entities to rest on a confusion between a disease and its cause. "The parasite," he wrote, "was therefore not the disease itself but only its cause" (p. 192). The confusion of the disease with its cause led to a "hopeless, never-ending confusion, in which the ideas of

being (*ens morbi*) and causation (*causa morbi*) have been arbitrarily thrown together, [and] began when microorganisms were finally discovered" (p. 192). The mature Virchow embraced a view of disease entities grounded in pathological findings, and he held that a disease entity is "an altered bodypart, or, expressed in first principles, an altered cell or aggregate of cells, whether tissue or organ" (p. 192). Further, "this conception is expressly ontological. That is its merit, not its deficiency. There is in actuality an *ens morbi,* just as there is an *ens vitae* (life force); in both instances a cell or cell-complex has the claim to be thus designated" (p. 207).

Genetic accounts can also interpret the disease entity as an empirical reality, to be found in genetic abnormalities (Anderson; Fowler, et al). The promise of somatic-cell gene therapy raises the question of a disease entity once again. That is, does the disease exist in the genetic structure, or is the structure the cause of the disease?

Current uses of the term *disease* in standard nomenclatures and nosologies (classifications) have a predominantly nonontological character. A conventionalist view allows one to choose, for example, whether one wishes to treat tuberculosis as an infectious, genetic, or environmental disease (recognizing that all three sorts of factors contribute to the development of tuberculosis), based on which variables are most easily manipulated. One may decide that it would be best to treat tuberculosis as an infectious disease because little is known about the inheritance of resistance against tuberculosis, or because any eugenic programs to eliminate tuberculosis would be very slow in taking effect. It may also be seen as an environmental disease that is brought about by socioeconomic conditions such as housing, food, and other such factors. It is meaningless to ask whether such a definition of disease is true or false, only whether it is useful (Wulff).

Diseases as Clinical Findings and Explanatory Accounts

Many people take the term *illness* to identify a subjective experience of failed function, pain, distress, or unwellness. *Disease,* in contrast, is then an explanatory concept, or part of an explanatory account (Boorse, 1975). Or one might identify illnesses as constellations of signs and symptoms and diseases as illnesses joined to disease models or explanations, where the content of the illness is augmented by the phenomena found on the basis of a disease model. But to recognize a state of unwellness as a state of disease is already to have begun to explain it and to recast the meaning of the findings within an interpretive context. A constellation of phenomena is held to be recurrent, and if such a constellation of phenomena is encountered again in the future, it can be identified. A specific set of symptoms, for example, can be identified as a case of chronic fatigue. Diagnoses of syndromes, of recurrent patterns of signs and symptoms, allow predictions to be made (prognoses) as well as the management of outcomes (therapy). Such predictions and attempts at therapy can succeed even in the absence of causal explanations.

During much of its history, medicine has been concerned with classifying patterns of signs and symptoms so that they can be recognized in the future with greater ease. Thomas Sydenham's classic *Observationes medicae* (1676) suggested classifying diseases in definite species, following the methods of botanists in classifying plants. His work was followed by Carolus Linnaeus's Genera morborum in auditorum usum (1759), François Boissier de Sauvages de la Croix's Nosologia methodica sistens morborum classes juxta Sydenhami mentem et botanicorum ordinem (1763), and William Cullen's Synopsis nosologiae methodicae (1769). These classifications functioned without causal explanations, though these were also given. Such medical descriptions and explanations at a clinical, phenomenological level are still employed whenever a new illness is identified for which a causal explanation is not yet forthcoming. For example, acquired immunodeficiency syndrome (AIDS) was first identified as a clinical, phenomenological entity.

Medicine also explains health and disease by relating what is observed via general laws of physiology, anatomy, psychology, genetics, and so forth to other phenomena. The result is a two-tier account of diseases. The first tier is that of the observed constellations of phenomena, such as a clinical description of yellow fever. The second tier is that of a model advanced within the laboratory medical sciences to explain the observed clinical phenomena, such as an explanation of the clinical findings in yellow fever in terms of the effects of a group B arbovirus (a group of viruses transmitted by mosquitoes and ticks) that causes the death of essential cells in the liver.

The laws of pathophysiology (the physiology of disordered function) and pathopsychology (the psychology of mental disease) relate new phenomena to the original clinical constellations of signs and symptoms. Some of these phenomena are then recognized as the causes of the illness. The concept of disease thus comes to identify disease models that support the search for unnoticed causal factors and expressions of disease. For example, Giovanni Battista Morgagni (1682–1771) in his *De Sedibus et causis morborum per anatomen indagatis* (1761) correlated clinical observations with postmortem findings, and Philippe Pinel (1745–1826) incorporated anatomical considerations into his *Nosographie philosophique* (1798), producing nosologies that embraced not only clinical observations, but anatomical

considerations as well. This change in focus was strengthened when Marie-François-Xavier Bichat (1771–1802) argued that constellations of symptoms and signs could be explained in terms of underlying pathological processes. According to Bichat, medical advances are best achieved through autopsies (Foucault). This shift to the study of pathological findings as a way to explain clinical observations was then supplemented by accounts drawn from microbiology, endocrinology, biochemistry, genetics, and other fields, producing contemporary explanations of illnesses.

In the process of moving from accounts of illness that were predominantly clinical observations to accounts based on observable illnesses of the anatomy, the meanings of diseases were altered. Individuals who once were thought to die of acute indigestion were now understood to die of a myocardial infarction. The meanings of the phenomena observed (e.g., clinical signs and symptoms) were reinterpreted in terms of disease models. As a result of this recasting, medical complaints often came to be considered legitimate only to the extent that they had a demonstrable, underlying pathophysiological or pathoanatomical lesion.

Health and Diseases: Discoveries or Cultural Inventions?

If certain physiological and psychological functions can be identified as natural or essential to humans, then their absence can be used to define disease states. Leon Kass and Christopher Boorse have argued that one can specify those functions that are integral to being human, and thus secure accounts of disease that are not relative to a particular culture or set of values. Such understandings of health and disease could then be used to sort out essential from nonessential (if not proper from improper) applications of medicine. However, such naturalistic views may depend on particular understandings of what is *natural.* Others appeal to an evolutionary account of what should count as species-typical levels of species-typical functions appropriate for age and gender (Boorse 1976).

In contrast, Joseph Margolis, H. Tristram Engelhardt, and others have argued that definitions of disease and health depend on sociological, culturally determined value judgments, and that these definitions can be understood only in terms of particular cultures and their ideologies (Margolis). A value-free account of disease cannot be given, some have argued, because diseases are defined not by their causes, but by their effects (Resnek)—and their effects gain significance within a cultural context. K.W.M. Fulford has also indicated deeply hidden but still crucial evaluative elements in medicine. He has done this through a linguistic-analytic examination of how disease language appears to be value-free, while still entailing values, with the result that controversies in medical health are engendered where relevant values are sufficiently diverse. Fulford also argues that part-function analysis, which focuses on the proper function of each part of the body, fails with psychotic mental disorders where the rationality of the person as a whole is disturbed. Others have explored the nature of disease through the use of action theory and by placing concerns about disease and illness within the larger holistic context of health (Nordenfeldt, 1995, 2001). Still others ground disease language in a notion of malady dependent on the universal features of human rationality, thus eliminating culture as a factor (Clouser).

The view that the concepts of health and disease are culturally determined has been supported by feminist writings on healthcare. Many authors have pointed out that the practice of medicine has had an androcentric (masculine) focus, that women's issues have largely been ignored, and that experiences reported by women that could not be documented have been treated as invalid (Rosser; Oakley).

Partisans of the view that social and cultural ideas influence concepts of health and disease stress that a definition of disease tied to evolution makes disease concepts dependent on particular past environments and past adaptations. Successful adaptation must always be specified in terms of a particular environment, including a particular cultural context. A culture-dependent account of concepts of health and disease need not deny that there will be great similarities as to what will count as diseases across cultures, for certain symptoms and conditions will probably be understood as diseases in most cultures. Supporters of a value-infected, culture-dependent account of disease have argued that those who would attempt a purely evolutionary account of disease have not reconstructed the practice of medicine, but rather some practice of characterizing individuals as members of particular biological species (Engelhardt, 1975). The practice of medicine, in this view, depends on culturally constructed understandings of health and disease.

How one understands health and disease will in turn influence how one conceptualizes medical practice. Henrik Wulff has argued that an exclusively biological or empirical model of illness contributes to paternalistic medical practice, for if concepts of health and disease can be fully understood in biological terms, then there may be no need to assign the patient an active role in the decision-making process. If, however, determinations of health and disease are not just empirical concepts, but are also related to cultures and values, the patient will have a more active role in determining the burden of the disease and the extent of treatment.

The conceptualization of medicine will certainly be influenced by developments in genetic research, which hold

the promise not only to correct diseases in patients, but to prevent them in future generations of patients (Anderson; Zimmerman). Thus, as the capacities of genetic medicine increase, preventive medicine will expand. Somatic and germ-line therapies will also be affected as choices are made about which genetic variances should be treated as disease abnormalities (e.g., homosexuality, alcoholism, shortness of stature).

Physical, Mental, and Social Diseases

It has been argued that only somatic diseases are legitimately diseases, while *mental diseases* are problems with living (Szasz). Following similar lines of argument, individuals have contended that enterprises such as psychotherapy are tantamount to applied ethics (Breggin), or that the cure of somatic disease constitutes the prime goal of medicine (Kass).

In response, some argue that such stark dichotomies or dualisms fail to offer satisfactory accounts of reality. If mental life is dependent on brain function, then all mental diseases can, in some sense, be tied to physical pathology or abnormal anatomy. For example, depression can be presumed to be dependent on a neurophysiological substrate, and thus, in principle, is open to pharmacological treatment. If one views diseases as explanatory models for the organization of signs and symptoms, then it does not matter whether the signs and symptoms identify physiological states ("I have a rash") or psychological states ("I feel depressed"). Nor does it matter whether models employed to correlate these phenomena are pathophysiological or psychological. Most accounts of disease will, in fact, mingle physical and psychological symptoms. As a consequence, one may come to view distinctions among somatic, psychological, and social models of disease in terms of pragmatic needs—of accenting the usefulness of particular modes of therapeutic intervention. One may even advance sociological models of disease, construing diseases primarily in terms of social variables and giving secondary place to the pathophysiological.

Distinctions between medical and nonmedical models of therapy, unlike somatic, psychological, and sociological accounts of disease, are often meant to contrast the autonomy of clients in nonmedical therapeutic models with the dependence of patients on healthcare practitioners in medical models. Talcott Parsons characterized the "sick role" as: (1) excusing ill individuals from some or all of their usual responsibilities; (2) holding them not responsible for being ill (though they may be responsible for becoming sick); (3) holding that they should attempt to become well (a therapeutic imperative) and seek out experts to treat their illness. Medical models tend to support paternalistic interventions by healthcare practitioners and to relieve patients of responsibility for directing their own care. Nonmedical models, in contrast, tend to accent the patient's responsibility.

Somatic models of disease may be employed within both medical and nonmedical models of therapy. For example, hypertension may be treated with antihypertensive agents or by enjoining the afflicted individuals to find ways to change their lifestyles with regard to stress, eating patterns, and so on. The same is true of psychological models of disease. Depression can be treated chemotherapeutically or by enjoining individuals to make changes in their ways of living.

As predisposing factors toward particular diseases become better known and easier to control or avoid, individuals are held increasingly responsible for becoming ill, even though they will remain nonresponsible for being ill. A person is not held to be responsible for having bronchogenic carcinoma in the same way that one is responsible for being a willful malingerer. In other words, one cannot be told to stop having cancer, but one can be held responsible for having developed cancer through one's smoking habits. As the impact of lifestyle on the development of diseases becomes clearer, the responsibility of individuals for their health may increase the possible scope of nonmedical models of therapy.

Animals and Disease

If concepts of human illness, disease, and health are, in part, social constrictions, there will be differences between the ways in which diseases are identified for humans and the ways they are identified for other animals. Illnesses and diseases in animals will be judged through the social or cultural criteria of human beings. Pets or domestic animals may be regarded as having disease or being healthy depending on how they are viewed through human purposes and constructs. The diseases or illnesses of those animals that are not pets, however, along with those of plants, may be understood less in terms of human social or cultural criteria and more in terms of generalized knowledge about the species. In the case of animals in the wild, there may not be concern for individual suffering, disability, or deformity, but rather with the general health of the species. Identifying the role human values play in the concepts of animal disease and illness expands the discussion of the ethical treatment of nonhuman animals in bioethics.

The Social Force of Diagnosis

Concepts of disease have been used to impose political judgments. For example, in the United States prior to the

Civil War it was proposed that the flight of a slave to the North and the absence of a wholesome inclination to do effective plantation work were diseases for which explanatory accounts and treatments could be provided (Cartwright). Masturbation was once viewed as a serious disease for which castration, excision of the clitoris, and other invasive therapies were employed. Individuals were even determined to have died of masturbation, and postmortem findings "substantiated" this cause (Engelhardt, 1974). In the case of the diseases of slaves, the motivation may have been to protect slaves from punishment. In the case of masturbation, the influence of cultural values on the psychology of discovery was not appreciated.

Historical perspective can increase our awareness that medical practitioners and researchers have tended to "discover" what already was assumed. More recent political uses of disease concepts (e.g., in psychiatry) have been closely connected with repressive goals and political agendas of certain governments. Social employment of disease definitions is often meant to be benevolent, however, such as advocating a view of alcoholism and drug addiction as diseases so as to recruit the forces of medicine to aid in their control. Moreover, such conditions may be termed diseases in order to relieve alcoholics and drug addicts of the social opprobria that attend what is often viewed as immoral behavior.

Summary

Concepts of health and disease shape descriptions of medical reality, convey explanations, advance value judgments, and structure social reality. They influence not only the scope of medicine, but healthcare policy as well. Because they may involve not only moral values but values associated with physical and mental excellence, they raise questions pertinent to both bioethics and the philosophy of medicine. These special concerns regarding medical explanation may sufficiently define a distinctive problem area so as to establish the philosophy of medicine as a field in its own right, despite arguments to the contrary. In any event, the concepts of health and disease, as well as their application, will continue to be the subject of debate in societies that are morally and culturally pluralistic.

V. THE EXPERIENCE OF HEALTH AND ILLNESS

Some would argue that given the wide range of historical, cultural, and individual differences concerning health and illness, little could be said on the topic that would have universal validity. Others would point toward certain invariant features of the human body, psyche, or society that could ground cross-cultural commonalities. Presented here is a description of health and illness as experienced within a contemporary Western context. While this description may not be universally applicable, it nonetheless provides a starting point for elucidating similarities and differences among cultures and individuals.

The Experience of Health

In setting out to portray the experience of health, one is struck by how little people are used to focusing on it. This tendency to overlook health—to take it for granted—is also reflected in the paucity of descriptive literature on the subject. In many ways this is precisely the point. To be healthy is to be freed from some of the limitations and problems that promote self-reflection. A healthy person need not pause before scheduling a dinner for later in the week or grabbing a shovel to clear the driveway of snow. The state of health that allows for such engagements remains the tacit background of what Maurice Merleau-Ponty, drawing on the work of Edmund Husserl, calls the bodily "I can": I can get out of bed, move across the room, brush my teeth, and so forth, without a need to explicitly define or acknowledge these abilities—or the wellness that make them possible.

Sometimes people are provoked to reflect on their good health: they revel in their renewed strength after a bout of flu, for example. Health is thus illuminated by contrasting experiences. Certain practices, such as yoga, tai chi, and exercise programs, can systematically teach one to cultivate and appreciate the healthy state, heightening self-awareness.

However, Western culture has tended to neglect or demean bodily experience in favor of a detached rationality or cultivation of the soul (Leder, 1990). People learn to overlook or overcome the body until it seizes their attention, as it does at times of pain and illness. Even preventative *health education* tends to focus on external guidelines concerning exercise, diet, and the like, but do little to cultivate an inner awareness of the body's own voice. Perhaps many illness states could be avoided if people were better listeners to the subtler messages of the body that signal a departure from good health. Yet to be healthy is ever a temptation to overlook, or look beyond, the body. The word *health* comes from the same root as the word *whole.* The healthy body operates as a harmonious whole, allowing one to feel at home in the world (Svenaeus) without the need for undue self-reflection.

Disease and Illness

Illness makes one aware of the precariousness of the world. To capture the profound dislocations caused by illness, it is useful first to distinguish between *illness* and *disease* (Cassell, 1985; Engelhardt, 1982). Modern medicine has been largely concerned with understanding and treating specific diseases. Yet to diagnose an individual as having a disease means looking beyond that particular individual: one notes a cluster of signs and symptoms that have repeatedly presented in a range of cases. The disease label also frequently (and

ideally) invokes an explanatory etiology, a prognostic picture, and a set of treatment options, all drawing upon the theories and knowledge base of medical science. Since the eighteenth century, disease classifications have progressively moved from a basis in the patient's reported symptoms to one grounded on the pathological lesions and processes exposed after death or, by medical technologies, in the living (Engelhardt, 1986; Foucault). Hence, *dyspepsia* has become *peptic ulcer disease.* This shift has greatly advanced the explanatory and therapeutic powers of modern medicine, but it has also diminished the attention paid to the patient's experience.

In contrast to the medical characterization of disease, the term *illness* refers to the *experience* of sickness. To fall ill is to undergo a series of transformations that distinguish this state from health. In a sense, any illness is inescapably individual. Even if one shares the same disease with another, the challenges, limitations, and suffering involved can vary considerably from person to person. Yet just as the physician-researcher can uncover the repeated patterns typical of a disease, one can describe certain features that commonly accompany the illness experience (Toombs, 2001).

ILLNESS AND THE EXPERIENCE OF THE BODY. If health is a kind of wholeness—an integration along a number of dimensions—illness involves a set of experienced *dis-integrations.* This is first seen in relation to the body. Ordinarily, the body operates as a seamless whole (Merleau-Ponty, 1962): in response to one's perceptions one moves through and acts upon the surrounding world, with the internal organs supplying the needed life energy. In illness, however, the body can split into problematic parts and functions. An aching stomach or a pulled muscle suddenly stands out from the rest of the body, demanding attention. As one's organic harmony is disrupted, so too is one's integration with the world. The ill body is no longer at home in its world, but is awkward and limited, and even simple physical acts become difficult.

This dis-integration of the body within itself and from its world also brings about a felt split between the body and the self. Ordinarily, the body is an inseparable part of one's identity, grounding one's interactions with the environment. When one falls ill, however, this body becomes something alien (Leder, 1990; Zaner, 1981), causing pain, limiting movement, or humiliating the ill person with an unpleasant look or odor. One's own flesh seems capable of thwarting and opposing one in a way health had not fully revealed.

This experience presents a severe challenge to one's usual sense of selfhood and autonomy. The ill person may neither understand nor control what is happening within the body, though one's life may depend upon the outcome. One's knowledge of the body becomes mediated through others: the physician who diagnostically probes it, or the surgeon who opens it up, scrutinizing organs the patient has never seen.

ILLNESS AND THE EXPERIENCE OF SPACE AND TIME. These modes of embodied dis-integration typical of illness also suffuse experiences of space and time. When a person is healthy, space unfolds as a field of possible movement, of activity, of desires to be fulfilled (Straus, 1963), whether it be a flight of steps one knows one can climb or an open street one can cross. With many forms of illness this spatial field is disrupted. One may remain confined in a bed or unable to climb a flight of stairs due to arthritis or a neuromuscular disease.

As space is thus altered by illness, so too is time. Ordinarily, human beings dwell largely in the future (Heidegger), with present activities geared toward the future accomplishment of desired goals—on the way to the paint store, one is envisioning the fully painted room. But when one is sick the way toward the future is blocked, and a claustrophobic world of concern closes in on the sufferer. Even a world traveler or delightful raconteur can transform into an intolerable bore who obsesses about illness minutiae.

There are avenues of escape for the ill person. One can "lose oneself" in a good book or television. One can dwell in nostalgia for a pain-free past or dream of a future restored to health. But these wanderings never fully lose their character as modes of escape from the confinements of illness.

ILLNESS AND THE EXPERIENCE OF OTHERS. This dis-integration of our spatiotemporal world is often matched by a felt disunity with others. When healthy, one is a part of the mainstream, involved with work, family, and socializing. Yet as simple a sensation as pain can suddenly open a profound distance (Scarry). Though just inches away and sympathetic, another person cannot experience one's pain. It may not even be possible to communicate one's pain, for this most private of experiences is notoriously resistant to expression.

Illness can cut one off from others not only through pain, but through disabling effects. One lingers in bed while everyone else heads off to the duties of a busy life. The energy to work and socialize may be lost. "I don't want you to see me like this" is a frequent refrain of the person reduced by illness to sallow skin or loose bowels, and the healthy may often wish to avoid the world of the sick, which only serves as a reminder of one's own vulnerability.

Loneliness can thus contribute greatly to the suffering of the ill. There is a sense of exile—from one's body, from

one's activities and goals, and from one's fellows. In the face of this exile, social connection often takes on heightened importance for the sick person. The compassion (etymologically, "to suffer with") that grounds another's willingness to listen to, touch, and care for the sick person can do much to alleviate suffering (Kane).

ILLNESS AND THE EXPERIENCE OF THE COSMOS. The term *cosmos* refers to the world discerned as an ordered and harmonious whole. This is precisely what illness can bring into question. Imagine discovering in the midst of an ordinary day a growth that is subsequently diagnosed as malignant. Questions scream forth: "Why has this happened?" "Why now?" "Why to me?" The possibility arises that these questions have no good answers. Ordinary structures of meaning are shattered.

This felt meaninglessness can prove all but intolerable. Any meaning may be preferable, even a negative one such as: "I have been bad and this illness is my punishment" (Kopelman). The ill often search for their offending infractions, be it smoking, eating fatty foods, having a "cancer-prone personality," or transgressions against God. This association of sickness and sin preserves the coherence of a just universe, as well as the sense of one's own power within it. However, this reading of illness brings its own sense of painful exile. Sickness remains a scarlet letter, branding the ill person's moral failings. The healthy, eager to strengthen their own illusions of security and superiority, may be willing to collude with this judgment.

Illness, then, is not simply a biological event; it is also an existential transformation. One may be stripped of one's trust in the body, reliance on the future, taken-for-granted abilities, professional and social roles, and even one's place in the cosmos.

Of course, this need not always be the case. The experience of illness varies widely, and much depends on the nature of the attacking disease, the vagaries of individual psychology, and the social milieu. Some of this diversity is captured in the growing literature on medical phenomenology and so-called pathographies—accounts of illness written by or about the sufferers (Brody; Hawkins). One can ultimately imagine textbooks of illness, as there are now for diseases, that would describe experiences typically or possibly associated with severe psoriasis, heart attacks, neurological diseases (Sacks), and other conditions.

ACUTE ILLNESSES AND INFLICTED TRAUMAS. With acute but transitory illnesses, such as the flu, discomfort and disability can shrink one's world and distance it from that shared by others, but the horizon of health remains visible. One is buoyed by the assurance that this illness is temporary, that after this brief visit to a foreign land one will surely return home. The sense of suffering and cosmic dislocation are thus held in check.

Then there are illnesses and traumas of acute onset but more catastrophic consequences. One may have a car accident, for example, or suffer a serious heart attack that threatens one's life even after recovery. The sudden anomalous nature of such events leaves its own psychic scars. The world and one's body seem less safe, more a house of horrors in which dangers can leap forth from anywhere. This sense may be especially acute when trauma is inflicted by another, as through a gunshot wound or sexual assault (Brison). The embodied self is revealed as profoundly vulnerable to disruption, penetration, or violation by others.

In the face of acute catastrophe, William F. May suggests that a person may experience something of an existential obliteration. He describes a patient suffering from severe burns covering two-thirds of his body, who calls out: "Don't you see, I am a dead man" (May, p. 16). However, this "death" can be followed by rebirth. This is not simply a reclamation of one's previous self, but the forging of a new self, with its own strengths and virtues (Brison).

This can be especially difficult, however for those victimized by others, as in cases of child molestation or spousal battering. Here, the confinements imposed by illness take on new dimensions. The victim is entrapped not only within physical suffering but by a double imprisonment, both external and internal. There are external barriers to breaking free of the violence—in the case of molestation, the power adults exert over children; in the case of a battered wife contemplating escape, the difficulty in attaining employment, financial independence, shelter, and child care. There are internal barriers as well. The victim often feels guilty, tainted, or shamed by his or her participation, and may thus become secretive and complicitous. Feelings of powerlessness and low self-esteem set in: "This will never change. There's nothing I can do. I'm not worth it anyway." Finally, as awful as this abusive world is, it is familiar, and one may cling to it for security amid the fear. Many break free, but social and psychological forces can also pull victims back, making escape an arduous struggle.

CHRONIC ILLNESS AND DISBILITY. Many illnesses are neither transitory nor based on acute events: Instead, they are chronic, lifelong, and involve relatively stable or progressive patterns of disability (Toombs et al., 1995). Forms of arthritis, bronchitis-emphysema, kidney disease, diabetes, Alzheimer's disease, colitis, and autoimmune diseases, for example, fall into this category. While onset may come early in life, the elderly often suffer from such degenerative conditions. Due to the aging of the overall population, along

with advances in the prevention and cure of acute disease, chronic illness is increasingly the staple of medical practices and hospital care.

Chronic illness can bring with it all of the dis-integrations described above. Unlike acute and treatable illness, there may be no horizon of health that allows one to look beyond present suffering. The day-in, day-out persistence of pain and disability, without hope of relief, can bring about a kind of existential fatigue that leads to despair. With severe arthritis, for example, even tying one's shoe can become difficult. But the chronic nature of such conditions can also give one time to work through its meanings, and to build strategies for physical and psychological coping. One needs to realistically accept limitations, while also claiming the possibilities that remain for fulfillment.

The burgeoning field of *disability studies* has supported sustained reflection on the phenomenology of specific conditions, such as paralysis (Robillard) or blindness (Hull), and the way these are socially constructed (Michalko). There is a danger to assimilating such conditions, sometimes present from birth, to an illness model that emphasizes suffering and limitation. The disabled individual has often developed alternative abilities that are powerfully life enhancing. It is therefore important to develop attitudes and social policies that respect the diversity of human embodiment.

Disability resulting from chronic progressive illnesses can pose a particular challenge to the individual. S. Kay Toombs, in her book *The Body in Multiple Sclerosis* (1992), discusses her condition in this light. The disease is typified by sudden exacerbations and remissions (e.g., of visual disturbance or bowel and bladder incontinence), but with a gradual buildup of neurological deficits over time. There is thus a continual need to redefine the self in the face of new incapacities. Adjusting to muscle weakness, one becomes accustomed to using a walker until, as the disease advances, one becomes wheelchair-bound. The dignity associated with the upright posture is thus lost, together with passage to regions formerly accessible. The ill person faces the Sisyphean task of repeated readjustment without promise of rest. Yet even under such trying conditions, individuals find modes of strength, support, courage, and consolation to meet the existential challenge.

Medical Treatment and Healing

Taken seriously, the experience of illness leads to the question of what impact the medical profession has upon the sufferer (Toombs, 1992b). When illness results from an easily curable disease, medical treatment surely plays a powerful role in restoring the individual to wholeness. Such a remedy is not always possible or immediate, however, nor are the experiential impacts of healthcare always benign.

While the concept of *iatrogenic disease* (disease caused by medical intervention) is well known, there is also the possibility of *iatrogenic illness.* Many of the experiential dis-integrations associated with illness can also be brought about or exacerbated by the process of medical treatment. When illness fragments the body into problematic parts and functions, and renders it alien to the self, the process is often intensified in the doctor's office. The physician has the patient disrobe, probes and palpates different organs, investigating the body as if it were a malfunctioning machine, and the patient learns to internalize an objectifying gaze on the body.

Similarly, treatment can exacerbate the disruption of space, time, and social relations. Hospitalization provides a vivid example. One's clothes, a mark of personal identity, are replaced by a hospital gown embarrassingly open at the back. One is dislocated from the routines of everyday life, leaving friends, family, home, and community for a world of strange rules and protocols, frightening technologies, and authorities who loom and disappear. Just when one's world most needs shoring up, it is further fragmented.

Medical language also effects subtle but pervasive displacements. Struggling to make existential sense of what is happening and why, the patient may find little help in diagnostic labels. In Tolstoy's story "The Death of Ivan Ilych," Ivan grapples with the profound issue of his life and death, but for the doctor, "the real question was to decide between a floating kidney, chronic catarrh, or appendicitis" (Tolstoy, p. 121). This exclusive focus on disease leaves the illness unaddressed. Loneliness is intensified when one most needs communion; the search for meaning is truncated by a heap of scientific words.

Some of these deficiencies so characteristic of contemporary medicine emerge from its basis in a mechanistic worldview. The seventeenth-century philosopher René Descartes, who helped lay the groundwork of modern science and medicine, took a dualist position. The human being, he argued, is a conjunction of two very different parts—the mind, imbued with rationality and free will, and the body, a mechanism governed by the same physical laws as the rest of nature. In this view, bodily disease can be understood according to the model of machine breakdown. Doctors become scientists or technicians who fix or replace broken parts. This Cartesian paradigm has generated the search for precision drugs and surgical procedures, the emphasis on scientific (rather than humanistic) training for the physician, and the hospital conceived as a temple to technology. Much of the efficacy of modern medicine rests on its dualist and

mechanist foundations. But this focus on the body-as-machine has also led to a neglect of the ill person struggling with profound existential dislocations (Leder, 1992).

Nonetheless, many sensitive clinicians do seek to be healers of illness. To "heal" is to begin reweaving into wholeness the tapestry of life shredded by illness. Even when disease is not curable, the practitioner can try to relieve pain and preserve physical function, explain what is happening within the patient's body, and encourage the patient to be an active participant in treatment. Thus, the ill person regains a measure of knowledge and control.

Cut off from others by the privacy of pain and the loss of function, the sick person may reach out to the provider with the longing of a shipwrecked castaway who spies a sail on the horizon. When the patient is permitted to tell his or her story—to voice fears, ask questions, and hear genuine responses—a social reconnection is forged. The practitioner furthers this process by informing and mobilizing the patient's support system. The participation of family and friends is welcomed, and isolating modes of treatment such as hospitalization can, when possible, be avoided.

Just as the body seeks to heal itself, so individuals seek an interpretive healing by trying to make sense of what has occurred (Kleinman) and telling stories about it (Frank, 1995). Anne Hawkins has studied written accounts of illness and charted out the mythic motifs the sick often use. People suffering from disease may see themselves in an heroic struggle against a dangerous foe, or as journeying to the underworld to retrieve a great prize. These myths can sometimes turn disabling, however. For example, the battle metaphor provides little guidance or solace when the disease finally emerges as the victor. Susan Sontag, in *Illness as Metaphor* (1990) focuses on such dangers of understanding disease metaphorically, suggesting that the practitioner may need to challenge a patient's unhelpful fantasy. But these mythic interpretations can also play a healing role, helping the ill person to render events coherent, to rise to the occasion, and to work creatively with the challenges faced (Hawkins). The practitioner who resists the temptation to rely on reductionist "medicalese" or on metaphors foreign to the needs of the patient can support the patient's own healing narrative.

Ultimately, healing is not just a reconstruction of a prior life, but the building of something new. Through illness people often develop a deeper compassion for others, a greater intimacy with loved ones, an attentiveness to the joys of ordinary living, or a reordering of lifestyle and priorities. It is not unusual to hear a patient say "This cancer [or heart attack, etc.] is the best thing that could have happened to me." For such people, illness is not the diametrical opposite of health. Rather, it is the first stage on a healing journey, summoning the person to needed changes, whether physical, emotional, social, or spiritual.

The suggestion that illness can be a grace is not a license to grow callous to the suffering involved, however. Few seriously ill people wish to be told, "Cheer up, this disease is great for you." But the patient and practitioner alike can remain open to the healing gifts that illness may bring, albeit wrapped in a dark package.

Bioethical Implications

The illness experience has implications not only for clinical practice but for the field of bioethics. Bioethical reflections need not be *top-down* starting from overarching theories and principles that then are applied to cases. They can be *bottom-up* commencing with the concrete situation of the ill and drawing out the needs and moral claims that follow. Indeed, some suggest that bioethics is undergoing a paradigm shift, with a new openness toward methodologies that pay close attention to the experiences of illness and caregiving (DuBose et al.; Welie). Several consequences might ensue for the field.

First, taking lived experience more seriously may shed new light on the traditional issues of bioethics. For example, *truth-telling* and *informed consent* are often supported by reference to a Kantian framework of "respect for persons." Within this framework, emphasis is placed on preserving the individual's autonomy. However, when moving from this abstraction to the concrete situation of the ill, new features come into view. It is not simply the *autonomous individual* of ethical theory who arrives at the doctor's office in pain. By this time the person's sense of lived autonomy may already be compromised by uncertainty and confusion, emotional turmoil, a threatened future, and a body run amok. In this light, informed consent becomes not simply a way to preserve autonomy prior to treatment; it also becomes a part of the treatment itself, restoring autonomy through enhancing the patient's knowledge, control, and trust in others.

Of course, much depends on how the *truth* is conveyed. Medical jargon that sets forth *the facts of the case* can actually disempower the ill person. As with Ivan Ilych's doctor, the physician's terms may obliterate the patient's narrative. Moreover, the theater in which this conversation is enacted is the physician's domain. He or she is in a position of power, with privileged knowledge, authority, and professional status (Zaner, 1988). To really understand informed consent these inequalities of power that define the doctor-patient encounter must be understood. In such ways, paying close attention to the experience of health and illness could reshape the current approach to traditional issues of

bioethics—including those of organ transplantation, abortion, the termination of life-support, and many others (Toombs, 2001).

At the same time, an experience-based bioethics might call attention to other issues that have hitherto been neglected. Bioethical discourse has typically focused on particular quandaries brought about by new technologies and conflicting moral intuitions. When should one "pull the plug"? Who has the right to refuse treatment? When can confidentiality be breached? While such issues are real, they often leave unquestioned the general context of medical practice, as if only special dilemmas call for bioethical thought. But the experience of illness and treatment is intrinsically a moral theater. The ill person is confronted with the dis-integration of his or her world and must grapple to restore "the good" or forge a new vision of it. The individuals and institutions involved in healthcare participate in this drama in myriad ways—the language used, the texture of personal relations, the fees exacted, and the structuring of space and time all have ethical significance.

One promising topic for an experience-based bioethics is thus the *moral ecology* of healthcare institutions. One example is George Agich's 1993 study of long-term care, which details how the lived experience of autonomy is enhanced or diminished by environmental patterns. Are schedules set for the convenience of a nursing home bureaucracy, or are the client's needs kept in mind? Are there spatial cues to orient the elderly resident, or does the layout of the home contribute to confusion, powerlessness, and isolation? Is infantilizing baby talk the everyday language, or is there an atmosphere that enhances dignity? Such issues are not as dramatic as those that make bioethics headlines, but they are at least as significant to the lives of many. One can imagine the day when institutional ethics committees attend to such issues of moral ecology, not simply the exceptional-quandary cases.

An experience-based bioethics would also look at the burden placed upon the individual practitioner by the special situation of the ill. This is not just a matter of "What action do I take?" (the focus of deontological and utilitarian ethics), but of "What kind of person should I, the caregiver, be?" (the focus of virtue ethics). The isolation and incapacity of the ill underscore the importance of needed virtues in the practitioner, such as compassion and trustworthiness (Pellegrino and Thomasma).

An experience-based bioethics also demonstrates that it is not simply the practitioner who is a moral actor, but also the ill person (Zaner, 1993). Though defined as *patient,* he or she is also an agent wrestling with a profound existential challenge (May) as described in illness narratives (Broyard; Price). In the face of the dis-integrations described above, the sick person cannot evade responsibility, literally the ability to respond to circumstances. Depending upon the qualities of this response, the individual can either forge a good life even in the face of suffering or yield in to bitterness and despair. Special virtues are called for in meeting the challenge of illness, including courage, patience, hope, humility, and proper assertiveness. Sickness is an arena that calls people to test and reforge who they really are and who they wish to be. For too long the ill person as agent has been absent from bioethical reflection, and from much of clinical practice. Close attention to the illness experience can help remedy this situation.

HEALTHCARE INSTITUTIONS

• • •

Healthcare institutions are often overlooked in discussions of healthcare policy, biomedical ethics, and the allocation of resources. Institutions, however, are major players within the ethical and policy arena of healthcare and should be considered when one examines the forces at work in any specific issue in healthcare.

A healthcare institution usually has been thought of as a hospital, a nursing home, a rehabilitation facility, or another such single-site entity. Such an institution consists of the human beings who work in many different capacities within it, the leaders who direct and manage it, and its governing body—usually a board of directors or board of trustees that is responsible for hiring (and firing) the chief executive officer (CEO) or president of the institution and for setting policy and direction in partnership with the employed leaders. Many institutions now, however, are much larger than a single facility. For example, there are integrated hospital healthcare networks that include everything from physician group practices to long-term-care facilities. There are also networks that provide a single level of care, such as nursing home chains and hospital chains. As the competitive

environment of healthcare continues to drive efforts to reduce costs and capture market share, institutions made up of multiple components will become increasingly more common. Nonetheless, whether institutions are single units or made up of multiple units, they have important characteristics in common that must be considered.

Institutional Missions

One of the most important functions of leadership and governance in an institution is to establish and articulate that institution's mission. This is usually written in a mission statement. An academic health center may have a mission that includes research, education, and patient care as equally strong components. A community hospital may point to excellent patient care and improvement of community health as its mission. A for-profit hospital or hospital chain may articulate excellent patient care and optimal return to shareholders as its mission. As one can imagine, this latter bipartite mission can lead to troubling conflicts of interest, which have been examined by ethicists in some detail (Gray).

The mission of an institution may also be articulated in the framework of its membership in a larger institution such as a church or religious network. Thus, some Catholic hospitals provide care to a large number of American patients (who are not necessarily Catholic), and their mission specifically derives from values espoused by the Catholic Church. Similarly, many other hospitals have emerged from religious systems because of the latter's commitment to helping the vulnerable and caring for the sick and suffering. Institutional missions may sometimes conflict with bedside ethical decisions, such as the decision to forgo life-sustaining therapy or to have an elective abortion. In these settings it is important for patients and providers alike to be clear about the underlying moral environment of the institution and the degree to which it may or may not be flexible on certain issues. Patients who feel strongly that they do not want care with those articulated standards should then have access to other institutions. Besides the question of abortion, the issue of forgoing life-sustaining treatment has been one of the most prominent in this kind of conflict. For example, the member of the patient's family who makes a decision about discontinuing nutrition and hydration in a comatose or unresponsive patient with far advanced dementing illness may find that the institution housing that patient does not allow nutrition and hydration to be withdrawn. If the underlying reason is fear of malpractice or liability concerns, it is sometimes possible for the institution to figure out a way to work together with and respect the wishes of the patient and family. If, however, the underlying reason is a moral or religious belief consistent with the underlying values of the governance of this institution, then it is less likely that a compromise can occur (Miles, Sinder, and Siegler).

Value Systems

To generalize about these many and varied institutions—both secular and religious, for-profit and not-for-profit—is not a simple matter, but it is useful to explore certain issues relating to the value systems that undergird their several missions and roles in society. Many of the older institutions were launched on the bedrock principle of simply caring for the sick and suffering, and many in the public still, quite unrealistically, think of all healthcare institutions in this way. Because the United States as a nation has not yet realized the right of equal access to healthcare for all its citizens and embraced the concept of healthcare as a social good, there is no consistent underlying covenant between the society and these institutions. A social covenant would lead to some kind of centralized planning for healthcare needs, and institutional missions would flow from this. Instead, the United States relies on marketplace values combined with a variable and often unreliable "safety net" of public institutions. It has proven to be very difficult for any of these institutions to live up to their traditional charitable-based institutional values and at the same time survive the economic and social realities of U.S. culture. The one shared ethical principle that all would espouse is the commitment to competence and excellence, values that have permeated Western medicine through its physicians since the time of the Greek physician Hippocrates (c. 460–c. 377 B.C.E.). This principle is not purely altruistic, however, because a minimum of quality is required for accreditation, and because evidence of excellent quality gives some institutions a market edge in attracting paying patients.

The public institutions created by a county, city, or state for the purpose of delivering health services to a specific population have an unambiguous mission and foundational institutional ethic: to carry out the function for which they were created and for which they continue to receive operating funds from the public sector. The objective of these institutions is to provide care in an appropriate and highly competent fashion to the specified population, usually those who are poor and without access to other sources of care. Whereas, on paper, the goals and objectives of these institutions never change, the public's commitment wavers from year to year, with the obvious result that there is considerable variation in the level of financial support the public is willing to provide; serious underfunding for many public hospitals thus significantly compromises the quality of care in many

places. So there remains the paradox, despite an unambiguously consistent mission statement: Compromised public commitment to provide services for the poor has translated to a serious loss of quality in some of these institutions. The profit motive seldom creates an untoward tension among workers at these institutions; the limits imposed by funding sources may, however, lead to the curtailing or closing of certain expensive services, perhaps to the detriment of the patients.

The private, not-for-profit institutions that were established for the purpose of serving the community may share a public-service vision with the public hospitals. Private, not-for-profit hospitals also, however, experience extreme pressures that run counter to their community-service mission. In the United States, since the early 1980s, these institutions have often thrived financially by maximizing income from insurance and philanthropy, both of which have supported the enormous growth of specialty medicine and heroic high-technology care. Governed by boards of directors made up of citizens of the community, these institutions can be expected to have an awareness of community needs. On the other hand, the charity care these hospitals may provide generally must be paid for in one of two ways: (1) by using available reserve funds, or (2) by shifting costs, overcharging those who can pay more, in order to make up for the losses in primary care, chronic care, and general care for the poor or uninsured.

The CEOs of the larger of these hospitals, especially those at the more prominent academic and tertiary-care institutions, are treated and paid as though they were corporate executives. This trend toward providing top-level management for these institutions came from the growing awareness beginning in the early 1970s that these institutions were administratively out of control or at the very least generally ill-prepared to fulfill their potential in a volatile marketplace. Few would argue that the majority of these institutions have become heavily bottom-line oriented. Balancing cross-subsidization among the various payers with issues of access for the poor is a fine art. Many of these hospitals, though losing money on every Medicaid and uninsured patient, manage to produce an overall surplus. They do this by increasing the volume of high-paying expensive procedures on insured patients. This goes far afield from a care mission of investing in prevention to foster healthier populations. Positive bottom lines are often then used to implement programs aimed at increasing "market share" for the hospital, rather than increasing services for the most needy.

Some not-for-profit institutions have extraordinarily idealistic community-service orientations, expressed through their written missions and goals. These orientations have sometimes become so consumed by the direction provided by bottom-line oriented, high-priced management teams that a variety of less-desirable and short-sighted practices have been implemented to produce a positive bottom line. These include the following:

(1) salary incentives to unit managers based primarily upon the financial performance of their cost centers;
(2) high-tech and manpower investment strategies determined primarily by their potential for high earnings;
(3) transfer policies that favor keeping patients whose care will add to the bottom line ("cream-skimming");
(4) policies to reduce existing teaching programs because of uncompensated expenses and negative impacts upon marketing strategies designed to reach more desirable clienteles; and
(5) different patterns of care based on whether or not patients possess ample insurance coverage or other financial resources.

Whether or not one finds these practices appropriate or inappropriate, whether they are more or less typical of not-for-profit as compared with for-profit institutions, the main lesson from these examples is that the pressures and forces inherent in the competitive market-oriented environment that has become dominant since the early 1980s have served to overtake the charitable values and philosophies that were central to the creation of many of these institutions. There is a tendency for healthcare institutions to believe that they are involved in a competitive fight for survival, and they all, in various ways, try to combine that pressure as best they can with the imperative to serve the sick.

Even institutions sponsored by religious organizations charge paying patients more than cost in order to cover the costs of nonpaying patients. Financial stability is the key to survival and thus to carrying out an altruistic mission. It is therefore more realistic to stop envisioning Saint Francis of Assisi when thinking about not-for-profit hospitals and begin thinking instead of "Saint Robin of Hood," robbing the rich to care for the poor.

Most observers see this behavior less as human frailty than as a system failure, the result of an environment that is filled with perverse incentives. In their detailed analysis of the ethics of for-profit as compared to not-for-profit healthcare institutions published in 1986, Dan W. Brock and Allen Buchanan concluded that there are no rationally compelling grounds upon which to find ethical fault with the profit motive in healthcare under the ground rules by which U.S. society now operates. Improvements can come only when

the ground rules and societal expectations are altered; it is not enough simply to hope that institutions will take the lead in changing their behavior, in the face of existing incentives to the contrary.

Governance

The role of governance is very important in the character of institutions. In many healthcare institutions, including those in the not-for-profit sector, the board of trustees may be made up largely of prominent businesspeople with a great deal of experience in running large and successful businesses, as well as otherwise wealthy and influential members of the local social circle who may themselves be important philanthropic supporters of the hospital and able to draw others into making major donations. Thus, it is often a minority of individuals on the board who have direct experience with healthcare, such as physicians or nurses, or whose major concerns are with education or research. Therefore it is not surprising that as healthcare has become a trillion-dollar business in the United States, even not-for-profit hospitals and health systems have looked at the bottom line as a marker of how well they are doing. Even though there are no shareholders to pay, an excess of revenue over expenses allows a nonprofit institution to initiate new programs and, in many cases, to salt away substantial reserves that both provide interest income and allow for a cushion in case of adversity.

Because so much money is involved and because of the business orientation of much of hospital governance, it is not surprising that the investments in new programs or the capital investments that are made when excess funds are available are not always, or even primarily, directed toward care of the poor and underserved but are often directed toward ensuring a continuing stream of revenue for the hospital. This usually means investing in additional high-technology medical care that will be marketed to insured patients. For this reason it is not hard to see why the Internal Revenue Service in recent years has begun to ask whether the not-for-profit hospital sector really ought to remain tax exempt. In order to maintain their tax exemption, these institutions must demonstrate that they are community-service organizations and that the educational research missions remain important to them, if not central.

Pressures for Change

In their comprehensive 1986 treatise, Brock and Buchanan made an important distinction between for-profit chains, generally owned by investors and listed on a stock exchange, and individual for-profit institutions, usually owned by an individual or small group of individuals (frequently physicians from the community). These organizational differences create different incentives and different institutional behavioral responses. In this entry it is the latter subset of for-profit institutions that are of interest, but this in no way ameliorates the validity of these conclusions. The thrust toward identifying healthcare as a commodity distributed according to business rules has, since the early 1980s, been the overwhelming ethical reality for private and not-for-profit private institutions. All of these factors have fueled the debate about the appropriateness of maintaining the tax-free status of not-for-profit hospitals (Gray). If the societal pendulum swings back toward the treatment of healthcare as a right, alterations in institutional behavior may occur that, nevertheless, need not drive the individual for-profit institution out of business.

It is probable that the implementation of national and regional policy decisions about healthcare (such as the trend toward capitation, community rating of insurance, universal access to care, and regional databases capable of rendering comparative institutional quality-of-care estimates) will have more to do with affecting the behavior of these independent institutions than anything else. The most far-reaching impact may result from the pressure on these institutions to join effective consortia or networks of healthcare providers; they may well need to become part of an organized delivery system in order to survive. Thus, by around the year 2005, the number of independent institutions may be severely reduced. Certainly, one already sees a trend in the direction of independents moving into organized systems, not only in the hospital industry but also in the traditionally "Mom and Pop" nursing home arena.

A wide variety of individually governed institutions play a wide variety of roles in the inchoate patchwork quilt of healthcare delivery in the United States. As the forces for systemic reform build, it seems clear that they will have a predominant influence on alterations in the behavior of these various entities. Until such changes occur, one can conclude that this independent sector will in general deliver the best healthcare it can under the vagaries of access, quality, and cost that are in general dictated by the perverse organizational and fiscal incentives created by U.S. society. As a result of a wise reform movement, one can hope for an improved, more equitable, and more uniform performance from this sector of the healthcare distribution system.

Future Trends

In an article in the December 5, 2001, *New York Times,* Milton Freudenheim reported that most of America's largest

insurers of healthcare are moving toward insurance design that increases segmentation of the private insurance market, with the sickest having to bear more of the costs while the well will be able to get coverage more inexpensively. This gives further impetus to the movement of employers to defined contribution for health insurance and the growth of high-deductible plans, leaving workers to decide for themselves how much to add from their own sources to acquire coverage. While framed as "choice," this leads to higher costs for patients, especially for the chronically ill or genetically at risk.

All this leads Victor Fuchs (2002) to join others in predicting that there will be a reemergence of interest in social insurance and a national insurance program, essentially because of the inequity and unfairness of what the employment-based system will have become.

At this point, it is safe to assume that healthcare institutions in the United States are caught in a continuing confluence of marketplace forces churning against strong ethical and social currents. Until this ambiguous situation is resolved, it is hard to predict the future for these institutions, but it is clearly more and more difficult for institutions such as hospitals and healthcare systems to be moral leaders.

HEALTHCARE PROFESSIONALS, LEGAL REGULATION OF

• • •

Licensure is "the process by which an agency of government grants permission to persons meeting predetermined qualifications to engage in a given occupation"; certification is "the process by which a nongovernmental agency or association grants recognition to an individual who has met certain predetermined qualifications specified by that agency or institution" (Welch, p. 179). The purpose of licensure, regulation, and discipline is to protect the public at large; the assumption that grounds these practices is that governmental and nongovernmental institutions are competent to judge how such protection should be accomplished.

Background

Public efforts to regulate the health professions, especially by imposing restrictions on those who shall be allowed to practice them, go back to the Babylonian emperor Hammurabi (d. 1750 B.C.E.). Rules for medical practice existed in ancient Greece and tenth-century Baghdad. By the Middle Ages in Europe, it was customary for civil powers

to demand a university education, examination, and experience as conditions for permission to practice medicine. In this period the first professional societies were founded, modeled on the merchant guilds (Gross). University and guild combined to link education to licensing—government permission to practice.

The first licensing statutes were passed in the American colonies in the seventeenth century, although not until the eighteenth century did the statutes seek to restrict practice. According to Eliot Freidson (1970), medicine did not emerge as a consulting, as opposed to a teaching, practice until the late nineteenth and early twentieth centuries. Throughout the two millennia since the time of the Greek physician Hippocrates (c. 460–c. 377 B.C.E.), the medical elite created by education and licensed by the state was supplemented by a vast number of unlicensed healers, mostly women (generally barred from medicine), who treated the common folk.

The trend to state regulation, endorsement, and protection of the health professions suffered a brief hiatus in the nineteenth century in the United States, when there arose a deliberate experiment in egalitarian deregulation following from a democratic belief that the common folk were as good as the educated elite in most matters. The experiment was abandoned later in the century, as Texas passed a medical practice act in 1873 and California followed suit two years later; by 1905, thirty-nine states licensed physicians (CSG). Nurses formed a national professional association in 1896; by 1926 forty states required licenses of nurses.

The trend is not, however, universal. Professional recruitment, standard setting, and discipline can be carried out by professional groups and associations without the protection of the state. Typically, groups of serious practitioners band together, agree to set standards, and develop informal review procedures for adherence to standards—for members only. Professional ethics and oaths, including professional standards of education and compensation, can be enforced by the professional association alone, and in some cases (various psychological and holistic health professions, for example) the process goes no further. In several healing professions, there is no regulation beyond that of the voluntary association; the only penalty for professional wrongdoing, if it is discovered, is loss of membership in that association.

Regulation tends to be reserved for those health professions that are widely perceived to have powers the abuse of which can lead to public injury. At one time, only the profession of medicine was included in that category; now it has extended through dentistry, nursing, pharmacy, and others (close to fifty, on one count; CSG/CLEAR), on a state-by-state basis (naturopathy, for instance, is regulated in some states but not in others). Licensure varies in kind as well as in range: As of 1973, nine states still had *permissive* licensing for nurses—an unlicensed nurse could practice without hindrance as long as she did not claim to be licensed. *Scope-of-practice statutes* ordinarily accompany licensure, defining the procedures for which the practitioner is licensed.

The Limited Competence of the State

Well established as the custom is, there is a certain awkwardness of fit between professional standards and state enforcement. The request by the health professions for state protection of their monopoly is certainly plausible. While the state can play little part in instructing or defining the work of the professions, it certainly has always had as part of its police power the protection of the public from outright dangers to health, including health frauds—quacks, charlatans, and sincere professionals whose education was simply inadequate to their tasks (*Dent v. State of West Virginia,* 1889). But a profession is defined in large part by its esoteric knowledge: Only professionals can set professional standards, determine when they have been violated, and, by extension, determine the sanction that would be appropriate as a punishment.

The result is that the public ends up enforcing rules that only a private association can set, presumably for its own benefit as much as for the public good. Nor is it clear that licensing in general, especially in the context of rigid scope-of-practice statutes, is in the public interest. The costs of licensing will normally be passed along to the consumer in the form of higher costs, and the license requirement restricts entry into the profession to those who can afford the initial outlay. The scope-of-practice acts make sure that auxiliary professions, with less expensive preparation and lower fees, cannot perform certain procedures that they may in fact be perfectly competent to perform (CSG/CLEAR). Built into the arrangement, if it is to be tolerable, is a strong presumption of altruism on the part of the professional and trust on the part of the public. Let either fail, and the system is in danger.

Professional Exclusion: The Flexner Report

In 1906 Abraham Flexner, an educator, obtained a grant from the Carnegie Foundation for the Advancement of Teaching to review the quality of medical schools. When his report was published in 1910, it revealed wide discrepancies among the 155 schools studied and produced a strong impetus to regulate medical education at the state and federal levels. Having no independent standards of their

own, nor any idea of how to develop them, the states appealed to the American Medical Association's (AMA) Council on Medical Education, which set new standards for accreditation of the medical schools. Physicians also staffed the state licensing boards. The consequence of this major public intervention in the healthcare professions was that by the mid-1920s the AMA had a virtual monopoly, guarding the gate to the medical profession at several levels: admission to medical school, choice of specialty, and obtaining a license to practice.

Such a state-sponsored monopoly is clearly subject to abuse, but it was widely imitated as succeeding levels of health professions sought and obtained state endorsement and protection. By tradition, the major regulatory role in the United States is played by the states, and the licensing laws are typically administered by state agencies and boards dominated by professionals.

Disciplinary Procedures

Disciplinary procedures responding to charges of fraud, incompetence, or malpractice occur at several levels. A certain amount of discipline is carried out by the professional association and is entirely a private matter among the professionals. At the state level, the procedure for disciplining delinquent practitioners varies, but generally it requires that some aggrieved party—a dissatisfied patient, a cost-conscious insurance company, or the plaintiff's lawyer in a malpractice case—register a complaint with the disciplinary board of the state. The agency in charge of these matters will investigate the case, assemble evidence, schedule a hearing, make a finding, and recommend appropriate action. Possible actions include dismissing the complaint, requiring some hours of community service, and removing a license. Increasingly, part of the decision is a refresher course in medical ethics.

The state medical boards are empowered to revoke a physician's license. Short of actual revocation of license, all actions taken against a professional are recorded and circulated through the National Practitioner Data Bank, where misconduct and malpractice findings are logged. The data bank is available to regulators in all fifty states. There are exceptions, but most health professions and practitioners are in the data bank.

Consumers' Protest

The federal government was active in the regulation of health matters for most of the twentieth century. The Pure Food and Drug Act, under which all drugs are approved for sale in the United States, was passed in 1906; since then the federal government has taken an active role in protecting occupational health and public accountability. Early in the 1970s, corresponding to the general wave of public skepticism regarding professional and corporate claims of authority and trustworthiness, a citizen/consumer rebellion turned on the health professions. Seminal works by Eliot Freidson and others spearheaded a literature of public protest against professional privilege and urged vigorous and vigilant oversight of the health professions, medicine in particular.

The protest tended to portray state legislatures as weak, ignorant, or pawns of the powerful professions and urged a drastic widening of the federal oversight function. Such expansion was made possible by the passage of Medicare legislation (1965), followed by Medicaid and other programs that cast the federal government in the role of major funder of healthcare. In a 1976 report titled *A Proposal for Credentialing Health Manpower,* the U.S. Public Health Service recommended that a national certification commission be established "to develop, evaluate and oversee national standards" for agencies that certify healthcare personnel. The National Commission for Health Certifying Agencies was formed on that recommendation, charged with developing universal standards for credentialing healthcare personnel. This effort was supported through the 1980s by the U.S. Department of Health and Human Services, through the Health Resources and Services Administration (CSG/CLEAR).

The origins of consumerism are generally attributed to Ralph Nader, whose investigations of the safety of the American automobile alerted a generation to the possibility that the goods and services available from the trusted providers of the American marketplace might not be as good as advertised. A Nader offshoot, Public Citizen's Health Research Group, maintains that the disciplinary and regulatory powers and laws currently available to the American public are completely inadequate to the task. These groups have changed the broad direction of legislative action. In the era of consumerism, the people's authority exercised at the state or federal level now protects the consuming public from the professional provider instead of aligning itself with the professional against fraudulent competition.

In a return to the democratic assumptions of the nineteenth century, the mantle of legal and moral credibility as protector of the public has passed from the profession to the elected legislature: In the areas of technical expertise and professional wisdom, as well as in the areas of economic self-interest, the American voters are now assumed to be the best guardians of their own interests. Patients' autonomy vis-à-vis their physicians has been generalized to public autonomy vis-à-vis the profession as a whole.

Typical of consumerist initiatives in healthcare is congressional action requiring nationwide licensing of nurses' aides. The bill was demanded by, among others, AARP, an interest group of older Americans with a strong stake in the conduct of nursing homes and chronic-care facilities. The passage of the legislation at the federal level (incorporated into the Omnibus Budget Reconciliation Act [OBRA] of 1987) made the law immune to the objections of state organizations of such facilities. Now the states must implement this law.

Also typical are the regulations proceeding from the work of the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, established by Congress in the 1970s in response to claims that patients were being abused by their physicians in pursuit of scientific research (and that aborted fetuses were being used for research). The commission's work resulted in an immense number of federal regulations to protect the rights of human subjects of clinical research, including the formation of institutional review boards in any institution where such research is carried on, charged with reviewing all research that receives any federal money (in effect, all research in the institution).

A third example of such initiatives is the Patient Self-Determination Act, passed as part of the Omnibus Budget Reconciliation Act of 1990, which requires that healthcare providers inform adult inpatients of their rights to refuse treatment; to submit to the provider a document, generally known as a *living will,* specifying their desires regarding treatment or nontreatment should they become terminally ill and unable to give consent to treatment on their own; and to appoint any adult to speak for them to ensure that the living will's instructions are carried out, should they become unable to speak for themselves.

The contrast between profession-oriented and consumer-oriented approaches can be seen in the norms governing confidentiality of investigations of professionals charged with incompetence or negligence. If government is to protect the profession, then the identity of credentialed professionals who are under investigation for wrongdoing must be kept secret until it is determined that they are unsalvageable in the profession, so as to maintain their good name and practice. Consumer advocate groups, on the contrary, demand that the names of accused professionals be made public as soon as the investigation begins, so that the public can take steps to protect themselves.

Rejoinders to consumerism in healthcare have come from diverse sources. One very influential reply, from the perspective of the medical profession, is Charles L. Bosk's 1979 account of a surgical training program, *Forgive and Remember.* In the training of surgical residents, as chronicled by Bosk, supervision was strict, the patients' interests were paramount, and discipline was swift, although generally informal, and highly effective. Bosk found in place an unwritten but well-understood set of rules, rapidly internalized by all surgical residents as a condition of success as surgeons and regularly enforced at all levels. The suggestion that emerged, although not explicitly, was that bureaucratic regulations could not possibly be as effective as this method of professional socialization in producing successful surgeons—at least at the level of the elite practitioners. On the other side, libertarian theorists have attacked regulation of all kinds, formal or informal, arguing that any regulation puts an artificial and uneconomic barrier in the free market. The libertarians achieved major gains in the last decade of the twentieth century.

Alternatives to licensing can easily be imagined. In 1984 Stanley J. Gross outlined a system of state registration of unlicensed practitioners whose competence is determined by the consuming public on the basis of full disclosure of background and skills. Given full disclosure and the absence of coercion, on the principle of freedom of contract, any two persons of mature years should be free to make between themselves any contract for goods and services. The point is primarily theoretical but of very wide application: If accepted, this doctrine would abolish a few dozen federal agencies and all state licensing and disciplinary functions. Concretely, this doctrine has been invoked as primary in cases in which patients request drugs not approved for distribution or sale, such as laetrile and other unproven cancer remedies or experimental AIDS drugs, or marijuana for medicinal purposes.

The Unwanted Participant: Business and the Professions

In the last decade of the twentieth century and the first few years of the twenty-first, the whole philosophy of licensing and regulation of the healthcare professions has undergone a sea change. By 1990, there was a strongly felt undercurrent that healthcare was taking up too much of the national budget (13 percent, higher than any other developed nation) and that it was badly distributed. Often the poor in this rich country had only minimal access to healthcare: They could not afford private fees, they received no health benefits through their employment, and they fell somehow through the cracks of the government-sponsored programs, Medicare (federally funded, for the elderly and disabled) and Medicaid (state funded, for the poor.) In 1992 Bill Clinton was elected U.S. president, and aided by his wife, Hillary

Rodham Clinton, he set out to create a single-payer system, a national health insurance plan, to provide universal access to decent healthcare. Overwhelmed by special interests (especially the private insurance companies, who wanted to run the system themselves), the Clinton plan failed in 1994.

In the aftermath of this failure, major insurance companies took over payment arrangements for the practice of healthcare, under a confusingly diverse pattern of plans. Some insurance company plans simply employ physicians, or contract with physicians' group practices, to provide services for all their subscribers. In such plans, a patient has to consult either physicians employed by the company or those in the groups under contract to the insurance company whose policy the patient purchased (or more likely, whose policy the patient's employer purchased). Other plans offer a choice from a select list of physicians and specialties. Most require preapproval for at least some medications and treatments, and some require preapproval for visits to the emergency room. No two plans cover quite the same list of consultations, treatments, medications and devices, under quite the same terms. The insurance companies arrange the terms, as they have had every right and duty to do, to serve the financial interests of their shareholders. Such arrangements include deliberate policies of delaying reimbursement payments to physicians and medical groups, because all funds retained can be invested for interest; refusal of authorization for payment for medical procedures or hospital days for those cases in which it seems that the patient would have no choice but to avail himself or herself of the service and pay anyway, out of pocket; and *selective deselection* of physicians who cost the plan more than the average over the course of the year because of referrals to specialists or the ordering of tests.

Deselection means that the plan subscribers can no longer receive reimbursement for consulting that physician. In effect, a deselected physician can no longer have those subscribers as patients. If the physician's income heavily depends on that group of patients, she may effectively find herself unemployed; if she belongs to a medical group that depends on a contract with that company, she may find herself rapidly separated from that group in order to preserve the contract. In both cases, because most practices depend heavily on insurance contracts and no group can afford an "outlier" who will attract negative attention to the group, the physician may be separated from all chance of making a living in the practice of medicine. Under the circumstances, it is not surprising that physicians feel that they have little choice but to stay well within the unspoken insurance guidelines, even if that means effectively turning away or deceiving certain patients.

The insurance contracts place healthcare professionals in a clear conflict of interest, a conflict that can affect the lives and health of their patients. (A conflict of interest, for a professional, involves any arrangement in which the personal interest of the professional [physician] is adverse to the interest of the client [patient].) Because all parties to the contract are competent adults, there is nothing the law can do to prevent such contracts from being signed. (Incidentally, according to the code that governs the ethical practice of law, which has legal force, any lawyer who put himself in such a position vis-à-vis a client could be disbarred.) The accrediting body for most U.S. hospitals, the Joint Commission for the Accreditation of Healthcare Organizations (JCAHO), has a special section on "Organizational Ethics" in the 2001 edition of its *Comprehensive Accreditation Manual for Hospitals.* The requirement of the main standard (RI.4) is simply the following: "The hospital operates according to a code of ethical behavior." Of particular interest in the context of bioethics is Standard RI.4.4: "The hospital's code of ethical business and professional behavior protects the integrity of clinical decision making, regardless of how the hospital compensates or shares financial risk with its leaders, managers, clinical staff, and licensed independent practitioners." Translated, this means that whatever impossible conflicts of interest physicians may have signed themselves into, it is the hospital's job to make sure that patient care is not affected. It is not clear how this standard might be met.

Bringing Miscreants to Justice

Notorious problems attend the disciplining of professionals for negligent, fraudulent, or otherwise unacceptable conduct. It is not the wealth or social status of the offenders that obstructs justice; there is no difficulty with trying these people for common crimes. But conflicting expectations arise around professional discipline—that the profession will discipline itself; that the hospitals will take responsibility for the competence of the professionals on their staffs; that state agencies will police the health marketplace and arrest wrongdoers; that the federal and state governments will use their power to withhold Medicare and Medicaid reimbursement to drive crooks and incompetents from the profession; that somehow insurance companies will act for and not against the interests of the patient; and that because the contract between professional and patient is a private one, private litigation is the best protector of rights.

The end product of these conflicting expectations is a nightmare of overlapping jurisdictions. There are, for example, clear cases of the *impaired physician,* usually a physician

involved in substance abuse, where there is a clear trail of substance consumption (e.g., bills from the liquor store, prescriptions not justified by patient need) and substandard practice. These are handled at the state level, with reasonable penalties and conditions of rehabilitation. For the remainder of allegations of inadequate care, no one is clearly in a position to initiate action. But once a health professional has been accused of misconduct, every agency—federal, state, or professional—involved at all with the profession typically attempts to get into the case. Routine involvement in all cases is the only way the agencies can ensure public perception of their importance and continued public support. Private lawyers preparing malpractice or negligence suits often alert public agencies to the possibility of professional (usually medical) incompetence because public citation will strengthen their case. When all the agencies take off after a physician at once—threatening loss of hospital privileges and/or the right to prescribe drugs, fines for incorrect billing of Medicare or Medicaid and insurance companies, and devastating publicity for the whole affair—the result can be personally and professionally catastrophic, and quite unjust. On the other hand, complaints continue that physicians work essentially without supervision, that it is very difficult for patients to criticize or check their work, and that bad physicians are practicing, able to evade all scrutiny.

Not all problems are technical or supervision problems. There are conflicting principles at the root of some problems. One of the most common is the conflict between patient autonomy and the protection of patient welfare. If adults regularly choose treatments or interventions that serve very little medical purpose (e.g., liposuction, cosmetic surgery or implants, experimental drugs), who shall be held responsible for the undesirable outcomes? To what extent shall the medical profession be forbidden, by law, to provide such services?

Another typical conflict is that between the salvaging of a professional career and patient protection. A health professional's training is long, difficult, and expensive, and society cannot afford to lose the investment that it represents. There is good reason, then, to try to rehabilitate health professionals who have mismanaged their practices. The problem lies in deciding which lapses are remediable and which are not. There is always a danger that the professional who has offended once will do so again, no matter how tight the supervision. The problem is compounded by the need, given the nature of the professional–client relationship in healthcare, to keep the professional's problems absolutely confidential. Typically, if the physician or other practitioner is *impaired*—psychologically incapacitated, found not guilty of a crime by reason of insanity, alcoholic, drug abusing, or otherwise unable to practice until a course of therapy has been completed—the records will be kept confidential while the person undergoes therapy. Should the physician leave therapy or breach other agreements (by testing positive for controlled substances, for instance), the matter becomes one of *misconduct* rather than *impairment* and is no longer confidential.

Another typical case of conflict, becoming more common, is between the patient and the insurance company, with the health professional caught in the middle. If the physician says that a treatment, test, or referral is needed, and the insurance company disagrees, whose side is the physician on? Since Hippocrates, the physician has been expected to advocate for the patient; under the new market dispensation, such advocacy may threaten a professional career.

The Future

In the future, licensing, regulation, and disciplinary action will no doubt respond to greater consumer insistence on quality and cost control, thus limiting professional autonomy still further. Meanwhile, new communication modalities will make possible much greater communication with all healthcare professionals as well as with the public. Three major trends can be discerned.

First, higher and more public standards for certification can be expected. Nonprofessional members have already been added to licensing boards in most states (CSG/CLEAR). It is likely that legal statutes will be enacted requiring that health professionals be recertified at some point or at regular intervals in their careers. The public is acutely aware that the scientific foundations of healthcare are rapidly changing, and that professional education has a half-life of less than ten years—five, in the case of certain medical specialties. Mandatory continuing-education requirements are already part of the licensing laws for medicine and nursing; it is not a large step from there to provisions for occasional retesting. Some observers foresee that "good moral character" requirements—already part of the licensing statutes in most states but undefined—will be made more precise and will be more vigorously enforced (CSG/CLEAR).

Second, the effort to control costs will be continued, whatever the fate of current insurance arrangements. There is still a widely held perception that health costs are too high and out of control. Major initiatives to limit them have been less than fully effective and have roused ire among health professionals and the general public alike. Yet to this moment there are no laws specifically excluding commercial arrangements from the healthcare marketplace, even those that entail the exclusion of sick people from private health

insurance. The Health Insurance Portability and Accountability Act of 1996 (HIPPAA) at least ensures that a person who becomes ill when insured, and then must change insurance plans, can enroll in the new one. In the past, the illness would constitute a *pre-existing condition,* a sufficient disqualification for enrollment in a new plan. But we have still no way to care for those suffering from serious chronic conditions prior to any insurance coverage.

Third, the entire process of licensing, regulating, and disciplining health professionals will become much more transparent. Both professionals and consumers have demanded this. As an encouraging start, many states have created web sites containing information on how to apply for licensure, listing job openings, and publishing all state laws regarding licensure.

The United States entered the twentieth century with the assumption that only one consent was needed for medical treatment: that of the physician or other health professional. In the last decades of that century it became clear that three consents are needed: the professional's, the patient's, and the payer's—the government agency or the private insurance company. That third consent may become much more problematic. Patients are also taxpayers and ratepayers. There is an increasing mandate to limit the amount of the national wealth that goes into healthcare, and there is no telling how far this new stringency will go in reshaping the health professions.

HEALTHCARE RESOURCES, ALLOCATION OF

I. MACROALLOCATION

The allocation of healthcare resources involves distributing health-related materials and services among various uses and people. The concept of allocation can imply that a designated individual or group is responsible for each level of decision making within a system that is designed to distribute fixed amounts of resources. Nevertheless, the degree to which such a system exists and such explicit allocation decisions occur varies widely. In the United States, for example, allocation of resources to and within healthcare has long been more the product of millions of individual clinical decisions and various market forces than the result of an overall social policy. Even in the United States, however, arenas exist where more explicit allocation occurs, such as the U.S. Veterans Health Administration with its Veterans Equitable Resource Allocation System (U.S. Veterans).

Healthcare allocations are commonly classified in terms of two levels of decision making: microallocation and macroallocation. Microallocation focuses on decisions regarding particular persons. It often involves "patient selection": determining which patients among those who need a particular scarce resource, such as a heart transplant, should receive treatment. Sometimes, however, microallocation entails deciding for an individual patient which of several potentially beneficial treatments to provide, particularly when only a limited time is available for treatment.

Macroallocation, on the other hand, entails decisions that determine the amount of resources available for particular kinds of healthcare services. Macroallocation decisions include how particular health-related institutions such as hospitals or government agencies such as the U.S. National Institutes of Health budget their spending (sometimes referred to as mesoallocation). Macroallocation also encompasses the decisions a nation makes concerning what resources to devote to particular institutions or, more broadly, to high-technology curative medicine as opposed to, for example, research or primary and preventive care. The extent to which health is fostered through medical care as opposed to nonmedical interventions such as environmental regulation is also a matter of macroallocation, as is the amount of money, time, and energy a society allocates to the pursuit of health rather than to education, defense, and other activities.

The term *rationing* is a much less clearly defined term that appears in discussions of macroallocation and microallocation alike. Because the debate over rationing raises issues at the foundation of healthcare allocation, it is the focus of the opening section below. The remainder of this entry discusses substantive standards for judging macroallocation, under three headings: the individual's right to healthcare, the community's responsibility for healthcare, and the importance of efficiency in healthcare.

Rationing

Rationing involves leaving some people, at least temporarily and against their wishes, without particular forms of healthcare that might benefit them. Some use the label "rationing" only if a person is barred from treatment by an explicit policy or decision. Those operating from this definition often oppose rationing because they believe there are sufficient resources, if managed and distributed correctly, to address at least the most important health needs of all. Others view the unavailability of care as rationing, whether or not explicit policies or decisions are involved. While part of this group also holds that there are sufficient resources to avoid rationing for the most part, the majority see implicit or explicit rationing as unavoidable and tend to favor developing explicit, ethical criteria (Ubel; Blank; Wikler).

A fundamental ambiguity, then, attends the word rationing. Moreover, the word's association with a short-term policy for handling a temporary crisis, such as a shortage of goods in wartime, makes it a misleading word to designate society's long-term task of healthcare provision. So the less ambiguous terminology of macroallocation and microallocation is probably more helpful in most discussions. Nevertheless, the debate over the term rationing has identified two important issues that should be examined before embarking on a more detailed consideration of macroallocation: (1) Does implicit allocation of desired and potentially beneficial healthcare actually occur? (2) Will some form of allocation be necessary in the future?

There is little dispute that implicit allocation of beneficial care does take place. For example, waiting lists for certain types of healthcare have been commonplace in Canada and Europe. There the structure of the system (referral and reimbursement policies, acquisition and location of technologies), rather than the explicit exclusion of

people or services from coverage, has limited overall national spending on healthcare (Grogan). In less developed countries, some resources are typically located only in major urban centers and have been unavailable to most of the population (Attfield).

Even in the United States, where per capita spending on healthcare exceeds that of any other country, many have not been able to obtain certain forms of beneficial healthcare. In recent decades, tens of millions annually have gone without any health insurance, and at least as many more have been underinsured—predicaments that have resulted in reduced access to healthcare and in poorer health (U.S. Congress). Employer decisions to limit employee health-benefits packages, as well as governmental decisions to omit services from the Medicaid and Medicare programs, have excluded certain people from potentially beneficial healthcare. So have decisions by health facilities not to operate in the most accessible locations or at the most convenient times, and insurance company decisions to exclude from coverage people with preexisting conditions or other high-risk factors.

Greater controversy surrounds the second question, whether healthcare resources can be allocated so that no one has to go without potentially beneficial healthcare (Kilner, 1990). The possibility of avoiding rationing in this sense of the term hinges on achieving sufficient cost containment. Proposed strategies include reducing expenditures on items less vital to society (e.g., potato chips and advertising); eliminating medical procedures with little health benefit; placing greater emphasis on preventive care that preempts the need for more expensive acute care; reforming tort law to reduce the need to practice defensive medicine; simplifying administration; imposing global budgets on the entire healthcare system; and limiting the large gap between the incomes of physicians and other full-time workers. Various forms of "managed care" arrangements pursue several of these strategies simultaneously by restricting patients to approved providers (e.g., in preferred provider organizations or health maintenance organizations) who agree to limit their charges or forgo fee-for-service entirely in exchange for a salary or per-enrollee payment.

Some commentators contend that significant cost savings could be obtained through each of these strategies. Others disagree, arguing that the scope and cost of potential healthcare benefits are so vast that any savings will prove insufficient to fund needed benefits for everyone. Time will tell how effective various cost containment strategies can be in reducing the need for limiting the access to healthcare. After initial cost savings, however, managed care in the United States apparently has been unable to check the growth of healthcare costs (Ginzberg). Meanwhile, ethical questions have arisen concerning the extent to which physicians can truly pursue patient well-being if they must also serve as "gatekeepers" to conserve society's resources (Willems; S. Daniels). At the same time, the experience of other countries such as the Netherlands, with healthcare systems more nationally coordinated than that of the United States, suggests the pragmatic limits of cost containment (The Netherlands, Government Committee on Choices). Such challenges underscore the importance of making allocation decisions explicit if allocation is not to be shaped by unknown factors and unethical considerations.

Major Macroallocation Standards

Numerous people have proposed ways to prioritize the potential uses of limited resources. These proposals tend to be rooted in one or more of three major ethical concerns: the individual's claim to healthcare, the community's responsibility for healthcare, and the importance of efficiency in healthcare. Within these three concerns, different understandings of justice are at work, and different weights are attached to competing ethical considerations such as liberty, care, and utility.

THE INDIVIDUAL'S CLAIM TO HEALTHCARE. Those who are primarily concerned about the healthcare that is due to each individual often invoke the notion of a right to healthcare. When the World Health Organization in its 1946 constitution affirmed the "enjoyment of the highest attainable standard of health" to be one of the fundamental rights of every human being, the statement both reflected and fostered a growing debate over health-related human rights.

The concept of a human right promotes the idea that each person is entitled to have something or to be free from something. It commonly reflects the basic conviction that each human being has special and great significance. While this conviction is not necessarily religious in nature, it receives special emphasis in theological traditions such as Christianity, Judaism, and Islam (Kilner, 1992; Zoloth; Rahman).

Negative and positive rights are frequently distinguished, as are moral and legal rights. Negative (or liberty) rights guarantee freedom from certain types of interference with the pursuit of one's interests. Positive (or material) rights guarantee access to important services and goods. Accordingly, a right to protection from anything that is seriously harmful to one's health is a negative right; a right to receive certain forms of healthcare is a positive right. Whereas moral rights involve claims about what one ought to have on

ethical grounds, legal rights involve claims about what one is actually entitled to by law. Whether everyone has an ethically justifiable right to healthcare is debated in the United States, yet Medicare legislation confers a legal right to healthcare on the country's elderly people.

Differing views. In light of such distinctions and the conflicting conceptions of justice and freedom that underlie them, it is not surprising that people have fundamentally different views about the meaning and legitimacy of a "right to healthcare." Some hold that there is a right to health. The point of the right is to make sure that people actually have health itself, not just access to resources. Others insist on a right to healthcare. Because of the fundamental importance of health, people should have guaranteed access to resources that foster it. Still others reject both positions. While all of these claims represent worthwhile aspirations, they argue, such claims are not rights because no one has the obligation to satisfy them. Probing this last argument first provides useful entry into the debate.

The most prominent basis for rejecting a right to healthcare is a libertarian view of justice that emphasizes negative rights over positive rights (Engelhardt). According to this view, people ought to be free to pursue their own life plans, including their economic livelihood. Government should prevent others from interfering with that pursuit. A right to healthcare that forces healthcare professionals to provide care—or that forces certain people to give up part of what they have earned to pay for other people's care—directly contradicts what justice requires. That some people lack healthcare (or the ability to pay for it) is simply unfortunate rather than unfair. No rights are violated in a market-based system where people are free to buy and sell as their resources permit.

Critics of this position argue that it is self-defeating and mistaken. It is self-defeating because in its zeal to protect people's freedom to use their resources for healthcare and other desired goods, it effectively ensures that those with insufficient resources will not have the freedom to obtain healthcare (Brennan). It is mistaken in three assumptions. First, some note the implausibility of assuming that the present distribution of general resources is fair. In their view, the vastly unequal distribution of the means by which people pay for healthcare is attributable to forces that have affected the fairness of the market over time.

Others doubt a second assumption, namely, that a free-market approach is appropriate for healthcare. Consumers in this case are frequently sick patients with limited knowledge about healthcare. For a free market to function well, consumers would have to be able to understand the costs and benefits of all the available medical options and be willing and able to trade health or even life for money. A free-market approach, then, unfairly discriminates against those who are uneducated as well as those who are poor because of social circumstances or genetic endowments beyond their control.

A third debatable assumption, most frequently questioned by those who operate from a theological perspective, is the understanding of liberty as autonomy. The term *autonomy,* derived from the Greek words *auto* (self) and *nomos* (law), tends to emphasize people's separateness from others. According to a more relational understanding, freedom entails "freedom *for*"—the ability (and obligation) to help others—as much as it involves "freedom *from*" the interference of others.

Some of those who reject a libertarian approach instead affirm the right to health. They insist that health, like life itself, is something so fundamental to human existence that it must be fostered as much as possible. Precisely what the right to health entails, though, is not always clear. It may involve only the negative right that would protect one's freedom from actions that undermine health. This formulation of the right is compatible with the libertarian outlook already discussed. Alternatively, the right to health may entail that people have an entitlement to be healthy and that others have failed in their moral obligations toward individuals who are not healthy.

Those who find this outlook objectionable worry about the prospect of making one person's health another person's responsibility. Such a view tends to undermine people's responsibility for their own health. Opponents also note that it is not possible to maintain someone else's health indefinitely—given that everyone dies eventually—so it seems mistaken to suggest that anyone has an obligation to do so.

A right to healthcare. To avoid these problems some people advocate the right to healthcare. The right to healthcare is a positive right that holds that all people are entitled to receive some measure of healthcare. Whereas some others argue that people are entitled only to an amount of monetary resources that they can spend on whatever they deem important (Brody), supporters of the right to healthcare insist that people must be assured healthcare in particular. Rights, they maintain, do not involve the sort of discretionary items on which people place differing priorities. Rather, they concern goods that all people require in order to pursue their various life courses.

Sometimes the right to healthcare is formulated in comparative terms. According to this view, everyone should have access to whatever healthcare is necessary to provide for a level of access—or even of health itself—equal to that of

others (Veatch). Many have resisted this egalitarian outlook because it tends to focus more on the value of equality than on the healthcare people receive. People with chronic illnesses or congenital disabilities may never achieve a level of health equal to that of others and so could claim an infinite amount of healthcare resources by invoking an egalitarian right to healthcare. Alternatively, this right could justify leaving all at a relatively low level of access or health, as long as everyone was treated alike. If, on the other hand, this egalitarian approach requires that everyone be able to receive every treatment that may provide any benefit, then it seems hopelessly unsuited to a world of limited resources.

To correct these deficiencies, various people have proposed identifying the right to healthcare with some sort of achievable standard of healthcare that could be guaranteed to all. They often suggest that because healthcare is provided in response to need, some standard of need should determine the level of healthcare to which all people have a right.

Others would similarly root the individual's claim to healthcare in a person's need for that care, but would appeal to various understandings of justice rather than to the notion of rights. For example, a contractarian approach, which appeals to what all people would agree to in hypothetically fair positions, usually advocates people's access to basic goods that anyone must have in order to carry out a personal life plan. Healthcare is one such good, and whatever amount is essential to enable people to function at a normal level is mandated by justice (N. Daniels; compare Toenjes, who sees the contract as one between physicians and society). Religious traditions that posit a divinely created world also tend to espouse a needs-based understanding of justice. They may, however, view *normal* more in terms of how people were created to be than how they typically are (Mackler).

A utilitarian conception of justice might also undergird a right to healthcare, but the support is tenuous. Because classical (or act) utilitarianism advocates acts that will produce the greatest good for the greatest number of people, it is often criticized for lacking any concept of justice to protect individuals from oppressive majorities. On the other hand, rule utilitarianism, which supports standards that produce the greatest good for the greatest number if followed consistently, might well support a standard of justice.

Standard of need. In light of the important place a standard of need commonly has in formulations of the right to healthcare and in conceptions of justice, it is essential to consider what this standard entails. Defining the standard and delineating its implications are not easy, because even marginal benefits can be considered *needs* (President's Commission). One definitional approach is to think of meeting needs in terms of restoring normal functioning. Another ties the meeting of needs to providing *significant* health benefit. Establishing significance might involve a careful assessment of the quality and length of life that various forms of healthcare would likely provide in various situations, together with some individual or societal evaluation of those benefits.

A broad range of considerations is relevant to the delineation of healthcare needs. In particular, needs less dramatic than the need for acute medical care must receive sufficient attention. Some non-healthcare goods can make an important claim on whatever portion of its resources a society devotes to the pursuit of health. Food, education, and shelter, for example, all contribute directly to health (Tuckson). So do programs that encourage healthy lifestyles. Habits of eating, drinking, sleeping, and drug use can all have a dramatic impact on health, although positive habits resulting in greater longevity may not reduce total healthcare expenditures over the course of an individual's lifetime (L. Russell).

Preventive medicine, supportive care, and medical research must similarly receive sufficient attention along with curative medicine. While preventive medicine is not necessarily less expensive or more effective than curative medicine, it can be both (Hope). Prenatal care for a mother as opposed to neonatal intensive care for her low-birthweight infant is a case in point. Analyses of need must give due attention to the importance of supportive care such as long-term care for elderly persons or effective pain relief for dying patients. Finally, fascination with current curative capabilities can all too easily siphon resources away from medical research. Without sufficient attention to research, there will be fewer new medical resources in the future, to the long-term detriment of society's health.

In the face of such a broad array of healthcare needs, many people believe that not everything that is needed can be provided for all. Accordingly, they conclude that justice or the right to healthcare must mandate only that each individual receive some reasonable level of healthcare—so-called essential care or a *decent minimum* (Eddy). Determining this exact level presents the same challenges as determining need, with the added task of tailoring the determination to the level of overall resources available at the time.

Moreover, people in different locations differ dramatically in their perceptions of need and essential care. Those in European countries, for example, avoid the notion of a decent minimum altogether. Nevertheless, each country's effort to provide comprehensive care is unique in terms of the particular forms of care that receive emphasis (Grogan).

Canada has typically acknowledged differences by allowing each of its provinces to determine which health-related services will be included in the package of guaranteed benefits.

The United States, lacking the nationally coordinated financing system of Canada, has traditionally left its states to develop their own priorities and healthcare systems (Moon and Holahan). For instance, Oregon has explicitly ranked all health-related services in terms of their funding priority. Hawaii has required all employers to provide health insurance to all employees working over twenty hours per week (Hawaii acted in 1974 before federal legislation barred this approach). Minnesota has linked improving healthcare access with an array of measures to control costs.

The differences among these and other state initiatives underscore what an international comparison also illustrates: that varying perceptions of need call forth different healthcare priorities and systems. Cross-cultural sensitivity will be essential if efforts to meet health-related needs are to cross national and international boundaries successfully (Attfield).

Employing need as a basis for allocation, then, presents various challenges. Challenges can be reasons for rejecting an idea. But challenges may be no more than obstacles to overcome so that a good idea may be implemented effectively.

THE COMMUNITY'S RESPONSIBILITY FOR HEALTHCARE. The substantial disagreement over the idea of the individual's claim to healthcare has made many people doubt its usefulness as a basis for allocating healthcare resources. Some have rejected the idea on more principled grounds as well. One prominent concern has been the impact that a preoccupation with the rights of the individual can have on the well-being of the community as a whole (Churchill). A case in point is the United States, a highly individualistic culture in which the use of the language of rights has been particularly prominent. The demand of U.S. taxpayers, patients, health professionals, and healthcare financers for the rights to pursue and satisfy their own various interests may have inhibited the development of an integrated, comprehensive healthcare system.

Those who would not jettison completely the notion of rights may argue—on theological or other grounds—that while people have rights, they have no "right to rights" (Kilner, 1992). According to this view, rights themselves (in the sense of freedoms and goods all people ought to have) are not the problem. The problem is people's preoccupation with their own (right to) rights—a preoccupation that undermines the commitment to pursuing the rights of all. In this sense, group rights are as problematic as individual rights, because attention to the claims of one's own group tends to encourage the same kind of self-focus and neglect of others as the pursuit of individual rights.

Therefore, some favor deemphasizing the notion of the individual's claim to healthcare—as well as rights language in general—or even replacing the notion with a more explicit conception of the community's responsibility for healthcare. Sensitivity to the needs of individuals and particular groups is not absent in this approach, but the driving concern is the community's obligation to ensure the well-being of the whole community.

In European societies such as Germany and the Netherlands, for example, discussions of healthcare have often invoked social solidarity as a fundamental goal to be pursued through resource allocation (Netherlands, Government Committee on Choices). In the United States, an increasing emphasis on community responsibility has been reflected in the ethics literature (Dyck; Tauber) and in the appearance of such interdisciplinary journals as *The Responsive Community.* Appeals to the common good have also become more frequent, especially in religious circles (Catholic Health Association). Increasingly, people are concluding that ethical macroallocation of healthcare resources in the United States will probably require a different way of thinking about the relationship between the individual and society.

Accordingly, the U.S. President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research, in its 1983 report titled *Securing Access to Health Care,* explicitly rejected the rights-oriented language in the 1952 report of the U.S. President's Commission on the Health Needs of the Nation, titled *Building America's Health.* Instead the 1980s commission affirmed the community's ethical obligation to provide all with equitable access to an "adequate level" of healthcare. In *Securing Access,* the commission argued that a community must ensure that all of its members can obtain such care because healthcare is so important in relieving suffering, preventing premature death, restoring functioning, increasing opportunity, providing information, and strengthening relationships of caring. This approach affirms that ungenerous or uncaring healthcare allocations are clearly as wrong as those that are unjust.

Caring in this context entails looking beyond what theoretical formulations of justice require. It means giving special consideration to those who have been marginalized in the allocation of healthcare resources. Identified in certain religious and liberationist contexts as "the preferential option for the poor," this sensitivity toward disadvantaged persons is characteristic of much feminist analysis as well (Caes; Holmes and Purdy). It embraces the notion of the

"common good," but not in the utilitarian or majority-rule sense of the term. It insists that there is no true common good if all do not have the good in common.

Emotional as well as rational, engaged as well as theoretical, a caring commitment to those who are least well-off may or may not justify a different healthcare allocation than that which a rights- or justice-based approach to healthcare allocation would advocate. Its proponents, however, maintain that such a commitment almost certainly will make a difference in the ways in which allocation is implemented. For example, it may be widely acknowledged that justice requires directing more healthcare resources toward African Americans and other disadvantaged groups in the United States (LaVeist). Reallocation, however, is not likely to take place as long as people do not see others' health as their responsibility in any way.

Basing allocation on the community's responsibility for healthcare, then, differs from basing it on the individual's claim to healthcare. But attributing responsibility to the community does not absolve the individual from responsibility. Because individuals are part of the community and share in its well-being, they must share the burden of paying for the cost of the community's healthcare in an equitable manner. Moreover, they have some responsibility for their own health. The implications of this responsibility are controversial. In particular, does an apparently irresponsible person forfeit the community's care?

Both justice and respect for people's liberty may entail that those who voluntarily cause their own health problems should take responsibility for them, particularly when there are insufficient resources to meet the healthcare needs of all. Holding people responsible in this way might have the added benefit of reducing illness and injury resulting from risky behaviors, thereby lowering related healthcare costs as well.

It is extremely difficult in most cases to prove, however, that people caused their illnesses and did so voluntarily. Often there are many causes of an illness, few of which are within a person's control. Even if a person's behavior, such as smoking or overeating, does cause an illness, the voluntary nature of the behavior is difficult to demonstrate conclusively. The person may have engaged in the behavior without understanding that it could cause the resulting illness. Regardless of foreknowledge, other factors—advertising, peer pressure, cultural values, dietary deficiencies, psychological instabilities, or genetic predispositions—may have significantly impaired the ill person's ability to act freely.

Even if a society becomes sufficiently adept at identifying those who have voluntarily caused their own health problems, three further ethical considerations are relevant. First, fairness may require that an allocation policy based on personal responsibility not apply only to those engaging in the least socially desirable behaviors. In other words, the policy should apply not only to smokers and intravenous-drug abusers but also to those who overwork or overeat, if responsibility can be established in all four types of cases.

Second, the idea that a society would have a responsibility to truly care for its members may call for the provision of more healthcare than strict justice alone requires, even for those who voluntarily engage in risky behavior. The healthcare professions have a long-standing tradition of offering care without making such offers contingent on the extent to which ill people caused their own need. Finally, if caring with fairness requires some form of accountability for risky behaviors, requiring payment of a tax to engage in those behaviors, say on cigarettes and alcohol, would be more humane than denying needed healthcare.

THE IMPORTANCE OF EFFICIENCY IN HEALTHCARE. Efficiency is also a central and disputed issue in ethical resource allocation. How best to eliminate health-related expenditures that are not truly beneficial in order to maximize funding for beneficial healthcare is only part of the efficiency problem. Even greater controversy surrounds proposed mechanisms for determining which forms of beneficial care are most worth their cost.

Two mechanisms for comparing costs and benefits have received particular attention as promising ways to pursue efficiency in healthcare: cost–benefit analysis and cost-effectiveness analysis. While both mechanisms typically involve assessing the costs of various forms of healthcare in monetary units, cost–benefit analysis also uses monetary units exclusively to assess the benefits of care, whereas cost-effectiveness analysis does not.

Cost-benefit analysis. Cost-benefit analysis is well-suited in principle to a broad range of resource allocation decisions both within and outside of healthcare. It employs identical units, such as dollars, to measure all costs and benefits. Accordingly, it can subtract total costs from total benefits to determine if an expenditure is wasteful (i.e., its costs outweigh its benefits). When applied to different health-related and other uses for the same funds, cost-benefit analysis can also determine which use will provide the greatest net benefit. This approach has proven particularly attractive to economists and policy analysts who must prioritize diverse uses of limited funds (Emery and Schneiderman; Oliver, Healey, and Donaldson).

Because cost-benefit analysis is the more familiar efficiency mechanism of the two, and because it alone has the potential to compare all possible uses of available funds, it

appears at first glance to be the superior mechanism for allocating healthcare resources. But cost-benefit analysis has a number of pragmatic and substantive weaknesses in its most common forms (B. Russell). Some of these difficulties are inherent in the overall way the mechanism operates. Identifying the numerous ways that people are affected by particular allocation decisions is difficult enough, but reducing the entire range of healthcare outcomes (including continued life itself) to monetary value is virtually impossible. More substantively, while cost-benefit analysis helps to identify the allocation of resources that yields the greatest balance of benefit over cost for a society as a whole, it may fail to consider how fairly the benefits and burdens of that allocation are distributed throughout society. Programs targeting affluent suburbs, for example, can tend to have better cost-benefit ratios than programs in poor inner-city areas because of the bad health fostered by poor social and economic conditions. Ethics, though, must attend to more than economics.

Other difficulties concern the methods cost-benefit analysis uses to convert lives saved and other benefits of healthcare into monetary units. One approach is the *past decisions* approach, which compares how much money a society spent on selected programs to save lives in the past with how many lives were saved as a result of those programs. The unique funding and implementation context of each such program, however, renders generalizations risky.

Two more popular conversion methods involve future earnings (human capital) and willingness to pay. The future-earnings approach determines the monetary value of a health benefit by calculating how much more money patients will earn in the future if they receive treatment than if they do not. Fairness again is a major problem, for this approach implies that the life of a person making twice the income of another person is twice as valuable (i.e., important to save) as that of the other person. Because women and minorities tend to receive less pay than white males for comparable work, this approach devalues the lives of women and minorities. In fact, whatever employment-related discrimination already exists in a society becomes compounded when healthcare allocation reflects salary level.

A willingness-to-pay approach, on the other hand, calculates the value of a health benefit on the basis of the amount of money people would pay to receive a specified increase in the likelihood of receiving that benefit over a particular length of time. This approach, like the previous one, tends to compound certain forms of discrimination. Because wealthy people are generally able to pay more for a program to reduce the risk of illness and death than are poor people, a willingness-to-pay approach systematically reproduces existing injustices in the distribution of wealth.

All forms of cost-benefit analysis, then, are vulnerable to the charges that they are inadequate measures of the value of lives and that they neglect some important ethical considerations in resource allocation. Accordingly, a better mechanism for maximizing the benefit of limited healthcare resources has been sought.

Cost-effectiveness analysis. Cost-effectiveness analysis has generally been the favored alternative because it avoids a major difficulty that troubles cost-benefit analysis: the need to convert health outcomes, including continued life itself, to a monetary equivalent. Cost-effectiveness analysis typically calculates the cost of alternative health initiatives in monetary terms. But it can adopt a nonmonetary unit for comparing the health benefits of these initiatives, such as degree of mobility restored or years of life saved. If, for example, two treatments for hip problems claim to improve mobility, cost-effectiveness analysis can determine which one restores more mobility for the same cost or identical mobility for less cost. It can also determine which use of earmarked funds will produce the greatest health benefits. While this approach cannot determine if costs outweigh benefits or compare all benefits inside and outside of the healthcare field, it can identify the cost per standardized unit of benefit for alternative health-related interventions.

Broad societal healthcare allocations, however, necessitate a more generic measure of health benefit than mobility. Because increased quality and length of life are the two primary goals of healthcare, the standard of *quality-adjusted life years* (QALYs) seems to many to provide a suitable measure (McCulloch; Nord). To determine the number of QALYs that a health-related intervention will produce, the number of years people will likely live after the intervention is multiplied by a percentage reflecting the quality of life to be experienced during those years—0 percent (0.00) signifying death, and 100 percent (1.00) signifying perfect health with no disability.

While QALY-based cost-effectiveness analysis represents an improvement over cost-benefit analysis for the purpose of comparing health-related allocations, it, too, has proven controversial (Harris; Menzel; Stolk, Brouwer, and Busschbach). For example, certain analysts, while affirming the approach in principle, note that studies to date have not yet gathered all of the necessary data on healthcare outcomes, costs, and quality-of-life preferences. More data is needed before cost-effectiveness can be consistently employed as a basis for making comprehensive healthcare allocations.

The state of Oregon, for instance, originally intended to use a form of cost-effectiveness analysis during the early 1990s when it redesigned its approach to allocating public

healthcare funds. Through a telephone survey, the state asked people to rank various functional limitations and other symptoms on a quality-of-life scale. The goal was to ascertain a quality-of-life score and cost figure for every health-related intervention so that these interventions could be prioritized for budgetary purposes. Reliable cost data proved so difficult to acquire, though, that the quality-of-life information was employed essentially only to identify which interventions produced the most benefit, irrespective of costs (Garland). Moreover, some rankings had to be altered in the end. The state discovered that interventions producing relatively little health benefit—if inexpensive enough—could rank higher than much more beneficial (even lifesaving) interventions.

Another methodological debate over cost-effectiveness analysis concerns who should assess quality of life (Fleck). The QALY approach determines the quality-of-life percentages for particular outcomes by interviewing large numbers of healthy people concerning the value they place on various qualities of life. Some insist that healthy people are the right ones to make these judgments because resource allocation is like purchasing health insurance. People will appropriately weigh alternative benefit packages before they contract a particular disease, but after contracting it they place disproportionate weight on covering that disease. Others cite studies documenting that healthy people frequently underestimate the quality of life of people who are ill or disabled. One inference drawn is that only those who have experienced such conditions can adequately assess the degree to which they render living more difficult (Lawton, Moss, and Glicksman; Kaplan).

The most heated disputes over the QALY approach, however, involve problems of fairness similar to those attributed to cost-benefit analysis. Although QALY-based cost-effectiveness analysis does not intentionally discriminate against certain groups, it tends to disadvantage patients who are older or disabled—in fact, anyone whose future length or quality of life is comparatively limited. Because QALY calculations are based on precisely these two variables, the treatments most beneficial to such persons tend to receive lower QALY scores and so receive low funding priority. For many who believe in the sanctity of human life, this discrimination is typical of the devaluing of certain types of people that generally results when anticipated quality of life is employed as a basis for ranking patients rather than as a desirable outcome to be sought for each individual patient.

As it turned out, the U.S. government refused the state of Oregon's initial application, which sought legal permission to allocate the state's limited Medicaid funds by ranking health-related interventions based on public quality-of-life judgments. The government's controversial rationale was that the approach discriminated against persons with disabilities. Oregon successfully revised its proposal by eliminating reliance on quality-of-life data. While cost-effectiveness analysis, then, attends well to efficiency, like other efficiency mechanisms it can easily be insensitive to other ethical concerns such as degree of need and fairness (Menzel et al.; Rosenthal and Newhouse).

Conclusion

The individual's claims, the community's responsibilities, and efficiency's importance all represent widely held ethical sensitivities to which resource allocation must attend. The ongoing challenge is to determine how to affirm the best elements of each, where they are not mutually contradictory, in a way that also minimizes their ethically objectionable features.

II. MICROALLOCATION

When the need or demand for healthcare resources exceeds the available supply, resources must be distributed on some basis. The more explicit the criteria, the more likely it will be that the term *rationing* will be applied, although the meaning of the term varies considerably in the bioethical, healthcare, economic, and public-policy literature. Rationing often refers to general limitations placed on the availability of certain types of healthcare, but it may also encompass specific treatment decisions for particular patients. Distribution of healthcare at a broad institutional or societal level is referred to as *macroallocation.* Macroallocation includes the way a hospital budgets its spending, as well as the amount of resources a nation devotes to primary and preventive care compared with high-technology curative medicine and nonmedical activities such as education and defense.

Microallocation, on the other hand, focuses on treatment decisions regarding particular persons. It may entail deciding which of several potentially beneficial treatments to provide an individual patient, particularly when only a limited time is available for treatment. Caregivers most commonly employ various medical criteria in order to make such decisions. These decisions, however, take place in institutional and societal contexts of limited resources. Accordingly, the relative merits of devoting particular resources to one patient rather than to others may exert at least an unconscious influence on treatment decisions, and nonmedical considerations may become involved. Patients' values and beliefs often play a role here as well.

Other microallocation decisions, sometimes referred to as *patient selection decisions,* more explicitly involve choices among patients. In the less developed countries of the world, large numbers of people continue to die for lack of vaccines to prevent disease, antibiotics to cure infections, oral rehydration therapy to replenish fluids lost through severe diarrhea, and healthcare personnel to administer such interventions (UNICEF, 1993, 2003). Microallocation decisions constantly determine who will receive the limited care that is available. Some countries not only continue to wrestle with these low-technology scarcities but also face the high-technology microallocation dilemmas commonly encountered in the more developed countries, where expensive medical technologies have proliferated.

Organ transplantation and hospital intensive care are two primary examples of such technologies. The expense of heart, liver, and other types of organ transplantation keep some patients from even considering such operations. Of those seeking transplantation, more than 6,000 patients in the United States alone die each year while waiting for a suitable organ to be donated (Organ Procurement and Transplant Network [OPTN]). Microallocation of hospital intensive care, meanwhile, must occur whenever more patients could benefit medically from access to it than the available space can accommodate—a persistent occurrence even in the more developed countries (Truog; Lantos, Mokalla, and Meadow).

Scarcities of vital healthcare resources are not likely to disappear in the future. The degree of scarcity in the less developed countries will likely decrease through worldwide cooperative efforts. Nevertheless, social, political, and economic constraints will continue to hamper such efforts. Even in the more developed countries, the need for microallocation will persist (and probably grow) for at least three reasons. First, many emerging technologies such as artificial organs and imaging techniques are so expensive that the cost of making them available to all who could benefit from them is prohibitive. Second, the scarcity of some treatments (e.g., organ transplantation) is not simply a matter of funding but reflects the limited supply of the critical resource itself (e.g., the donated organ). Third, technological development will continue to yield new resources that only a limited number of patients can obtain until the capacity to produce those resources expands sufficiently. The history of healthcare is filled with examples of such scarcity, including the early years of the polio vaccine, the antibiotic streptomycin, the hormone insulin to treat diabetes, the iron lung to enable patients with polio to breathe, and the dialysis machine to filter people's blood when their kidneys fail (Mehlman).

Those responsible for microallocation decisions have adopted a wide range of criteria for determining which patients receive available resources. Sometimes a *triage* model has been used, drawing on the experience of prioritizing the treatment of casualties on the battlefield or patients in the emergency room (Rhodes, Miller, and Schwartz; Bell). At other times these criteria have only been implicit, as was common during the early years of kidney dialysis in the

United States, prior to universal funding by the federal government in 1972. Many dialysis centers employed an ad hoc approach, in which particular patients were selected from eligible pools without any set of guidelines developed in advance. The resulting decisions were widely criticized as arbitrary. Of greater concern is the tendency of ad hoc decision making to reflect the biases and preferences of the decision makers (Fox and Swazey).

Ad hoc decision making continues to take place when individual caregivers, ethics committees, or healthcare institutions make microallocation decisions without first developing an explicit set of allocation criteria to guide them. Nevertheless, significant attention in practice and theory has been devoted to formulating a more ethically acceptable decision-making approach. Overall approaches are discussed in the closing section of this entry.

Allocation Criteria

Before examining such approaches, this entry addresses the justifications and weaknesses of the major allocation criteria from which implemented or proposed approaches have been constructed. As one nationwide questionnaire study of microallocation criteria favored by selected medical directors has documented (Kilner, 1990—hereafter, "U.S. Study"), these criteria can be clustered into four major types: social, sociomedical, medical, and personal criteria.

SOCIAL CRITERIA. The characteristic feature of social criteria is that they seek to promote some particular or general social good as a result of the allocation decisions made. There are five such criteria: social value, progress of science, favored group, resources required, and vital responsibilities.

Social value. Of the social criteria, the most basic is a social value criterion. Given some place in microallocation decisions by 56 percent of the U.S. Study participants, this criterion gives preference to patients judged to be of greatest value to society, according to whatever standards of value the decision makers decide to employ. While the criterion may be explicitly invoked, it can also operate covertly to influence treatment decisions. One result in the United States has been that socially privileged groups such as whites and males have received scarce treatments disproportionately often (AMA, 1990, 1991; Institute of Medicine).

The primary attraction of employing a social value criterion is that it helps to maximize the amount of benefit derived from healthcare resources. Because society has invested its resources in a patient's treatment—or at least in developing the possibility of that treatment—it is understandably interested in a good return on its investment. Absent this criterion, there might well be an undesirable loss of some of society's most gifted people. A social value criterion usually employs a utilitarian calculus, according to which the patients judged most likely to be most valuable to society in the future are favored. Past contributions to society may also enter the calculus on the basis of just reward or gratitude for a patient's past.

In any form, this criterion is highly controversial. Conscientiously ranking people according to social value is a virtually impossible task. Agreeing on a ranking of all possible social contributions—based on an accurate understanding of future as well as present needs—is extremely problematic even in a setting much more homogeneous than the United States. Assessing how particular individuals rank on this scale requires a virtually unobtainable level of knowledge about people's lives. The omniscience and wisdom required has led critics to label the use of this criterion "playing God." The criterion is also criticized for unfairly discriminating against individuals or groups who cannot contribute as much to society as others. Their relative inability may be due to unchangeable genetic factors or uncontrollable social circumstances (e.g., past discrimination that has undermined either their ability or society's appreciation of their contributions). Moreover, the toll on the caregiver–patient relationship can be severe. Patients can no longer be sure that confidential information about embarrassing symptoms or lifestyle habits, which caregivers often must know in order to treat patients effectively, will not be used to deny them treatment in deference to another more socially promising patient.

Progress of science. Closely related to a social value criterion is a progress of science criterion, which received roughly the same support in the U.S. Study (58% of the participants). It gives priority to patients whose treatment will yield the most scientifically useful information. For example, during the years when kidney dialysis was still scarce in the United States, a hypothesis surfaced that dialysis might alleviate the mental disorder schizophrenia as well as replace kidney function. Under such circumstances, a progress of science criterion favors treating patients who have both medical needs. Because the same number of people will be treated with or without the criterion, it is arguably best to learn as much as possible, through careful patient selection, about the full beneficial potential of a scarce resource.

On the other hand, many of the shortcomings of a social value criterion also apply to a progress of science criterion. For example, the pragmatic difficulties of identifying precisely which patients or groups of patients, if treated, will yield the most important scientific information loom large. So does the coercion inherent in the experimentation

(with possible added tests or procedures) the criterion entails. Those eligible for priority treatment must either consent or risk a lower priority of being treated—which could mean substantial suffering or even death. Ultimately the criterion may not really be necessary, because patients with scientifically interesting conditions are usually selected through the application of other criteria. Such patients can volunteer for any special tests or procedures, and data on those patients can be pooled in a central location.

Favored group. According to a favored-group criterion, people of a certain type (e.g., children or military veterans) or who live within certain geographic boundaries receive priority. Much of healthcare operates on this basis, both for the sake of convenience and in order to enhance the quality of care for particular groups. Such justifications become problematic, however, when resources are limited and people who are denied care at a particular facility on the basis of this criterion cannot always obtain it in a different location. Accordingly, only 27 percent of the participants in the U.S. Study supported it.

On the other hand, some rationales for this criterion are more strictly medical and may apply to any patient. For example, when either patients receiving treatment and follow-up care or perishable resources such as transplantable organs must travel long distances, medical outcomes may suffer considerably. If medical considerations are central, though, then at issue is really some form of medical criterion, not one's group identity per se. Moreover, it is arguably better to try to remedy barriers to treatment—for example, by relocating people nearer to a treatment facility—than to employ barriers as grounds for denying treatment.

In certain cases, a very different favored-group justification is at work. A group, even an entire state or country, should arguably have the freedom to produce special resources available only to its own members, as long as the resources available to others are not thereby limited. In practice, though, such is rarely the case. Consider organ transplantation. Because the supply of organs itself is limited, giving some people special access means less access for others. Moreover, neither a particular U.S. state nor the country as a whole can claim all the credit for developing every aspect of the technology required. Accordingly, some have proposed eliminating geographic boundaries or at least implementing regional or national quota systems that would establish priorities without completely excluding any group (Task Force).

Resources required. A resources-required criterion received somewhat more support (66% of the participants in the U.S. Study) than the preceding social criteria. It prioritizes treating those who need less of a given resource before patients who need more of it, though it is usually restricted to situations in which its application will likely increase the number of lives saved. Saving lives is a central task of healthcare and a praiseworthy goal from most philosophical and religious perspectives. The requirement of a greater lifesaving potential most clearly distinguishes the criterion from a more general social value criterion. Usually only patients requiring substantially fewer resources than other patients are favored by the criterion. For instance, patients needing temporary rather than long-term use of a scarce drug receive priority, as do patients needing a single-organ rather than multiple-organ transplant. The criterion is not designed to bias patient selection automatically against patients who have previously been treated for the same problem, such as those whose failing organ transplants must be replaced.

A resources-required criterion can be criticized as too attentive, or not attentive enough, to maximizing good results from treatment. It is too attentive if the life-threatening needs of each patient requiring a particular treatment should receive equal weight regardless of the overall number of lives saved. It is not attentive enough if many characteristics of people should be considered other than whether or not they will survive. From this latter perspective, saving the life of one outstanding person could be preferable to saving two who are not.

Vital responsibilities. According to 69 percent of the participants in the U.S. Study, a vital responsibilities criterion has a legitimate role in microallocation decisions. Intended for exceptional situations only, this criterion accords special priority to patients on whom others depend. The broadest form of the criterion favors any patient who has *family dependents.* Generally, though, there must be some sort of unusual social need that requires special treatment for particular people. In a disaster situation, for example, treating those with medical expertise first may make it possible for them in turn to save additional lives. As in the case of a resources-required criterion, the strictest form of the vital responsibilities criterion requires more than producing general social value: Additional lives must be saved every time the criterion is applied.

Without this lifesaving requirement, the criterion is merely a specific type of social value criterion and therefore open to all of the critiques to which that criterion is vulnerable. Invoking the criterion to favor patients with family dependents is particularly problematic because not everyone has equal access to having children. In some cultures, moreover, sustaining the life of one who has not yet maintained the family name by having children is more important than treating one who already has children. On the other hand, if the pursuit of general social value in

microallocation decisions is ethically legitimate, then allowing a vital responsibilities criterion to apply only when additional lives are saved by it is unduly restrictive.

SOCIOMEDICAL CRITERIA. Three other microallocation criteria—age, psychological ability, and supportive environment—are similar to the social criteria, in that they generally seek to promote some social good. They are distinctive, however, in that their stated justifications are often medical in nature, and they are therefore known as sociomedical criteria.

Age. Old age has long been employed as a reason for limiting medical treatment on the basis that elderly people do not sufficiently benefit from it because of their weakened physical condition. At issue may be the likelihood of benefit, the length of benefit, or the quality of benefit. So it is not surprising that 88 percent of the participants in the U.S. Study supported an age criterion to some degree.

In response to book-length justifications of an age criterion that addresses far more than aspects of medical benefit (e.g., Callahan; Daniels), a wide body of literature has emerged (e.g., Homer and Holstein; Walters; Thomasma; Hansen and Callahan). Some supporters of the criterion favor younger candidates for treatment over older candidates in order to give all an equal opportunity to live. A healthcare system, first of all, should keep people from dying "early." Others argue that whereas all people may have an equal claim upon available healthcare resources, that claim diminishes once people have achieved their so-called natural lifespan (perhaps seventy-five or eighty years). Furthermore, were people themselves given the choice, they might prefer to concentrate life-sustaining resources in their earlier years if that would make possible better long-term and supportive care in their elderly years.

Those who reject an age criterion find all such justifications unconvincing. Medical justifications arguably support medical criteria rather than a criterion based on age per se. Equal regard for persons appropriately focuses on persons as a whole—persons who should receive needed healthcare whenever that need occurs—rather than on persons as accumulations of life years, the number of which is to be maximized in the name of equal opportunity. Limiting equal access to people who have not yet lived their natural lifespan, meanwhile, relies on the debatable notion that there is a fixed natural lifespan. Moreover, it imposes on older people the judgment that, relatively speaking, their lives are not worth living, even if they disagree. (At least such is the case if age per se, rather than quality or length of life, is at issue.) Finally, if given a choice, people might well prefer criteria other than age for allocating limited resources. They would likely recognize that in people's actual experience, they would not be denying certain forms of healthcare to their own older selves, but rather the rest of the community would be denying needed life-sustaining care to a certain group of its members. This denial is more discriminatory than it may at first appear, because the group denied is not only old but also largely female (Jecker).

In the end, all rationales for limiting healthcare for elderly persons are often suspected of being fueled, at least unconsciously, by a utilitarian preference for the achievement and economic productivity more characteristic of younger persons. Not only is the unbounded pursuit of social value itself controversial, but the economic productivity orientation of that pursuit also reflects the questionable bias of Western culture toward productivity even at the expense of personal relationships (Kilner, 1992).

Psychological ability. In the U.S. Study, 97 percent of the participants acknowledged that psychological ability plays at least some legitimate role in allocation decisions. The ability of patients to cope emotionally and intellectually with treatment is commonly assumed to be essential to effective healthcare. Without this ability, patients are unable to follow medical instructions and may even reject treatment or life itself after considerable resources have been expended. Such patients are the most difficult to treat and tend to be the least valuable to society.
