A key historical puzzle is why the notion of care has not become better known and has not exerted more influence in ethics, in view of its highly significant, if somewhat limited, history. The answer lies, in part, in the fact that care has always been a minority tradition of thought and practice. As this survey exemplifies, care is a deeply engaging emotion/idea that has confronted and challenged rationalist, abstract, and impersonal systems of thought, with far-reaching social, political, ethical, and religious implications. In this sense, care has had a countercultural role.

More recently, care may be acquiring a "mainstream" importance, especially in the area of the ethics of healthcare. The following two entries will show how some elements in the history of the idea of care have become ingredients in an emerging ethic of care in the context of healthcare, while other historical elements have been overlooked.

All ethics assumes a vision of the human condition. The ethics of care rests on a vision of the capacity to care or be concerned about things, persons, a whole life-course, a society, one's self. The history certainly is not compatible with reducing care to caregiving. The Myth of Care suggestively offers a care-based genealogy of morals that is deeply ingrained in human psychology, anthropology, religion, and altruistic service. The philosophical and psychological developments in the idea of care have built on this basic vision of being well cared for. That the history of the idea of care also suggests many practical ideas—for example, the call and the limits of taking care of others; dealing with the negative side of care; and the intergenerational function of care—makes it all the more useful for a contemporary ethic of care.

II. HISTORICAL DIMENSIONS OF AN ETHIC OF CARE IN HEALTHCARE

In the context of healthcare, the idea of care has two principal meanings: (1) taking care of the sick person, which emphasizes the delivery of technical care; and (2) caring for or caring about the sick person, which suggests a virtue of devotion or concern for the other as a person. At times these

two aspects of care have been united; at other times they are in conflict.

Taking Care of: Competent, Technical Care

When speaking of the medical aspects of "taking care of" the patient, one often uses the language of taking good care, or receiving appropriate care. This practical vision of care can be viewed historically from the perspectives of medical competence and technical excellence. The Greek demigod Asklepios, because of his reputation for competence, became the "patron of human healers" (Jonsen). The virtue that motivated the physician of classical Greece was *philotechnia,* or love of the art (May, 1983; Laín Entralgo). In the Greek tradition, "the love of technical skill included not only an appreciation of the good which the application of that skill might achieve but also a kind of natural piety that recognized the limits of the art" (May, 1983, pp. 92–93). The ethic of competent care can also be called a Hippocratic ethic, after Hippocrates (c. 460–378 B.C.E.), the "father of medicine." One phrase in the Hippocratic oath—"I will act for the benefit of my patient according to my ability and judgment"—implies the imperative of the competent practice of the art of medicine (Jonsen). Under these historical influences, competence, "in the sense of a disciplined understanding of the science and skilled manipulation of the art [of medicine]," was regarded as the first virtue of medical care at least through the seventeenth century (Jonsen, p. 22).

In modern times, competence has become the essential and comprehensive virtue of medicine; medical practice and education came to emphasize ever-more-complete scientific knowledge and ever-more-competent clinical performance. This demanding standard of competence in turn fueled a drive toward biomedical excellence and deepened the sense of meaning and pleasure gained from practicing the art of medicine (May, 1983; Jonsen).

At the turn of the twentieth century, as medical competence focused more and more intently on the principles of pathophysiology and factual diagnostics, medical "care" came to be defined by objective data. Clinical and laboratory efforts to comprehend, apply, and evaluate medical data led physicians increasingly to divorce the disease from the patient, thus marginalizing personal care. The desire for liberation from the sometimes oppressive consequences of emotional involvement in "caring for" the person who is in critical condition may have contributed to this trend. As increased technical expertise raised expectations of what "taking care" should mean, legal and ethical requirements of "due care" spelled out the criteria for medical care, prompting clinicians to focus even more on the technical ideal of competence in "taking care of the sick" (Annas).

By the 1920s, competent care was becoming the moral meaning of "taking care of" the patient. Richard C. Cabot (1868–1939), a renowned professor at Harvard Medical School, articulated and championed this new ethic of competence. The humanistic virtue of "caring for" the patient was quickly pushed to the periphery of medicine, for that sort of care was viewed as bearing no apparent relation to the highly esteemed "hard data." This narrowing of the notion of care placed medical ethics in crisis (Jonsen).

Caring for the Sick Person

While "taking care of the patient" in competence had been pushing "caring for" the patient to the periphery of medical concerns, "caring for" the patient received a major impetus at Harvard during the 1920s. This section will consider what altruistic terms and virtues "caring for" replaced, why they had lost their meaning, an account of the onset of the term *caring for,* and its meaning in healthcare prior to 1982.

The moral term *caring for* was turned to at a time when the altruistic virtues that had shaped the care of the sick for centuries had lost much of their luster, particularly terms like hospitality, philanthropy, charity, love, and sympathy.

For example, hospitality, which meant the friendly and cordial taking in of strangers or travelers, had enormous influence as an altruistic virtue for healthcare; it was a model in rabbinic Judaism, early Christianity, and Islam (Exod. 23:9). Christianity had transformed hospitality from a private into a public virtue of mercy and beneficence that was often directed to the sick stranger (Bonet-Maury). Hospitality prompted establishment of travelers' inns, which evolved into hospices where healthcare was sometimes provided, and eventually to hospitals, especially in the Byzantine East but also eventually in the Latin West (Miller). But by the 1920s, this religious term had lost its force; even Christians no longer spoke of hospitality as a major public virtue motivating healthcare.

Philanthropy had, for centuries, been a dominant altruistic motive for "caring for" the sick in most religious traditions, but it has virtually disappeared from the moral sphere of healthcare. The ideal of philanthropy (from the Greek *philanthropos,* meaning humane or benevolent) encouraged a love of humankind that expressed itself in concrete deeds of service to others. Philanthropy, associated with the Christian ideal of charity, made it possible for the sick person to assume a preferential position in society (Sigerist) and motivated the establishment of hospitals starting in the fourth century in the East, until modern times in the West. The ideal of philanthropy also appeared strongly in the first code of medical ethics, adopted by the American

Medical Association in 1847. But by the 1920s, professional philanthropy, from which modern professionals had derived much of their authority and prestige, had lost much of its respect, and the significance of the word *philanthropy* had been reduced to its meaning of private (and to some extent, public) support of the arts, education, and research (May, 1983, 1986).

Sympathy and compassion have exerted a strong public influence on caring for the sick in times past, in particular by motivating the sensitivities of individual medical practitioners. Codes and oaths have exhorted health practitioners throughout the ages to care for the sick out of motives of compassion and sympathy. John Gregory (1724–1773) spoke of the sensibility of heart that makes us feel for the sick and arouses in us the desire to relieve their distresses. Use of the word *sympathy* to motivate personalized medical care appeared commonly right up to the 1920s and beyond. But the word *sympathy* lost its effectiveness as it often came to be regarded as the condescending manifestation of pity; the word *compassion* was looked on with some disfavor as it came to suggest too much identification with the suffering person.

In addition, there is an overarching reason why the previous caring virtues were discounted, leaving room for the new, secular term of care. In criticizing ecclesiastical institutions in the eighteenth century, Enlightenment thinkers denounced charity for the sick and philanthropic hospitals because these activities were tainted by the essentially self-centered gifts and legacies of pious people who sought to atone for their sins by acts of charity in support of the hospitals. Eighteenth-century rationalists emphasized that the poorly organized philanthropic hospitals of Christian Europe did little to help the sick get well; and some Enlightenment thinkers blamed the very concept of Christian charity for these abuses. Furthermore, Christian charity was regarded as too closely linked to dead traditions and blind superstitions to have a close relationship with science (Locke). The attempt by some philosophers in the eighteenth, nineteenth, and twentieth centuries to base an altruistic care of the sick on a secular notion of sympathy was, in part, a result of these developments.

By the 1920s, the secular term *care* had begun to replace the earlier altruistic terminology. By this time, the history of the idea of care had progressed to the point that the term was coming to be known for its moral implications. In addition, *care* had special appeal as a virtue for healthcare because the same word had—for centuries and in a variety of languages—been the descriptive term for "taking care of" sick people. It should be no surprise, then, that for a number of decades prior to 1982—when the idea of care began capturing widespread contemporary attention—there appeared a small body of literature in the clinical ethics of physicians and nurses as well as in religious medical ethics that focused attention on the moral meaning and practice of care, as well as on an ethic of care.

"Caring for" in Clinical Medical Ethics, 1920–1982

In championing the fast-developing technical art of medicine, Richard C. Cabot acknowledged and seemed to acquiesce in the fact that doctors and nurses were not caring for the whole patient: Their attention was "too strongly concentrated" on the difficult tasks of diagnosis and treatment, and "there is not enough attention left to go round" (Cabot, p. 16). He was certainly in favor of manifesting courtesy and patience with sick people; but under some conditions, he said, it is not advisable for the physician to care for anything but the patient's body; and when care for the whole person is desirable, others—medical students, social workers, and even ministerial students—can suitably offer that kind of care (Cabot). To carry out his purpose of designating surrogates who would "care for" the patient, Cabot was instrumental in establishing the professions of medical social work and clinical pastoral care.

The following year, Francis Peabody, a physician-professor colleague of Cabot at Harvard, offered the opposite point of view. "Caring for" the patient is essential to the practice of medicine, he argued; physicians must engage in this sort of care in order to achieve the goals inherent in medicine. His 1927 essay "The Care of the Patient" is one of the foundation stones of an ethic of care in twentieth-century medicine in the United States (Peabody).

Peabody acknowledged that the "enormous mass of scientific material" to which a young doctor must be exposed, the depersonalized aspects of modern hospital practice, and physicians' bias toward organic disease could jeopardize the personal aspects of the art of medicine. To remedy these problems, he urged the physician to form and be attentive to a personal relationship with the patient and with the patient's "environmental background." The treatment of a disease, which may be impersonal, "takes its proper place in the larger problem of the care of the patient" (p. 396), which "must be completely personal" (p. 389). His oft-quoted principle was: "One of the essential qualities of the clinician is interest in humanity, for the secret of the care of the patient is in caring for the patient" (p. 401).

The physician must be attentive to particular circumstances of the patient, "not from the abstract point of view of the treatment of the disease, but from the concrete point of view of the care of the individual" (p. 398). Peabody was

clearly attempting to exonerate the usefulness—indeed, the necessity—of care in the practice of good clinical medicine when he argued that neglect of careful attention to the true situation of the whole patient, including functional disorder, jeopardizes diagnosis, treatment, and effectiveness of care. Furthermore, the mere caring effort in the relationship with the patient, aside from drugs or other treatments, can help patients get well. This sort of care requires attentiveness and alertness to what kind of a person the patient is; sympathy for the patient's total situation; friendliness that elicits trust; and a consideration expressed in "little incidental" actions that assure the patient's comfort—which may require that the physician learn much from the nurse regarding practical care and comfort of the patient.

Following Peabody's clarion call for care in 1927, several physicians, writing in the 1960s and 1970s, advocated a caring perspective in professional attitudes, practices, and moral analysis in medicine. The starting point that convinced these writers of the need for "caring for" was the depersonalization of medical care in hospitals. Clinical care oriented to the disease in the body leads caretakers to allow technical considerations to dominate, avoid death at any cost, and ignore patients' preferences; this produces indignities for patients and suffering for caregivers (Benfield).

The concept of caring is defined in the literature of the 1960s and 1970s as implying a broader concern for the whole patient, or for the quality of the patient's life, rather than just for the patient's disease (Menninger; Benfield). Caring involves sympathy with the patient, which entails entering into or sharing the feelings of the patient. To prevent loss of objectivity and perspective, "compassionate detachment" (Blumgart, p. 451) is recommended, which is "to sense the patient's experience empathically without becoming so involved sympathetically that the physician's rational and effective clinical judgment is impaired by emotional involvement" (Menninger, p. 837).

Caring for the patient embraces both the science and art of medicine; both are oriented to the patient, and both should meet in the individual physician (Blumgart). A caring solicitude for the individual patient is integral and essential in the practice of clinical medicine (Tisdale); failure to practice caring medicine leads to incomplete or inaccurate diagnosis and ineffective treatment (Blumgart). On the other hand, patients manifest care-seeking behavior (Tisdale). Receiving the sought-for care can be crucial for the patient's "adaptation to various maladjustments, including illness" (Menninger, p. 836). The role of the physician and other healthcare providers in our society is one of a surrogate caregiver, who has the power to give attention to the ill and excuse them from the performance of everyday duties (Menninger).

There are several obstacles to caring in medicine. The demands of the scientific and technological aspects of medicine, combined with physicians' fascination with disease, achieve great progress for humankind but tend to block out compassionate attention to suffering and the particular needs of the ill individual who has the disease. In addition, patients and families are reluctant to communicate their feelings with health professionals, who are too busy monitoring the patient's physical condition to listen. Other factors that obstruct person-oriented caring are (1) lack of teamwork among healthcare providers, coupled with overemphasis on the physician's hierarchical authority; (2) caregivers' feelings of inadequacy due to lack of training in caring for critically ill or dying patients and their families; and (3) time pressures on health professionals (Blumgart; Benfield).

Acts of caring, some of which counteract the obstacles to caring, include: listening to patients with personal attentiveness, particularly as a history-taking technique that enables patients to relate their experiences in terms of their own values and concerns (Tisdale; Blumgart); being attentive to both the physical and the emotional components of illness (even though medical education and practice tend to focus on the physical—in fact, all medicine is psychosomatic, since the emotional and bodily factors always interact in every disease) (Blumgart; Menninger); and offering maximum understanding, freedom, and support to the individual patient (Tisdale).

Caring is also expressed through acting as companion to a bereaved family; solicitous communication regarding the nature of the illness and its expected course; sharing the patient's and family's responsibility and agony of deciding whether to continue care; relieving the patient of suffering from pointless dehumanizing treatment; and caring for caretakers who suffer the stress of the combined roles of technical caregiver and concerned caregiver (Benfield).

William Tisdale, writing in 1979, contended that modern medical ethics, with its concern for "the neon problems" of high controversy, is ill-adapted to account for an ethic of care. Because clinical caring pertains to the usual and the commonplace in medicine, it is more difficult to isolate and analyze. William Tisdale appealed for an inquiry into the unresolved and even the unrecognized problems inherent in basic clinical care and the problems inherent in care that are more demanding from an ethical perspective than the usual moral quandaries in medicine. In formal ethical terms, Tisdale saw clinical caring as characterized by the ideals of love and charity and as a form of duty beneficence, a duty to benefit others apart from special relationships and responsibilities. Making certain that expected benefits of a particular

procedure outweigh the definite risks is a characteristic of caring for one's patients.

In the highly influential book published in 1970, *Patient as Person,* Paul Ramsey linked care with "covenant fidelity," which he saw as the appropriate norm for the relationship between physician and patient. Covenant fidelity always requires care, which is directed to the person of the patient. But at the end of life, when attempts to cure are no longer appropriate, one must always care even if one only cares—through keeping company and offering comfort—while permissibly withdrawing medical care.

Caring for the sick, the wounded, and the troubled has been characterized through the centuries by altruistic motives and virtues. By the 1920s, an interest had arisen in the virtue of care as the basic moral orientation to healthcare, based in feelings for the other. Practitioners felt that care could provide the grounding for the moral practice of healthcare and for mitigating some of the excesses of medical technique. Still, very little by way of a formal ethic had arisen.

Caring in Nursing Theory, Philosophy, and Ethics

It required the intellectual and moral energy of feminist perspectives on care in the 1980s to establish a noteworthy movement promoting an ethic of care that reached deep into the field of bioethics.

Nursing theorists, educators, and philosophers explored and applied a more extensive theory and ethic of care prior to 1982 than any other single group had. Their contributions differed considerably from those of physician-writers: The nursing theorists paid much more attention to the meaning and theories of nursing, examined the structures and functions of care, turned occasionally to philosophers who had explained the meaning of care (such as Martin Heidegger and Milton Mayeroff), developed the implications of care for nursing practices and skills, considered the status of caregivers, showed an interest in the historical links between nursing and maternal care, and proposed educational improvements to foster professional care.

The strongest impetus for an examination of the role of caring in nursing came from Madeleine Leininger, who has organized national conferences on caring and published on the topic (1981). Leininger was one of the pioneers who fostered the idea that caring is the essence of nursing and the unique focus of the profession. Leah Curtin went a step further when she claimed that the distinctiveness of nursing cannot be located in functions, but in "the moral art of nursing," in its primary moral conviction, by virtue of which nurses "are committed to care for, as well as to the care of, other human beings" (p. 26).

Nursing theorists offer a variety of definitions of care: for example, the explanation that caring in nursing is a process in which one shows "compassionate concern for the individual" (Gaut, in Leininger, 1981, p. 18). Leininger suggests this definition of professional nursing care: "those cognitively learned humanistic and scientific modes of helping or enabling an individual, family, or community to receive personalized services through specific culturally defined or ascribed modes of caring processes, techniques, and patterns to improve or maintain a favorably healthy condition for life or death" (1981, p. 9). This definition includes concepts of compassion, concern, nurturance, stress alleviation, comfort, and protection.

The precise historical origins of a concern for caring in nursing are unclear, but a number of authors trace them to the writings of Florence Nightingale. However, nurse theorists have relied not so much on a history of care in nursing as on the writings of social scientists and existentialists such as Buber, Erikson, and Rogers (Gaut, in Leininger, 1981).

Why did nursing theorists turn so strongly to the idea of care in the 1970s? Marilyn Ray explains that as nursing became increasingly technological, bureaucratic, managerial, and supervisory, nurses began experiencing a struggle relative to their central focus as a "direct caring profession" (Ray, in Leininger, 1981, p. 28). Barbara Carper (1979) answers the question by mentioning two factors that have had the effect of eroding care in health generally, not just in the experience of nurses: depersonalization of healthcare due to the fragmentation of specialized treatment, the subdivision of tasks, and highly institutionalized bureaucracy; and technological progress and technical expertise, which she saw as having the potential of overshadowing individuals, "reducing them to objects or abstractions" (p. 13). Within such a system, even when competent, scientifically based care is delivered, it "is often perceived by the client as lacking the 'personally experienced feeling of being cared for'" (p. 13, quoting Menninger, p. 837). This depersonalization of the individual entails the devaluing and loss of identity of the individual. She sees a compelling metaphor for the relationship of technology to care in the novel in which Dr. Frankenstein created a monster. Frankenstein's tragedy was not due to his scientific triumph over nature, but "his *failure to care* for what he had created. He was unable to recognize or experience the humanness of another's self" (Carper, p. 13).

Finally, even prior to the emergence of an ethic of care in other disciplines, nurses were already applying the idea of care both to nursing practice and to nursing ethics. For example, Carper argued that caring is the most essential

ingredient in the curative process, because caring acts and decisions "make the crucial difference in effective curing consequences" (Carper, p. 14, quoting Leininger, 1977, p. 2). Anne J. Davis stimulated reflection on the relationship between caring and ethical principles in the context of taking care of the dying. She contrasted the compassionate meaning of care (to undergo with, to share solidarity with) with the technical terms *nursing care* or *medical care.* She argued that situations of serious illness and dying call for putting aside the instrumental meaning of caring and instead manifesting "the most demanding and deeply human aspect of caring: the expressive art of being fully present to another person" (p. 1). A caring attitude would incline the nurse not to turn away from the stranger's world of suffering, but to appreciate the other person's independent existence and enter into and share his or her pain as much as possible. Caring for the sufferer is an ethical obligation inherent in the health professional's role. But caring transcends role obligations: It acknowledges the vulnerable humanness of the other and reinforces the caring of the one who cares. Ethical principles are not at variance with care: They provide specific judgments in the context of caring for another person. A caring disposition inclines caregivers to respect the patient as an autonomous agent and to recognize the patient's considered value judgments, even if they go contrary to what the clinician expects.

The foregoing presents a few indications of the pioneering work in nursing care theory and ethics in the 1970s. As the following entry indicates, the ethics of nursing care expanded considerably after the notion of care came to be more widely acknowledged through the writings of women social scientists.

III. CONTEMPORARY ETHICS OF CARE

A major contemporary impetus to scholarly discussions of caring occurred with the 1982 publication of Carol Gilligan's *In a Different Voice: Psychological Theory and Women's Development.* Nursing theorists—and, to a lesser extent, physicians—were exploring moral dimensions of caring prior to the publication of Gilligan's work; but her book led, for the first time in the history of the idea of care, to widespread efforts to develop a systematic philosophical ethic of care beyond the world of healthcare practitioners.

Contemporary Elements of an Ethic of Care

In a Different Voice begins by contrasting the primary moral orientation of boys and men with the primary orientation of girls and women. Gilligan proposes that females and males tend to employ different reasoning strategies and apply different moral themes and concepts when formulating and resolving moral problems. According to Gilligan's analysis, females are more likely than males to perceive moral dilemmas primarily in terms of personal attachment versus detachment. From this perspective, which she dubs the *care perspective*, central concerns are to avoid deserting, hurting, alienating, isolating, or abandoning persons and to act in a manner that strengthens and protects attachments between persons. In this analysis, the moral universe of girls and women tends to be primarily "a world of relationships and psychological truths where an awareness of the connection between people gives rise to a recognition of responsibility for one another, a perception of the need for response" (p. 30). For example, Amy, an eleven-year-old girl whom Gilligan interviews in her book, describes herself in terms of her connection with other people: "I think that the world has a lot of problems, and I think that everybody should try to help somebody else in some way …" (Gilligan, p. 34).

By contrast, Gilligan argues that the primary moral orientation of men and boys tends to focus on moral concerns related to inequality versus equality of individuals. Rather than emphasizing the importance of sustaining personal relationships, this approach emphasizes abstract ideals of fairness and rights, and requires abiding by impartial principles of justice, autonomy, reciprocity, and respect for persons. Viewed from this perspective, which Gilligan refers to as the *justice perspective*, moral dilemmas are defined by hierarchical values and impersonal conflicts of claims. The moral agent, like the judge, is called upon to "abstract the moral debate from the interpersonal situation, finding in the logic of fairness an objective way to decide who will win the dispute" (p. 32). To illustrate justice reasoning, Gilligan describes the moral reasoning of Jake, an eleven-year-old boy interviewed for her book. Asked how he would resolve a conflict between responsibility to himself and other people Jake answers, "You go about one-fourth to the others and three-fourths to yourself," and adds that "the most important thing in your decision should be yourself, don't let yourself be guided totally by other people …" (p. 35–36). Gilligan concludes that Jake understands this moral dilemma as an abstract mathematical equation and perceives his responsibility for others as potentially interfering with his personal autonomy.

Gilligan, a developmental psychologist, argues that an ethic of care has been generally ignored in the past because girls and women have been excluded as subjects in the study of moral development. For example, accounts of moral maturation described by Lawrence Kohlberg (1981, 1984) and Jean Piaget were based entirely on studies and observations of boys and men. These male-based theories of moral psychology, when applied to girls and women, were interpreted as showing girls and women to be deficient in moral development. Gilligan identifies an ethic of care as a distinctive form of moral reasoning.

Implications for Ethics of Healthcare

The implications of Gilligan's analysis for contemporary bioethics are the subject of ongoing discussion. First, an ethic of care may lead to positive changes in bioethical education, including placing greater emphasis on healthcare providers' communication skills and emotional sensitivity, and on the effects that ethical issues have on relationships (Carse). To the extent that bioethicists with formal training in ethics are inclined to emphasize justice over care, it may be desirable to broaden their training to include an ethic of care (Self et al.).

In addition to producing changes in ethics education, a care orientation within bioethics arguably requires placing

greater emphasis on beneficence as the healthcare provider's primary responsibility to the patient (Sharpe). Finally, an ethics emphasizing caring for others may produce substantive changes in the way we resolve moral problems. It may encourage resolutions of moral problems that give greater authority to family members in healthcare decision making (Hardwig, 1990, 1991; Jecker, 1990), or it may lead to paying greater attention to how various relationships are affected by moral decisions (Jecker, 1991).

One area within bioethics where an ethic of care has been studied in some detail is abortion. Gilligan found that women who face abortion decisions tend to frame moral issues in terms of a responsibility to care for and avoid hurting others. These women often base decisions about having an abortion on "a growing comprehension of the dynamics of social interaction … and a central insight, that self and others are interdependent" (p. 74). In other words, rather than conceptualizing abortion in terms of abstract values, such as *life,* or in terms of competing claims or rights, these women tend to see abortion as a problem of how best to care for and avoid harming the particular people and relationships affected by their choices. Considered in this light, the resolution of abortion requires taking stock of how any decision might affect not only the pregnant woman and fetus, but also the relationship between the pregnant woman and biological father, and relationships and persons within the wider family circle (Jecker, 1999). Arguably, an ethic of care illuminates the moral issues abortion raises better than an ethic of justice, because only an ethic of care portrays individuals as uniquely constituted by their connections to others (Gatens-Robinson).

In addition to these proposed changes, introducing a care orientation within bioethics may shed a negative light on more traditional forms of bioethical analysis (Carse). For example, Virginia Sharpe claims that a justice orientation has dominated bioethics in the past, and this has encouraged ethicists to treat provider–patient relationships as free exchanges between equals. She argues that this picture of the provider–patient relationship is seriously distorted. Rather than being equals in relationships with healthcare providers, patients typically experience diminished power and authority as a result of being physically and emotionally vulnerable and in need of the provider's help (Sharpe). Others charge that a justice orientation has traditionally prevailed within bioethics, resulting in too much focus on competition for power, status, and authority and too little focus on the human relationships at stake (Warren). For example, the autonomy–paternalism debate within bioethics concentrates on who has the authority to make treatment decisions. Similarly, when bioethicists emphasize impersonal ethical principles, such as autonomy, nonmaleficence, beneficence, and justice, the particular persons and relationships involved in ethical dilemmas can become incidental, rather than essential, to the crafting of moral responses.

Feminist versus Feminine Ethics

Gilligan's ongoing effort (Gilligan et al., 1988; Gilligan et al., 1989; Brown and Gilligan) to characterize the moral reasoning of girls and women in terms of care has occurred in tandem with important developments in feminist ethics. It is useful, however, to distinguish between the care ethic that Gilligan describes, which has been called a *feminine ethic,* and the development of *feminist ethics.* According to Susan Sherwin, the primary concern of feminine ethics is to describe the moral experiences and intuitions of women, pointing out how traditional approaches have neglected to include women's perspectives.

In addition to Carol Gilligan, both Nel Noddings and Sara Ruddick have made important contributions to feminine ethics. Whereas Gilligan emphasizes the unique form of moral reasoning that caring engenders, Noddings focuses on caring as a practical activity, stressing the interaction that occurs between persons giving and receiving care. From this perspective, she identifies two distinctive features of caring: *engrossment* and *motivational shift.* Engrossment refers to a receptive state in which the person caring is "receiving what is there as nearly as possible without assessment or evaluation"; motivational shift occurs when "my motive energy flows towards the other and perhaps … towards his ends" (Noddings, 1984, p. 33, 34). Critics of Noddings's approach raise the concern that her interpretation of caring may lead to exploitation (Houston) or complicity in the pursuit of evil ends (Card, 1990).

Unlike Gilligan and Noddings, Ruddick emphasizes *maternal thinking,* which she says develops out of the activity of assuming regular and substantial responsibility for small children. Although Ruddick acknowledges that the work of mothering falls under the more general category of *caring labor,* she argues that it cannot simply be combined with other forms of caring because each form of caring involves distinctive kinds of thinking arising from different activities (Ruddick). Ruddick delineates maternal thinking as a response to the small child's demands for preservation, growth, and acceptability. These demands elicit in the mothering person the responses of *preservative love, fostering growth, conscientiousness,* and *educative control,* which Ruddick identifies as the hallmarks of maternal thinking.

In contrast to feminine ethics, the primary concern of feminist ethics is to reject and end oppression against women. Susan Sherwin defines *feminist ethics* as "the name given to the various theories that help reveal the multiple,

gender-specific patterns of harm that constitute women's oppression," together with the "diverse political movement to eliminate all such forms of oppression" (p. 13). By *oppression,* Sherwin means "a pattern of hardship that is based on dominance of one group by members of another. The dominance involved … is rooted in features that distinguish one group from another" and requires "exaggerating these features to ensure the dominant group's supremacy" (p. 24). Feminism aims, in this interpretation, to show that the suffering of individual women is related because it springs from common sources of injustice. According to Rosemarie Tong, feminist ethics is typically far more concerned than feminine ethics with making political changes and eliminating oppressive imbalances of power (1993).

In many respects, however, feminine and feminist ethics are interrelated. The careful study of women's lives and moral reasoning that feminine ethics undertakes can contribute substantially to dismantling habits of thought and practice that enable women's oppression to continue. Both feminine and feminist ethics share the goal of adding women's voices and perspectives to various fields of scholarly inquiry. Finally, as Ruddick notes, feminist ethics can lend important support to the ideals that feminine ethics upholds. For example, feminist ethics can help to ensure "women's economic and psychological ability to engage in mothering without undue sacrifice of physical health and nonmaternal projects" (p. 236).

Objections to an Ethic of Care

Since the publication of *In a Different Voice,* the proposal to develop a feminine ethic of care has met with a variety of concerns and objections. One set of concerns is that a feminine ethic of care may unwittingly undermine feminism. These concerns stem, in part, from a belief that the qualities in girls and women that feminine ethics esteems have developed within the context of a sexist culture. Thus, some suspect that women's competency at caring for and serving others is an outgrowth of their subordinate status within modern societies (Sherwin; Moody-Adams), and worry that emphasizing caring as a virtuous feminine quality may simply serve to keep women on the down side of power relationships (Holmes). Susan Moller Okin, for example, cautions that women are often socialized from a very early age into strict gender roles, involving caring for and serving others. This socialization radically limits their future prospects by diminishing women's capacity to choose alternative life plans. We should therefore reject traditional socialization, because it seriously violates the equality of persons basic to liberalism. Others urge women to aspire to assertiveness, rather than caring, in order to challenge conventional images of women as concerned with serving and pleasing others (Card, 1991). Feminist critics also warn that caring cannot function as an ethic that is complete unto itself. Observing that caring can "be exploited in the service of immoral ends" (Card, 1990, p. 106), Card insists on the need to balance caring with justice and other values. Exclusive attention to caring can also lead to overlooking "the lack of care of women for women" and may preclude "the possibility of our looking at anything but love and friendship in women's emotional responses to one another" (Spellman, p. 216). Finally, excessive focus on caring at the expense of other values can blind us to the critical assessment of the object of caring. As Warren Thomas Reich noted in 2001, care by itself can be easily manipulated, and does not offer tools for analyzing the moral importance of what we care about.

In response, defenders of feminine ethics distinguish between *distorted* and *undistorted* forms of caring (Tong, 1998). Distortions of caring include the exploitation, abuse, or neglect of careers. As Tong notes, just because caring can become distorted does not suffice to show that an ethic of care is inherently distorted. Nor does it establish that "every woman's caring actions should be contemptuously dismissed as yet another instance of women's *pathological masochism* or *passivity*"; instead care should be preserved and celebrated in its undistorted form: "rescued from the patriarchal structures that would misuse or abuse it" (Tong, 1998, p. 171).

A second family of concerns about a feminine ethic of care relates to the belief that caring for others can lead to neglect of self. The phenomenon of *burnout,* for example, refers to the situation of parents, nurses, family caregivers, or other individuals who become utterly exhausted by the physical and emotional demands associated with giving care. Especially when care is conceived to be an ethic that is sufficient unto itself, the tendency may be to continue caring at any cost. Attention to other values, such as respect for the rights of the one caring, may be necessary in order to preserve the integrity of the caregiver: Arguing along these lines, Nancy Jecker notes that "if women are seen as having the same possibility men have to create a plan of life that places central importance [in activities other than caregiving] …, then a duty … [to care] can potentially stand in the way of what a woman wants to do" (2002, p. 128). The idea here is that individuals presumably prefer to protect, as much as possible, their freedom to choose whether or not to devote themselves to caring (2002). Others suggest that in order to care for others—which is an inherently limited ability—one must first be cared for by other individuals, by communities, and by oneself (Reich, 1991).

A third group of objections to developing a feminine ethic of care holds that the concept of care is not helpful at the social and institutional level. This group of objections may acknowledge that an ethic of care serves well within the limited sphere of personal ethics, but finds care unhelpful outside of this sphere. One form this objection takes is to argue that an ethic of care cannot be formulated in terms of the general rights and principles that are necessary for designing public policies. Proponents of a care ethic sometimes acknowledge this limitation. Thus, Noddings states, "to care is to act not by fixed rule but by affection and regard" (1984, p. 24). Similarly, Patricia Benner and Judith Wrubel maintain that caring is always specific and relational; hence, there exist no "context-free lists of advice" on how to care (p. 3). They reject the idea of formulating ethical theories or rules about caring on the grounds that general guides cannot "capture the embodied, relational, configurational, skillful, meaningful, and contextual human issues" that are central to an ethic of care (p. 6). Despite this view, there exist historically important examples of using the vocabulary of general rights and principles to formulate an ethic of care. For example, the UN's *Universal Declaration of Human Rights* identifies "motherhood and childhood" as "entitled to special care and assistance," and that organization's *Declaration of the Rights of the Child* asserts general principles of caring for children, noting that children need "special safeguards and care" on the basis of their "physical and mental immaturity."

Another reason why care may be assumed unworkable at a social or institutional level is that historically, public and private spheres have been distinguished as separate moral domains (Elshtain). During the nineteenth century, for example, the doctrine of separate spheres held that the family constituted a private sphere in which a morality of love and self-sacrifice prevailed; this private domain was distinguished from the public life associated with business and politics, where impersonal norms and self-interested relationships reigned (Nicholson). To the extent that these historical attitudes continue to shape present thinking, they may lead to the mutual exclusivity of care-oriented and justice-oriented approaches. In response to this structural objection, some ethicists have argued that justice and care are compatible forms of moral reasoning (Jecker, 2002).

A final set of objections to a feminine ethic of care does not deny the importance of care, but rather argues that care is not properly interpreted as an ethic that expresses an exclusively feminine form of moral reasoning. Iddo Landau, for example, argues that the significant factors for preferring the use of care or justice ethics are, in fact, not masculinity or femininity, but factors such as education and economic class. Landau concludes that "Justice and care ethics should be seen as the ethics of certain economic classes and levels of education, not of men and women" (p. 57). Defenders of feminine ethics often meet this objection by claiming that their approach has been misunderstood. Thus advocates of feminine ethics may deny that care is an ethic that only women articulate, or an ethic that is valid only within the moral experience of women. According to Noddings, caring is an important ingredient within all human morality, and moral education should teach all people how and why to care. She concludes that "an ethical orientation that arises in female experience need not be confined to women"; to the contrary, "if only women adopt an ethic of caring the present conditions of women's oppression are indeed likely to be maintained" (1990, p. 171). Gilligan and Jane Attanucci also reject the idea that an ethic of care correlates strictly with gender, and instead report that most men and women can reason in accordance with both care and justice. Gilligan's research supports the more modest claim that care is gender-related. That is, although women and men can reason in terms of both care and justice, women are generally more likely to emphasize care while men generally emphasize justice. Thus she states that the so-called different voice she identifies is characterized "not by gender, but by theme," and cautions that its association with gender "is not absolute" and is not a generalization about either sex (p. 2).

Caring and Contemporary Nursing

Within healthcare, attention to caring is perhaps most evident within nursing. Emphasizing caring as a central value within nursing often provides a basis for arguing that nursing requires its own description, possesses its own phenomena, and retains its own method for clarification of its own concepts and their meanings, relationships, and context (Jameton; Fry, 1989a, 1989b; Watson; Swanson; Reverby, 1987a, 1987b). For example, Jean Watson holds that nurses should reject the impersonal, objective models that she says currently dominate ethics and choose instead an ethic that emphasizes caring.

Those who invoke caring in developing a theory of nursing ethics often assign caring a privileged or foundational role. For example, Sarah Fry posits caring as "a foundational, rather than a derivative, value among persons" (1989b, p. 20–21). She argues that other ethical values, such as personhood and human dignity, are an outgrowth of nurses's caring activity. Similarly, Benner and Wrubel argue for the primacy of caring on the grounds that skillful technique and scientific knowledge do not suffice to establish ethical nursing in the absence of a basic level of caring and attachment.

Like Fry, Kristen Swanson regards caring as central to nursing ethics. According to her analysis, caring requires acting in a way that preserves human dignity, restores humanity, and avoids reducing persons to the moral status of objects. Specifically, caring requires:

1. knowing, or striving to understand an event as it has meaning in the life of the other;
2. being with, which means being emotionally present to the other;
3. doing for, defined as doing for the other as he or she would do for himself or herself if that were possible;
4. enabling, or facilitating the other's passage through life transitions and unfamiliar events; and
5. maintaining belief, which refers to sustaining faith in the other's capacity to get through an event or transition and to face a future of fulfillment.

Susan Reverby finds caring to be a central ethic throughout nursing's history. Tracing the history of nursing to its domestic roots during the colonial era, when nursing took place within the family, Reverby argues that caring for the sick was originally a duty rather than a freely chosen vocation for women. Reverby suggests that nurses today possess "some deep understandings of the limited promise of equality and autonomy in a healthcare system. In an often implicit way, such nurses recognize that those who claim the autonomy of rights often run the risk of rejecting altruism and caring itself" (1987a, p. 10).

Some have challenged the proposal to consider care as a foundational or unique concept for nursing ethics. Invoking a Nietzchean method of analysis, John Paley rejects the idea that caring is the *core* of nursing on the ground that it bears a striking resemblance to a *slave morality* and thus deteriorates into *a celebration of weakness*. He urges nursing to aspire instead to *noble values,* including competence in the management of recovery and rehabilitation. Other approaches do not reject a care ethic outright, but question the attempt to regard an ethic of care as unique to nursing. Robert M. Veach, for example, suggests that care is essential to human relationships generally. Others hold that care itself is still too broad a concept to demarcate what is unique about ethics in nursing, and instead identify nursing with maternal practice, a specific kind of caring activity (Newton; O'Brien). For example, Patricia O'Brien defends the importance of nursing's maternal function by noting that historically the source of nurses' prestige has been the manner in which nurses blend home and hospital. That is, nursing's strength has come from nurses' skill at the traditionally female tasks of feeding, bathing, cleaning, coaching, and cajoling those in one's care. Just as mothers make a home, it is female nurses who have been able to make a home of the hospital, to personalize an increasingly impersonal environment.

Critics of the maternal paradigm for nursing fault this approach as casting women in traditional and stifling roles. Historically, for example, nurses were socialized into the healthcare field to know their place and were relegated to the bottom of the pyramid and taught not to ask questions (Murphy). Casting nursing practice in terms of mothering potentially reverses progress made in the late 1970s when nurses began to see themselves as shared-decision makers rather than handmaidens to physicians (Stein et al.).

A further objection to identifying ethical ideals of nursing with ethical ideals of mothering holds that nurses's proper function is to serve as patients's advocates, rather than as patients' parents. Gerald Winslow, for example, argues that advocacy of patients' autonomy, rather than paternalistic promotion of patient benefit, should guide nursing ethics.

Caring and Contemporary Medicine

Whereas nursing is often associated with a caring function, doctoring has traditionally been associated with a curing function. However, the tendency to associate caring exclusively with nursing is misleading for a variety of reasons (Jecker and Self). First, both doctors and nurses are engaged in caring for patients. In addition, assigning caring activities to nurses and curing activities to doctors is misleading because certain meanings of *curing* are actually derived from *caring.* Thus, the Latin definition of *cure* comes from the word *curare,* meaning "care, heed, concern; to do one's busy care, to give one's care or attention to some piece of work; or to apply one's self diligently"(Oxford English Dictionary).

Although there has been less explicit attention to an ethic of care in medicine than in nursing, caring for patients represents a central component of ethics in medicine. Caring is inextricably linked to the physician's obligation to relieve suffering, a goal that stretches back to antiquity (Cassell, 1982).

There are several more specific ways in which an ethic of care becomes manifest in the practice of medicine. First, caring is manifest in the activity of healing the patient. Whereas curing disease typically requires the physician to understand and deal with a physical disease process, healing requires that the physician also respond to the patient's subjective experience of illness (Cassell, 1989). For example, healing a patient who is suffering from a serious infection requires not only administering antibiotics to kill bacteria but also addressing the patient's feelings, questions, and concerns about his or her medical situation. In cases of serious illness where cure is not possible, caring for the

patient may become the primary part of healing. For example, when patients are terminally ill and imminently dying, physicians' primary duty may become providing palliative and comfort care. Under these circumstances, healing emphasizes touch and communication, psychological and emotional support, and responding to the patient's specific feelings and concerns, which may include fear, loss of control, dependency, and acceptance or denial of death and final separation from loved ones.

Caring is also evident in what Albert Jonsen calls the "*Samaritan principle*: the duty to care for the needy sick, whether friend or enemy, even at cost to oneself" (p. 39). The tradition of Samaritanism dates to the early Christian era and the parable of the Good Samaritan described in the Gospel according to Luke; it persists during the modern, secular era as a central ethic for medicine. Jonsen argues that although the original Christian parable of the Samaritan refers to giving aid to a particular individual, the ethical tradition of Samaritanism within medicine bears relevance to entire groups of patients. So understood, Samaritanism underlies the physician's broader social duty to care for indigent persons. In contrast to the past, when physicians provided charity care for indigent persons without financial remuneration, universal health insurance is the norm in most developed countries. Therefore, in contemporary times physicians are generally compensated for their services through a private or government health insurance mechanism. In the United States, however, large numbers of patients continue to lack health insurance. A principle of Samaritanism continues to be evident in the legal and ethical requirement that U.S. physicians provide emergency treatment to any patient regardless of the patient's ability to pay for care. A stronger Samaritan ethic, mandating access to all forms of basic healthcare, would require, in the United States, successful implementation of healthcare reform.

A third way in which caring is manifest in the ethics of medicine is through the healing relationship of doctor and patient. Edmund Pellegrino and David Thomasma regard this relationship as one of inherent inequality because the patient is vulnerable, ill, and in need of the physician's skill. In light of the patient's diminished power, Pellegrino and Thomasma argue that the physician incurs a duty of beneficence, a duty requiring the physician to respond to the patient's needs and promote the patient's good. Other ethical values in medicine can presumably be derived from the physician's primary duty of beneficence. For example, according to Pellegrino and Thomasma, a duty to enhance patients' autonomy is based on the duty to benefit patients.

Some, Sharpe for example, have sought to identify the principle of beneficence that Pellegrino and Thomasma delineate with an ethic of care. However, beneficence and care differ in crucial respects. Whereas a principle of beneficence identifies promoting the patient's good as a requirement for right action, an ethic of care is a type of virtue ethic that is basically concerned about the affective orientation and moral commitment—that is, the concern—of the one who cares. For example, a physician may perform actions that promote a patient's good, and thus meet the requirement of beneficence, without caring about or feeling any commitment toward the patient. If this analysis is correct, then actions that fulfill the principle of beneficence do not necessarily fulfill standards associated with an ethic of care. An ethic of care suggests both a feeling response directed to the object of care and a commitment to ensuring that things go well for that person.

Despite the integral role that an ethic of caring plays in medicine, contemporary physicians sometimes neglect to offer adequate palliative and comfort measures to patients. This may stem from a failure to teach and nurture empathy in medical education (Spiro et al.) and from financial incentives that discourage spending time at patients's bedsides and getting to know patients as persons. In addition, physicians may overlook caring for patients when conflicts exist about the use of futile treatments (Schneiderman et al.). For example, members of the healthcare team may become distracted debating the appropriateness of high-technology interventions and neglect to care for patients's spiritual and emotional needs.

Conclusion

Although the development of theories of an ethic of care for healthcare is new, the idea of care has long presented a moral standard or ideal for healthcare. Although caring has been an abiding concern within nursing practice, within medicine care has sometimes been overshadowed by other ethical values and goals. The emergence of feminine ethics can play an important role in reemphasizing the value and importance of caring within medicine. However, the close association of care with gender and with the feminine voice may hinder efforts to develop a broader human understanding of care, such as the understanding of care that emerged earlier in human history.

CASUISTRY

• • •

Casuistry, a term derived from the Latin word meaning "event, occasion, occurrence" and in later Latin, "case," was coined in the seventeenth century to refer pejoratively to the practice described by contemporary Christian theologians as "cases of conscience" (*casus conscientiae*). Today the word might be defined as the method of analyzing and resolving instances of moral perplexity by interpreting general moral rules in light of particular circumstances. This entry will relate the origins and development of casuistry in Western culture, its decline, and its revival as a method of ethical analysis, particularly in bioethics.

Origins of Casuistry

The earliest discussions of morality in Western philosophy reveal the tension between general moral norms and particular decisions. The Sophists of fifth-century Greece maintained that since no universal truths could be affirmed in moral matters, right and wrong depended entirely on the circumstances: ethics consisted in the rhetorical ability to persuade persons about "opportune" action. Plato devoted his *Republic* to a vigorous refutation of this thesis, placing

moral certitude only in universal moral truths: ethics consisted in transcending particularities and grasping permanent ideals from which right choice could be deduced. Aristotle proposed that in ethical deliberations, which deal with contingent matters, formal demonstration was not possible. Rather, plausible argument would support probable conclusions. Ethics belongs, he maintained, not in the realm of scientific knowledge but in the domain of practical wisdom (*phronesis*). *Phronesis* is a knowledge of particular facts and is the "object of perception rather than science" (*Nicomachean Ethics,* VI. viii. 1142a). Criticism, interpretation, and amplification of these theses constitutes much of the history of moral philosophy. The Aristotelian viewpoint, which places moral certitude in the domain of practical judgments about what ought to be done in the actual circumstances of a situation, is the remote philosophical ancestor of the casuistry that developed in Western culture.

The Roman philosopher and statesman Marcus Tullius Cicero (106–43 B.C.E.) designed an approach to moral problems that would powerfully influence the casuistic authors of the Middle Ages and Renaissance. Cicero, although a philosophical eclectic, inclined to Stoic thought in ethics. Drawing from the Stoics Panaetius and Posidonius and inspired by the Roman passion for practicality, he held that to be a virtuous person one must become "a good calculator of one's duty in the circumstances, so that by adding and subtracting considerations, we may see where our duty lies" (*On Duties,* I, 59). This adding and subtracting was done by offering and evaluating "probable reasons." The primary moral problem was the continual conflict between duty and utility, a conflict resolved only by examining the circumstances of cases. In his *On Duties,* Cicero proposed a number of cases, some drawn from the Stoic philosophers and others from Roman history. Each case, representing an apparently insoluble conflict between duty and utility, was then analyzed to show how, if circumstances were taken into account, one could discern one's moral duty. Cicero also espoused the Stoic doctrine of natural law and often referred to its overarching precepts in his analyses of cases; but the problem, he affirmed, was how these precepts were to be interpreted in context. *On Duties* remained one of the most studied texts of antiquity through the subsequent centuries. By its organization of material and its methods of reasoning, *On Duties* powerfully influenced the way in which morality was conceived and taught in the Western world, and thus sanctioned subsequent casuistry.

While moral discourse always moves between the broad generalizations of principle and the particular decisions made in specific circumstances, religions that are monotheistic and moral in nature face a particular problem in moving from the general to the particular. The three "religions of the Book"—Judaism, Christianity, and Islam—have in common a Scripture in which the word of God is recorded; that is, in which God speaks to believers in concrete and specific language. Also, the divine message contains imperatives that enjoin moral obligations, sometimes stated in broad terms and sometimes referring to specific forms of behavior. It becomes necessary for believers to understand how the broad general imperatives apply to the great variety of daily life, and to learn how specific commands expressed in the language and cultural setting of the past are to be followed in the circumstances of later times. Thus, each religion of the Book developed a moral teaching that begins with affirmations from the divine text, moves through traditional interpretations of that text by the saintly and the scholarly, and comes, finally, to the task of bringing text and interpretation to bear on particular circumstances of time and place. Each of these religions, then, has developed a casuistry or manner of working at the task of concrete application. The particular forms of Jewish and Islamic casuistry are discussed elsewhere; this entry will relate the development of casuistry in Western Christianity.

Christianity introduced a powerful and original morality into the Greco-Roman world. The thought of its founder, Jesus, both reflected the dedication of Jewish law to the sovereignty of God and refashioned it to include a demanding commitment to himself as Lord as well as self-sacrifice for one's neighbors, spelled out in strenuous, often paradoxical commands. His early disciples, seeking to follow these commands, preached an ascetic repudiation of "the ways of the world." This meant that the moderate virtues prized by the pagans among whom the early Christians lived were often deprecated and the vices of pagan life, which even pagan authors often criticized, were reviled. The morality of the Hebrew Scriptures and the Christian Gospels, which condemned many attitudes and practices common in pagan culture and demanded adherence to self-discipline and altruism, posed profound difficulties to believers. How were they to live in a world that held different values? How were the "hard commandments" of the Gospels to be carried out in daily life? These problems perplexed Paul of Tarsus, the most influential of Jesus' first followers, whose efforts to answer them, especially in his First Letter to the Corinthians, adumbrated the work of later Christian casuists. In addition, early Christian thinkers were suspicious of the philosophical thought of the Greco-Roman world. However, by the third century, many Christian scholars had come to accept that Christian belief and "pagan" philosophy were compatible in important respects. The authors of the patristic era (second to sixth centuries) reflected on Christian moral problems with the help of Plato, Aristotle, and Cicero. The framework of virtues, natural law, and practical reasoning elucidated in

these and other pagan authors were modified and incorporated by Christian authors and teachers. They sought, as did their pagan mentors, to understand the nature of the moral life but were concerned, above all, with providing practical advice about how the faithful should live a Christian life in a non-Christian world. Many Christian authors used Cicero's *On Duties* as a model for treatises on morality: St. Ambrose of Milan (339–397), friend and teacher of the great St. Augustine, also titled a book *On Duties* and, closely following Cicero, attempted to refashion the latter's thoughts within the perspective of Christian faith.

Christian teaching does not merely require belief; it strongly stresses the importance of morally correct behavior. While killing, deception, and adultery are condemned as sins, and charity, self-denial, and honesty are commanded, inevitably questions arise about what sorts of behavior belong in these general categories. Early Christians were intensely aware that failure to follow the rigorous commandments of their faith separated them from God and from their fellow believers. The practice of confession of one's sins before the community of believers and the imposition of penance that would once again reconcile the sinner to God and to the community became common in the early centuries. By the eighth century, private confession to a priest, who had the ecclesiastical authority to absolve the repentant sinner from guilt, had been introduced. This practice of sacramental confession and penance enhanced the need for clear descriptions of the moral dimensions of various behaviors and of the ways in which various circumstances excused or aggravated the seriousness of those behaviors. From the eighth to the twelfth centuries, educators of the clergy produced penitential books that presented systematic catalogs of sinful and virtuous actions under various typical circumstances (e.g., the killing of another out of vengeance, in fear, in ignorance, etc.). The motives, the consequences, and the social status of the agent were important considerations in evaluating the responsibility and seriousness of behavior. Appropriate penances were assigned in view of the gravity of the sin.

These penitential volumes, the earliest examples of which came from the Irish and Welsh churches, became widespread throughout Europe. In the course of four centuries, their content became more elaborate and their format more systematic. The first were collections of crudely described cases with simple distinctions, elaborated with biblical or patristic quotations. Later examples incorporated advancing biblical and theological scholarship and, above all, the work of the canon lawyers who, since the rediscovery of Roman law in the eleventh century, had exercised increasing influence over the formulation of church law as it touched the organization and practices of Christian life. The work of Peter the Chanter (d. 1197), Alain of Lille (d. c. 1203), and Thomas Chobham (c.1200) were filled with well-described cases of moral perplexity, analyzed with reference to biblical texts, maxims from the fathers of the church, and the growing body of church law. These books were not only for the education of the parish priest but also to guide the ecclesiastical hierarchy in the formulation of policy and the making of judicial decisions. Some of these books were written for the instruction of the laity in making a proper confession and leading a good life.

During the twelfth through fourteenth centuries, great theological scholars such as Abelard, Peter Lombard, Albert the Great, Thomas Aquinas, Duns Scotus, and William of Ockham elaborated systematic treatises or *summas* in which they attempted to present the full range of Christian belief and to support it with rational argument. In doing so, they placed the questions of morality within larger frameworks of interpretation and justification, drawing heavily on philosophers of antiquity. These treatises did not discuss cases, as did the penitential literature, but created theoretical foundations for the discussion of cases. The relevance of scriptural admonitions, natural law, custom, and civil and canon law to moral decisions was explored in great depth; the relevance of principle, motive, and circumstances was carefully examined. These theologians, while not casuists, greatly influenced the next generations of casuists.

Casuistic Writings

Through the fourteenth and fifteenth centuries, many books of cases of conscience were published. The *Summa Angelica* (1480) and the *Summa Sylvestrina* (1516) were the most famous. However, these works were staid, unimaginative, and formalistic; many authors simply plagiarized from more celebrated authors. But casuistry properly speaking came into its own in the mid-sixteenth century. In 1556 a Spanish canonist, Martin Azpilcueta, published *A Handbook for Confessors and Penitents,* which revitalized the literature of cases of conscience. This book abandoned the practice of listing moral problems alphabetically and adopted a less frequently used device of organizing various sins under the Decalogue. This allowed for a more flexible and nuanced treatment and for comparison between various categories of moral behavior. Above all, it introduced the analysis of issues from the more clear and obvious to the more complex, a method that later casuists would exploit and that is described below as reasoning by paradigm and analogy.

Azpilcueta's style was widely copied. The Jesuit order, founded in 1534, was dedicated to the work of moral

education and guidance of conscience, especially in sacramental confession. The Jesuits introduced Azpilcueta's approach into their own training of priests as ministers of the sacrament of penance. They published many volumes of cases of conscience. John Azor's *Moral Instruction* (1600) was the preeminent work. Jesuit casuistry was, in general, careful, scholarly, sensible, and practical. It was also comprehensive. While the general rubric of the Decalogue was used to organize materials, the duties of various occupations, the obligations of princes and bishops, and the moral dimensions of diplomacy, Jesuit casuistry also dealt with economics, warfare, and exploration. It has been suggested that the origins of modern economics, sociology, and political science lie in the work of the seventeenth-century casuists. Certainly, their advice was often sought by popes and kings in matters that we would today consider political or economic rather than moral. But in the seventeenth century, the moral questions on a king's or pope's conscience often concerned politics and finance.

The seventeenth-century casuists not only analyzed and resolved complex cases. They also elaborated speculative positions, writing treatises on topics such as justice, usually as prolegomena to their analyses of cases of government or trade. Among the central speculative questions was that of the degree of moral certitude required to act in good conscience, that is, how sure a person must be that a casuistic resolution of a moral problem is the correct one before acting upon it. A vigorous intellectual debate on this question took place in the last half of the seventeenth century between the Jesuits and their theological rivals, the Dominicans, and among the Jesuits themselves. From that debate, the position of the leading Jesuit theologians emerged as dominant. That position, *probabilism*, maintained that a person was entitled to act in good conscience if there were probable arguments in favor of the choice; probable arguments are those supported by solidly reasoned opinion and defended by respected authors. Probabilism, while defended with elegant argument and sanctioned by ecclesiastical authority, remained a contentious issue and led to the tarnishing of the casuists' reputation in the seventeenth century, since many critics accused them of being able to find any probable argument to justify their preferences.

The Jesuits were by no means the only authors of casuistry; many other Catholic theologians were so engaged. Anglican divines produced clear and sensible books of casuistry; and since most works of classical casuistry have not been translated from their original Latin, Anglican casuistical books offer the best access to casuistry for English readers (see Perkins). Lutherans were not well disposed toward casuistic analysis: Luther had cast into the flames the *Summa Angelica,* calling it "Summa Diabolica." Still, the Jesuits attained the reputation of being the premier casuists. Since they were deeply involved in the religious and secular politics of the era, they won enemies on every side and their casuistry appeared to many to serve their own interests rather than the good conscience of their penitents. In particular, the genius mathematician Blaise Pascal found distressing the Jesuits' opposition to Jansenism, a particularly rigoristic Catholic theology that he favored; and at the urging of other Jansenists, he set out to destroy the Jesuits' anti-Jansenist arguments.

Pascal's *Provincial Letters* (1656) was a brilliant and wittily written refutation of the Jesuit arguments against Jansenist theology and, in particular, of the casuistry that, he claimed, made a mockery of Christian moral beliefs. He gave numerous examples of Jesuit resolution of cases of conscience and found them tainted by a probabilism that bred moral laxity, intellectual sophistry, and disguised heresy. Despite the fact that Pascal took cases out of context and chose only those that suited his polemical purposes, his diatribe became immensely popular. At best, it can be said that his critique demolished not casuistry itself but the lax casuistry that was counted reprehensible even by the Jesuits whom he accused. It was not only Pascal's popular book that tarnished casuistry's reputation. Certain casuists, few of them Jesuits, did take the skill at case analysis to an extreme: Almost any argument could be presented plausibly and fine distinctions could be drawn to make, as Plato said of the Sophists, "the worse appear the better." Casuistry and sophistry became invidious synonyms, as did casuistry and Jesuitry. And casuistic argument, once quite liberal, became legalistic in tone and content, promoting a morality of observance rather than of conscience. Finally, casuistry was falling out of step with the prevailing intellectual progress. The interest in intellectual systems, seen in Isaac Newton, Gottfried Wilhelm Leibniz, Baruch Spinoza, and Hugo Grotius, made the casuists' interest in particular cases appear disorderly and without solid foundation. By the end of the seventeenth century, casuistry was discredited in the European intellectual world. The word *casuistry* was invented as a term of abuse (earlier the word *casista* was used merely to describe a scholar who presented cases of conscience). Bayle's *Dictionary* (1697) defined *casuistry* as the "art of quibbling with God." At the close of the eighteenth century, Kant, who was familiar with traditional casuistry as a way of teaching ethics, found the only interesting question to be how to transform the limited and probable maxims of moral discourse into categorical certitude.

Casuistic writing continued through the eighteenth and nineteenth centuries within the Roman Catholic tradition, particularly in the education of the clergy, but it was a desiccated casuistry, wary of innovative solutions and bound

by ecclesiastical pronouncements on moral matters. The work of the French Jesuit J. Gury (1862) was representative of the fading tradition; a journal titled *The Casuist,* published for American Catholic clergy (1906–1917), shows the tradition at its nadir. Still, casuistry continued to serve the practice of sacramental penance for which it had been created. Outside this tradition, remnants of casuistry lingered in the teaching of ethics. The textbooks of the time included fragments of Aristotle and Cicero and many of the classical cases, loosely grouped around virtues and duties. In 1870, revolted by the untidy and incoherent presentations of these texts, Henry Sidgwick, professor of casuistical divinity at Cambridge University (he had his chair renamed "moral philosophy"), undertook to construct a systematic presentation of an ethical theory, utilitarianism, in which tenets were tightly argued, inconsistencies rectified, and opponents refuted. The progress of moral philosophy from Sidgwick's time until recently has been toward greater articulation of theory and away from analysis of cases of conscience.

The Practical Need for Casuistry

Casuistry then almost disappeared from the formal academic disciplines that study moral discourse. However, in the 1960s, a number of important moral questions began to trouble the American conscience, and moral philosophers were spurred to attend to the practical application of their discipline. The war in Vietnam required many to examine their consciences concerning support of and participation in what they felt was an immoral war. At the same time, the civil rights movement stimulated consciences concerning discrimination and racial injustice. The analytic moral philosophy current in academic circles had little advice to offer. Even the widely accepted and elaborate utilitarian theory seemed to lead to no firm conclusions.

The emerging interest in the ethics of medical and healthcare also opened vistas for a new casuistry. Medical care is about cases: the illness and the treatment of particular persons with particular diseases. Philosophers and theologians who engaged in this work had initially tried to bring the standard ethical theories to the analysis of medical problems, but they found themselves discussing cases, not theories, and felt the need for an approach that would stay closer to the particulars of the case under discussion than did the standard theories. Above all, they realized that cases were being discussed not merely to elucidate the meaning of concepts but also to arrive at a resolution: physicians, nurses, and patients were interested in what moral philosophy had abandoned: answers to practical moral perplexity. By the late 1970s, talk of "case method" had become common in bioethics. At the same time, ethical issues in business, government, and journalism seemed to call for study of individual cases rather than flights into ethical theory. Also, influential moral philosophers were beginning to criticize the dominance of moral theory in practical ethics and to call for approaches that were more concrete than speculative.

Albert Jonsen and Stephen Toulmin published *The Abuse of Casuistry* in 1988. Aware that many were interested in inventing a "case method" for ethics, they hoped to show that such a method had been invented long ago and that, although discredited and seemingly outmoded, classical casuistry had much to offer modern ethicists. Case method in ethics might be similar in many respects to the case method in Anglo-American common law, which had developed in parallel with classical casuistry. Both the common law, about which much research has been done, and casuistry, which has been invisible to the scholarly world for several centuries, need to be explored if a case method for ethics, of "morisprudence," is to be re-created. These authors attempted to restore casuistry to intellectual respectability. After a historical survey of the rise and fall of casuistry, they contrast it with current approaches to moral philosophy and define it as follows:

> [T]he analysis of moral issues, using procedures of reasoning based on paradigms and analogies, leading to the formulation of expert opinion about the existence and stringency of particular moral obligations, framed in terms of rules and maxims that are general but not universal or invariable, since they hold good with certainty only in the typical conditions of the agent and circumstances of the case. (p. 257)

Methodology

The term *methodology* may be too formal a word to describe how casuistry works. The casuists of the past left almost no formal description of their way of working; the casuists of the present, pressed by their critics based in moral philosophy, are still asking themselves questions about methodology. Still, certain characteristics of the casuistic approach can be noted. These characteristics appear to have their origins in the classical discipline of rhetoric rather than in philosophy as such. The historical casuists had, like all educated persons of their time, been educated thoroughly in rhetoric. Aristotle and Cicero, the authors from whom they learned rhetoric, also taught them ethics. Classical rhetoric was defined as having a moral purpose: the persuasion of persons toward right and just action. Indeed, the classical books of rhetoric, because they were so rich in comments about and examples of moral behavior, were often used as texts in

ethics. In the centuries during which casuistry flourished, moral philosophy was not a clearly defined discipline. Thus, it is not surprising to find the historical casuists implicitly using the techniques of rhetoric in their analysis of cases of conscience. Both rhetoric and casuistry had morally correct attitudes and action as their ultimate goal.

Two characteristics of rhetorical technique are particularly important for casuistry: topics and the comparison of paradigm and analogy. Rhetoricians taught that discourse in general could be divided into a set of common ideas, such as "causality," "temporal sequence," and so on, which they called "topics." Each of these topics had sets of definitions and forms of argumentation that were invariant. Also, each special realm of discourse, such as discourse about politics, art, or economics, has its own set of "special topics," the features of the field that must be understood and discussed if an adequate argument is to be made about what should be done. A casuistic approach to an ethical problem, then, requires that the field of discourse be analyzed to designate the invariant features. For example, it has been suggested that the topics of clinical ethics are: (1) medical indications, (2) patient preferences, (3) quality of life, and (4) contextual features, such as costs of care and allocation of resources (Jonsen, Siegler, and Winslade). Each of these topics has certain definitions, maxims, and arguments that must be taken into account in discussion of any case. The particular circumstances of time, place, personal characteristics, various behaviors, and so on that are the details of any case are viewed in the light of these topics.

Once the particular case is described by its circumstances and topics, casuistical analysis seeks to place this case into a context of similar cases. The classical casuists were accustomed to line up cases of similar sorts, so that cases describing various sorts of homicide, for example, were aligned in order that the similarities and differences between cases would become clear. This enabled the casuist to see those cases in which the moral principles and maxims appeared to lead to an unambiguous resolution. Thus, the prohibition against killing another human being seemed most obviously to hold if the circumstances described a vicious, unprovoked attack on an unoffending person; the prohibition would allow an exception if the circumstances described a killing that resulted from that unoffending person's self-defense against a lethal attack. This technique of lining up cases, rather than seeing them in isolation, is the essence of casuistical analysis. It is called by some authors the technique of paradigm analogy: The paradigm case is the case in which circumstances allow moral maxims and principles to be seen as unambiguously relevant to the resolution of the case; the analogies are those cases in which particular circumstances justify exceptions and qualifications of the moral principles. A high degree of assurance, or moral certitude, pertains to the resolution of paradigm cases, while varying degrees of moral probability, or probabilism, attach to the resolution of analogous cases.

Finally, the resolution of each case depends on what Aristotle called *phronesis,* or moral wisdom: the perception of an experienced and prudent person that, in these circumstances and in light of these maxims, this is the best possible moral course. As one commentator on modern casuistry has written, "for casuistry, moral truth resides in the details … the meaning and scope of moral principles is determined contextually through the interpretation of factual situations in relation to paradigm cases" (Arras, p. 37).

Bioethics is the most prominent field in which casuistry is beginning to be reintroduced as a method for ethical analysis. This is not surprising, since a strong interest of bioethics is the clinical care of patients, and many cases that came to the early attention of bioethicists involved life-and-death decisions arising from the use of new medical technologies. Cases about whether life-supporting technologies should or should not be continued for particular patients lend themselves to casuistic analysis. The differing circumstances of individual patients, the topics (the significant categories into which a medical-ethical decision can be factored), and the maxims (such as "do no harm" or "respect the patient's informed choices") are each in their own way crucial to the resolution of any case. The placing of the case in a lineup of paradigm and analogy, from the most obvious—in which the patient is brain dead, or continued care is manifestly futile—to the problematic, in which diminished quality of life or unclear preferences are at issue, allows for discretionary judgment between cases (Jonsen). This sort of casuistry can also be applied to questions of healthcare policy, such as those surrounding the various programs proposed for allocation of resources, although relatively little of such analysis has been done.

Casuistry, then, keeps moral reflection close to cases. Neither classical nor modern casuistry repudiates principles: Casuistry is not merely another name for situationism or contextualism. Rather, principles are seen to be relevant to cases in varying degrees: In some cases, principles will rule unequivocally; in others, exceptions and qualifiers will be appropriate. Modern casuists dislike the description of casuistry as "applied ethics," since they explicitly repudiate the notion that an ethical theory must be elaborated and then "applied to" the circumstances of the case. Still, the relationship between cases and ethical theory is unclear and poses the principal speculative problem that casuists and moral philosophers must ponder, just as the historical casuists pondered the problem of the certitude of practical judgment. On the one hand, casuistry is not simply applied ethical

theory; on the other, it is not simply immersion in the factual circumstances of cases, which would reduce it to situationism. Casuistry is not tied to any single theory of ethics but can be comfortable with selected elements of multiple theories. For example, a casuistic argument might draw on utilitarian, deontological, and contractual justifications in a single case. Also, the designation of topics and the selection of paradigms have theoretical presuppositions. Finally, the normative nature of principles and maxims, which must be clarified in order to specify the obligatory nature of casuistic resolutions, requires reference to theory. Casuistry, then, is not "theory free" but is rather, as one commentator has suggested, "theory modest" (Arras, p. 41). Theories, for contemporary casuistry, are not mutually exclusive, a priori foundations for practical ethical discourse but limited and complementary perspectives that illuminate practical judgment. Much work remains to be done on the relationship between theory and practical judgment. Still, as suits the style of casuistry through its history, it can grapple effectively with difficult cases even though all speculative and theoretical questions about its methods and presuppositions have not yet been answered.

CHILDREN

I. HISTORY OF CHILDHOOD

Childhood is a culturally determined social construct that might be thought of as a set of expectations for children. The principal dynamic in the history of childhood involves changes in these expectations. The history of childhood can be organized around three fundamental concepts: socialization, maturation, and modernization. Socialization is the process whereby a child incorporates the principal elements of the culture into which she or he is born. Maturation is the biological process of growing up. Modernization is the large-scale transformation of economies and societies—of European countries first, and then others. This process includes industrialization, urbanization, and the expansion of capitalistic systems of economic organization. The most dramatic changes in socialization and maturation of children come from the impact of modernization.

In traditional societies, socialization usually took place within families at a gradual pace and in informal ways. Sons learned the skills and practices of adult males by working alongside their fathers. Similarly, daughters worked and learned in close contact with their mothers. In the modern world, new agencies such as schools appeared and became part of the socialization process; and the process of maturation, formerly a natural process marked, perhaps, by rites of passage from youth to adulthood, now became the focus of serious social thought and practice. Put another way, maturation has been redefined in the modern age as a time of

"identity crisis" for youth. In the modern age, youths have a greater range of choices for adult roles than did their ancestors.

The pioneering work in the history of childhood is *L'Enfant et la vie familiale sous l'ancien régime,* published by Philippe Ariès in 1960 (and translated into English as *Centuries of Childhood: A Social History of Family Life* [1962]). Ariès not only wrote one of the first modern scholarly treatments of the history of childhood, he also made the central point that childhood is socially constructed; that is, that ideas about and expectations for children are determined by social leaders and experts (advice-givers). Another early writer on the history of childhood, Lloyd deMause, in a work titled *The History of Childhood,* argued that "The further back in history one goes, the lower the level of child care and the more likely children are to be killed, abandoned, beaten, terrorized, and sexually abused" (p. 1). Professional historians have modified the views of Aries and deMause as they have developed deeper knowledge of the ways earlier societies regarded and treated children. The lasting importance of both scholars is that they founded the field of history of childhood and stimulated others to further investigations and revisions.

Childhood in the Ancient Western World

We know that childhood, a period of relative freedom from work, existed in the ancient world because children's play was depicted on Greek vases and Roman sarcophagi. There were several ancient treatises on the diseases of children and a recognition that children were to be treated differently from adults. Thus there was a tradition of childhood in the ancient world that saw children as passing through stages of growth, as being malleable, as being fragile, playful, and sometimes headstrong. This tradition saw children as individually different and in need of protection from abuse by adults. Ancient philosophers, particularly Plato and Aristotle, wrote about child-rearing practices and regarded children as a link to the future. Some children's toys have survived—dolls, small versions of weapons, and the like—and they point to adult agendas for future citizens. Epitaphs remind us that ancient parents mourned the death of their children.

The Greeks and Romans devoted special attention to children and child-rearing practices. Women were the child rearers, and a number of other adults worked with children: midwives, teachers, tutors, and physicians. Both Plato and Aristotle recognized five stages of childhood (expressed in modern terms):

1. Babyhood, from birth to about two years—that is, until the child is weaned and can talk;
2. The early preschool age, from two to three years or later—when the child is separating emotionally from the mother, becomes more active physically, and begins to play games alone;
3. Later preschool age, from ages three to seven—a stage when children become more active and more involved in social groups;
4. School-age children (up to puberty)—a time of intense competition, especially among boys; and
5. The stage between puberty and adulthood—which continues into the late teens or early twenties.

The last stage may have been brief or nonexistent for girls, who married at a relatively early age. In their broad outline, however, these stages closely resemble modern child-development theory.

Threats to Children in the Ancient World

Childhood in the ancient world had a darker side: some people practiced infanticide as a means of birth control or eugenics (French); some children were sold into slavery; and some of the little slaves were maimed so that they could be more pitiable beggars. Additionally, the use of wet nurses for the newborn was common and undoubtedly led to higher infant mortality rates. Wet nursing led to higher infant mortality because there was a greater possibility of disease, the wet nurse had less concern for the child than the mother did, and the amount of nourishment from the wet nurse might have been less. Infanticide was common, and such evidence as there is suggests that it was more common for female children than for male children to be killed by being abandoned and left to starve. A Roman law, for instance, said that all boy children and at least one girl born to a family had to be raised. In Sparta (from 700 to about 350 B.C.E.) infanticide was part of a program of eugenics whereby defective children were exposed. Illegitimate children were also disposed of through infanticide. Most children grew up in small nuclear families with one or two siblings. These small families were of concern to the Romans, who sought to increase the birth rate through incentives.

Childhood in Medieval and Early Modern Times

Very little is known about child-rearing practices and childhood in the early centuries of the Middle Ages because the historical sources for this period are very scattered and fragmentary. But it is known that children were valued. Among the Visigoths, for example, a male baby had a blood price (*wergild*) of one-tenth that of an adult male. As the child aged, the wergild increased. Female children had a

blood price half that of male children, but adult women's wergild was five-sixths that of an adult male. There was some schooling in this period; scattered references attest to schools in palaces and monasteries, although the practice of taking in small boys as oblates by monastic orders was already declining. For much of the population the process of maturation involved a long apprenticeship with children working alongside adults and thereby learning adult roles and responsibilities.

Literary references suggest that adults treated young children in a kindly fashion but that they had little regard for young people in their teens. Laws set the age of criminal responsibility (when a child could be charged with a crime) at seven and the age of majority (when a person could make a binding contract) at eighteen or older. As in the ancient world, medieval parents clearly mourned the deaths of their children. Medieval commentaries on childhood saw three stages in place of the ancient world's five (again expressed in modern terms):

1. Infancy, up to the age of two;
2. The preschool period, from age two to age seven;
3. Puerility, from age seven to age fourteen.

There were texts that stressed the importance of breast-feeding (and by inference pointed to the dangers of wet nurses), but the use of wet nurses was common among the upper classes. An English bishop wrote of the importance of cradles (which would prevent infant deaths resulting from suffocation in the parental bed). Some children's toys—miniature figurines, for example—have survived from the period.

Infanticide was still common for female babies, but illegitimate children were sometimes added to the father's household. To counter the pattern of infant exposure and abandonment, orphanages appeared, the first being established in 787 at Milan. By the early fourteenth century, there were two hospitals in Florence that accepted foundlings, and in 1445 a separate foundling hospital, the Innocenti, was established. Other foundling hospitals appeared in Rome, Bologna, Pavia, and Paris by the end of the fifteenth century.

During the course of the Middle Ages, opportunities for schooling expanded from the limited possibilities offered by palaces, monasteries, or nunneries. Schools began to appear in the major cities of Europe; many of them, such as the grammar school at St. Paul's Cathedral in London, which was revived by John Colet early in the sixteenth century, were founded for the express purpose of training boys in business.

Most medieval children left home fairly early. Girls entered the work force at around age eight as servants, and boys typically were apprenticed to learn a trade. In effect these children traded their labor for their upkeep in their new households.

The death rate for children in the medieval world was extremely high—from 30 to 50 percent of children did not live to maturity. Besides disease, infanticide, and wet nursing, accidents claimed a great many children. There was little supervision of young children. Newborn children were swaddled (tightly wrapped with strips of cloth so that they could not move about or even move their limbs). Older siblings might provide some care, but most children were left alone; many of them suffered accidents, such as falling into an open fire, as a result.

European living patterns in the medieval and early modern period are comparable in some ways with traditional Japanese households. In traditional Japan the household was a residence as well as a legal, economic, affective, and ritual unit. In it children were regarded as treasures, although only one child would remain in the household as heir (the heir could be either male or female). The other children became apprentices or spouses or servants or remained in the household as dependents. The successor inherited all the assets of the household and was responsible for the continuity of the household and its reputation. The household was child-centered and stressed socialization into traditional roles. In recent times, as a result of the modernization of Japanese society, the process of socialization has changed. Japanese children do not remain in the traditional households, and younger families move to cities, where schools and other institutions have replaced the household as the primary agent of socialization because new occupations require different forms of preparation.

A similar transformation occurred in the Muslim Middle East. Ironically, it began with a reemphasis on the traditional household, which had been devalued by Westerners since the modern colonial period began in 1798. The family became a point for resistance to colonialism and strengthened paternal authority at a time when Western families were becoming more democratic. As the nations of the Middle East gained independence in the last half of the twentieth century, these traditional households began to give way before the process of modernization. And, as was the case in Japan and early modern Europe, schools and other institutions supplemented the family as agents of socialization.

Childhood in the Modern Western World

As modernization transformed western Europe and North America in the eighteenth and nineteenth centuries, a new and distinctive pattern of childhood emerged that was the

result of a number of influences—economic changes such as the intensification of a market economy, a decline in family size, the rise of rationalism in public discourse, to name a few. In addition, several important European thinkers were midwives to this new form of childhood. John Locke helped to undermine the dominant Puritan conception of children as innately evil, that is, born in sin, when he published his *Essay Concerning Human Understanding* in 1690. In it he argued that ideas could come from experience and thus were not innate. In 1693 he issued *Some Thoughts Concerning Education,* in which he attacked the doctrine of infant depravity. Locke did not regard children as innately good; rather, he argued that they were morally neutral—blank tablets.

Another central figure was the French philosopher Jean-Jacques Rousseau, whose *Émile* (1762) was the story of a boy and his tutor. Rousseau argued that children should be reared more naturally, making use of their innate curiosity to motivate their learning. For Rousseau both nature and the child were innately good. Evil arose from the corruptions of civilization. One of Rousseau's followers who put his ideas into practice was Johann Heinrich Pestalozzi, who founded a school in Switzerland in 1799.

Yet another important figure in the emergence of the modern concept of childhood was the English novelist Charles Dickens, whose well-known child characters Oliver Twist, Charley Bates, Jack Dawkins, and the Artful Dodger personalized some of the tragic effects of the industrial revolution in England. Dickens vividly described the desperation of the urban working classes and the processes whereby homeless children had to fend for themselves. His writings, supported by the findings of royal commissions and by the work of social reformers, helped transform the social attitudes of the Western world. In 1848 the English established "Ragged Schools" for the children of the urban working classes. Later they created a system of universal public education with the Forster Education Act of 1870.

In the United States in the nineteenth century, Charles Loring Brace, a New York clergyman and reformer, founded the Children's Aid Society in 1853 to ship "surplus" urban children—whether orphaned or not—to rural areas. The Children's Aid Society also founded lodging houses for homeless newsboys and industrial schools for homeless girls of the streets. (It was hoped that by teaching the latter unfortunates a trade such as sewing, they might be rescued from prostitution.) Later in the nineteenth century another New York reformer, Elbridge Thomas Gerry, founded the Society for the Prevention of Cruelty to Children in 1875. Popularly known as "the Cruelty," the organization sought to reduce or eliminate the worst instances of child abuse and neglect.

While these reforms and the expansion of public schools sought to provide opportunities for the child victims of modern society, the problem of child labor proved more difficult to solve. In part this was because few people—and certainly not most parents or employers—regarded child labor as a problem. For one thing, children had always worked before the modern era. Only the sons and daughters of the privileged elite escaped labor during their childhood. In the preindustrial world most families, whether urban or rural, relied on the labor of their children. Children in that world were regarded as a renewable labor supply. They began doing simple chores as early as possible, and they continued to work throughout adulthood and into old age, as long as they were able. Children also functioned as safety nets for parents. As parents became too infirm to work, they relied on their offspring for food and shelter. This family labor system moved with families to industrial cities. Thus, in nineteenth- and twentieth-century factories children joined their parents on the shop floor, first as helpers and later as hands. Industries welcomed child labor because it guaranteed a steady supply of trained workers, and families depended on the income the children produced.

But modern society demanded more skills from its work force than the family labor system was able to deliver. As a result, families had to forgo the income from some of their children so that they could learn the skills necessary to obtain employment. At the same time, reformers began to define child labor as a social problem and to expand the availability of schools. By the 1920s, child labor was on the decline in the Western world as schools, child labor laws, and technological innovation finally reduced the supply of child laborers and the demand for them.

In the process of expanding schools and trying to reduce child abuse and to regulate child labor, Western society was redefining childhood. Childhood now became a special, protected status, a time during which biological maturation could run its course, and children could come to know the complexities of the modern world and find their places in it. Two other social developments were significant in this process of redefinition: the creation of the federal Children's Bureau and a federally funded program to reduce infant mortality in the United States. The Children's Bureau, established in 1912, was an outgrowth of the First White House Conference on Children, convened by President Theodore Roosevelt in 1909. At first it concentrated on the reduction of infant mortality, which led in 1921 to the passage of the Sheppard-Towner Act, a program of matching grants for states. The grants helped states set up programs of education and prenatal clinics. This program of prevention and education had the desired effect, but was

killed by lobbying from the American Medical Association in 1929.

Other social advances in the nineteenth and twentieth centuries included the rise of pediatrics as a medical specialty and the rise of child psychologists, psychiatrists, and social workers. By the late twentieth century virtually all advanced industrial countries, including many outside the West, had made significant strides in reducing some of the threats to children's health and well-being.

Conclusion

The experiences of children in the recent past cannot be reduced to simple generalizations; there are too many variables. But it is obvious that region, economic health, and aspects such as race, class, and gender all have a major impact on children and childhood. Having noted these difficulties, some observations are possible. Abortion is more common in the industrialized world, whereas infant mortality is much lower. Children are less likely to become orphans in industrialized countries, to experience the death of a sibling, or to die before reaching adulthood. Children in industrialized countries will probably know their grandparents, and their parents may well have been divorced; many of them live in single-parent households, a sharp contrast to the extended households of traditional cultures.

Children in industrialized countries will spend more time in schools than children did in the medieval world, or than they do now where traditional cultures prevail. They will spend more time in groups with children of the same age. Their parents will have relied more heavily on experts, and they will probably have only a few siblings and perhaps a room of their own. They will have money of their own, and parts of the media will cater especially to them. They will also have a legal status that is clearly spelled out, although their status will vary from country to country. Of course even in industrialized countries poorer children will enjoy fewer privileges than the children of middle-class or elite parents.

In the twentieth century the improvements in children's lives in industrialized countries have been dramatic. In the United States, for example, in 1900 infant mortality was estimated to be more than 160 per 1,000 live births; by 1990 this rate had dropped to around 10 per 1,000. In Japan the rate was 5 per 1,000. Similar improvements occurred in access to schooling and literacy. In 1900 high school graduates in the United States constituted less than 4 percent of the seventeen-year-old population. By 1990 they represented approximately 75 percent. Similar evidence of significant improvement in children's health and education can be cited for most, if not all, industrialized nations.

In the modern world childhood has been extended, redefined, and supported by an array of experts and social institutions. Maturity, once a biological matter worth little notice, has become a complex process perhaps more social and psychological than physical in nature. Similarly, the process of socialization is now much more complex, reflecting, as always, the society into which children are to be socialized. In complex modern societies, the preparation necessary to become a productive adult is much longer and more intensive than formerly. In recognition of this, students now extend their schooling well into their twenties and even beyond. Maturation, modernization, and socialization as they have interacted have created an entirely new world of childhood.

II. RIGHTS OF CHILDREN

Since about 1970, philosophical interest in the rights of children has grown substantially. This growth owes much to the social upheavals of the 1960s and 1970s, especially the civil rights and women's movements, both of which employed the rhetoric of rights. When the plights of children, homosexuals, and the disabled began to be highlighted, it was natural that advocates for these groups also used the rhetoric of rights.

The invocation of rights in connection with children, however, predated the 1960s. In 1959 the United Nations General Assembly (1960) adopted a ten-principle *Declaration of the Rights of the Child*, itself a descendant of one adopted by the League of Nations in 1924.

Why Rights?

Why do activists concerned with the lives of children attempt to protect children's interests by invoking the notion of rights? The key features of the rhetoric of basic rights are (1) that rights are entitlements, and (2) that they impose duties on others. To claim something as a fundamental right is to make the strongest kind of claim one can make; it is to claim that something is an entitlement, not a privilege—something it would be not merely inadvisable or regrettable, but wrong and unjust, to withhold. And, typically, if one person is the bearer of rights, some or all others are the bearers of obligations. In the case of basic rights, the responsibilities fall either on all others as individuals or on the government, which in the case of democracies means on individuals acting as representatives of the citizenry. This is easily seen in the cases of the rights of adults to free speech and to healthcare.

The rights to free speech and healthcare illustrate two broad classes of rights given a variety of names by theorists. These may be designated *option* rights and *welfare* rights respectively (Golding). The idea behind option rights is that there is a sphere of sovereignty within which the individual cannot be intruded upon by government, even for the greater good. This idea is at the heart of classical liberal theory. Option rights are rights to choose. For instance, although persons have the right to speak, they may remain silent if they wish. Welfare rights, on the other hand, are rights to direct provision of services, such as medical care, that meet a basic need.

Do both categories apply to children? The notion of option rights motivated children's rights activists who saw children as oppressed by adults. Psychologist Richard Farson stated, "Children, like adults, should have the right to decide the matters which affect them most directly. The issue of self-determination is at the heart of children's liberation" (p. 27). The authors of the United Nations *Declaration*, on the other hand, focused almost exclusively on welfare rights. For example:

> The child, for the full and harmonious development of his [*sic*] personality, needs love and understanding. He shall, wherever possible, grow up in the care and under the responsibility of his parents, and in any case in an atmosphere of affection and of moral and material security; a child of tender years shall not, save in exceptional circumstances, be separated from his mother. (United Nations, p. 113)

Although some children's advocates urge recognition of both option and welfare rights, the underlying rationales are quite different. While the rationale for according children option rights conceives of minor status itself as a disabling condition that ought to be removed, the rationale for welfare rights urges that various goods and services be provided to minors as minors.

Most sensible people would look askance at putting children, especially young children, on a par with adults, insofar as freedom to live as they wish is concerned. The notion of a protected sphere of autonomous decision making is closely linked to the presence of developed capacities

for rational choice, capacities that usually are only potential in young children. It may well be that the development of autonomy is impeded when children are not permitted to exercise choices in their lives, but advocating that children be given some options is a far cry from asserting that children have the same rights as adults to live their lives as they please. Paternalism, the coercion of individuals for their own good, is odious only when those coerced are capable of exercising rational choice.

Why Not Rights?

Rights discourse does have some limitations in the context of advocacy for children. An initial difficulty lies in identifying universal rights while taking account of the limited resources and diverse values of particular societies. It may not be possible in some countries to fulfill the universal right to grow up in an atmosphere of material security, due to lack of resources. A second difficulty is that alleged welfare rights may be in tension with each other—for example, the right of a child to grow up in material security and the right to love and understanding.

A danger of rights discourse derives from the fact that, taken literally, respect of children's rights may permit substantial intrusion into parents' lives. For example, should government agents monitor parents to make sure they provide their children with the love and understanding they need? A less obvious danger derives from the fact that some of a child's most important needs, such as the need for love, cannot be coerced. If love fails, must the child be taken from the parent and given to another who is known to love the child? It is apparent that the struggle for children's rights may have the potential of making parents and children into adversaries.

Alternatives to Rights

Given children's vulnerability to abuse and neglect by immediate caregivers and by society at large, what ethical bases other than rights might serve to enhance children's welfare? Philosopher Onora O'Neill (1989) suggests that Immanuel Kant's notion of imperfect duty provides such a basis. An "imperfect" duty—the duty to contribute to charity is an illustration—differs from a "perfect" duty in the latitude allowed for fulfillment; toward whom and how much the duty requires is not specified. Thus, although we all have an obligation to help the next generation not only to survive but also to develop its capacities, we may meet this obligation in different ways—some as parents, some as professional caregivers, some as taxpaying citizens. The idea is attractive philosophically, but it admittedly lacks the precision, and hence the force, of the language of rights. Since the precise nature of the duty cannot be specified, it will be difficult to determine when people have or have not done enough to help needy children.

Another stream of ethical reasoning centers on character and virtue. So-called virtue ethics takes the focus away from whether particular acts are obligatory, permitted, or forbidden, and explores the notion of a good or virtuous person, a notion it alleges is fundamental. Proponents of virtue ethics would say, for example, that the idea of a virtuous or good mother cannot be reduced to that of a mother who performs or refrains from performing specific actions viewed as duties. A decided advantage of virtue ethics is that it encourages us to ask a key question: What legal and economic structures are conducive to "good parenting"? Virtuous parents, for example, take time to be with their children, especially when they are ill, but such virtuous actions will be more likely if employed parents enjoy legal protection against punitive actions by employers for their taking family leave.

Unlike the children's rights approach, which may pit parents against children, this approach does not put parents on the defensive. But virtue ethics also has theoretical difficulties, chief of which is defining character traits in ways that do justice to the diverse cultural ideals present in a heterogeneous population like that of the United States. Everyone will agree that virtuous parents, for example, need to teach their children to distinguish right from wrong, but may they use corporal punishment in the process? Here, consensus will break down. Another limitation of the approach is that virtue ethics has little to say about what precisely is owed to, or what ought to be done for, children whose primary caregivers have already failed them.

Care ethics, a variant of virtue ethics, is utterly antithetical to the Kantian emphasis on general principles and the development of rational agency. Deriving primarily from the work of feminist psychologists and philosophers, this approach takes close personal relationships, such as that between mother and child, as a model for all moral relations. Emphasis is placed on the need for compassion and empathy in the context of relationships to particular others in concrete settings, rather than on allegiance to abstract principles. Parents, for example, often succeed in meeting the needs of their children because they can empathize with them in particular situations; no abstract duty to care for one's children needs to be evoked. The ethic of care counters a philosophical focus on rationality as the defining essence of humanity.

Is care ethics sufficient to meet the needs of all children? For example, should affluent citizens provide funds for

intensive professional care of babies born with drug addictions, babies they never will meet? If the answer to such a question is yes, then the notion of duty may provide a more secure basis for persuading people that such contributions are obligatory, since emotional identification with those one does not know is likely to be weak.

If both justice and care are regarded as virtues, then virtue ethics may have the potential to offer moral grounds for the protection and care of all children. Whether such a reconciliation of alternative approaches is possible remains an open question. If it is not possible, then philosophical ethics offers a number of lenses through which to view the status of children. As in the case of actual lenses, however, there may be no single lens that fits all purposes.

III. HEALTHCARE AND RESEARCH ISSUES

Access to good parenting, food, housing, and sanitation is the primary method for enhancing children's well-being and opportunities. The consensus that children also should have basic healthcare and social services grew throughout the twentieth century. Initially, advocates for better health and social care for impoverished, neglected, abused, and exploited children included those active in the women's rights movement, the newly recognized specialty of pediatrics, and the visiting home-health nursing programs. As the century progressed, lawyers and social scientists joined the reform movement, attacking the long-dominant views that children are the property of their parents or guardians and that the state has no authority to intervene even if children are abused or neglected.

Children gained rights to certain medical services and the right to be protected from abuse, poverty, neglect, and exploitation; adolescents gained liberties such as the right to consent to some kinds of treatments or services without parental approval or notification (Holder, 1985, 1989). Scientists helped transform children's programs through studies of children's growth, development, needs, experiences, illnesses, and perspectives, showing the importance of candor and respect for children's views. A distinctive feature of advocacy for improved health and social care for children can be summarized as follows: Others make most decisions for minors in terms of their personal care and the allocation of funds for children's programs.

Moral disputes about healthcare for children will be discussed under four headings: Who should make decisions for children? How should those decisions be made? When should children be enrolled as research subjects? How much of society's healthcare funds should be allocated to children's programs?

Basic Moral Values

Different solutions to these questions are evaluated herein in terms of basic moral values: Solutions are judged to be superior when they fairly promote children's well-being and opportunities to flourish and help children become empowered, self-fulfilled persons who can develop their potential. The United Nations *Declaration of the Rights of the Child* (United Nations General Assembly) endorsed these basic values, underscoring their wide acceptance.

These values received international support because most adults want to help children and recognize their responsibility to assist them. They also promote stability by helping address inequalities of the "natural lottery" (inequalities caused by nature, such as health status) and the "social lottery" (inequalities caused by social factors, such as wealth, schooling, and family). Children are not responsible for those inequalities, yet they affect whether children will thrive and flourish. Adequate healthcare and social services enhance children's well-being and opportunities by treating diseases, in some cases returning children from the brink of death or permanent disability to full and healthy lives. These services also restore or maintain compromised function, avert or ameliorate suffering, and prevent disease or disabilities through interventions or counseling. Basic prevention, diagnosis, treatment, rehabilitation, and social services not only make children's lives better, they provide society with healthier and more productive citizens.

The focus of this discussion is primarily on preadolescent children, who clearly are not responsible for their quality of life or its inequities and who need help in making prudent decisions.

Who Has the Authority to Decide for Children?

Adults are presumed competent and minors incompetent to consent to medical treatment or participation in research. Minors generally lack the capacity, maturity, foresight, and experience to make important choices for themselves and cannot determine which choices will promote their well-being or opportunities. In general, the younger and less experienced the child, the greater the presumption that he or she cannot participate competently in healthcare decisions but the trend is to include children as young as five years old. Many older children, especially adolescents, clearly overturn this presumption that they cannot participate.

SHARED DECISION MAKING. Ideally, important healthcare choices should represent a consensus among parents, doctors, nurses, and the child if he or she is mature enough and willing to participate. Together they find the option best suited to the child and the family (U.S. President's Commission, 1982). In the final analysis, however, parents or guardians generally have legal and moral authority to make medical decisions for minor children.

PARENTS' OR GUARDIANS' AUTHORITY. Parents and guardians have the authority to make healthcare decisions for the same general reasons they can select their children's religion and schooling. The philosophers Allen Buchanan and Dan Brock (1989) discuss several reasons for this policy. First, parents and guardians are generally most knowledgeable about and interested in their children and so are most likely to do the best job for them. Second, the family usually bears the consequences of the choices that are made for a child. Some choices and their consequences suit certain families better than others. Third, children learn values and standards within their families, and different values and standards may lead to different healthcare choices. Within limits it is important to honor the standards and values of families because it is primarily in the family structure that people in society learn values. Fourth, families need intimacy with minimal state intrusion. Thus, unless a child is placed at risk, there is reason to tolerate the choices that families make for their children and give families wide discretion in selecting children's healthcare.

Parents or guardians maintain this authority as long as they promote the well-being and opportunities of those under their care and prevent, remove, or minimize harms to their minor children. Their authority can be contested, however (Rodham; Holder, 1985; Kopelman, 1997). Moral disputes over when to challenge parental authority to make healthcare decisions often center on practical and theoretical issues about when harms or dangers to children warrant interfering with parental authority and what restrictions on parental choice are needed to secure a child's well-being.

Parents who abuse, neglect, or exploit their children may lose custody of them temporarily or permanently. Physical, sexual, or emotional abuse inflicted on children constitutes grounds for the loss of parental authority. In addition, parents who make imprudent or neglectful decisions may lose custody temporarily or permanently. For example, parents may lose custody temporarily if they endanger a child by declining standard antibiotic care to treat the child's bacterial meningitis, preferring the use of herbal teas. Parents also may lose custody temporarily if they endanger a child by acting on certain beliefs. For example, Christian Scientists object to surgery and Jehovah's Witnesses object to blood transfusions, yet courts can order either intervention if a child is endangered (Holder, 1985; Rodham; Kopelman, 1997). Because children cannot protect themselves, healthcare professionals, teachers, neighbors, and other members of the community have a duty to report suspected child abuse, neglect, or exploitation to state agencies for investigation. When parental acts or omissions pose an imminent danger to children, doctors, nurses, hospital administrators, and social workers have a moral and legal duty to seek a court order for proper care (Holder, 1985; Kopelman, 1997).

CHILDREN'S ASSENT AND CAPACITY Decisions about when to consult or inform children about their healthcare options usually are important for older children and those with serious illnesses in cases in which distinct choices result in different outcomes. Some, but not all, children want to understand the decisions about their healthcare and often have an opinion about their care (Buchanan and Brock; Holmes; Matthews). Moreover, adolescents do not always need parental consent to obtain services such as treatment for substance abuse, abortion, and contraception (Holder, 1985, 1989).

This trend toward informing or consulting children stems from several sources. First, it results from research about what children of different ages and stages of development can understand. Social-science research has found that many children understand a great deal about their diseases and even their imminent death (Bluebond-Langner). They sense when people are not truthful, and this can cause them to suffer by feeling isolated from discussions, decisions, and support (Bluebond-Langner; Matthews).

When children have capacity and are prepared appropriately, truthfulness usually has good consequences by promoting cooperation and enhancing trust in their caretakers. Truthfulness also can foster decision-making abilities and maturity. When children have life-threatening or chronic illnesses, it may be especially important to them to gain some control over their lives and some respect for their views. For those facing death, opportunities to become self-fulfilled and self-determining persons may be restricted to choices about how they will live their last months.

Second, this trend stems from an understanding that capacity is task-related. In assessing ability the question must be asked: Capacity for what? People are capable of doing some things and not others and thus may have the capacity to make some healthcare decisions but not others (Buchanan and Brock; Faden et al.; Kopelman, 1990; Matthews; U.S. President's Commission, 1982). An eleven-year-old child with cancer may understand a great deal about the illness because he or she has had experiences beyond those of most eleven-year-old children. Consequently, the child may be better able than most children of the same age to understand or participate in healthcare decisions.

Children are increasingly able to participate in healthcare decisions as they become better able to understand and reason about their options and life plans. Although young children cannot do this, some adolescents may be as capable as most adults in these respects (Holmes).

In recent literature *competent* and *incompetent* are used as legal categories. The presumption is that unless the courts decide otherwise, adults are legally competent and minors are not. In reality, many legally competent adults lack decision-making capacity and many older minors are as capable as most adults. For the purpose of healthcare, decision-making capacity concerns the individual's ability to understand and appreciate the information needed to make informed decisions, evaluate that information in terms of stable personal values, and be able to use and manipulate the information in a reasonable way (Applebaum and Roth; Buchanan and Brock; Kopelman, 1990). To decide whether minors have the capacity to participate in important healthcare decisions, adults should assess how well children can understand the information, deliberate, appreciate the situation, and make, defend, and communicate choices. In addition, it is important to determine whether a minor has reasonable and stable personal values. The more they have such abilities, the more they should participate.

Many authors favor a sliding scale to determine whether a person is capable of making medical decisions (Applebaum and Roth; Kopelman, 1990). The lower the probability and the magnitude of the risk of harm from the decision, the less the need to scrutinize the decision-making capacity of the person giving consent. However, the greater the probability and the risk of harm from the decision, the higher the level of scrutiny that the decision is rational. The reasoning of parents who refuse chemotherapy for a child with cancer, for example, has to be assessed very carefully.

How Should Decisions Be Guided?

There are four important standards for healthcare decision making:

1. The first standard—self-determination—applies primarily to the voluntary decisions of legally competent and informed adults who make their own choices about their well-being and opportunities as long as they do not harm or violate the rights of others. As minors become more mature, they should be accorded more self-determination, but their preferences need not be honored as are those of adults (Holder, 1985, 1989). An adolescent with cancer who insists that he or she would rather die than lose a leg needs help to understand that reaction. The degree of irreversibility and the severity of the consequences often determine whether a minor's preferences should be honored. Minors' choices generally become more morally binding on adults when minors show that they understand and appreciate the nature of the situation in relation to their life goals. Adult guidance is needed when minors cannot demonstrate that their choices enhance their well-being and opportunities.

2. Like some adults, older children may prepare advance directives about their healthcare choices if they become incapacitated. Although a minor's choice need not be honored in the same way as an adult's decision, it may be an important consideration or seem morally binding in some circumstances. Dying children may, for example, indicate that they wish to donate organs or plan their funerals. Parents may want to follow such instructions carefully out of respect to the child's wishes.
3. A third standard—substituted judgment—applies to someone who once was able to express preferences. In using this standard, people select the option they believe the person would choose if he or she were able. Families often know their relatives well enough to predict the choices their relatives would have made. Children, especially those with serious or chronic illnesses, also may express general preferences that should guide parental choices. One child who was very sick insisted that he did not want to be maintained in a persistent vegetative state (PVS) "like a zombie."
4. The best-interest standard applies to those who do not have the ability or authority to make decisions for themselves. This standard maintains that decision makers should try to identify a person's immediate and long-term interests and then determine whether the benefits of an intervention or procedure outweigh the burdens. This does not mean that they seek what is absolutely best, because that may be impossible (the best doctor cannot treat everyone), but that they seek the best among the available options. This standard permits complex judgments about what on balance is likely to be best for an individual in light of the available options (Buchanan and Brock; Kopelman, 1993, 1997). For example, the benefit of obtaining a long and healthy life would outweigh the burden of enduring intense pain for a short time. The best-interest standard, however, might be used by parents, doctors, and nurses to withhold or withdraw maximal life-support treatment from children who have intense and chronic pain, with no prospects of improvement or foreseeable pleasures, understanding, or capacities for interaction.

In some cases objectively or intersubjectively confirmable estimates about pain and a well-understood prognosis force parents and doctors to choose between preserving biological life and providing comfort. Some children live in considerable discomfort from the technologies that keep them alive, such as a gastrostomy (a tube through which food goes directly into the stomach), intravenous lines, ventilators (breathing machines), long stays in intensive-care units, and a tracheotomy (a hole in the throat that aids breathing).

One goal of medicine, which should be balanced against others, is to preserve and prolong biological life. Since ancient times this ideal has been understood to mean that one ought to prevent untimely death. However, a question remains regarding the best interests of a person whose life is continued by means of maximal treatment that is a burden to that person (U.S. President's Commission, 1983; Buchanan and Brock; Kopelman, 1993). In cases where doctors and others disagree about what is best, it is hard to apply the best-interest standard. In such situations and for the general reasons discussed above, which give parents wide discretion when doctors disagree about what is best, an established legal and moral consensus using the best-interest standard allows parents to choose from options advanced as best (Buchanan and Brock; Holder, 1985, 1989; U.S. President's Commission, 1982, 1983).

The best-interest standard was challenged by President Ronald Reagan (1986) and Surgeon General C. Everett Koop (1989), who believed that quality-of-life considerations were likely to be abused. Under their influence the federal government in 1984 amended its child-abuse laws and adopted the so-called Baby Doe guidelines ("Child Abuse and Neglect," 1985). These rules forbid withholding or withdrawing lifesaving care from a sick infant unless the child is dying or is in an irreversible coma or when treatment is both virtually futile in terms of survival and inhumane. To forgo lifesaving treatments it is not sufficient that the treatment be inhumane or gravely burdensome, as it would be in the Roman Catholic tradition. Suffering cannot be taken into account except when the child cannot survive even with maximal treatment (Kopelman, 1989a, 1993).

The Baby Doe rules are controversial because they radically restrict parental discretion and standard medical practice. In a 1988 survey U.S. neonatologists indicated that the use of this policy for judging when to withdraw or withhold care for infants would result in overtreatment, poor use of resources, and insufficient attention to suffering (Kopelman et al., 1988).

Defenders maintain that properly understood, the best-interest standard is a useful way to protect children and others who are incompetent (Kopelman, 1997). For example, the U.S. President's Commission states, "This is a very strict standard in that it excludes considerations of the negative effects of an impaired child's life on other persons, including parents, siblings and society" (U.S. President's Commission, 1983, p. 219).

Allen Buchanan and Dan Brock (1989) argue that quality-of-life assessments are not open to abuse if they are limited to judgments about what is best for the individual patient. The courts and others who reject such judgments

made on behalf of incompetent people, they argue, do not distinguish two kinds of quality-of-life judgments. Quality of life judgments based on considerations of social worth try to weigh the interests or value of a person's life against the interests or value of other people's lives; they are comparative. In contrast, noncomparative quality of life judgments try to consider the value of the life to the person, comparing the value of living the individual's life to having no life at all. Although this comparison is difficult to make, it can be guided by choices made by competent adults who decide that there are worse things than death, including certain burdensome treatments to keep them alive. Buchanan and Brock (1989) hold that in applying the best-interest standard one should use noncomparative estimates, contemplating only the quality of life for that individual; a person's social value should not be part of the assessment. Noncomparative quality-of-life judgments, then, should be circumscribed very carefully and strictly. It is possible to reflect, for example, on whether most people would want to live such a life.

To some extent the effectiveness of the best-interest standard relies on the degree of social consensus about what is best for children and other persons who lack decision-making capacity. Consequently, it is hard to use in cases in which there is sustained disagreement, as there may be about when and how to use quality-of-life considerations. Arguably, one cannot avoid quality-of-life decisions entirely. For example, the Baby Doe regulations state that one need not provide maximal treatment to those who are permanently comatose, and that is a quality-of-life judgment. The debate also concerns what discretion should be given to parents, physicians, and other clinicians to select the best available option.

Kopelman (1997) has argued that some of the criticisms of the best-interest standard stem from confusing its different meanings. First, it is used as an ideal. For a child to receive a very scarce resource for a marginal benefit may be ideal yet unreasonable once one considers the claims and needs of others and the available resources. Nonetheless, it is important to consider what might be ideal for a child in framing what should be done in light of others' needs and the available resources. Ideals are also important in giving direction to people's efforts. The ideal of no children being abused or neglected gives direction to advocates for children.

Second, the best-interest standard is used in the sense of what is best given the options or what is best all things considered. For example, it may not be possible to give each child ideal healthcare, but it may be realistic to seek basic healthcare for all children. Another example is that some parents are not ideal guardians, but the state does not step in unless their children are endangered. If parents refuse lifesaving healthcare for children, the courts may remove custody from the parents temporarily or permanently; they then may use the best-interest standard to seek what is best for the child given the available options. They are not seeking what is ideal, because that may not be realistic, but what is best, all things considered, for the child given the available options.

Children as Research Subjects

Children are not responsible for their illnesses. The natural and social lotteries leave some children with diminished opportunities as a result of illness. Good health and social services may be essential to give these children a chance to flourish and develop their potential as self-fulfilled and self-determining persons. In addition, good healthcare helps children by preventing many illnesses and allows for early diagnosis and treatment. Good healthcare, however, is the product of study and research, and the problem is how research should be conducted to help children.

The ethical basis for research policy with children concerns promoting the same primary values that shape treatment decisions: enhancing well-being and opportunities. Because many children, like adults severely impaired with mental illness or retardation, lack the capacity to give informed consent, they are regarded as vulnerable research subjects. Like policy regarding treatment, research policy with children is shaped by different authority principles (who decides) and guidance principles (substantive directions about how decisions should be made). There is, however, an additional problem.

Pediatric research regulations and policy must deal with a dilemma: With too few protections, children selected as subjects may be exploited. If the regulations impose too many protections, however, it may become so difficult to conduct research that the knowledge base for making good decisions for children will erode. Different policy options try to solve this dilemma but do so differently:

1. The *surrogate* or *libertarian* solution allows the same sort of research with children as with other subjects if the parents consent. This solution may not offer adequate protection to children because it permits parents to enroll them in potentially harmful research even if it holds out no direct benefits to them. Parents' legal and moral authority presupposes the promotion of children's opportunities and well-being and the prevention, removal, or minimization of harms to them. Parents have no authority to enroll their children in potentially harmful research that hold out no benefits to them. Volunteering to put another person in harm's way may violate a guardian's protective role.

2. The *no consent–no research* or *Nuremberg* solution excludes children because children are not considered competent to give informed consent to being enrolled as research subjects. This view, expressed in the Nuremberg Code (Germany [Territory under Allied Occupation], 1947), seems too restrictive. It prohibits enrolling a child in a study even if the project could benefit the child directly. Moreover, to test the efficacy of treatments for distinctive groups, some members of those groups must be subjects. Competent, normal adults cannot serve as subjects in projects that test children's growth or maturity, drugs for premature infants, and treatments for children's life-threatening asthma.
3. The "risk-benefit" solution allows research with children if it benefits them directly or does not place them at unwarranted risk of harm, discomfort, or inconvenience. To balance the social utility of research with respect for and protection of children, this option stipulates that the greater the risk, the more rigorous and elaborate the procedural protection and consent requirements. Many countries, such as the United States, Canada, the United Kingdom, South Africa, Australia, and Norway, in addition to international organizations such as the World Health Organization in its *Declaration of Helsinki* and the Council for the International Organizations of Medical Science, favor this solution. Research should be approved by local boards known variously as institutional review boards (IRBs) ethical research committees (ERCS), or research ethics committees (RECs) and in some cases by federal boards as well. Approval is based on findings that subjects have been selected fairly and that the risks to them are minimized and reasonable in relation to the anticipated benefits of the study ("Protection of Human Subjects," 1993). Adequate provisions also must be made for the safety and confidentiality of subjects. Investigators must seek parents' informed consent. When possible, they also must obtain the child's assent, where assent means a positive agreement, not merely failure to refuse. Children's refusals are not binding when their parents and doctors judge that it is in their interests to participate, for example, in studies in which children may obtain a scarce resource to treat a deadly disease. This risk–benefit solution tries to determine whether the risks are proportional to the benefits for each individual and uses risk assessment to try to balance the social utility of encouraging studies that maintain respect for and protection of children's rights and welfare.

Using a likely harms-to-benefit calculation, U.S. regulations ("Protection of Human Subjects," 1993), as outlined below, specify four categories of research with children. As the risks increase, the regulations require increasingly more rigorous documentation of appropriate parental consent, children's assent, direct benefits to the child, or benefits to children with similar conditions. Local IRBs can approve studies only in the first three categories.

The first category of research permits research with no greater than a minimal risk provided that it makes adequate provisions for parental consent and children's assent. Many important studies are safe, such as asking children to perform simple and pleasant tasks. Using this category, investigators might gain approval to study at what ages preschool children can name colors, identify animals, and perform simple tasks such as stacking blocks on request.

The second category of research permits the approval of studies with greater than a minimal risk if (1) the risk is justified by the anticipated benefit to each subject; (2) the risks in relation to these benefits are at least as favorable to each subject as are the available alternatives; and (3) provisions are made for parental consent and the child's assent. This category permits a child to get an investigational drug that is available only in a research study. Moreover, because children have unique diseases and reactions, to study the safety and efficacy of many conventional, innovative, or investigational treatments for children, some children have to serve as subjects in controlled testing.

The third category of research permits research (1) with a minor increase over minimal risk that holds out no prospect of direct benefit to the individual subject; (2) in cases in which the study is like the child's actual or expected medical, dental, psychological, or educational situation; (3) in cases in which the study is likely to result in very important information about the child's disorder or condition; and (4) in cases in which provisions are made for parental consent and the child's assent. In using this category, investigators have been permitted to perform additional lumbar punctures on children with leukemia, who get them anyway, to help study that disease.

Research that cannot be approved under the first three categories may sometimes be approved if (1) it presents a reasonable opportunity to understand, prevent, or alleviate a serious problem affecting the health or welfare of children; and (2) the study is approved by the secretary of the U.S. Department of Health and Human Services (DHHS) after consultation with a panel of experts about the value and ethics of the study and determination that adequate provisions have been made for public comment, parental consent, and the child's assent. In using this category investigators might gain approval to conduct studies to prevent or treat epidemics affecting children, such as the acquired immune deficiency syndrome (AIDS) epidemic, or a new infectious

disease like the killers of the past (pneumonia, scarlet fever, diphtheria, and polio).

DIFFICULTIES. Unfortunately, the risk–benefit solution leaves key terms undefined or poorly defined, allowing different interpretations concerning when risks of harm are warranted and what constitutes a benefit (Freedman et al.; Kopelman, 2000, 2002; National Bioethics Advisory Commission [NBAC]). For example, consider the pivotal concepts of a "minimal risk" and a "minor increase over minimal risk." The federal rules state: "*Minimal risk* means that the probability and magnitude of harm or discomfort anticipated in the research are not greater in and of themselves than those ordinarily encountered in daily life or during the performance of routine physical and psychological examinations or tests" ("Protection of Human Subjects," 1993, section 102i). The first part of the definition focuses on everyday risks, and the second on routine examinations. (Interestingly, the National Bioethics Advisory Commision [2001] recommended dropping the second part of the definition in favor of the more permissive first part, whereas the Council for International Organizations of Medical Science [CIOMS] omits the first [Council for International Organizations of Medical Science, 2002].)

Kopelman has argued that this definition is morally and conceptually problematic, especially the part using "everyday risk": First, how should people establish thresholds for the probability and magnitude of harm used to identify everyday risks, and even if they solve this problem, why are everyday risks morally relevant for determining acceptable research risk? People's daily risks may include car accidents and terriorist attacks. Is it possible to know the nature, probability, and magnitude of these everyday hazards well enough that they could serve as a baseline to estimate morally acceptable research risks for children? It seems easier to determine that a study asking children to stack blocks is a morally acceptable, minimal-risk study than to estimate the nature, probability, and magnitude of whatever risks of harm people normally encounter.

Second, given the different hazards in different countries and communities, what locale or locales should be used to assess everyday risks in determining morally acceptable research? Some favor a relative standard by which minimal risk is judged against the background of the children's location, environment or condition. Others reject this "relativistic" standard in favor of an absolute standard, saying that all children should have the same standard; otherwise one reaches morally abhorrent conclusions such as that more risks can be taken with children in dangerous neighborhoods than with children in safe and affluent neighborhoods. Third, why should everyday risks of harm be regarded as morally relevant for determining that research risks are minimal when some everyday risks are great?

Fourth, if this is a useful and clear standard, why has there been sustained disagreement over whether common procedures should be viewed as having a minimal risk, a minor increase over minimal risk, or greater risk? Since the regulations appeared decades ago, there have been sustained and substantive differences among pediatric experts in both treatment and research settings about how to assess the risk of procedures such as venipuncture, arterial puncture, and gastric and intestinal intubation (Janofsky and Starfield). Investigators and others concluded that better standards of risk assessment in children's research had to be formulated (Janofsky and Starfield; Lascari; National Bioethics Advisory Commission; Kopelman, 2002).

In addition, the U.S. regulatory definition of minimal risk offers little guidance about how to assess psychosocial risks such as breach of confidentiality, stigmatization, labeling, and invasion of privacy. Risks are allegedly minimal if they are encountered ordinarily in daily life or during routine examinations. Doctors, nurses, and psychologists, however, "ordinarily encounter" many psychosocially sensitive discussions in routine examinations and testing, including those about family abuse, substance abuse, sexual preference, and diagnoses, any of which could affect how people are viewed or whether they will be able to get jobs or buy insurance. Moreover, psychosocial-risk assessment is an increasingly difficult problem. Some genetic and other testing has low physical risks, such as taking a drop of blood, but high psychosocial risks. For example, Huntington disease is a genetic condition that causes progressive dementia and loss of motor function typically when the person becomes an adult. A person known to have this condition could be denied a job or insurance or be stigmatized in the community. Thinking of risks of harm as merely physical ignores such profound psychosocial risks.

Moreover, there is no definition of "a minor increase over minimal risk," the upper limit of risk that many review boards can approve. The courts have begun to consider what risks of harm are permissible and may help standardize interpretations (Kopelman, 2002).

Even when it is agreed that the ethical basis for research policies with children is to promote their opportunities, well-being, fair treatment, and self-determination, it is difficult to articulate policies that balance the need to protect children and the need to gain knowledge. If research is not conducted with children as subjects, children may be denied the benefits of advances stemming from research and good

information about which procedures or interventions promote health and prevent, treat, or diagnose disease. However, if children are enrolled as research subjects, vulnerable individuals who cannot give informed consent are being used.

Resource Allocation

Many children do not receive basic healthcare or social services. In some cases, countries that can afford to provide those services allocate insufficient funds for them. For example, the main health problems of children in the United States arise from failure to provide such basic care for children's allergies, asthma, dental pathology, hearing loss, vision impairment, and chronic disorders (Starfield; Newachecket et al.). Basic healthcare and social services promote children's well-being, enhancing their opportunities in fundamental ways and correcting some inequities caused by the natural and social lotteries. Children who are sick cannot compete as equals and thus lack equality of opportunity with other children. The more these conditions are easily correctable, as many of them are, the more unjust it is to leave children sick or disabled. Failure to provide children with basic healthcare and social services when a society has sufficient means is unjust on the basis of any of four important theories of justice: utilitarianism, egalitarianism, libertarianism, and contractarianism. This point of agreement among widely divergent positions serves as a powerful indictment and proof that as a matter of justice goods, services, and benefits should be redistributed more fairly to children to provide them with basic healthcare and social services.

Four theories of justice offer different guidance about how to allocate goods, services, and benefits. Proponents have used them to determine children's fair share of healthcare funding in relation to adults (intergenerational allocation) and ways to set priorities for funding within children's healthcare programs (intragenerational allocation). Each theory addresses what kinds of benefits, goods, and services should be provided to people as a matter of justice and how to choose from among programs when not all can be funded. Although there are many variations of these positions, each seeks a defensible standard to help make choices fairly.

UTILITARIANISM. Utilitarianism offers one solution to the problem of allocating healthcare justly between generations and among children's programs. In a well-known version, the philosopher John Stuart Mill (1863) argued that a just allocation provides the greatest good to the greatest number of people; the utility of following principles of justice is so great that these are among the most fundamental moral principles. People should not consider only the utility of isolated acts, Mill maintained, but also the rules of conduct that, if adopted and adhered to, maximize utility. Actions are right insofar as they fall under such a rule.

In their efforts to maximize utility for the greatest number in accordance with just rules, utilitarians seek to prevent or cure the most common illnesses, adopt programs that help many rather than few persons, and use funds where they will have the greatest impact for the most people. For example, utilitarians would resist funding expensive organ transplantations that help relatively few persons for a short time if those transplantations sidetracked programs that could help many people.

Some of the least expensive and most beneficial interventions are education about the benefits of exercise, a good diet, prevention of teenage pregnancy, and avoidance of alcohol, tobacco, and harmful drugs (U.S. Department of Health and Human Services). Relatively inexpensive interventions can aid in the treatment of many problems common in childhood, including vision impairment, hearing loss, dental pathology, allergies, and asthma, as well as the variety of chronic disorders that cause considerable functional impairment (Starfield; Newachecket et al.). Utilitarians favor providing such healthcare for children because it greatly increases their well-being and opportunities. It is socially useful and cost-effective because it can prevent costly illnesses and benefit the current generation of adults, who, when aged, will need support from a healthy, stable, and productive work force.

Utilitarians might even favor preferential consideration of children. Interventions that benefit both children and adults generally offer children the most years of benefit. Those added years increase the net good and thus could justify some preference toward children. For example, in some countries children receive dental care that is unavailable to adults because it has lifelong benefits and prevents costly future problems. Daniel Callahan (1987, 1990) believes that the young have a stronger claim to healthcare than the old and should be given priority; the healthcare system should see as its first task helping young people become old people and help older people become still older only if money is available. He argues, moreover, that medicine should give its highest priority to the relief of suffering rather than the conquest of death.

In choosing among children's programs for funding, defenders of utilitarianism assess the net benefit for the community of children. A utilitarian would favor funding routine care, mass screening, and prevention programs that help many children rather than the development of costly therapies that help few children. Consequently, utilitarians

probably would resist using state funds to give otherwise normal short children growth hormone for many years, at a cost of many thousands of dollars a year, to increase minimally their adult height. Utilitarians, however, might permit private insurance or payment (in a multitiered healthcare system) for these and other services if it increased or did not diminish the net good.

Defenders of utilitarianism presuppose that it is possible to calculate what is best for the greatest number, but critics question that presumption (Brock). Moreover, critics state, whole groups could be excluded from beneficial healthcare for the sake of the common good, such as people with expensive or rare conditions and those with illnesses that are stigmatizing.

Utilitarians might respond that society would suffer from such exclusions, showing that this is not a good option even if one uses utilitarian calculations. This presupposes, however, that enough people would know about the exclusions and be distressed enough to alter the calculation. Sympathy for utilitarianism may depend on beliefs about whether it is possible to make utility calculations and whether a theory is acceptable if it permits people to exclude some groups for the common good regardless of the results of the utility calculation (see Brock). Defenders of rule utilitarianism, a version of utilitarianism that clarifies the role of rules in assessing utility, respond that, properly understood, utility prohibits unfair exclusions of individuals or groups; people adopt rights and justice principles because they are useful, and unjust exclusions undercut the utility of those rights and principles for all (Buchanan; Mill). Even if it is cost-effective or politically expedient to exclude a particular person or group, that exclusion undercuts something more important for all of us, namely, fair rules.

Utilitarians favor basic healthcare and social services for all children because of the utility to the children and to society. For example, suppose society could save a great deal of money by excluding certain children from healthcare services. Although this might save money in the short run, defenders of rule utilitarianism might argue that it is unjust because adapting and adhering to the rule that all should receive basic services are more useful in the long run than is excluding a few to save money. Accordingly, the rule that all children should receive basic care is vindicated because the rule is useful and making exceptions is less useful.

EGALITARIANISM. Egalitarianism is a theory of justice whose proponents attempt to solve allocation issues and intergenerational disputes by holding that access to the same benefits, goods, and services should be provided to everyone on the same basis. It is a principle of justice that requires society to try to make all people's objective net well-being or opportunities as equal as possible. Most people do not want dialysis because they do not have kidney disease, but people want access to dialysis if they should need it. Egalitarians, then, do not want exactly the same treatment for everyone as a condition of justice but want everyone to have access to the same goods, services, and benefits on the same footing.

Egalitarians look at outcomes of distribution schemes to determine whether distributions are fair. Accordingly, proponents of egalitarianism judge it to be unfair, for example, that adults over sixty-five can get diabetes and asthma treated free of charge in the United States but children cannot. Age might be a determinant in deciding who gets benefits, goods, and services, but only as one among other prognosticators of success. For example, people over eighty or under two years of age might be excluded from consideration for a certain type of surgery because they are unlikely to survive the procedure.

Defenders of egalitarianism hold that what is provided to one person should be available to all similarly situated persons. The advantages of good healthcare are such that in fairness they should be distributed on as equal a basis as possible. There should not be a multitiered system with one level of goods and services for the rich and another for the poor. If society allows some normal short children to have growth hormone for many years at a cost of thousands of dollars a year, all who are similarly situated should have access to similar services. For expensive or scarce resources, many egalitarians favor lotteries so that all those who are similarly situated have an equal opportunity and are recognized as having equal worth (Childress; Veatch). Consequently, if organs for transplantation can be provided only to some children, there should be a lottery among those who meet whatever standards are set. In this way people acknowledge the value of each person and the importance of fair access of all to scarce or costly benefits, goods, and services. One difficulty for egalitarians is that some people's needs are so great that they could consume most of the resources of a healthcare system. Robert Veatch (1986) tries to defend a commitment to those who are so disadvantaged that they could use unlimited resources while placing limits on their claims on other members of society.

In defending egalitarianism it is difficult to clarify what kind of equality is important. If it is *access* to the same benefits, goods, and services, age bias and discrimination could be introduced through preference for certain benefits, goods, and services. For example, treatment for prostatic hyperplasia and Alzheimer's disease helps only adults; other care helps adults much more than children, such as treatments for heart disease or lung cancer and treatments at the end of life. Some funding choices discriminate by excluding services equally and for all diseases afflicting people with

stigmatizing conditions, such as sexually transmitted diseases. This parallels a problem of utilitarianism in which whole groups can be excluded if society decides, to save money, that none will have treatments for certain conditions.

If, however, equality is understood in terms of *outcomes* rather than access, age bias and discrimination also can be introduced through the method of collecting and presenting data (Starfield). In the United States, for example, data collection to determine the health of different populations focuses on life-threatening illnesses and death. Relatively few children have such morbidity or mortality in comparison to adults, giving the impression that children are generally healthy. This impression, however, is a consequence of how the data are collected. Most children's needs stem from problems that are not life-threatening illnesses but have a profound effect on health, such as dental problems, vision impairment, allergies, and asthma. Moreover, although the death rate of children in the United States is low compared with that of adults, it is the highest among equally affluent countries (Starfield). Looking at certain outcomes, then, promotes an unfair view of childhood health and morbidity. Programs based on such data can create unjust age bias against children. Thus, treating everyone as equals is problematic if the measures favor certain groups.

People's willingness to defend egalitarianism depends in part on whether they believe it is fair to restrict choices by insisting that no one can have healthcare that cannot be provided to all on the same basis. If people can squander their assets on entertainment and clothes, it seems unfair to insist that they cannot spend it on marginally beneficial, exotic, or expensive healthcare for their families. Some respond that rich people dread single-tiered systems because it means that they cannot have their usual advantages through money and forces them to live by the same rules as others. They argue that allocation of healthcare (especially in life-and-death situations) is too important to be left to unregulated personal choice and market forces. Some defenders of egalitarianism modify their view to permit people to use their discretionary resources as they wish.

LIBERTARIANISM. Libertarians generally agree that competent adults should not be forced to do anything by the state unless it prevents harm to third parties. Coercion is permissible to prevent theft, murder, physical abuse, and fraud; enforce contracts; and punish competent people for harming others (Buchanan). The best-known defender of this view, Robert Nozick (1974), follows the eighteenth-century philosopher John Locke in maintaining that people's right to their fairly obtained property is fundamental and determines the proper functions of the state and the moral interactions among individuals.

People are entitled to their holdings and may dispose of them as they wish, according to this view. They argue that the state should not redistribute people's wealth in accordance with a pattern of distribution that examines outcomes (such as utilitarianism and egalitarianism) or uses coercive measures to take people's holdings, and adults should be free to fashion social arrangements out of their ideas of compassion, justice, and solidarity (Engelhardt). People do not have a responsibility to be charitable, say libertarians, but acts of charity are praiseworthy and should be encouraged.

Libertarians hold that children's healthcare is the responsibility of their guardians, not the state. Market forces of supply and demand and choices about how to use their own money should shape the kind of healthcare people select for themselves and their children. If parents want to pay for special services such as growth hormones or repeated organ transplants, they should be permitted to do so. H. Tristram Engelhardt, Jr., argues that societies can decide morally who is entitled to healthcare of a certain kind within certain limitations. However, a society does not, for example, have "the moral authority to forbid consensual acts among agreeing adults, such as agreement to sell an organ" (Engelhardt, p. 10).

Sympathy for libertarianism depends on whether it is believed to offer enough protection for people, especially children and impoverished or incompetent adults. This view arguably benefits the wealthy and powerful; because most children are neither, it might create an age bias against children. Libertarians argue that competent adults should pay their own way, but when do people really do that? Typically, people's healthcare insurance gives them access to institutions heavily subsidized by public money. People who "pay their own way" may pay just a bit more for many more services. Those who cannot pay more are unfairly excluded. Libertarians might agree that separate institutions should be set up in which people truly pay their full share even if that would mean that few could afford such added care.

Libertarians usually favor special state protection for children, allowing the state to interfere with parents who endanger, neglect, or harm children. This can include providing children with a "safety net" of basic healthcare and social services. A system favoring special benefits based on redistribution of wealth for competent adults, however, is considered unjust. Hence, a system like that in the United States that provides many social and health benefits to competent and even wealthy adults but not to children, for example, in the allocation of healthcare benefits, goods, and services, would be viewed by libertarians as unjust.

CONTRACTARIANISM. Contractarians hold that distributions of social goods are fair when impartial people agree on

the procedures used for distribution. The best-known defender of this position is John Rawls, who in *A Theory of Justice* (1971) and *Political Liberalism* (1993) contends that people form stable and just societies by building a consensus that merits endorsement by rational and informed people of goodwill.

This entails a commitment to three principles of justice. First, "each person is to have an equal right to the most extensive system of equal basic liberties compatible with a similar system compatible for all." Second, "offices and positions are to be open to all under conditions of equality of fair opportunity—persons with similar abilities and skills are to have equal access to offices and positions." Finally, "social and economic institutions are to be arranged so as to benefit maximally the worst off" (Rawls, 1971, p. 60). These principles are ordered lexically such that the first, the greatest equal-liberty principle, takes precedence over the others when they conflict and the second, the principle of fair equality of opportunity, takes precedence over the third, the difference principle. Nowhere is healthcare as a right mentioned specifically in Rawls's attempt to frame the basic structure of a just society. This is understandable because a society may not have enough healthcare goods, services, or benefits to distribute. In a society that does have such goods, services, and benefits, however, their fair distribution seems central to promoting fair equality of opportunity and benefits to the worst off.

Norman Daniels (1985), building on Rawls's work, argues that society should provide basic care to all but redistribute healthcare goods and services more favorably to children. The moral justification for giving children access to basic healthcare, argues Daniels, rests on a social commitment to what he and Rawls call "fair equality of opportunity" (or affirmative action). Healthcare needs are basic insofar as they promote fair equality of opportunity. Healthcare for children is especially important in relation to other social goods because diseases and disabilities inhibit children's capacity to use and develop their talents, thus curtailing their opportunities. For example, children cannot compete as equals if they are sick or cannot see or hear the teacher. Thus, a society committed to a fair equality of opportunity for children should provide adequate healthcare.

Daniels holds that to assess whose needs are greatest, people have to use objective ways of characterizing medical and social needs; the ranking of needs helps determine what is basic and who profits most from certain services. Using the difference principle, free, additional service might be provided to the poorest children to help level the playing field so that they could compete more effectively with those from more affluent homes. Unlike utilitarians, who would be guided by where money would have the greatest overall impact on the health of the greatest number of children, contractarians try to bring all children of similar talents to the same level of functioning so that they can compete as equals.

Contractarianism has certain difficulties. Some regard it as a method for arriving at ethical principles, not as an alternative to views such as utilitarianism, egalitarianism, and libertarianism (Veatch). Accordingly, those who think it generates a unique theory need to clarify how it has a distinct content. In addition, it is hard to specify what is meant by "people's normal opportunity ranges" or to decide how to apply fair equality of opportunity. This position seems to suggest (arguably similar to egalitarianism) the unsatisfactory consequence that people should fund treatments, however exotic and costly, that offer a chance for the most disadvantaged to improve their normal opportunity range irrespective of the needs of the many; gifted children could be denied opportunities to excel so that others could enhance their normal opportunity range or be brought to the level of well-being and opportunities of average children. Another problem is that contractarianism presupposes, like utilitarianism, that there is a fair and objective system for ranking medical and social needs and deciding who benefits most from services (Brock). It is unclear whether such a comprehensive and objective ranking is possible. Such "objective" choices about appropriate or useful programs might be mixed with social and personal biases. These problems, however, do not undermine the contractarians' commitment to the justice of equal opportunity for children, including the fairness of providing basic health and social care for children.

A PROPOSED CONSENSUS. Each of these theories of justice supports the claim that children are entitled to basic healthcare and social services to correct inequalities and promote their flourishing as free and self-determining people who can develop their potential. The fact that defenders of such divergent approaches agree on this entitlement reflects a consensus that children's distress ought to be relieved whether it is related to inadequate healthcare, poverty, abuse, neglect, malnutrition, or exploitation. A primary duty of a just society is to promote fairly its children's well-being and opportunities to become self-fulfilled persons through access to basic healthcare and social services and to address the inequities resulting from life's natural and social lotteries. Children living in low-income homes in the United States are two to three times as likely as children in high-income homes to be of low birth weight, get asthma and bacterial meningitis, have delayed immunizations, and suffer from lead poisoning. Poor children are also three to four times as

likely as rich children to become seriously ill and get multiple illnesses when they become sick (Starfield).

The gap between the rich and the poor is increasing, and the rise of poverty is most rapid among children. Healthcare costs, driven higher by an aging population and increased demands for expensive technologies, will make it harder for societies to allocate costs justly. In addition, the AIDS epidemic has left many children sick, orphaned, or both, and many children live in the developing world, where resources that could help them are meager. Consequently, disputes involving intergenerational and intragenerational allocation from national and international funds are likely to continue as programs compete for funding. Because children depend on others to advocate for them, adults should continue to set aside their individual interests and consider children's well-being, needs, and opportunities as a matter of justice.

IV. MENTAL HEALTH ISSUES

Conceptualizing a domain of "mental health and children" represents an advance in cultural and societal thinking. The various impediments to this view are well known among students of the history of childhood—at least in Western cultures. These include the concept of children as property, and the broader ignorance and denial of children's affective and cognitive development.

More modern concepts of children and childhood provide a foundation for focusing on the mental health of children as a vital concern. One testament to this development is the passage in 1989 of the United Nations *Convention on the Rights of the Child*. The convention provides a view of children and childhood in which mental-health concerns are central, one that goes beyond the ideas contained in the 1959 *Declaration of the Rights of the Child*.

The convention makes it clear that mental-health issues (e.g., policies that facilitate prevention, and access to services, among others) are primary implications of children's rights. Children, the convention asserts, are entitled to basic psychological resources. These include mandates to ensure family and social identity, empathic and stable care, protection from exploitation, and rehabilitative treatment when experiencing mental-health problems or being exposed to trauma, such as war and abuse.

This rights-focused orientation to the mental health of children reflects a growing appreciation for the scope, depth, range, and subtlety of children's experience. Indeed, in the field of children's mental health there has been a growing recognition and empirical exploration of the existence and

characteristics of child variants and precedents of most major adult mental-health problems. Important examples are those of schizophrenia, post-traumatic stress disorder, and depression.

Schizophrenia

There is evidence that schizophrenia, one of the most devastating mental illnesses with a whole life prevalence rate of about 1 percent, is a developmental disorder, tracing its origin to abnormalities in brain development, which cause subtle and non-specific behavioral changes in childhood and later lead to full blown psychosis, usually in adolescence. Duration of untreated psychosis seems to be a significant predictor of poor outcome (Harrigan et al.), thus making early identification and treatment of first-episode schizophrenia especially important. However, because of the limited specificity and predictive value of the known risk factors for schizophrenia, treatment of asymptomatic subjects with psychotropic drugs is considered unwarranted from a clinical and ethical perspective (Heinssen et al.).

Childhood Experience of Trauma

Trauma—the overwhelming arousal and cognitive dislocation that results from experiencing horrible events—is an important field of study for those who seek to understand mental health in childhood. As with depression, it was once thought that children were incapable of experiencing genuine psychological trauma (Van der Kolk). But research and clinical experience since 1980 have established that trauma and post-traumatic stress disorder play significant roles in the mental health of children.

Children experience trauma in many settings: televised violence, community violence, domestic violence, war, and homelessness. All point to the need to develop a better understanding of the impact of trauma on childhood as part of a larger commitment to understand the mental health issues facing children.

Children may suffer from post-traumatic stress disorder as a consequence of their experiences at home, in school, or in the community. Symptoms in children include sleep disturbances, daydreaming, re-creating trauma in play, extreme startle responses, diminished expectations for the future, and even biochemical changes in their brains that impair social and academic behavior. Trauma can produce significant psychological problems that interfere with learning and appropriate social behavior in school and the family, the bedrocks for mental health in childhood.

The children least prepared to master trauma outside the home are those who experience psychological, physical, or sexual maltreatment at home. Hundreds of thousands of children face the mental health challenge of living with chronic community violence, whether it derives from war or domestic crime. Some 30 percent of the children living in high-crime neighborhoods of Chicago had witnessed a homicide by the time they were fifteen years old, and more than 70 percent had witnessed a serious assault (Garbarino et al.). In refugee camps around the world, children witness and are subject to violence and exploitation.

The experience of community violence takes place within a larger context of risk for these children. They are often poor; often live in families where the father is absent; often contend with their parents' depression or substance abuse; often are raised by parents with little education or few employment prospects; and often are exposed to domestic violence. This constellation of risk by itself creates enormous mental-health challenges for young children. For them, the trauma of community violence is often literally the straw that breaks the camel's back.

Depression in Children

Until the 1970s, many clinicians and scholars expressed doubt that children experience *genuine* depression. The common view held that children were incapable of experiencing full-blown depression. It is clear that children do experience depression, but do so and express it differently from adults (e.g., in offering less verbalization concerning mood and symptoms). With proper developmentally appropriate rewording, the same diagnostic criteria for major depression that are used in adults can apply to children. Depression becomes increasing common as the child grows and reaches a prevalence rate among adolescents that is comparable to that in adults. It is estimated that up to 9 percent of adolescents meet current criteria for major depressive disorder (MDD) and up to 25 percent had suffered from it by their late teens (Kessler et al.). While depression seems to equally affect boys and girls before puberty, female teenagers have a substantially higher rate of depression than their male peers. As in adults, in youth depression is a major risk factor for suicide, which in 2003 ranked third among the leading caused of death among adolescents.

Some children mask their depression by denying symptoms to avoid humiliation and embarrassment, to *protect* vulnerable adults who do not appear to be able to tolerate the child's sadness, or to avoid therapeutic intervention that children perceive adversely (e.g., a child may resist the idea of missing recreational activities to attend therapy or may not acknowledge symptoms of depression to avoid causing parental upset or even conflict).

More generally, one of the important breakthroughs in understanding the mental health of children has been the recognition that "what children can tell us depends upon what adults are prepared to hear." That is, children reveal their mental health status in ways that make sense to adults *if* the adults have the technical skill and psychological availability necessary to receive the child's messages. For adults to be responsive to the mental health issues facing children, they need to understand some basic features of child development, particularly the operation of risk and opportunity.

Risk Factors and Opportunities

Children face a variety of opportunities and risks for mental health and development because of their genetic makeup and because of the social environments they inhabit. Like in other areas of medicine, genetic and environmental factors act in concert in increasing or decreasing the risk for mental disorders. For instance, it has been determined that the risk for antisocial behavior was increased among maltreated boys who also had a genotype resulting in low levels of monoamine oxidase A (MAO), which is an enzyme involved in the metabolism of neurotransmitters (Caspi et al.). The importance of these findings rests on the fact that it was only the coexistence of maltreatment and low MAO expression genotype that conferred an increased risk, whereas either condition in isolation did not. Thus, environment can affect mental health through its impact on the genetically determined makeup of the child. In addition, specific environmental toxins can negatively impact the brain during development. For example, environmental lead poisoning of children may lead to mental retardation and/or behavioral problems. There are also many examples of positive impact of environment during development, such as proper education and non-abusive discipline, which can prevent the emergence of mental disorders even in the presence of an increased genetic risk for these conditions. The complex interaction of risk and protective factors, either environmental or genetic in nature, has profound implications for understanding the mental health of children. The *accumulation of risk factors* is especially important. For instance, the average IQ scores of four-year-old children were found to be related to the number of psychological and social risk factors present in their lives, including socioeconomic conditions as well as intrafamilial, psychosocial factors (Sameroff et al.). But this research reveals that the relationship is not simply additive. Average IQ for children with none, one, or two of the factors is above 115. With the addition of a third and then a fourth risk factor, the average IQ score drops precipitously to nearly eighty-five, with relatively little further decrement as there is further accumulation of five through eight risk factors. This is important because IQ plays an important role in resilience and coping. Thus, low IQ is a risk factor for children's mental health.

Windows of opportunity (opportunity that arises at particular points in development) for intervention on behalf of the mental health of children appear repeatedly across the life course. What may be a threat at one point may be harmless or even developmentally good for a child at another. Classic analysis of the impact of the Great Depression of the 1930s in the United States reveals that its mental health effects were felt most negatively by young children (Elder). However, some adolescents, particularly girls, benefited from the fact that paternal unemployment often meant special opportunities for enhanced responsibility and status in the family.

Opportunities for development include meaningful relationships in which children find material, emotional, and social encouragement compatible with their needs and capacities at a specific point in their developing lives. For each child, the exact combination of factors depends upon temperament, family resources, potential, skill, and the role of culture in defining the meaning and social significance of specific characteristics or behaviors, within some very broad guidelines of basic human needs that are renegotiated as development proceeds and situations change.

Participation of Children in Mental Health Research

Like in other areas of health, human research has shown to be the most efficient means of acquiring critical knowledge on how to prevent and treat mental illness among children. Direct participation of children in research is considered necessary as research in adults is neither fully relevant nor sufficient due to developmental differences. Thus, treatments of proven efficacy and safety in adults have been found to lack efficacy or to be toxic in children. Child participation in research is subject to special ethical requirements that are in addition to those common to all human research (Code of Federal Regulations). Based on the type of research activity, the concepts of *favorable risk/benefit ratio, minimal risk,* and *minor increase over minimal risk* are especially important in determining whether a particular study is ethically acceptable (Vitiello et al.).

Conclusions

The right to mental health is considered an integral part of children's basic rights. Recent years have seen major advances in understanding child development, especially with respect to the interface between neurobiological and

psychosocial components and the interaction between genetic endowment and environment. Research on child mental health has emerged as an essential means of developing effective and safe mental health preventive and treatment interventions for children. Participation of children in research raises important ethical issues, thus making child mental health bioethics a particularly lively and rapidly developing area.

CHRISTIANITY, BIOETHICS IN

• • •

As western culture moves ever deeper into the period characterized in the mid-twentieth century by historian Christopher Dawson as "secularized Christendom," the emerging interdisciplinary field that since 1970 has gone by the name *bioethics* can be understood only as a microcosm of the whole. In certain defining respects the impact of the Enlightenment of the eighteenth century was felt uniquely in the closing decades of the twentieth, in effects good and bad. The effacing of religious discourse from the public square, and the steady fragmentation of the professions under the reductionist pressures of economic and other social forces, show this delayed impact in contexts that have radically shaped the possibility of a bioethics rooted in the Christian vision of the western tradition. If religion is removed from the metaphor of public affairs, it is only in translation that the Christian worldview retains any opportunity to shape the public institutions of the culture. The predicament of Christianity in bioethics at the cusp of this third millennium C.E. lies precisely here. Yet at the same time, the subject matter of bioethics could hardly be of greater moment to those who hold the Christian view of the world.

The core question of which every bioethics issue is ultimately derivative is that of human nature. The vision of human beings defined by their creation in the image of God sets the Christian agenda, to be addressed within public and professional contexts in translation. As has been somewhat ruefully observed (Verhey and Lammers), the exercise of translation has itself led to the *marginalization* of religion. Stephen Lammers notes it at the micro level: The ubiquitous hospital ethics committees, often established under the tutelage of chaplains or other religiously-motivated professionals, immediately take their place in the secular institutional life and language of even religious hospitals. At the macro level, as the ebb tide of the sea of faith runs fast, it has become standard practice to translate Christian moral argument into secular language for public purposes. As a communications strategy in a changing culture, this is perhaps as inevitable as it is estimable. Yet the strangely invidious position in which it places the Christian religion has profound consequences for Christian engagement in bioethics. So it is worth exploring at more length the dynamics of

bioethics on "Dover Beach" (Matthew Arnold's elegy on the collapse of the Victorian age of faith).

History of Bioethics

The half-century history of bioethics is emblematic of the relations of Christianity and the culture of the west. Arising as an interdisciplinary field in the aftermath of World War II, still in its old name of *medical ethics,* it focused the new ethical uncertainties of the generation of Joseph Fletcher. The promulgation of the *Declaration of Helsinki* by the World Medical Association (WMA) was intended to reassert Hippocratic medical values as the foundation for the reconstruction of medicine in light of the Nazi horrors revealed in the so-called "Doctors' Trial" at Nuremberg. Yet its supplanting of the Oath (a pagan document that was nonetheless powerfully theistic in orientation and had long sustained the theological ethics of the Western medical tradition) with a *Declaration* (that could of course be revised by vote, as it would be in response to liberal abortion) set the scene for the reconstruction of medical values on fresh, open-ended, terms. Powered by the continuing cultural weakness of the Christian religion and a succession of new scientific and technical achievements (and corresponding dilemmas) in medicine in the second half of the twentieth century, bioethics has emerged as the quintessentially ambiguous gift of the church to a culture struggling to free itself from the entailments of Christendom. The general failure of a *Christian bioethics* to take hold even within the churches and their educational and medical affiliates has led to a blending of religious and secular in a manner that, for all the good intentions of religious contributors, has tended to extinguish their distinctive character and give primacy to the secular debate and its categories. Thus the most prestigious American graduate program in bioethics is located at an institution of the Society of Jesus (Georgetown); yet its programmatic importance for the development of the discipline is focused in its advocacy of the *principlism* epitomized in Tom Beauchamp and James Childress's influential *Principles of Biomedical Ethics*, the embodiment of secular bioethics.

In Europe, by contrast, where the pattern of religious observance is in general substantially lower than in the United States, Christian participants in the bioethics community tend to be more distinctive in their approach, and in turn the community more accepting of religious perspectives. For example, the Roman Catholic university of Louvain (in the Netherlands) is overtly religious and theological in its approach; and the European Association of Centers of Medical Ethics, the major institutional network, includes a significant minority of explicitly Christian institutions, Catholic and Protestant. The explanation of this contrast lies in wider European–United States differentia, including assumptions about church–state issues and the public legitimacy of religious speech, and the more tradition-conscious nature of European debate, in which *medical ethics* remained for a generation the default term and bioethics was often noted as an Americanism; though the Council of Europe established in the 1980s an Ad Hoc Committee on Bioethics (CAHBI), its major fruit was the European Convention on Human Rights and *Biomedicine* (a favored European term). In parallel, in Europe the continuance of the idea of bioethics as an interdisciplinary field, in which theology is a legitimate participant, can be observed; this stands in marked contrast to the increasing specialized and reductionist approach to bioethics in the United States as a secularized quasi-discipline of its own.

The *magisterium* has given clear guidance to faithful Catholics on many of the questions of bioethics, but there has not emerged a major *school* of Roman Catholic writers within or even over against the bioethics community. By the same token, the substantial growth of conservative Protestantism in the United States during this period, despite its influential political stance on the question of abortion, has failed to initiate a commensurable intellectual movement in bioethics. The tendency of Protestant and Catholic participants has been to aggregate themselves to the secular bioethics mainstream, as they have played their own ironic part in the marginalization of the dominant tradition of western medical ethics (their own). Harder to explain is their failure to develop in parallel serious centers of intellectual gravity for their distinctive bioethics agendas, especially in the United States. This is more surprising in the case of the Roman Catholic church, possessed as it is of research universities and an extensive system of hospitals that have generally maintained stronger connections with their Catholic roots than their Protestant equivalents. As Albert R. Jonsen comments, even "theologically trained bioethicists … remain, in their bioethical analyses, outside the faith" (p. 58).

Christian Theology and Bioethics

From its beginnings, Christianity has displayed an interest in questions of health and healing that has verged on preoccupation. The gospels tell the story of one who went about *doing good* often in the form of miraculous interventions in the form of healings (throughout the Gospels) and, in certain cases, resurrections (e.g., Lazarus). In the ensuing story of the church the care and healing of the sick has had a special place, and medical missions have often been at the heart of the church's missionary thrust. In light of what is often taken to be a Christian focus on the life to come and

the transitory nature of life in this world, this enduring theme of Christian service to health here and now may seem curious. Though Christian traditions have differed markedly in their approach to *miraculous* healing understood as a spiritual gift—denied absolutely by some, ignored by many, practiced as central to their faith within the Pentecostal and related traditions—the practical focus on medicine and nursing has led to the development of major hospital systems in the United States as well as mission hospitals in many centers of the developing world. Jesus's ministry focus on healing, evidence of miraculous healing in the early church, and the fact that much of the New Testament (Luke, Acts) was written by a physician, lie in a theological context that is not widely understood but sets the place of medicine at the heart of the Christian vision. Within orthodox Christian theology, explicated first and most fully in the Pauline corpus in the New Testament, the origins of human death and the disease that presages mortality are treated as fundamentally unnatural, the consequence of divine judgment on human sin (Romans 5). By the same token, among the benefits of the new order in Jesus Christ, who has stood in as representative and substitute and taken our death penalty as his own, will come not simply the resurrection but, specifically, the *redemption of the body* (Romans 8) as the final undoing of sin and its dire effects. This readily explains the focus on healing, as anticipatory of the final redemption; and the dramatic resurrections even of those who would *die again* like Lazarus. Whatever else these statements mean, they serve as object lessons in the faith that grant a sampling of the kingdom that is to come.

Behind these concerns lies the question that is emerging with increasing candor as the subject matter of contemporary bioethics conversation, the nature of human being. Within the Judeo-Christian tradition the answer has been unambiguous and, in the context of Western culture, profoundly influential. Human beings are constituted by their bearing the divine image (*imago Dei*), and from that fundamental fact flows their unique and inviolable dignity as persons. As the agenda in bioethics shifts from discussion of conditions under which human life may be taken (abortion, euthanasia, embryo experimentation, in the context of what we call here Bioethics 1) to our employment of the fresh manipulative powers that biotechnology is urging into our hands (cloning, inheritable genetic modifications, cybernetics—Bioethics 2), the relevance of this fundamental understanding grows markedly. Whether the churches and their theologian-ethicists will find it within themselves to rise to these immense challenges remains to be seen.

In light of the *imago Dei* question, and a historic commitment to the questions of sickness and healing, it is extraordinary that the distinctively Christian contribution to bioethics has, after an initial firm beginning, rapidly lapsed into a desultory state in which Christian and secular interpreters are generally indistinguishable; only a minority report offers trenchant engagement from within the "distinctive vision" of the Christian worldview. This is all the more surprising since the two most influential figures in the first generation of bioethics were theologians, who actually wrote explicitly theological ethics (from very different perspectives): Joseph Fletcher, whose innovative book *Morals and Medicine* (1954) framed the questions and sought radically fresh approaches in the 1950s, in effect seeking from the inside to subvert the Christian tradition at every key point and prepare the way for the post-Christian bioethics to come; and Paul Ramsay, whose work in the 1960s and 1970s set out a massive defense of Christian ethics even as he engaged the philosophy and emerging jurisprudence of his day.

As commentators have widely noted (Verhey and Lammers; Jonsen), the tendency has been for Christians writing in bioethics to be accommodated to the secular mainstream that since the waning of Ramsay's influence has set the tone for American bioethics. Across Catholic and Protestant thought alike we may note a spectrum of responses. At one end are writers who have essentially been absorbed by the categories and conclusions of the secular bioethics flow. In the center are others who while generally adopting the terminology of secular bioethics have sought to influence or restate it in terms that reflect Christian convictions; or, perhaps, to translate key components in the new bioethics into terms that are related to Christian theology. At the other end are those who take a classical approach from within the Christian tradition. While they sometimes use the public speech of secular bioethics, they are translating distinctively Christian ideas that are developed in explicit theological categories.

Throughout the second half of the twentieth century—from Joseph Fletcher on—much of the bioethics debate focused substantively on the question of the sanctity of human life (abortion, euthanasia, the use of human embryos in research, protocols for organ transplant, definition of death, scare resource allocation, and others), and procedurally on autonomy as the organizing principle of the new bioethics (centered on the role of the patient in decision making, and symbolized by the advanced directive and its culture of individualism in end-of-life choices). Indeed, the movement of bioethics has tended to be from substantive to procedural, and the bioethics literature is little focused on the rights and wrongs of such questions as abortion. The euthanasia debate, potentially of vast significance though on the sidelines of bioethics as a public policy concern, is encapsulated in the

focus on *physician-assisted suicide,* which essentially turns substance into protocol. The sanctity of life, long the central feature of our civilization's medical values though seen by many in the bioethics community as perverse, is rarely a locus of bioethics debate; its central place in a Christian bioethics, stemming from the Judeo-Christian doctrine of the creation of human beings in the image of God, has had slight impact on the bioethics mainstream. Peter Singer's *speciesist* challenge—an upending of the *image Dei* that suggests it is as irrational and as unethical as racism—has evoked little Christian response.

The Future: Emergence of Bioethics 2

A similar spectrum of responses from those writing within the Christian tradition is already evident as the questions of Bioethics 2 begin to focus discussion. The advent of in vitro fertilization in the late 1970s heralded a developing agenda in which the focus would cease to be on the old clinical ethics with its dilemmas grouped around the sanctity of life and move to the new manipulative powers of biotechnology. However, one decisive difference is now evident. As a range of fundamentally new questions is raised for biomedicine and the human good, the Christian mind is one generation removed from the influence of Ramsey and still further from the older tradition of candid theological engagement with the earlier issues of bioethics. The prospect of cloning and germline genetic interventions, coupled with crucial policy issues focused in patent law, reveal the paucity of Christian resources since the fundamental questions of anthropology that are at stake in these debates have been comprehensively neglected by theologians and Christian bioethicists alike. C.S. Lewis's prophetic essay *The Abolition of Man* is widely quoted in the near-absence of more recent and more detailed theological reflection on what is widely agreed to be the most serious set of questions ever to have confronted the human race.

These unfolding questions raise the most profound concerns, both for the Christian understanding of human procreation and of human nature itself. The significance of such basic theological themes as the nexus of marriage/sexuality/family and the nature of human being itself are at stake, as the frontiers of the debate move from whether and when life may be taken to the logic of procreation-reproduction and the manipulative capacities of biotechnology to re-make human nature. It is for Christians an open question whether it is worse for life that is made in God's image to be taken, or for life to be made in an image of our own devising, in a wholly fresh assault on the sanctity and dignity of human being. There is no greater need than for fresh exploration of the significance of both the *imago Dei* and the incarnation of Jesus Christ for our human nature in light of the new, emerging powers of biotechnology and cybernetics. The challenge to Christian theology is both to articulate the distinctive implications of the Christian understanding of human nature for Christians themselves, and then, with equal vigor, to translate that understanding into public terms, drawing on the common language and values of our cultural tradition and engaging in arguments from natural law. Christian thinkers have so far shown little appetite for either of these tasks.

CHRONIC ILLNESS AND CHRONIC CARE

• • •

This entry traces the ethical topography and presents concepts entailed in chronic illness and chronic care. There is no authoritative definition of chronic illness or chronic care. However, a *consensus definition* for purposes of this entry can be found on the Public Broadcasting System (PBS) web site (Fred Friendly Seminars, 2001b), where chronic illness is defined as "a condition that lasts a year or longer, limits activity, and may require ongoing care." Some persons describe chronic as "illnesses or impairments that cannot be cured" (Institute for the Future, p. 260; Summer, p. 2). An incurable chronic condition can be manifest at birth, as in Down's syndrome.

Chronic illness is contrasted with acute episodes of illness or injury that will either result in death or will be treated and the person restored to *health.* Although chronic diseases differ from acute diseases, they can have acute episodes or flare-ups. Persons with chronic conditions may experience accidents or comorbidity in addition to their ongoing problem(s).

Paradoxically, as various public health measures, pharmacological agents, and other medical interventions become more effective in either preventing or curing diseases and postponing death, the number of persons with chronic conditions increases in both absolute and relative numbers. "Over the past century, the economically more developed countries of the world have gone through considerable change in their population structure and the types of diseases which afflict them—the so-called demographic and epidemiological transitions" (Harwood and Sayer, p. 1).

Care of a person with chronic illness should involve productive interactions between patients and providers; the latter may include medical and social support. Responsive providers and services are key in such care, as are the financial resources to enable the person to utilize them. Three elements seem to differentiate sound chronic *care,* at least in emphasis, from ordinary, good medical practice in general: continuity over time; management of any accompanying frailty and dependency; means to pay for the extraordinary costs of drugs, prosthetic devices, and care both in the home and in alternate living situations.

Three Related Concepts

PROGRESSIVE INTERMITTENT FRAILTY. Frailty can be seen as a condition at a given point in time and as a process over time. It denotes a condition in which a person has difficulty with activities of daily living and is vulnerable to various *assaults* upon his or her person both from within, (e.g., organ failure) or without (e.g., falls). Frailty, especially in the elderly, often continues over time in a progressive fashion with periods of remission and exacerbation until the person becomes substantially dependent and dies.

Persons who are frail may have difficulties with activities of daily living either on a temporary or an ongoing basis. Frailty often accompanies chronic illness, though not all chronically ill persons are frail. Some frailty results from general system(s) failure that is associated with age and the gradual molecular deterioration accompanying it; other frailty can be associated with a transitory illness or trauma.

DEPENDENCY. Dependency is a state in which a person requires the assistance of others. It may be temporary or permanent, intermittent or continuous. It may or may not be associated with chronic illness. Chronic illness, depending on severity, may or may not create a dependent state.

NATURAL DEATH AND DYING. All will die. Dying occurs in different modes. It may be caused by sudden organ failure or by disease or infection. A relatively new phenomenon is the increasing number of persons with serious chronic illness at the end of life. Certain patients function quite well for a time, with substantial decline in the last few weeks before death, typical of cancer. Others experience a less predictable course, with periods of disease exacerbation interspersed with periods of higher functionality, as in organ system failure of the heart or lung. Some go through a drawn-out course with early loss of function and incremental decrements in function and vigor over many months or years before death, characteristic of frailty and dementia (Lunney, Lynn, and Hogan; and Lynn).

As the trajectory toward death becomes more apparent, even if still somewhat unpredictable as to its exact time, specific medical, psychological, and spiritual interventions become central, emphasizing physical and emotional comfort rather than seeking to cure the underlying cause.

Seeking to Understand the Challenge

Given the lack of an agreed upon definition of chronic illness, it is difficult to estimate with any precision the aggregate numbers and costs. In addition to the confounding element of what to include as a chronic condition, each possible candidate has its own life course and associated costs. However, all agree there are large numbers of people with chronic illnesses. In fact, virtually all who die in old age will have one or more chronic conditions.

Having noted the imprecision of definitions and insurmountable difficulty of quantifying the extent and costs of chronic illness, some representative statements can contribute to an understanding of the dimensions of the problem:

- Almost one-half of the U.S. population of 276 million people in the year 2000 had a chronic condition in some form (Partnership for Solutions, 2001).
- In 2020, about 157 million people will live with chronic conditions, and about 81 million, more than half of these people, will have multiple chronic conditions (Partnership for Solutions 2002a, pp. 6–7).
- In one listing, thirty-seven conditions are characterized as chronic illnesses (Fred Friendly Seminars, 2001a). There may be more.
- Each chronic condition has its own etiology and course history and is experienced by a person unique in his or her personhood and cultural/social milieu.
- Each person has greater or less access to, or is in command of, a different array of help.
- Chronic conditions may be more or less debilitating at different parts of the course of the illness.
- About *60 million* people experience comorbidity, and more than *3 million* of these have five chronic conditions (Partnership for Solutions, 2001).
- Some chronic conditions can be ameliorated for long periods of time with medications and/or prosthetic devices; others may have a decided trajectory in which increasing, albeit sometimes periodic, disability requires hands-on assistance or a more supportive environment.
- The various treatment regimens for people with multiple chronic conditions can interact to diminish health and increase disability (Partnership for Solutions, 2002b).
- Some chronic conditions can render a person more vulnerable to disease or accidents.
- Not only do poor and disadvantaged people experience greater prevalence of chronic conditions, those who are unemployed, less educated, and uninsured suffer more from these conditions (Bethell, Lansky, and Fiorillo).

- According to a 1998 Medical Expenditure Panel Survey, 78 percent of healthcare dollars was spent on care of chronic conditions for noninstitutionalized persons, and approximately 58 percent of healthcare dollars was spent on the 21 percent of those suffering from more than one chronic condition (Partnership for Solutions 2002a, pp. 17 and 19).

Commonalities in Chronic Illness

The conceptual embrace of chronic illness has become so broad and varied that the utility in using this concept to inform policy may be compromised. However, all chronic conditions have common threads. Chronic conditions intrude upon the quality of life and life patterns of individuals. They not only alter the life of the persons closest to the afflicted individuals but many with whom these individuals come in contact on a daily basis, for example, employers, fellow employees, neighbors, and even strangers. Chronic illness sufferers need extra, even in some instances extraordinary, resources to ameliorate the effects of their illnesses, and this in turn generates costs to society either in the form of risk-sharing schemes such as insurance (public or private) or through welfare/charitable support.

Ethical Topography of Chronic Illness

Chronic illness occasions decisions that have an ethical component since it constitutes an interruption for a significant time in the life and life plan of an individual, and by extension, that of those who are closely associated with the individual. Furthermore, it constitutes a societal issue because of the *costs* involved.

DOMAINS. A chronic illness evokes responses with ethical implications in various domains. Each choice has implications for the well-being of the person with the chronic condition, those who are part of his or her primary social network, and the broader society.

THE INDIVIDUAL. While one must be cautious in blaming the victim, some, but by no means all, chronic illnesses have their origin in lifestyle choices. At the outset of ethical reflection, one must consider individual behavior not only because of a fundamental responsibility to self but also because of its consequences to others, both proximate and remote. For example, 80 percent to 90 percent of chronic obstructive pulmonary disease (COPD) cases are the result of long-term smoking (Ames). A substantial number of cases of human immunodeficiency virus (HIV) disease are caused directly or indirectly by unsafe sexual activity or needle sharing by drug abusers. Refusal to wear seat belts or helmets increases the risk of incurring catastrophic, debilitating injuries.

Regardless of the etiology of the chronic illness, the person suffering with it faces ethical choices that have an impact on his or her well-being, as well as that of other individuals and society in general. For example, one with chronic illness can be compliant with medical regimes or not, behave in a risky manner or not, and make treatment choices that can influence the quality and length of life and entail costs.

THE PERSON'S SOCIAL NETWORK. Depending on the severity of the illness and the moral/psychological bonds, the lives of family and psychologically significant others become a party to the disease. Each person impacted confronts ethical choices on how he or she will respond to the person in need.

Friends, neighbors, and even strangers are actors and reactors since physical proximity creates a moral field within which responses are evoked. Persons may or may not come to the assistance of others when that assistance is needed in a particular instance or over time. The need of the person, the relationship to *the other,* the inconvenience or costs (opportunity, monetary and psychological), and the availability of other assistance all enter into the ethical equation facing the potential helpers.

THE WORK ENVIRONMENT. Many persons with chronic conditions are employed or employable. While the Americans with Disabilities Act requires reasonable accommodations in the workplace, ethically based attitudes and interactions with co-workers will either enhance or detract from the well-being of persons with chronic conditions. For example, at one end of the spectrum are those co-workers who consistently respond with grace and enthusiasm from day to day. Their personal principles would propel them to risk their lives to help another co-worker in a wheelchair exit the building in an emergency. At the opposite end are those who frequently regard chronically ill co-workers with irritation or agitation; in an emergency situation, compromised co-workers with chronic conditions would not get their attention.

PRIVATE SECTOR POLICY. ***Insurance.*** Insurance in the private sector is driven mainly by marketplace forces and actors. It is also subject to both ethical considerations and to incentives and disincentives provided through public policy for taxation of employee benefits and for the regulation of insurance markets.

Insurance involves the sharing of risk. Paying a certain cost (premium) makes access to care affordable and possible for an expensive event that will occur in a group but not *to all* members of the group. Persons choose certainty over uncertainty and presumably pay premiums that they and their insurers hope will total considerably less than the costs associated with untoward events. However, when these events have already occurred or their imminent onset is highly probable (e.g., when a person over sixty-five pays his or her first premium), then insurance becomes a method of financing burdens that is unlikely to be profitable.

Insurers are economically motivated to exclude very sick and high-risk persons from coverage in order to lessen the cost of premiums and increase their corporate margins. Often they attempt to exclude persons with pre-existing conditions entirely, although this is more difficult to do under 2003 federal law. In lieu of such an option, actuarial considerations dictate a higher premium, which places a burden on all covered persons.

Faced with competitive pressures, major insurers are structuring boutique-type policies for healthcare, and to a lesser extent, long-term care, so that employers can offer lower premiums to presumably low-risk employees. This results in more costly options for those at higher risk. Some employers are moving toward a contribution to the individual for the purchase of insurance in the marketplace rather than offering an employer-sponsored plan. Presumably this will make the purchase of affordable insurance more difficult and costly for higher-risk persons. Such trends disadvantage chronically ill persons because they consign them to high-risk, high-cost pools.

A subset of ethical and public policy issues arises with chronic illnesses and conditions that have been associated with lifestyle choices, for instance, from motor vehicle accidents in which appropriate safety devices were not used (helmets or seat belts) and some AIDS patients. Should such persons be afforded benefits born by others because of their risky behaviors?

While these scenarios are the very stuff of free enterprise, they are not without ethical implications for insurers, group purchasers, and regulators.

Genetic testing. The field of genetics is in its infancy and holds promise in the prevention and treatment of all diseases, especially those that tend to be chronic. However, the knowledge gained by testing may identify the person as being at such risk of a particular chronic condition that he or she becomes *uninsurable* and, despite the absence of any indication of the disease, unemployable.

"At present the predictive value of most genetic tests is limited" (Anderlik and Rothstein, p. 425). These authors find scant evidence of discrimination to date on the basis of genetic testing in health insurance markets in the United States. This finding holds for states that do and those that do not regulate the use by insurers of genetic information. However, they note a particular problem for persons seeking long-term care insurance as genetic testing improves to permit discrimination among risks: *Medical underwriting* of long-term care insurance (in contrast to the provision of social insurance) could discriminate against persons with serious chronic disease because coverage is "directly tied to the provision of necessary health care" while the "premium structure … is based on mortality risk" (Anderlik and Rothstein, p. 425).

This potential for future discrimination as genetic testing is perfected is a concern in the insurance field, the popular press, and other countries. Dr. John W. Rowe, Chairman and CEO of Aetna, called for legislation and industry-wide guidelines to promote genetic testing and counseling with provisions for strict confidentiality. Furthermore, he advocated a prohibition of the use of genetic information to establish risk selection or classification (Aetna, Inc.). An editorial in *USA Today* on August 20, 2002, ends with "Medicine is giving people a chance to gaze into their futures—and maybe change them. But until their genetic secrets remain just that, the scientific breakthroughs could cause more problems than they solve" (*USA Today,* p. A.10). In 2001, the Human Genetics Commission of the British House of Commons "concluded that it was important to establish a clear and defensible regulatory system which not only balances the interests of insurers, insured persons, and the broader community but also enjoys the confidence of the public" and thus "decided to recommend to Government an immediate moratorium on the use by insurance companies of the results of genetic tests."

PUBLIC POLICY. The costs associated with chronic illness, the possible limitations of earning capacity, and the way others may treat those who have some limitation all make governmental action an important factor. Public policy affects not only access to needed services but continued participation in the life of the community for chronic illness sufferers.

Public policy emanates from the democratic process with its often messy and contentious elements. However, in many instances it finds justification, if not its origins, in widely held ethical perspectives. Among these public values are the convictions that people should not be denied opportunity because of particular characteristics and that the most vulnerable should have at least basic dignity.

Discrimination. Government has had a role in protecting the rights of individuals, especially those most at risk

as evidenced in affirmation of voting rights, fair housing laws, and nondiscrimination in employment and public accommodations, as well as opportunities for participation for the disabled. While these result immediately from legislation and court decisions, they have foundation in a public ethic.

Income support. The costs often involved with chronic illness make governmental support a vital aspect for the well-being of those afflicted.

Based both on pragmatic and ethical considerations, the U.S. has enacted programs of social insurance requiring risk sharing and consequent creation of entitlement to meet basic needs in those areas in which people would be unable or unwilling to make prudent economic decisions about future need.

Social Security was enacted to assure a floor of income for those who cease to work because of age (1934) or disability (1956). It assures continued participation in the economy and offers support for those unable to work and their survivors. Social Security mandates equal contributions by employees and employers to a premium during employment in view of a possibility of unemployment. It offers a greater return to those who have modest employment earnings than to those who have been fortunate enough to have better earnings.

It has been United States policy since the 1930s that income in retirement should be considered to have three sources: Social Security, private pensions, and personal savings. There is growing evidence that income from these sources will be inadequate to meet basic living costs (including the costs of managing chronic illness) for most persons born between 1946 and 1964 who are living alone, and especially the oldest persons (Employee Benefit Research Institute [EBRI] Education and Research Fund and Milbank Memorial Fund; Dugas). The causes of this shortfall, which will be catastrophically expensive for society, include:

- structural problems in the private pension system;
- projected shortfalls in the Social Security Trust Fund that are tempting policy advocates to propose remedies that put individuals at higher risk;
- the difficulty most Americans have in both saving and maintaining their standard of living during their working years; and
- the periodic decline and routine volatility of the financial markets in which pension savings are invested.

Each of these causes raises ethical issues.

Financing and organizing care during acute episodes of illness. Most of the health insurance offered by government (Medicare and coverage of public employees most importantly) and the private sector (individual and group coverage) is derived historically from plans to cover infectious disease, injuries, pregnancy and childbirth, and episodes of chronic degenerative diseases requiring hospitalization and medical specialty services. Although this coverage has evolved gradually to include many services for managing chronic illness, payment is still driven mainly by diagnosis and is more generous for invasive procedures than for either counseling or outpatient drugs (Fox). As a result, most persons who experience progressive intermittent frailty (which means, in fact, most persons) are at high risk of receiving care that is discontinuous, fragmented, and inappropriate.

Financing and organizing long-term care. The United States has devised a vast system of long-term services based on the organizational concept of the nursing home and the financing assumption that individuals and families will pay for care with government serving as the payer of last resort. This system is a logical counterpart of a health insurance system created to respond to the most serious acute manifestations of disease. Nursing homes, the dominant institutions, are stripped down (or not so stripped down) hospitals in which persons wait, secure against injury but isolated from their community, until the next acute episode of illness returns them to the acute care health sector. Since waiting is deemed a residual activity, it is logical for individuals to pay for it out of income and savings unless (or until) they are too impoverished to do so. Then society (through Medicaid, Supplemental Security Income, and charity) pays the cost. This model for organizing and financing long-term care, like the health insurance model described in the previous paragraph, is deeply flawed: conceptually and financially, and many have argued, ethically. There is growing analysis and advocacy on behalf of alternative models for organizing and financing long-term care that take account of the inevitability of progressive intermittent frailty for most people and recognize the well-documented desire among Americans to spend as much of their later lives as possible in homelike, minimally restrictive settings (U.S. Department of Health and Human Services). One of these models is the Program for All-Inclusive Care of the Elderly (PACE). PACE is a risk-sharing system that provides for all acute, long-term care, and hospitalization needs of frail elderly participants in one program. Participants pay a capitated fee rather than fee for service with their Medicaid and Medicare entitlements. Most of the PACE participants can still live at home or in a community-based setting and are transported to the program's day health center one or more times a week for care of their medical and social needs.

To provide this "all-inclusive" care, the health center is staffed with an interdisciplinary team (Centers for Medicare & Medicaid Services, 2002). Another example allowing for various flexible state-designed alternative models is the Medicaid Home and Community Based Services (HCBS) 1915(c) Waivers Program. The U.S. government allows the states to provide HCBS waiver programs for certain segments of their Medicaid-eligible population. One segment is the elderly. Under an HCBS waiver program for care of the elderly, a state can ask the federal government for waivers of certain Medicaid requirements so that Medicaid benefits can be provided in the home or a community-based setting as well as in an institution (Centers for Medicare & Medicaid Services, 2003).

Research. Vast and increasing amounts are spent on research pertinent to chronic disease in the United States, primarily by the federal government, through the National Institutes of Health (NIH) and the Veterans Health Administration (VA), and by the pharmaceutical industry. The two most prominent objects of this research are the mechanisms of chronic disease and the development of drugs and devices to treat, cure, and manage them. Consumer and professional groups are prominent advocates of increased public research budgets for particular diseases, often with overt or covert support from the pharmaceutical industry and manufacturers of medical devices. However, enthusiasm for developing and testing new interventions distracts attention and resources that could be invested in new randomized controlled trials of existing interventions, research on head-to-head comparisons of competing treatments, and replacement of open or arbitrary drug formularies with preferred drug lists based on systematic reviews employing the methods of research synthesis. This hopeful and lucrative focus on new ways to prevent, cure, and manage disease has made it difficult for advocates of the rapidly developing science of research synthesis to make their case. This recently emerged area of research makes it possible to evaluate more confidently than ever before the effectiveness of health and social care interventions, including drugs, devices, diagnostic tools, and methods of organizing services (Chalmers et al.).

Social Solidarity and Concern for "The Other"

While individual autonomy is inherent in the notion of dignity, humans are social beings who inherit from the past, live in community in the present, and perceive themselves as having responsibility to the future. Humans are free to pursue their own goals as long as they do not interfere with others, a negative right. There is a generally recognized corollary that humans live in community with a positive obligation to contribute to the common good and share others' burdens. Personal responsibility is indicated not only for the sake of the person but because "no man is an island," and his or her well-being or disorder has social ramifications. Maintenance of health and function is significant not only to the individual but also to all who are part of his or her social network. Aristotle has been credited with teaching that a just society is one in which burdens are shared by equals equally and unequals unequally in accord with capacity and need.

The pluralistic nature of contemporary society makes it easier to identify when and where ethical issues occur than to apply universally accepted approaches to their solution. Yet, at least at the societal level, decisions have and will be made through the democratic process, largely driven by self-interest but often with appeals to a sense of fairness and decency. However, a recent study of policy makers' use of ethicists' advice concluded that persons who emphasize ethics "will always be disappointed by the politics of policy making in any countries that are fit to live in" (Fox and Klein). On the more personal level, however, such decisions are made, for better or worse, on a daily basis, either easing the burden of chronic illness or leaving the chronically ill person ever more isolated in his or her distress. Decisions of fairness and decency and those that ease the burden become ever more vital as the number of people affected by chronic illnesses increases in the first half of the twenty-first century.

CIRCUMCISION, FEMALE

• • •

Female circumcision is the term used to identify the practice of removing healthy normal female genitalia by surgical operation. Because of the severity of the operation and its known harmful effects, the term *female genital mutilation* is now generally used. There are three increasingly severe types of this operation, and each makes orgasm impossible. Clitoridectomy, or sunna (Type 1), is the removal of the prepuce of the clitoris and the clitoris itself (Figure 1–1). When excited, the clitoris swells and becomes erect, and it is this excitement that causes female orgasms. Excision, or reduction (Type 2), is the removal of the prepuce, the clitoris, and the labia minora, leaving the majora intact. The labia minora produce secretions that lubricate the inner folds of the lips and prevent soreness when these lips rub against each other (Figure 1–2). Infibulation, or pharaonic circumcision (Type 3), is the removal of the prepuce, the clitoris, the labia minora and majora, and the suturing of the two sides of the vulva, leaving a very small opening for the passage of urine and menstrual blood (Figure 1–3). This type of circumcision is referred to as pharaonic probably because it is identified with circumcision methods of ancient Egypt under the pharaohs.

In a study of the various types of circumcision undergone by women in Sierra Leone (Koso-Thomas), it was found that 39.03 percent of the women had undergone Type 1, 59.85 percent, Type 2, and 1.12 percent, Type 3. In Somalia, 80 percent of the operations are Type 3 (El Dareer). The prevalence of circumcision in Africa ranges

from 10 percent in Tanzania to 98 percent in Djibouti (Toubia).

The most common and basic procedure followed during circumcision is the traditional method. In this method, usually employed by circumcisers who have no medical training, the female is firmly held down on dry ground with her legs wide apart to expose the genitalia and the parts to be removed. In some cases, the genital part to be excised is held with a special hemostatic leaf before excision, or the candidates are made to lie near a cold flowing stream so the excised area can be bathed in chilled water to numb the pain. The implements used are often unsterilized razor blades, knives, scissors, broken bottles, or any other sharp implement. Some form of herbal dressing is applied to the raw wound after the operation. The same implement is used for successive operations without sterilization. When the operation is carried out in modern clinics, standard modern surgical practice is followed.

Origin of the Practice

We do not know with any precision when, why, and how female circumcision began. There is evidence that female circumcision and female genital surgery have been done in many parts of the world, although currently it is mainly done in different communities in parts of Africa, Asia, the Far East, Europe, and South America.

The early Romans, concerned about the consequences of sexual activity among female slaves, adopted the technique of slipping rings through their labia majora (Figure 1–4) to block access to the vagina. In the twelfth century C.E., Crusaders introduced the chastity belt in Europe for the same purpose; the belt prevented girls and women from engaging in unlawful or unsanctioned sex. This method caused little permanent physical damage to the individual. Genital surgery was permitted in North America and Europe in the late nineteenth century with the intention of curing nymphomania, masturbation, hysteria, depression, epilepsy, and insanity. There is no evidence that such surgery was associated with any ritualistic activity. Elsewhere, the surgery has historical links with either religious or ethnic rituals. It is believed that the ancient Egyptians and ancient Arabs practiced this form of surgery. Genital mutilation seems to have been transplanted to Latin America from Africa during the slave trade and may have taken root first in the central part of Brazil, where groups of West Africans were resettled after the abolition of the slave trade in the middle of the nineteenth century, and to eastern Mexico and Peru through migration. In Asia genital mutilation is found among Islamic religious groups in the Philippines, Malaysia, Pakistan, and Indonesia. Where the mutilation exists in the Middle East and Asia, it is strongly associated with Islam. Female genital mutilation is not practiced in all Islamic countries. Those societies known to practice it, namely, the United Arab Emirates, South Yemen, Oman, and Bahrain in the Middle East, and northern Egypt, Mauritania, Sudan, Somalia, Mali, and Nigeria in Africa, probably inherited it from pre-Islamic cultures.

Alleged Benefits of Female Circumcision

The modern defense of female circumcision allows us to reconstruct the ancient rules that governed moral action or behavior in polygamous communities. The defense enumerates a wide range of health-related and social benefits alleged to result from the practice:

1. maintenance of cleanliness;
2. maintenance of good health;
3. preservation of virginity;
4. enhancement of fertility;
5. prevention of stillbirths in women pregnant for the first time;
6. prevention of promiscuity;
7. increase of matrimonial opportunities;
8. pursuance of aesthetics;
9. improvement of male sexual performance and pleasure; and
10. promotion of social and political cohesion.

Cleanliness is regarded as a great virtue by women in countries where the practice is common. In some cultures, particularly in Africa, women are required to cleanse their genitalia with soap and water after urinating. Those who justify removing parts of the genitalia that produce secretions cite this preoccupation with the cleanliness of the genital organs. Some traditional circumcision societies claim that circumcised women are generally healthy and that the operation cures women suffering from problems resembling those identified in nontraditional societies as depression, melancholia, nymphomania, hysteria, insanity, epilepsy, and the social disorder of kleptomania. In situations where proof of virginity is essential for concluding a marriage transaction, circumcision is believed to be the guarantee against premarital sex. This guarantee benefits parents who are able to demand a high bridal price for their daughters. Marriage immediately after the transaction ceremony is common, and such marriages, involving pubertal girls, are usually followed by pregnancy within a very short time. Circumcised girls and women are regarded as having an advantage over the uncircumcised in marrying. Where female genital mutilation is an established custom, tradition

forbids men to marry uncircumcised girls; hence, circumcision of girls ensures they will be marriageable. Certain traditional communities, such as the Mossi of Burkina Faso and the Ibos of Nigeria, believe that a firstborn child or even subsequent babies will die if their heads touch a mother's clitoris during the birth process. The clitoris is therefore removed at the time of delivery if this has not already been done. Since female genital mutilation reduces or even eliminates sexual pleasure, the practice presumably eliminates the risk of female promiscuity. The justification of the practice to preserve chastity, eliminate promiscuity, foster or improve sexual relations with men, generate greater matrimonial opportunities, protect virginity, and increase fertility reflects the existence in traditional societies of strict controls on social behavior.

The belief that circumcision enhances beauty stems from the claim that the male prepuce or foreskin is removed mainly for aesthetic reasons, and that the clitoris, the female counterpart to the penis, should be removed for the same reason. If left intact, the clitoris is believed likely to grow to an embarrassing and uncomfortable size. In some patriarchal societies, female genital mutilation is also said to benefit the male by prolonging his sexual pleasure, since the clitoris is thought to increase male excitement during sexual intercourse with a female partner and may rush a man's orgasm. Of great importance to women in such cultures is the status circumcision bestows on the circumcised. It entitles them to positions of religious, political, and social leadership and responsibility.

The argument in favor of circumcision serves narrow social interests and does not achieve the goods desired or guaranteed. Failure to achieve these goods, moreover, is often blamed on the woman rather than the ritual. For example, maintaining cleanliness becomes an agonizing task. The hardened scar and stump that result from circumcision are unsightly, and they halt the flow of urine and menstrual blood through the normal channels. This obstruction causes unnecessary fluid retention and results in odors more disagreeable than those from the natural hormonal secretions that tradition teaches are degrading. Associating the death of babies at childbirth with clitoral contact is clearly refuted by the evidence that millions of healthy babies are born to uncircumcised mothers.

While the desire of organized society to maintain control over people's actions may be understandable, not all such control promotes their well-being or self-determination. Such rituals also cause harm to society by increasing morbidity and mortality levels. In addition, although these rites may promote social and political cohesion, they thwart the individual's freedom to determine what is right and in her best interests. Even women who learn that circumcision is an unsafe and harmful practice may feel pressure from society to agree to it for themselves or their children in order to marry or remain members of the group.

Harmful Effects of Female Circumcision or Female Genital Mutilation

The medical consequences of female genital mutilation are quite grave (El Dareer; Koso-Thomas). In Africa an estimated ninety million females are affected (Hosken). Three levels of health problems are associated with the practice. Immediate problems include pain, shock, hemorrhage, acute urinary retention, urinary infection, septicemia, blood poisoning, fever, tetanus, and death. Occasionally, force is applied to position candidates for the operation, and as a result, fractures of the clavicle, humerus, or femur have occurred. Intermediate complications include pelvic infection, painful menstrual periods, painful and difficult sexual intercourse, formation of cysts and abscesses, excessive growth of scar tissue, and the development of prolapse and fistulae. A fistula is an abnormal passage: a hole (opening) between the posterior urinary bladder wall and the vagina or a hole between the anterior rectal wall and the vagina. Late complications include accumulation of menstrual blood of many months or even years, primary infertility, painful clitoral tumors, recurrent urinary tract infections, and kidney or bladder stone formation. Obstetric complications such as third-degree perineal tear, resulting in anal incontinence and fissure formation, and prolonged and obstructed labor are also known to occur. Psychological problems of anxiety, frigidity, and depression, as a result of the physical inability to have a clitoral orgasm, may also develop.

Women who undergo circumcision suffer various degrees of emotional and mental distress depending on the nature of complications following their operation. Records show that 83 percent of all females undergoing circumcision are likely to be affected by some condition related to that surgical procedure requiring medical attention at some time during their lives. This level of health risk should be of concern to nations with a large proportion of circumcised women, because such women may never make the progress toward the economic and social development required of them.

Application of Modern Medical Practice to Female Genital Mutilation

Modern medicine has made impressive strides in investigating, preventing, and treating a wide range of ailments. Through its investigative approaches it has judged that unwarranted surgery is wrong. In the case of female genital mutilation, studies have found that certain of the resulting medical conditions are serious and can lead to complications and permanent health damage requiring both medical treatment and counseling (Koso-Thomas). Awareness of female genital mutilation's harmful effects has encouraged changes in how the operation is performed, changes that may include sterilization of equipment and dressings and administration of local anesthetic, antibiotics, and antitetanus injections prior to circumcision.

Ethical Aspects

Since some followers of Islam in Africa, the Far East, and the Middle East endorse circumcision, it has been widely identified as an Islamic rite. However, female genital mutilation is not practiced in Saudi Arabia, Algeria, Iran, Iraq, Libya, Morocco, or Tunisia. Many Islamic and Christian religious leaders have categorically denied that female circumcision or female genital mutilation is an injunction in the Qur'an or a "commandment" in the Bible. Since the foundations of the practice lie outside Islamic or Christian religious law, the origins of circumcision and its justification must lie in the moral, social, and religious structure and operation of societies practicing it. Individuals practicing it act within a system of rules that strictly regulate sexual behavior in society. Female genital mutilation generally thrives in communities with strictly enforced conventions and social rules.

With the knowledge of its harmful effects now common, no social system endorsing this kind of mutilation can be said to promote a favorable climate for a fulfilling life.

The attitudes of women toward circumcision depend on their experiences and level of education. Most women affected by the practice are unaware that circumcision is the cause of their health difficulties (Koso-Thomas). Once aware of this relationship, however, many women who have some education and training and who are exposed to a modern environment are better able to assess what is involved in circumcision actions and, on that basis, to make a reasoned judgment of its rightness or wrongness. Many such women have come to believe that the practice is unacceptable and have refused to allow their female children to go through the same traumatic experience. Many feminists and health professionals have openly displayed a higher regard for women's health than for tradition.

It has been shown, however, that some women who admit to suffering under the unexpected effects of the operation still feel obliged to support the practice. A study carried out to obtain opinions on circumcision involving 135 men and 120 women showed that 25 percent were shocked at what happened to them on their circumcision day, as it was not what they had expected (Koso-Thomas). The majority of them, either semi- or nonliterate, believed that they had done the right thing and planned to have their daughters circumcised. Those women who were not shocked by their experiences were also mainly illiterate and did not see why their daughters should not undergo circumcision. The attitude of men in the sample also varied according to their level of education. Illiterate men insisted that all women should be circumcised to keep them in their place, while the literate men argued that women should be given a choice as to whether or not to be circumcised. They felt that to deny women this choice was a violation of their human rights. It has also been found that circumcision is supported in most women's organizations, particularly political and social groups, since these groups reflect the feelings of the majority in the community.

Usually the decision to have a girl circumcised is made by the female elder members of the family/clan who insist on carrying out the procedure. An aura of secrecy, celebration, and pride surrounds the circumcision and encourages voluntarism on the part of recruits by making membership in the group seem more attractive. A few educated women, however, who have had access to modern medical assessment of their health as well as information on the dangers of the practice also support circumcision but advocate changes to reduce its health hazards. A few healthcare personnel have felt that medical intervention at the early stages of the operation might prevent the more serious health consequences of circumcision. Since circumcision cannot take place without health consequences, the position of these women and health practitioners is untenable.

Women who live in a traditional environment tend to judge their actions on the basis of traditional rules and principles of their society. There may be some misogynistic attitudes among such women, but the dominant force directing their actions comes from the society that demands, among other things, that this ritual be performed in order for them to qualify for marriage and social acceptance.

There are also attitudes inherent in African sexuality that not only permit circumcision but foster it. In most African cultures, sexuality is regarded as a gift to be used for the procreation of the human species, and any public or even private display of sex-related feeling or enjoyment is seen as debasing this gift. In some communities, only a token expression of the sexual self is permitted. The issue of sexual fulfillment is unimportant. Thus, controls over the sexual behavior of women are designed to curb female sexual desire and response and to encourage disregard for the sexual aspects of their lives. The removal of the organ or organs responsible for sexual stimulation is therefore taken as necessary for the fixation of certain values within the community and for ensuring the acceptance of rigid standards of sexual conduct. Thus, the underlying concern of those who defend the institution of female circumcision is that women's sexuality will be corrupted if women are allowed the freedom to control it or indeed to pursue the personal satisfaction of their sexual desire. Implicit in this argument is the major premise that it is immoral for a woman to act on her sexual desire. Women who still support the practice continue to promote injury with confirmed medical consequences. In this respect the role of the healthcare practitioner in the society is crucial and may lead to personal dilemmas that have to be resolved. Many feel anger against the executors and supporters of the ritual and sadness at the futility of the exercise and at the intransigence of traditional circumcising communities. Healthcare professionals presented with the choice of treating or not treating women who have chosen to be circumcised are often determined to rescue a life they see as poised on the brink of destruction. On the other hand, traditional circumcisers have no moral dilemmas about the practice. They believe that they have no choice in a matter which concerns the preservation of their cultural heritage. That heritage dictates how women must live, and to them, life should be one of happiness in subservience to the will of the people and in obedience to customary and religious laws.

UPDATE

The United Nations International Children's Emergency Fund (UNICEF) estimates that "between 100 million and 130 million women suffered female genital mutilation or cutting as children" and that another 2 million are at risk each year (UNICEF). It calls on all nations to honor their commitments to eliminate those practices by 2010. The World Health Organization (WHO), UNICEF, and United Nations Population Fund (UPFPA) (WHO, 1997) issued a joint statement advocating a zero-tolerance view, but it has not been endorsed universally (WHO, 2000). The worldwide scrutiny of ancient practices in which some or all of women's genitals are removed, usually during infancy or childhood, stems from several movements that began in the 1980s.

Ongoing Disputes about Zero Tolerance

In the 1980s a growing number of activists in countries where these rites are popular tried to stop these practices or at least substitute less mutilating rites (nicking the labia or the foreskin around the clitoris) for the more mutilating forms, which were and in some cases still are practiced widely, especially in Africa, and some Middle Eastern countries. Those rites include Type 1 (removal of the prepuce with or without removal of all or some of the clitoris), Type 2 (removal of the entire clitoris and all or most of the labia minora), and Type 3, or pharaonic circumcision (removal of all of the clitoris and labia minora and parts of the labia majora) as well as the practice of infibulation (the wound to the vulva from the cutting is stitched closely, leaving a tiny opening so that the woman can pass urine and menstrual flow). Also included among those rites are scraping or cutting tissue at the vaginal opening or the vagina and placing corrosive substances into the vagina to induce bleeding or narrow or tighten it (WHO, 2000).

Prominent African activists, including Olayinka Koso-Thomas (author of the main entry above), Nahid Toubia, and Raquiya Abdalla, have long advocated stopping all forms of genital mutilation and cutting while retaining the cultural and religious rituals that educate and welcome girls into adulthood and the community. They favor "circumcision through words" and family-planning education that includes telling young males about the health hazards to women and asking them to make a vow not to require circumcision as a condition of marriage. Those changes might accommodate important religious, cultural, economic, community, and family considerations without harming girls.

Others argue that a more effective approach to zero tolerance would be to replace the mutilating rituals with removal of the foreskin around the clitoris or tiny nicks in the labia (Davis; El Dareer). This, they argue, might "wean" people away from the more extreme forms of genital mutilation. If there are no complications, the tiny nicks do not preclude sexual orgasm later in life. The chance of success with this tactic is more promising and realistic, they hold, than would be the case with an outright ban; people could maintain many of their traditions and rituals of welcome without causing as much harm, especially if the operations were done by doctors and nurses under sterile conditions. However, Nahid Toubia objects, stating that removal of the clitoral hood invariably causes considerable, even if unintended, harm to the clitoris because tissue from the clitoris is very likely to be taken.

Dena Davis expresses the concern that something other than zero tolerance could send the wrong message to immigrants:

> Because FGA [female genital alteration] in its most common forms around the world is mutilating and life threatening, it is reasonable to adopt a "zero tolerance" policy to make it absolutely clear to immigrants that this practice is never acceptable …

> further, an argument could be made that, once a "nick" is allowed, it would be difficult if not impossible for the state to make sure this did not become a loophole through which the worst elements of FGA would slide. As MGA [male genital alteration] is not anywhere close to as mutilating and threatening to life and health as are many forms of FGA, this argument would serve as a constitutionally valid distinction between the two practices. (p. 561)

In the end, however, Davis tries to justify a compromise for the sake of cultural sensitivity, legal consistency, and medical safety, arguing that procedures might be permitted that allow roughly the same harm done to girls as is done to boys in male circumcision: a minor nick in a girl's labia or clitoral hood.

Raquiya Abdalla, however, objects to equating female circumcision with male circumcision because their purposes differ and the degree of harm frequently is drastically different. For some people the best reason for drawing parallels between male and female genital cutting is to help abolish both practices. Even if the timetables do not coincide exactly, they hold, comparisons should not be used to allow some female circumcision in countries that permit male circumcision. Still others maintain that there are health benefits to male circumcision that justify distinguishing the two. Most agree, however, that it is unfortunate that the same word, *circumcision,* is used for the full range of practices, from trivial to mutilating. Removal of the clitoris is comparable to amputation of the penis rather than removal of the foreskin in men.

Findings about Morbidity and Mortality

In the 1980s some African clinician-activists from countries that practice those rites documented and brought to the world's attention the accompanying morbidity and mortality. Those pioneering medical studies include the ones conducted in the Sudan by Asma El Dareer (1982), in Sierra Leone by Olayinka Koso-Thomas (1987), and in Somalia by Raquiya Haji Dualeh Abdalla (1982). The death, infection, and disabilities associated with the rites are well established, challenging local beliefs that the rites promote health and well-being. For example, as Koso-Thomas (p. 10) pointed out, stable medical evidence discredits the belief that "death could result if, during delivery, the baby's head touches the clitoris," and Abdalla (p.16) pointed to the disutility of regional practices of putting "salt into the vagina after childbirth … [because this] induces the narrowing of the vagina—to restore the vagina to its former shape and size and make intercourse more pleasurable for the husbands." Some of those studies suggest that many women would prefer not to perform the rites if they were not necessary for the marriage of their daughters and that more younger women are having second thoughts about this cultural practice for their own daughters (Moschovis).

Other epidemiological studies have confirmed the morbidity and mortality associated with those rites and have demonstrated that they are still widespread in some regions. For example, Daphne Williams Ntiri (1993) found that in some African countries most young girls between infancy and ten years of age have received Type 3 circumcision from traditional practitioners who often used sharpened or hot stones, razors, or knives, frequently without anesthesia or antibiotics. The WHO estimates that worldwide about 80 percent of the rites involve excision of the clitoris and labia minora and that infibulation is done in about 15 percent of all cases (WHO, 2000). In some regions, such as Egypt, Guinea, Somalia, Eritrea, and Mali, national surveys indicate that 94 to 99 percent of women are circumcised (WHO, 2000, 2001).

Oppression of Women

Beginning in the 1980s, despite insistence by people within the culture about their good intentions, voices worldwide condemned the rites as brutal forms of oppression of women comparable to making men eunuchs (removal of the testes or external genitals). International organizations denounced the practices, including UNICEF, the International Federation of Gynecologists and Obstetricians, and WHO, along with the American Medical Association and many women's groups. They deny that this is just a cultural issue, arguing that the rites should be opposed with the same vigor as other violations of human rights (Schroder; Toubia). Pressure from human rights groups, for example, forced some governments to ban all registered health professionals from performing female cutting or infibulation and helped women find political asylum in other countries to avoid genital cutting.

Some countries are more willing to pass laws prohibiting the rites than to enforce those laws. UNICEF (2003) is troubled by governments' lack of will to confront those practices, educate their communities about the risks, and enforce existing laws that prohibit them. UNICEF promotes challenges to the beliefs, attitudes, and customs that support these rites and discrimination against uncircumcised women. Even in the United States, the United Kingdom, France, Canada, and other countries where female circumcision is viewed as child abuse, it is practiced in "back rooms" (Davis). UNICEF praised the European Parliament's launching of an initiative called "Stop FGM" in

December 2002. Whether or not the intent of the rites is to honor women, UNICEF and others regard them as "culturally sanctioned forms of women's oppression, male domination, and control of women's sexuality" (UNICEF, 2003).

Immigration

After 1980 waves of immigrants from North Africa and southern Arabia made the rites better known and widely condemned. Those immigrants came from regions where most women receive Type 2 and Type 3 forms of circumcision and moved to areas of the world where those rites are viewed as horrific and oppressive practices that put young girls at terrible risk of death and chronic disability. Consequently, families that seek female genital cutting in their adopted countries generally avoid the healthcare system, and the risks of nonmedical circumcision are assumed to be very high (Davis).

Cultural Sensitivity

The cultural clashes that have resulted from criticisms of female circumcision have centered on whether there is any justification for interfering with the deeply held practices of other cultures. Extreme ethical relativists state that there is no moral or epistemological basis for interfering with popular customs in other countries and that meddling constitutes cultural imperialism (Scheper-Hughes; Ginsberg; Shweder). This view, which once was popular among anthropologists and others, has been challenged on many sides (Kopelman, 1994, 1997).

First, shared goals and methods sometimes can be used to assess other cultures in a way that has moral and epistemological authority. For example, most people share the goal of seeking health for woman and infants and endorse similar methods of logic, science, and medical investigation. Medical research is respected in those communities and their own studies show that the rites cause pain, emotional trauma, infection, chronic disease, disability, and death. These shared goals and methods can be used to help reason with people about destructive cultural practices that involve not just female genital cutting but wars, pollution, and epidemics.

Second, criticism of these practices within those communities is growing (Moschovis), and as a result the depth of the commitment to the rites is changing. As the investigators who originally touched off the contemporary debate over female circumcision illustrate, cultures are not monolithic but contain passionate disagreements and may change rapidly. Moreover, most people do not live in only one culture but cross easily from one culture to another in their professions, religions, and ethnic groups. People who brought the practice of female genital cutting with them when they moved, for example, live in more than one culture. It no longer is possible to count or separate cultures sharply when world travel and communication are so easily available. Cultural, religious, professional, ethnic, and other groups overlap and have many variations within nation-states. To say that people belong to overlapping cultures or that people cannot distinguish precisely between or count cultures, however, undercuts extreme ethical relativism and its tenet that the only way to determine whether something is right is to see if it has cultural approval (Kopelman, 1994, 1997).

Third, cross-cultural criticism seems to be important and even obligatory when one considers cultures that engage in terrorism, war, torture, mass rape, infanticide, and slavery, and so people should be able to criticize female genital cutting on the same basis. Otherwise, people would be led to the very problematic view that any act is right if it has cultural approval even if it is a culturally endorsed act of war, oppression, enslavement, aggression, rape exploitation, racism, or torture. In this view the disapproval of other cultures is irrelevant in determining whether acts are right or wrong. Even if this version of ethical relativism is defended consistently, its plausibility is eroded by its conclusion that the disapproval of people in other cultures, even victims of war, oppression, enslavement, aggression, exploitation, rape, racism, or torture, is irrelevant in deciding what is wrong in the aggressor culture (Kopelman, 1994, 1997).

Consistency

Finally, scrutiny has revealed apparent contradictions in the beliefs and attitudes associated with the rites. For example, on the one hand people from those regions say that nothing is given up because women cannot enjoy sex, but on the other hand they say that the rites are needed to control women who mighty be sexually out of control without the surgeries (Kopelman, 1994, 1997). (This fear that girls will be sexually promiscuous is a frequently given reason for doing the surgery in the West, where girls and young women have considerable freedom compared with the situation in their original homelands.) Another apparent inconsistency concerns insistence that respect for cultural mores requires that deeply embedded cultural views about female genital cutting must be respected in the adopted countries even if this means violating the deeply embedded views of the dominant culture of the new land. It is inconsistent to insist that their deeply embedded views must be respected—but not those of other cultures. Finally, some say that there is no

way to determine what is right when cultures disagree but also insist on transcultural universal normative principles such as "every culture counts for one," "preserve ancient cultures," and "when in Rome do as the Romans do."

Worldwide attention to female genital mutilation and cutting rituals since the 1980s has made those rites the center of controversy about practical and theoretical issues concerning human rights, ethical relativism, and the limits of tolerance of cultural diversity. Medical studies document the resultant morbidity, mortality, and disabilities and the resulting lack of sexual sensitivity and satisfaction for millions of women. Proposals by activists in those regions include stopping clinicians from participating in the rites and adopting and enforcing meaningful legislation, but many people believe that education about the harms of genital cutting and infibulation may be the most important way to stop the practices (El Dareer; Abdalla; Dirie and Lindmark; Toubia).

CIRCUMCISION, MALE

• • •

Male circumcision entails the surgical removal of the foreskin that covers the glans of the penis. The relative simplicity of the surgical procedure itself belies the complexity of the conflicting values surrounding this minor operation. The primary ethical question is whether the pain, risks, and costs of routine neonatal circumcision are justified by the potential medical and social benefits to infants who undergo this

procedure. Given the strong opposing opinions surrounding circumcision, there is some question as to whether children should undergo the procedure prior to an age when they can provide informed consent on their own behalf. Circumcision in adults is less common and will not be the focus of discussion here.

The Prevalence of Male Circumcision

Circumcision is the most common procedure performed on males in the United States—an estimated one million procedures are performed per year. Only about 20 percent of the procedures are performed for religious reasons; the majority are performed in newborns for medical, cultural, or aesthetic reasons. Estimates suggest that circumcision is performed on 60 to 90 percent of boys in the United States. Although observers have noted some variations by region and by cultural group in the use of this procedure, accurate rates for circumcision are not available (Wallerstein). The best documented rates of newborn circumcision in the United States come from a study of infants delivered in U.S. military hospitals (Wiswell, 1992). The rate of circumcision in 1971 was estimated to be 89 percent, falling to 70 percent in 1984, with a subsequent rise to 80 percent in 1990. These differences suggest that parents' decisions about circumcision are influenced by the ebb and flow of social debate over the procedure.

The high rate of nonritual circumcision places the United States in a unique position in the world. In regions where the majority of the world's population lives, including western Europe, the former Soviet Union, China, and Japan, male circumcision is not performed. In 1985, Edward Wallerstein provided the following estimates of circumcision rates: In Great Britain an estimated 1 percent of the male population is circumcised; in New Zealand the figure is about 10 percent; in Australia, 35 to 40 percent; and in Canada, 35 to 40 percent. Circumcision is performed commonly as a religious ritual by Jews, Muslims, many black Africans, and nonwhite Australians.

The History of Circumcision

The walls of Egyptian tombs depict male circumcision, so the practice is known to be at least 5,000 years old. The Jewish and Muslim traditions of circumcision have their origin in the Old Testament. Jews accept the practice as a sign of the covenant between God and Abraham. In Genesis 17:12, God instructs Abraham: "He that is eight days old shall be circumcised among you, every male throughout your generations." As a Jew, Jesus was circumcised, and the early Christian church debated the need for circumcision as a criterion for joining the Christian fellowship; it was decided that circumcision was not necessary for salvation. According to the apostle Paul, "For in Jesus Christ neither circumcision availeth nor uncircumcision; but faith which worketh by love" (Gal. 5:6). These religious traditions remain strong, although the health debate has led to a questioning of the religious practice by a few members of the Jewish community (Milos and Macris).

The practice of routine neonatal circumcision has been debated within the U.S. medical profession for over a century. Circumcision was initially advocated in the Victorian era as a measure that would reduce masturbation. Medical benefits from the procedure were first widely proposed in 1891 by P. C. Remondino, who claimed that circumcision prevented or cured a host of diseases, including alcoholism, epilepsy, asthma, and renal disease (Wallerstein). More scientific studies of the potential medical benefits of circumcision began to appear in the professional literature in the 1930s. Urologists observed an association between penile cancer and an intact foreskin (Schoen, 1992). During World War II, American troops stationed in the Pacific and in desert climates had problems with irritation and infection of the penis because of sand and the inability to maintain adequate hygiene. The military response was to circumcise many of the affected soldiers. However, the Japanese did not use circumcision despite their war experience in the same environments (Wallerstein).

Circumcision became popular, indeed almost universal, after the war. Rates remained high until the 1970s, when both the medical profession and the general public began to question the widespread use of the procedure for newborns. The American Academy of Pediatrics issued two separate statements, in 1971 and 1975, declaring that there were no valid medical indications for neonatal circumcision (Committee on Fetus and Newborn). Specific concerns were raised over the pain of the procedure and over potential complications in the face of questionable medical benefits. In 1985, the first in a series of papers was published that documented an increased risk of urinary tract infections in uncircumcised neonates (Wiswell et al., 1985). These reports came in association with an apparent increased risk of sexually transmitted disease, specifically the human immunodeficiency virus (HIV), in uncircumcised males (Schoen; Bailey). In 1989 the American Academy of Pediatrics issued a revised statement that concluded that there were both medical advantages and medical disadvantages to the procedure and that full information and informed consent were important for parents who were making this decision.

Medical and Ethical Issues

The basic ethical question regarding circumcision is whether it is justified to perform a surgical procedure on a healthy, unconsenting child to prevent the possibility of future disease. The primary ethical task is to balance the pain and potential complications with the potential benefits. In addition, there is a strong tradition of respecting parental wishes when their decisions are not clearly contrary to the welfare of the child. Although the full details of the risks and benefits are beyond the scope of this discussion, key issues will be outlined.

Proponents of circumcision claim several advantages for the procedure, including decreased incidence of urinary tract infections in infancy, decreased risk of penile cancer in adults, and decreased risk of sexually transmitted diseases (Wiswell, 1992; Wiswell et al., 1985). In addition, routine circumcision prevents occasional penile problems such as phimosis (a narrowing of the foreskin that prevents its retraction), balanitis (an infection of the head of the penis), and posthitis (an infection of the foreskin). Significant complications of the procedure are quite rare, occurring in less than 1 percent of circumcised neonates (Kaplan). Until the mid-1980s, circumcision was performed commonly without anesthesia. Current techniques permit the pain of circumcision to be reduced with a number of simple techniques. In contrast to female circumcision, the procedure has no significant effect on sexual function or pleasure (Collins et al.).

Social issues are a significant element in the debate. Many parents would like their sons to look like the majority of their peers, and many parents would like their sons to look like their fathers, the majority of whom are circumcised. Finally, parents who have grown up in a society of circumcised men may find a circumcised penis to be more aesthetically agreeable.

Those who question the value of the procedure counter that the case for reductions in urinary tract infections, cancer rates, and sexually transmitted diseases is not convincing, or that many of the same benefits may be achieved through better personal hygiene (Poland; Milos and Macris). While the procedure is generally safe, according to George Kaplan, there are risks of excessive bleeding, infection, removal of too much tissue, tissue damage and scarring, reactions to anesthetic agents, and retention of urine. It is also argued that the penile problems that may arise in uncircumcised males, such as phimosis or balanitis, can be prevented or effectively treated when they occur. Further, it is noted that pain-control measures are not consistently effective, carry their own risks, and are associated with some pain as well. Marilyn Milos and Donna Macris note that some have claimed that the foreskin provides a protective covering for the glans, making the uncircumcised penis more sensitive during sexual activity.

Since the 1960s, a cultural shift has placed a higher value on preserving the natural look. Uncircumcised males are common enough, the argument goes, that the appearance of an uncircumcised penis in a high school locker room will not be cause for embarrassment. Finally, it is claimed that a simple explanation from father to son will prevent a son's confusion about a different look to his penis.

Of all of the potential medical advantages of circumcision, the reduced risk of urinary tract infection in the infant is the best documented, and this is the benefit most likely to be experienced by the child (Wiswell, 1992; Schoen). Urinary tract infections in neonates are potentially serious infections that may be life-threatening and, if recurrent, may lead to the later development of renal insufficiency and hypertension. However, the risk of urinary tract infection in uncircumcised infants is still relatively small, occurring in approximately 1 to 4 percent of infants. Of those infected, only a small minority will suffer long-term kidney damage (Chessare). Further, it is estimated that eighty infants would need to be circumcised to prevent one urinary tract infection (Lerman and Liao).

Parents are thus left with a difficult decision. Circumcision might be delayed until the child is old enough to make his own choice, but this alternative obviates the primary medical advantage of decreasing the risk of urinary tract infection in infancy. In addition, performing the procedure beyond the newborn period may be associated with greater risks (Wiswell et al., 1993). Therefore, reliance on surrogate decision making by the parents for the newborn boy remains an ethically appropriate approach. With all of the current data in hand, many physicians and parents find themselves falling between the polar positions in this debate. The AAP drew the following conclusions in its 1999 policy statement on circumcision:

> Existing scientific evidence demonstrates potential medical benefits of newborn male circumcision; however, these data are not sufficient to recommend routine neonatal circumcision. In the case of circumcision, in which there are potential benefits and risks, yet the procedure is not essential to the child's current well-being, parents should determine what is in the best interest of the child. To make an informed choice, parents of all male infants should be given accurate and unbiased information and be provided the opportunity to

discuss this decision. It is legitimate for parents to take into account cultural, religious, and ethnic traditions, in addition to the medical factors, when making this decision. Analgesia is safe and effective in reducing the procedural pain associated with circumcision; therefore, if a decision for circumcision is made, procedural analgesia should be provided.

For many parents the final decision will be made primarily on cultural and social grounds, with less weight placed on the potential health benefits or risks. Fortunately, there is some evidence that most adult men like the way they are, whether circumcised or not (Lee).

There has also been a vocal debate over the practice of female circumcision (AAP, 1998), which has led some to draws parallels between male and female procedures. While both procedures are performed primarily for cultural reasons, there are dissimilarities worthy of note. There are a few well-documented medical benefits to male circumcision and no long-term morbidities, unlike the female procedure. Further, male circumcision is not associated with sexual control and subjugation, cultural attitudes that are at the foundation of the tradition of female circumcision.

The social debate over the procedure in the United States is likely to continue. In this context, the responsibilities of both the physician and the parents are to make sure that all are fully informed about the benefits and risks of this procedure, and that the procedure, if elected, is performed in a competent and humane manner.

CIRCUMCISION, RELIGIOUS ASPECTS OF

• • •

Throughout history different cultures have used genital alteration of males and females to express religious identity, inscribe social values, and enforce social norms of marriage, sexuality, and appropriate gender behavior. Societies differ greatly on whether they practice genital alteration on males and females, both, or neither, and on the stage of life at which procedures are done. Male circumcision, for example, is done on the eighth day of life by observant Jews, at around four or five years of age by Muslims in Turkey, and at puberty in some sub-Saharan African cultures.

Genital alteration became the subject of controversy toward the close of the twentieth century for a number of reasons. First, it is primarily performed on children and women, two groups perceived to be especially vulnerable. In the case of children, there is obvious lack of informed consent. Second, as immigrants from cultures that performed female genital alteration settled in Western countries, healthcare providers became aware of the procedures and of their negative effects on women's health. Third, a strong international feminist movement produced critics of the female procedures, both from within and without the indigenous cultures. Fourth, a century-long controversy in the United States over the health benefits of the male procedure began to move the practice away from routine recommendation of male circumcision. Fifth, a nascent *children's rights* movement began to question the ethics of performing surgery to excise healthy, normal tissue, with no proven medical benefit and, some argued, a diminution of sexual function.

The content of the controversy can be categorized into three parts. First, although there is no dispute over the lack of health benefit to females and the terrible impact of these surgeries on women's health, lively controversy exists over the negative and positive impact of male circumcision on males's health and sexual function.

Second, there is serious disagreement over appropriate language, reflecting the competing values in the debate. Male newborn genital alteration is almost always referred to as *circumcision,* a vaguely medical term that signals society's acceptance of this procedure. Conversely, the term *uncircumcised,* as opposed to *intact* or *natural,* signals the normative status of the circumcised male in American culture. When writers use circumcision to refer to the female procedure, there is often an outcry; opponents of the female procedure and defenders of the male procedure alike object to casting them in the same light. The term *female genital mutilation,* preferred by most opponents of the procedure and the term officially adopted by the World Health Organization (WHO), has its own problems. For one, as anthropologists Sandra D. Lane and Robert A. Rubinstein point out, "mutilation implies removal or destruction without medical necessity," which logically ought to refer to routine male circumcision as well (Lane and Rubinstein, p. 35). Further, the term ignores the meanings of female genital alteration in the cultures in which it is practiced, in which not to be circumcised is to look weird and disgusting. Finally, the term polarizes people rather than inviting discussion. *Cosmetic genital surgeries,* as a term for male and female procedures, has the advantage of inviting comparison with more widely accepted surgical interventions, such as breast augmentation, but the disadvantage of misleadingly implying a surgical environment, a far cry from the primitive conditions that attend most female genital surgeries. This entry uses the neutral terms *male and female genital alteration.*

Third, there is debate about whether genital alterations stem from *religion* or *culture,* with the explicit or implicit inference that the former commands more respect.

Male Genital Alteration

The origins of male genital alteration predate any religion now in existence. It is certain that ancient Egyptians practiced some form of adult male circumcision; there are many theories about how and why the practice made its way from Egyptian culture to the Israelites, who became the first people known to genitally alter infants.

According to the Hebrew Bible, Abraham was the first Israelite to be circumcised; performing the operation on himself at the age of ninety-nine. He then circumcised all the members of his household. The Biblical injunction reads: "Every male among you shall be circumcised. And ye shall be circumcised in the flesh of your foreskin, and it shall be a

token of a covenant betwixt Me and you. And he that is eight days old shall be circumcised among you, every male throughout the generations" (Gen. 17: 11–12). Both of Abraham's sons were circumcised: Ishmael, the child of Abraham's servant Hagar, and Isaac, the son of Abraham's wife Sarah.

Male Genital Alteration in Judaism

While circumcision is the sign of belonging to the covenant, it does not confer Jewishness. Uncircumcised males can still be considered Jewish; Judaism does not practice female circumcision, but females are not thereby excluded from the covenant. In order for the religious obligation of circumcision to be fulfilled, the surgery must be set in the proper context, which includes the blessings, the correct procedure, the appropriate mindset, and the religiously mandated day of performance.

The Jewish ritual of male circumcision is called a *berit milah,* or a *bris.* It has two components: the cutting and the naming of the baby. The cutting is performed by a *mohel,* who may also be a physician. On the eighth day of the baby's life, the *mohel* comes to the home. The *berit milah* is a social occasion; friends and family are invited. Although there are many variations in how the ceremony is performed, the core ritual commonly begins with the lighting of a candle. One or two people have the honor of bringing the baby to the *throne of Elijah,* a special chair set aside for the male (often the baby's grandfather) who will hold the baby during the cutting. Traditionally, the mother remains in another room. After the ritual cutting, the baby is rediapered and allowed to nurse. The baby is given his Jewish name, and the *mohel* or rabbi, if one is present, recites blessings for the rapid healing of the baby and the continued recovery from childbirth of the mother. This is followed by a festive meal. The foreskin may be buried in the earth. In one custom, it is buried beneath a tree whose branches are later harvested to make the boy's wedding canopy.

Male Genital Alteration in Islam

In Islam male circumcision is performed for reasons of ritual cleanliness or purity; the term used is *fitra,* which implies both physical hygiene and inner purity. Cleanliness is required for prayer to be efficacious; the uncircumcised male faces the possibility that some trace of urine will remain under the foreskin and his prayers will be nullified. Circumcision is not mentioned in the Qur'an, but is part of the second source of Islamic law: *hadith* (the sayings and doings of the Prophet). Further, the obligation of circumcision can be inferred from the fact that Allah (God) told the Prophet Muhammed to follow the religion of Ibrahim (Abraham), and Ibrahim considered circumcision important enough to rectify his own uncircumcised state even at the advanced age of ninety-nine.

Depending upon the particular Islamic tradition and which scholars are most influential, male circumcision can be considered either obligatory or strongly recommended. The Prophet Muhammed recommended that circumcision be performed at an early age. In many Muslim cultures, the preferred time is on the seventh day after birth, and that is the common practice among North American Muslims.

Female Genital Alteration

It would be a mistake to assume an identity between Islam and female genital alteration. Saudi Arabia and Iran, two of the most conservative Muslim nations, abjure the practice, while non-Muslim minorities living in predominantly Islamic cultures sometimes embrace it. Further, traditional genital surgeries are performed in some non-Islamic African cultures. Nonetheless, the majority of people who practice some form of this custom identify with Islam, either as a religion or as a culture.

As is the case with male circumcision, the female procedure is not mentioned in the Qur'an, but claims for its legitimacy come from *hadith.* The use of the word *sunna* (meaning to follow the path of the Prophet) as the term signifying one form of the female procedure suggests that the practice is commendatory or virtuous. Similarly, the colloquial Arabic term for female circumcision is *tahara¸* referring to a state of ritual purity. The *hadith* include a saying of the Prophet that ritual circumcisers should "not overdo it, because [the clitoris] is lucky for the woman and dear to the husband." This *hadith* (although considered somewhat weak in its authenticity) is used by some Muslims to argue against the more severe forms of female genital alteration (Winkel).

Religion and Culture Intertwined

The controversies over genital surgeries often include intense debates on the question of whether they are religiously or culturally inspired. In the United States, defining a practice as religious tends to surround it with an aura of heightened respect and protection not granted to those deemed *merely* cultural. However, it is often impossible to distinguish religious motivations from cultural ones.

Among all but the most traditional Jews, it is probably correct to say that the reasons for performing newborn circumcision are made up of religious elements, medical beliefs, and familial and communal motivations. In the United States, where approximately 80 percent of all males

are circumcised, the practice of Jews is simply subsumed into the general norms. Although statistics are not available, it is generally believed that the majority of American Jews who have their newborn sons circumcised do not do so in a *berit milah.* Thus the circumcision does not fulfill the religious obligation, and will have to be repeated (in a nominal fashion) should the boy grow up to be a religious Jew. Other American Jews go through the religious ceremony, but do not partake of any other elements of Jewish religious or communal life. A high percentage of Jews genitally alter their sons in response to societal, community, or familial pressures, or simply so that a boy will look like his father. These reasons attest to the way in which male circumcision remains an important element of the communal *glue* that holds Jewish culture together, especially in tolerant America, where assimilation is feared more than anti-Semitism.

Some Jewish feminists have expressed criticism of *berit milah* because it surrounds the birth of a boy with more importance than that of a girl (although naming ceremonies for baby girls are becoming more common), and because it seems to imply a necessary connection between the male body and membership in the Jewish covenant. Miriam Pollack argues that the ritual cutting topples the mother from her rightful role as protector and nurturer of the baby, ignoring her biological instincts and "mother wisdom" (p. 171).

Female genital alteration is also practiced in response to a mix of religious, cultural, nationalist, and quasi-medical beliefs. A good example of this mix occurred in Egypt, where the proportion of genitally altered women is among the highest in the world. In 1994, at the International Conference on Population and Development in Cairo, a horrifying CNN film about female circumcision was shown, depicting the brutal cutting of a little girl. Members of Parliament responded with proposed legislation to criminalize the practice, but conservative religious authorities countered that female circumcision was an Islamic duty, and in integral component of Egyptian national identity. Other religious leaders claimed that female circumcision was a weak duty in Islam, at best, and that the issue should be decided by medical experts.

Anthropologists Lane and Rubinstein comment that, "Although it is not a practice of the majority of Muslims in the world, among those who do practice it female circumcision is nonetheless often considered to be legitimized by religion" (p. 34). Other reasons, often closely interwoven with religious ones, include the belief that without circumcision girls will *run wild,* become sexually active, and besmirch family honor (thus also flouting religious norms). The more extreme forms of genital alteration *guarantee* a daughter's virginity until marriage. In cultures in which some form of alteration is the norm, parents worry that uncircumcised daughters will be unmarriageable.

Group identity and communal cohesiveness are other motivations for female genital alteration. As new national boundaries threaten to disrupt historical tribal dominance in particular geographic areas, a process accelerated by urbanization, genital alteration can be seen as a way of marking and strengthening distinct village and tribal identities. In fact, war and dislocation can stimulate people to defend and display their cultural identity by intensified adherence to the practice. In 1997 women in displaced persons camps in Sierra Leone celebrated the end of war and their imminent return to their homes by holding a series of circumcision rituals. "'I decided to go to the bush and have this done now because I am a mature woman now,' said Bateh Kindoh, a shy 16-year-old who sat with two other recent initiates to speak with a visitor. 'We will go back to our villages soon, and I wanted to become part of the Bondo [women's communal society] first. This is a happy time for us.'" (French, p. A4).

Male and female genital alteration has an abundance of layered meanings: religious, cultural, familial, and political. There are also economic incentives for professional circumcisers to continue to defend their practice. Any discussion of these practices must take these meanings into account.

CLIMATE CHANGE

• • •

In recent years many environmental problems have come to public consciousness. Of all of these problems, global climate change could prove to be the most dramatic and least reversible. It could have profound implications for the health of humans and other beings.

A climate change is quite different from a change in the weather. While weather constantly changes, climate is relatively stable. One can discuss the North American climate during the last ice age, but when one talks about the cold and snow in Boulder, Colorado, yesterday, they are talking about the weather. Weather systems last from a few hours to a few weeks and range from about 10 to 10,000 horizontal kilometers in size. A climate regime may persist for millennia, with variability in temperature and precipitation being part of a stable climate system. The climate system involves complex interactions between the atmosphere, oceans, land surface, snow and ice cover, and the biosphere. Researchers are learning that human activity is also a part of the dynamic that affects climate.

The Discovery of Anthropogenic Climate Change

On June 23, 1988, a sweltering day in Washington, D.C., in the middle of a severe drought in the United States, James Hansen of the National Aeronautics and Space Administration (NASA) testified before the U.S. Senate Committee on Energy and Natural Resources. It was 99 percent probable, Hansen contended, that global warming had begun. His testimony, which was covered by media all over the world, appeared to many people to come from nowhere. But like most overnight sensations, speculation about climate change has a history.

In the eighteenth century Benjamin Franklin surmised that the hard winter of 1783 to 1784 was due to excessive dust in the air, either from the destruction of meteorites or from volcanic eruptions. Early in the nineteenth century the French mathematician Jean Baptiste Fourier (1768–1830) speculated that the atmosphere might function like the glass in a greenhouse, warming Earth's surface by preventing heat from escaping. In 1861 British physicist John Tyndall (1820–1893) showed that slight changes in the composition of the atmosphere could significantly raise Earth's temperature. The Swedish Nobel Prize winner Svante Arrhenius (1859–1927) theorized in 1896 that the use of fossil fuels would increase atmospheric carbon dioxide, thereby changing climate and affecting biological processes. He calculated that a doubling of atmospheric carbon dioxide would lead to an increase of four to six degrees centigrade in Earth's mean surface temperature. In the 1930s the British engineer George Callendar revived Arrhenius's ideas and asserted that global warming had already begun. Working in the United States, Gilbert Plass, Roger Revelle, and Hans Suess brought these ideas into the scientific mainstream in the 1950s. A very influential article by Revelle and Suess in 1957 asserted that because of the exponentially increasing use of fossil fuels, an experiment was in progress that could not have happened in the past and that could not be reproduced in the future. Their work led to the establishment of the Mauna Loa Observatory in Hawaii, which has been measuring carbon dioxide concentrations in the atmosphere since 1958.

The climate anomalies of 1972 and the global food shortages of 1972 to 1973 brought the possibility of climate change to the attention of a broader audience. Droughts in the Sahel region of Africa in the late 1960s and early 1970s had reminded people how dependent on climate humans remain. When drought also occurred in the Soviet Union in 1972, world grain prices doubled and global food shortages

followed. During the same year, frost destroyed coffee plantations in Brazil, and changes in seawater temperatures (related to a climate anomaly called El Niño) had a severe impact on Peru's anchovy fisheries. U.S. Secretary of State Henry Kissinger raised the possibility of climate change in a 1974 speech to the United Nations.

The climate change scare of the early 1970s was a fear of cooling. From the 1940s through the 1960s, Earth's mean surface temperature had declined; there was concern that another ice age was beginning. The Central Intelligence Agency undertook a study of how such a cooling might affect agricultural production in the Soviet Union; and the same Senate committee that fifteen years later would hold hearings on global warming held hearings on global cooling.

Whether the fear was of a cooling or a warming, climate increasingly came to be viewed as a dynamic system that is vulnerable to human action. By the mid-1970s the possibility of climate change had been discovered.

The Current Scientific View

Throughout the late 1970s and 1980s, conferences and studies were instituted by a wide range of national and international organizations. The culmination of this activity was the 1990 report of the Intergovernmental Panel on Climate Change (IPCC). The process that led to the development of this report involved 170 scientists from 25 countries; 200 other scientists reviewed the results. The goal of the IPCC process was to determine the international scientific consensus about climate change. The conclusion was that if emissions of *greenhouse gases* (primarily carbon dioxide, methane, chlorofluorocarbons, and nitrous oxide) continue as usual, Earth's mean surface temperature could rise 0.2 to 0.5 degree centigrade per decade, with a likely warming of 1 degree centigrade by 2025, and 3 degrees centigrade by the end of the twenty-first century. This would be the greatest temperature change to have occurred on Earth for at least 10,000 years.

The eight warmest years in the historical record have occurred since the publication of the first IPCC report in 1990. This, combined with scientific advances in the understanding of climate and increasingly sophisticated climate models, has strengthened the case for anthropogenic climate change. This has been reflected in subsequent IPCC reports. The 1995 Second Assessment concluded that "[t]he balance of evidence suggests a discernible human influence on global climate" (p. 5). The Third Assessment, published in 2001, stated categorically that "[a]nthropogenic climate change will persist for many centuries," estimating that the Earth's global mean surface temperature will increase from 1.4 to 5.8°C from 1990 to 2100 (p.17).

Although some remain skeptical, one thing that is certain is that there is a *greenhouse effect.* According to climatologist Stephen Schneider, it is "one of the best, most well-established scientific theories in the atmospheric sciences" (Boyle and Ardill, p. 12). Were it not for the greenhouse effect, all of the planets of the solar system would be cold and lifeless. But as researchers have learned in other areas, such as medicine, too much of a good thing can be a bad thing.

The greenhouse effect occurs when a planetary atmosphere, due to its physical/chemical composition, permits solar radiation to heat the surface of the planet but traps some of the heat that would otherwise radiate back into space. The greenhouse effect explains, at least partially, the differences between conditions on the surfaces of Venus, Mars, and Earth. Venus has an extremely dense, carbon dioxide-rich atmosphere that traps so much heat that life is not possible on the surface of the planet. Mars has a very thin, carbon dioxide–poor atmosphere, and mid-latitude surface temperatures on Mars are about the same as those of Earth's polar winters. Earth is just right for evolving and sustaining life—at least for the moment.

Another fact about which researchers are certain is that human activity is affecting the chemical composition of Earth's atmosphere. From 1860 to 2000 there was an increase of about 34 percent in atmospheric carbon dioxide, more than half of that occurring since the 1960s. Other greenhouse gases have increased by even greater percentages during the same period. Concentrations of these gases have risen as a result of activities that are essential to economic growth and development, at least as they are presently conceived: fossil fuel combustion, deforestation, food-animal production, rice-paddy agriculture, and fertilizer use.

What is certain, then, is that the greenhouse effect exists, and that concentrations of greenhouse gases in the atmosphere are increasing. However, not all scientists agree about the likely effects of these increasing concentrations. There are extremely complicated and ill-understood feedbacks in the climate system. The effects of these feedbacks could be to stabilize climate even in the face of changes in the atmosphere, or to exaggerate the effects of climate change. Since these feedbacks are not well understood, the scientific community's prediction of a significant greenhouse warming is a cautious one.

The Effects of Climate Change

The image that many people have of a global warming is that all regions of Earth would be warmed equally, as if one turned up the thermostat in the global house. This image is quite misleading. The impacts of global warming would be

very diverse. Some regions would warm while others would cool. Precipitation patterns would change, and extreme events (e.g., droughts and hurricanes) would become more frequent. While this much is clear, it is extremely difficult to say how particular regions would be affected. The predictions generally agree about the global effects of climate change but disagree to a great extent about its regional effects.

Impacts of climate change fall into three categories. First-order impacts involve physical changes such as rises in sea level, effects on biological systems and circulation of water and so on. A large number of species will become extinct and many ecosystems will fracture and disintegrate. Some of the most dramatic first-order effects of a global warming would be the inundation of island nations, such as the Maldives, Kiribati (Gilbert Islands), and the Marshall Islands. Egypt could lose 1 percent of its land due to flooding. Second-order impacts involve the direct social, economic, and health effects of first-order impacts. An example would be the economic, social, and cultural consequences of Egypt's loss of 1 percent of its land. The part of Egypt that would be threatened by a sea-level rise is the Nile delta, home to 48 million people and contributor of 15 percent of Egypt's GNP. Third-order impacts of climate change involve the indirect social and political responses to the first- and second-order effects. Third-order impacts might include massive emigration from affected regions such as the Nile delta, and international conflicts resulting from economic dislocations and changing patterns of resource use.

The impact of climate change on human health is an area of research that has been receiving a great deal of attention. In particular, there is concern that infectious diseases such as malaria and dengue fever will become more prevalent, along with water-borne diseases such as cholera. There are already 300 million clinically confirmed cases of malaria in the world, causing more than 1 million annual deaths. Infectious diseases are currently the largest source of mortality in the developing world, and until sometime in the twentieth century they were also the largest killer in most of the developed world. Increases in the prevalence of infectious disease could have devastating effects on the human population.

Until the late 1980s it was commonly said that all people would suffer from climate change. However it has become increasingly clear that climate change will involve winners and losers, and most experts believe that the rich countries will do better than the poor ones. Rich countries can build seawalls and dikes to protect coastal areas against rising sea levels. They can even gain economically by developing and exporting technologies that will help in adapting to climate change. Rich countries can pay more for food if climate change adversely affects agriculture. In general, their control of capital can be used to shield them from many effects of a changing climate. Poor countries do not have resources to protect themselves in these ways. Moreover, some poor countries (e.g., Bangladesh) already suffer enormously from extreme climatic events.

But even though it may generally be true that the rich would do better than the poor in adapting to climate change, there are still reasons for the rich to be concerned. Rich people are often more averse to risk than poor people, for they have more to lose. Moreover, if climate change occurs, there will be differential effects across both rich and poor countries. For example, according to some scenarios, agriculture in the U.S. Great Plains might dry up and blow away, while in some arid regions of Africa precipitation might increase.

Although the regional effects of global climate change are uncertain, it is clear that there will be winners and losers. When human action has consequences that benefit some and burden others, it becomes a matter for moral evaluation.

Risk and Insurance

Some commentators have tried to transform the ethical problems implicit in the possibility of climate change into problems of rational choice. One approach has been to think of the possibility of climate change as a risk, and the costs of emission reduction, mitigation, and adaptation as the premium paid for insurance against this risk. However tempting this approach may be, the insurance metaphor is misleading. An insurance company is able to set rational premiums because of actuarial tables that are based on the frequency with which compensable losses occur. But however strong the theoretical reasons are for thinking that climate change will occur, researchers have nothing like actuarial tables that tell them about the frequency of climate change when the atmosphere is loaded with greenhouse gases. Moreover, the idea that society is in a position to reasonably assess the potential damages of climate change is quite absurd. No one knows what all the economic and health effects of a greenhouse warming would be, much less how to attach meaningful economic values to the loss of many wild species and the destruction of societies and cultures. As a result, economists who work on climate change tend to focus on the more easily quantifiable costs of emissions reductions rather than on the damages that such investments might help society to avoid. While it is easy to talk about the importance of taking out insurance against the possibility of a greenhouse warming, at present there is no way to determine what it would be rational to pay for such insurance.

Finally, the insurance metaphor defers rather than evades the ethical questions. Even if one were able to determine a rational premium, the question of how the costs should be distributed would remain. Talk of purchasing insurance against the risk of a greenhouse warming does not free society from the hard ethical discussions.

Moral and Political Issues

Philosophers often distinguish duties of justice from other sorts of duties. For present purposes, however, one can think of climate change as posing questions of justice with respect to human contemporaries (intragenerational justice), descendants (intergenerational justice), and possibly nonhuman nature. Because climate change is by its very nature global in scope, the questions of justice that it provokes are international.

The rich countries of the world have loaded the atmosphere with the greenhouse gases that may already be changing climate. They have benefited from their actions by developing economically. While rich countries have gained the benefits, the deleterious effects of their emissions will be felt by everyone. If climate change-induced floods occur in Bangladesh, it will not be due to the actions of the Bangladeshis. They will not have caused the floods, nor will they have benefited from the past emissions of greenhouse gases that caused them.

In addition to these historical inequities in emissions, there are important differences in present emissions. A handful of industrial countries emit between one-half and three-quarters of all greenhouse gases. Yet at the United Nations-sponsored Conference on Environment and Development, held in Rio de Janeiro in June 1992, the rich countries were unwilling to agree to timetables and targets even for stabilizing their emissions, much less reducing them, mainly due to the intransigence of the United States. Finally at Kyoto in 1997 the nations of the world did agree to binding timetables and targets for emissions reductions, only to have the United States and Australia jump ship after doing everything they could to weaken the agreement.

Rich countries became rich in part by taking actions that are changing the global climate. This climate change may have devastating impacts on poor countries. What do the rich owe the poor as a consequence of their actions? This question arises against the background of an international system characterized by radical and increasing inequality. According to Sir Crispin Tickell, in 1880 the ratio of real per capita income between Europe, on the one hand, and India and China, on the other, was two to one; in 1965 it was forty to one; and in the 1990s it was seventy to one. Even on the most conservative assumptions, between 1820 and 1970 global inequality doubled (Dollar and Kraay). One way of making this inequality vivid is by considering these examples from the *Human Development Report 1998: Consumption for Human Development* (United Nations Development Programme, p. 29). In 1960, 20 percent of the world's people who lived in the richest countries had thirty times the income of the poorest 20 percent, and by 1995 eighty-two times as much income. The wealth of the fifteen richest people in the world exceeds the total GDP of sub-Saharan Africa. The assets of the eighty-four richest individuals in the world are greater than the GDP of China at the beginning of the twenty-first century. The 225 richest people in the world have combined wealth that is equal to the annual income of the poorest 47 percent of the world's population. In absolute terms, more than 1 billion people live on less than $1 per day, and nearly 3 billion live on less than $2 per day (World Bank).

Underlying these problems of inequality and poverty are an exploding population in some parts of the developing world and increasing overconsumption in the developed world. The United States, with 5 percent of the world's population, annually consumes 25 percent of the world's fossil fuels, 33 percent of its paper, 24 percent of its aluminum, and 13 percent of its fertilizer. A child born in 1994 in the United States will in his or her lifetime drive 700,000 miles, using 28,000 gallons of gasoline; produce 110,250 pounds of trash; eat 8,486 pounds of red meat; and consume enough electricity to burn 16,610 pounds of coal. Earth simply cannot support many Americans. The world population as of 2003 is more than 6.2 billion, and is increasing by 75 million per year. An optimistic scenario calls for world population to stabilize at more than 10 billion in the twenty-third century. Many observers expect population to grow far beyond that.

One way of trying to understand the joint impact of overconsumption and exploding population is to consider the following facts. Sweden is a country that enjoys one of the highest standards of living in the world, yet its per capita carbon dioxide emissions are little more than one-fourth of those of the United States. If Sweden's level of per capita emissions were to be established as an international ceiling, the United States would have to reduce its emissions by vastly more than anyone is willing to even consider. Yet, even given such painful reductions on the part of some countries, on this scenario world emissions would increase by more than one-third, reflecting the large populations of some less developed countries that consume very little energy.

Philosophical theorizing about international justice is underdeveloped, and very little work has been done on international environmental justice. The most influential philosophical theories of justice were formulated with an eye

to what constitutes a just national distribution of private goods. Pattern theories such as that of John Rawls, and entitlement theories such as that of Robert Nozick, have received the most attention. Although one can speculate about what these theories might imply with respect to climate change, neither philosopher has had much to say about global justice, much less global environmental justice.

Rawls' principle of distributive justice is the "Difference Principle": Social and economic inequalities are to be attached to positions and offices that are open to all under conditions of fair equality of opportunity, and they are to be distributed to the greatest benefit of the least advantaged members of society. Whether one takes the subjects to be individuals or societies, it seems quite obvious that the global distribution of social and economic benefits is unjust according to this principle. Moreover, if one were to use the Difference Principle as a test for who should benefit from further releases of greenhouse gases and who should bear the costs of reduction, it seems equally clear that current policies would not satisfy this principle.

Nozick argues that the moral acceptability of a distribution depends entirely on how it came about. If the present distribution resulted from a just initial distribution through voluntary exchanges, then it is just, regardless of how unequal it may be. But given the global history of domination, imperialism, and exploitation, it seems clear that the present global distribution is unjust on Nozick's grounds. According to Nozick, any complete theory of justice must include a principle specifying how past injustices are to be rectified, but he has little to say about what such a principle may require.

Although it appears that both Rawls and Nozick are committed to the view that the current international order is unjust, neither deals specifically with this question or with the distribution of environmental benefits and burdens. Moreover, there are reasons for supposing that many environmental goods resist treatment as distributable benefits and burdens. The bad effects of climate change would include spillover effects suffered by some parties who had virtually no role in bringing them about. On reasonable human time scales, a stable climate is irreplaceable and irreversible. Furthermore, modeling aspects of the environment as distributable goods may be misleading and inappropriate. Such an approach neglects the fact that humans are situated in an environment that conditions and affects everything they do, and in part constitutes their identities.

While there is good reason for supposing that both historical and current patterns of greenhouse gas emissions are part of an unjust system of intragenerational relationships, philosophical theories of justice have not yet given the conceptual resources to address these issues in a detailed and meaningful way. More work needs to be done.

In addition to questions about intragenerational justice, global climate change poses moral questions about intergenerational justice. Those who come after us will live in a very different world than the one we inhabit in the early twenty-first century, due in part to actions that we are taking. Some who are influenced by utilitarian philosophers such as Henry Sidgwick may think that we owe just as much to future people as to present ones, since once they come to exist, they will be just as real as present people and will have the same moral status. On this view, the claims of future people should not be treated less seriously than those of present people simply because they are remote from us in time. But barring a complete collapse of Earth's human population, over the course of millennia there will be vastly more people in the future than exist now. If we take each future person as seriously as each present person, it would appear that the interests of the present would be swamped by virtue of the size of our future human population.

Other thinkers, impressed by an argument in Derek Parfit's 1984 book titled *Reasons and Persons*, may conclude that we have no obligations to future people (although this is not Parfit's conclusion). On this view, future people who feel disadvantaged would have no cause for complaint against us because their very existence would be contingent on actions that we have taken. If our present actions were other than they are, then different people would come to exist in the future. Thus, no future person can say that he or she would have been better off had we made different choices; for if we had made different choices, then that person would not have existed at all.

Many economists would grant that we have obligations to those who will follow us, but they would argue that these obligations are easily fulfilled. Suppose that, because in 2003 we act in such a way as to change the climate, our descendants living in 2103 incur damages valued at N dollars. In order for our climate change activities to be justified, we must profit enough from them to provide our descendants with N dollars when they come into existence. Because of the power of compound interest, small present benefits justify large future damages. If N dollars come due in a century and we can obtain a 5 percent return on our investments, our present benefit from climate-changing activities would have to be only $.0068N$ dollars (compounded monthly) in order for them to be justified. In other words, a present benefit of $100,000 would justify inflicting a compensation of $14.68 billion on those living a century hence.

There are many problems with such an approach. Even if we were able to compensate future people adequately in

this way, they will have been deprived of the ability to make some significant choices. For example, they will not have been able to choose to preserve a stable climate regime, even if that implies a lower standard of living.

This approach also involves the ludicrous idea that we can attach meaningful economic values to the loss of many wild species, the destruction of societies and cultures, and the unknown health effects of significant climate change. There simply are no credible attempts to carry out a benefit-cost analysis of the warming of Earth's median surface temperature by 3 degrees centigrade. This is hardly surprising, since there is often a great deal of disagreement about such relatively simple questions as the short-term effects of a change in the marginal tax rate of a single country.

Peter Brown and Edith Brown Weiss have argued that we have a fiduciary trust to preserve Earth's natural and human heritage at a level at least as good as that we received. On this basis, Weiss argues that we should reduce greenhouse gas emissions, take steps to minimize the damage that results from climate change, and develop strategies to assist future generations in adapting to climate change. This is a sensible approach that has the virtue of squaring with many people's moral intuitions. It suggests that we have significant obligations to future people, but that they do not entirely swamp the interests of the present.

Unfortunately, the fiduciary view verges on the platitudinous. Among those who believe that the buildup of greenhouse gases poses a threat, not many would deny that we need to reduce emissions, minimize harms, and develop adaptation strategies. What people disagree about is how aggressively we should pursue these policies, what the proper mix of them is, and who should bear the burdens. The fiduciary approach stops short of trying to answer these hard questions.

Furthermore, if we take seriously the idea that each generation has an obligation to preserve Earth's natural and human heritage at a level at least as good as what was received, then we are immediately faced with questions about how to evaluate the goodness of our own heritage and various changes that we might make with respect to it. These are the sorts of questions that economists try to answer, using various techniques of benefit-cost analysis, such as interviewing people about their willingness to pay (or accept compensation) for environmental good, that ethicists typically find unsatisfactory.

In addition to the problems of human health and welfare that are likely to be caused by climate change, nonhuman nature will also be affected. Climate change is likely to be much too rapid for most plants and animals to adapt to or migrate from. Even when migration would in principle be possible, no migration routes will be available for most plants and animals in a densely populated and developed world.

In recent years a powerful literature has developed that argues humans have obligations to nonhuman nature. Some philosophers, such as Peter Singer, argue that our direct obligations end at the border of sentience; others, such as Holmes Rolston III, argue that we have obligations to virtually every element of the natural order. Whatever we may think about this dispute, only someone who believes that our obligations are exhausted by our duties to humanity can remain unmoved in the face of this anticipated destruction of nonhuman nature.

Indeed, even someone who believes that our obligations are only to humans may feel that massive destruction of nonhuman nature is morally appalling. Humans have preferences about what happens to nature, and insofar as nature's destruction is contrary to human preferences, this destruction can be morally condemned. Moreover, anyone can be morally appalled by the character of a culture that would so willingly destroy nature in order to preserve a way of life that is rooted in overconsumption. One might think of nature as being like a work of art. We may not think that works of art are the direct objects of moral concern, yet we may morally condemn those who would vandalize them—say by burning the contents of the Louvre in order to warm their houses by one or two extra degrees for a year or so.

Climate change poses serious threats to human health and welfare and raises questions about our global duties and our duties to nonhuman nature. As the concentration of greenhouse gases in the atmosphere continues to increase, the moral issue of climate change will grow in importance.

CLINICAL ETHICS

• • •

I. DEVELOPMENT, ROLE, AND METHODOLOGIES

Formal efforts to address clinical ethics first developed in the United States and Canada, though similar efforts are clearly underway in western and central Europe and Japan. Indeed, interest in clinical ethics has spread to many areas of the world, including parts of Central and South America, eastern Europe, and parts of Africa. Though variously defined, clinical ethics involves the identification, analysis, and resolution of value conflicts or uncertainties that arise in the provision of healthcare in clinical settings (Fletcher and Boyle; Jonsen, Siegler, and Winslade). Clinical ethics activities include examination or formulation of relevant policies, ethics education, and ethics consultation to healthcare professionals, patients, families, surrogates, or organizations. Unlike some solely academic domains of the broader field of bioethics, clinical ethics must take into account the actual context in which clinical ethical issues arise because it aims to make contributions to clinical practice and to policy governing clinical practice. This context includes complex psychosocial, medical, legal, cultural, and political dimensions that have implications both for the types of ethical issues that arise and how those issues may be resolved (Aulisio, Arnold, and Youngner, 2000, 2003; May).

Traditionally, clinical ethics discussions tended to focus on issues related to informed consent, confidentiality and privacy, decision capacity or competence, decision making involving minors, resource allocation, and end-of-life care. Though these issues remain central to clinical ethics, the mid-1990s through early 2000s saw a growing recognition of the important relationship between clinical, organizational, and business ethics (Schyve et al.), along with the

development of a number of new areas of concern, including physician-assisted suicide (Battin, Rhodes, and Silvers), palliative care (Barnard et al.), medical mistakes (Rubin and Zoloth; Institute of Medicine), ethics and genetics (Juengst), and even bioterrorism (Gostin).

The typical mechanism for addressing issues in clinical ethics in most healthcare institutions is an ethics committee. Ethics committees are present in most hospital settings in the United States and Canada, and increasingly in other settings, such as long-term care, as well. In some clinical settings, most often academic medical centers, ethics committees are part of a much larger clinical ethics program. Such programs are commonly staffed by full-time ethicists who are responsible for ethics education, service, and research.

Development

Renée C. Fox and David J. Rothman both argued that bioethics began in the 1960s as a social and intellectual movement. The earliest concerns of bioethics were focused on acute ethical problems in research settings. Influenced by the U.S. civil rights movement, bioethical inquiry also exposed weaknesses in institutional arrangements that no longer adequately protected research subjects or patients (Fletcher). From its origins to the present, the bioethics movement has had two arms: (1) an interdisciplinary dialogue, known as bioethics, that became a new academic subdiscipline in the larger field of ethics; and (2) an agenda for institutional and social change to prevent abuses and enhance the values that guide decision making concerning research subjects and patients. Social changes in research settings to protect human subjects preceded such changes in patient-care settings by almost a decade.

The 1960s saw a number of widely publicized and much debated cases that brought to the fore the value-laden nature of clinical practice and the difficult choices posed, in part, by rapid advances in medical technology (Jonsen, 2000). The invention of a plastic arteriovenous shunt by an American physician, Belding H. Scribner, in 1960 made possible chronic hemodialysis and, simultaneously, created a profound ethical dilemma because there were far more patients in need of chronic hemodialysis than the Seattle Artificial Kidney Center could accommodate. This dilemma led to the establishment of the Admissions and Policy Committee, later infamously referred to as the "Seattle God Committee," which employed "social worth criteria" to select candidates for dialysis. Throughout the decade, successes in organ transplantation created similar ethical dilemmas related to resource allocation. In 1967 South African surgeon Christiaan Barnard's successful transplantation of a beating heart from a patient with "irreversibly fatal brain damage" raised serious ethical questions about the definition of death. In response, a committee at Harvard Medical School, the following year, formulated a statement that defined "brain death" (Jonsen, 2000).

If the ethical dilemmas raised by chronic hemodialysis and organ transplantation remained a bit removed from the lives of ordinary people, the 1970s were dominated by cases that clearly resonated with the general populace. In the racially charged climate of the early 1970s, the *New York Times*' 1972 expose of the U.S. Public Health Service's forty-year Tuskegee Syphilis Study of the progression of untreated syphilis in African-American men powerfully demonstrated how social values, even disvalues such as racism, can dramatically affect "scientific" practice in clinical settings. The study, which ran from 1932 to 1972, enrolled 600 African-American men from Tuskegee, Alabama. All participants were told that they had "bad blood" and were in need of regular medical exams, including spinal taps. In exchange for these exams, participants were given transportation to and from the hospital, hot lunches, medical care, and free burial (upon the completion of an autopsy). Of the study participants, 200 did not have syphilis, while the other 400 were diagnosed with syphilis but were never told their diagnosis or treated for their disease (even after effective treatment became available) (Jonsen, 2000; Pence). In January 1973, less than a year after the Tuskegee expose, the value-laden nature of clinical practice was again thrust into the public eye when the U.S. Supreme Court handed down its landmark decision in *Roe v. Wade.* In setting off a decades-long struggle over the morality and legality of abortion, the case also introduced extramedical notions such as "personhood," "viability," and "privacy" into the public debate.

Despite the significance of Tuskegee and *Roe,* no single case captured the public imagination or shaped the development of clinical ethics more than the tragedy of Karen Ann Quinlan did (Pence). Quinlan was a twenty-one-year-old patient at St. Clare's Hospital in Denville, New Jersey. Having lapsed into a coma in April 1975 as a result of the combined effects of alcohol, Valium, and, possibly, Librium, she was dependent on a respirator (ventilator) and was eventually deemed to be in a *persistent vegetative state* (sometimes referred to as being *permanently unconscious*). In addition to the respirator, Quinlan was dependent on the technological administration of nutrition and hydration through the use of a nasogastric (NG) tube (one that delivers food and water to the stomach through the nose). After months of anguished deliberation, Quinlan's parents, Julia and Joseph Quinlan, in consultation with their parish priest,

decided to remove her from the respirator and let her die. The Quinlan's decision, however, was opposed by hospital officials on the grounds that to remove the patient's respirator support in order to let her die was euthanasia—the moral and legal equivalent of murder (Pence).

Though New Jersey Supreme Court, in a 1976 ruling, ultimately supported the rights of the Quinlans to remove their daughter from the respirator, the tragedy of Karen Ann Quinlan had a dramatic impact on society and, in particular, on the rise of clinical ethics. Quinlan's dependence on a respirator and feeding tube came to symbolize, for many, "an oppressive medical technology, unnaturally prolonging dying" (Pence, p. 31). Once again, technological developments in medical science, this time the respirator and NG tube, had created new and difficult ethical dilemmas. Before the advent of respirators and feeding tubes, patients in Quinlan's situation simply died. There were no questions about "withholding" or "withdrawing" treatment, "active" or "passive" euthanasia, "ordinary" or "extraordinary" means, or who should be allowed to make life-and-death decisions and under what circumstances. If some people could not identify with chronic hemodialysis, organ transplantation, and the like, everyone could identify with the plight of Quinlan. Indeed, the New Jersey Supreme Court seemed to recognize this when it suggested that ethics committees be developed in hospitals so that future cases might be addressed before reaching the courts (*In re Quinlan,* 1976).

Not surprisingly, then, the 1970s saw the first clear growth of formal efforts in clinical ethics. Ethics committees began to be established in major hospitals. Scholars in bioethics increasingly taught new courses as faculty members of medical, nursing, and other professional schools. Bioethics scholars also served developing programs in the "medical humanities." In addition, some academic medical centers began to use bioethics and medical humanities scholars to offer ethics education and even ethics consultation in cases involving patients (Jonsen, 1980).

Throughout the 1980s difficult cases continued to spur the development of clinical ethics. In part because of the *Quinlan* case and a national debate on end-of-life decisions, 1980 saw the establishment of the President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research, which in 1983 issued its groundbreaking report, *Deciding to Forego Life-Sustaining Treatment.* The 1980s also saw the debate about withholding/withdrawing life-sustaining treatment extend to neonatal intensive care medicine with a series of hotly debated "Baby Doe" cases involving impaired newborns. The cases of Nancy Cruzan (*Cruzan v. Director,* 1990) and Elizabeth Bouvia (*Bouvia v. Superior Court,* 1986) raised additional ethical issues concerning end-of-life decisions and adults: Is artificially administered nutrition and hydration medical treatment? What evidentiary standard should be satisfied in making end-of-life decisions for formerly competent, but now incompetent, adults? Who is authorized to set such a standard? Does a competent adult have a right to refuse nutrition and hydration? Finally, the emergence of the HIV/AIDS epidemic raised a host of ethical issues that surfaced throughout the 1980s, including, but not limited to, concerns about: confidentiality and privacy; health professionals' duties to treat HIV-infected patients and duties to disclose their own HIV/AIDS status; duties to warn at-risk third parties; patient duties to disclose HIV/AIDS status to health providers; and mandatory testing for health professionals and others.

During the 1980s, several postgraduate training programs, some textbooks, and one journal declared that they addressed *clinical ethics,* a term that had not been used in the earlier bioethics movement. The practice of ethics consultation began to be defined in the early to mid-1980s (Fletcher, Quist, and Jonsen), and ethics committees multiplied in clinical settings to protect shared decision making with patients and family members.

With the Patient Self-Determination Act of 1991 and the stipulation of the Joint Commission on Accreditation of Healthcare Organizations (1993) that member institutions must have a "mechanism" for "the consideration of ethical issues arising in the care of patients and to provide education to caregivers and patients on ethical issues in health care" (R.1.1.6.1, p. 9), the importance of formal efforts in clinical ethics was given expression through regulatory requirements in the United States. These rules intensified the need for competence and leadership in clinical ethics. Partly in response to this, the 1990s saw efforts by groups in Canada and the United States to address standards for ethics consultants and consultation. From the mid- to late 1990s physician-assisted suicide and palliative care captured much of the clinical ethics debate, and the rise of managed care pushed organizational ethical issues into the clinical domain.

There can be little doubt that clinical ethics is becoming an established subdiscipline of the broader field of bioethics. Highly multidisciplinary, clinical ethics is pursued by clinicians—physicians, nurses, social workers, and other health professionals—as well as by those with backgrounds in the humanities (including philosophy, theology, history, and literature), social sciences (including sociology, anthropology, and public health), and law. By 2001 there were at least forty-seven academic institutions offering graduate training programs (including certificate and fellowship programs) in bioethics or medical humanities; a number had clinical ethics components; and several were specifically devoted to clinical ethics (Aulisio and Rothenberg). Despite

the rapid increase in graduate training programs in bioethics and medical humanities, the vast majority of the people offering clinical ethics services at healthcare institutions have little or no formal education and training in clinical ethics (Aulisio, Arnold, and Youngner, 2003). This suggests a continued need for educational and training programs tailored specifically to this group.

Role and Methodologies

Education and service (e.g., consultation and policy formation) are the foci of clinical ethics efforts in most healthcare institutions. Typically, a clinical ethics program in a healthcare institution, such as a large hospital, will provide staff and community education, policy critique and formulation, retrospective and prospective case review, and case consultation. The most active clinical ethics programs tend to be at academic medical centers that employ clinical ethicists. In the academic medical setting, clinical ethicists may be involved in teaching at all levels of health-professional education (preclinical, clinical, graduate, postgraduate, and continuing education). Some institutions with programs in clinical ethics offer advanced education and training through fellowship or degree programs. They may also have outreach efforts to assist in the formation of clinical ethics programs and the training of leaders for these programs.

Although education and service are central to any clinical ethics program, research can be an important component as well, particularly in an academic setting. Such research may include the type of conceptual and analytic work characteristic of humanities research (e.g., case analysis, conceptual clarification, normative assessment of particular clinical ethics issues) or the type of empirical research more characteristic of the social sciences (e.g., frequency occurrence of various ethical problems; the practical impact of various policies or practices; attitudes and beliefs of specific populations toward particular ethical issues; effectiveness of certain interventions designed to promote informed consent, protect privacy, and so forth) (Singer, Siegler, and Pellegrino). The increasingly vast clinical ethics literature is indicative of the dramatic growth in clinical ethics research since the 1980s.

Like clinical ethics itself, discussions of methodological issues in clinical ethics have evolved and developed over the years. As clinical ethics emerged, the prevailing approach to bioethical inquiry (Beauchamp and Childress) used systematic reflection on moral principles and their relevance for resolving ethical problems in biomedicine by weighing and balancing the claims of competing principles (an approach known as *principlism*). Although this mainstream approach achieved valuable work, criticisms pointed to three ways in which the approach needed to be strengthened: (1) more attention needed to be given to the nature of diseases and the clinical contexts in which clinicians and patients face ethical problems (Sider and Clements); (2) the criticism that principlism appeared to promote a hierarchical form of reasoning that deduced ethical resolutions for complex clinical problems from fixed moral principles and rules needed to be addressed (Jonsen and Toulmin); and (3) in addition to moral principles, more conceptual and methodological resources for ethical inquiry needed to be developed, because principlism appeared too vague and flexible to yield well-reasoned conclusions (Clouser and Gert).

In response to these perceived inadequacies in the forms of ethical inquiry, Glenn C. Graber and David C. Thomasma attempted to recast the theory and practice of medical ethics in terms of a "unitary ethical theory" founded in clinical medicine itself (Ackerman et al.). Their contribution, with strengths and weaknesses, was expertly reviewed in 1990 by Richard M. Zaner, a philosopher with significant clinical experience, who enriched the literature with narratives of illness and of the ethical conflicts over uses of high technology that are frequent in tertiary-care centers. Other contributors to the clinical ethics literature responded by drawing on the works of feminist (Gilligan; Noddings; Wolf; Tong) and theological (Hauerwas) writers who criticized bioethics for neglecting the ethical significance of specific clinical virtues, such as caring for persons in concrete human relationships.

Additional methodological resources for ethical inquiry appeared in the renewal of interest in casuistry, the art of ethical analysis that compares and contrasts relevantly similar cases (Jonsen and Toulmin; Brody, 1988; Arras). Clinical decision making is case-specific: It is directed at the care of a particular patient faced with a particular illness or injury. Each case has a history: what preceded the problems that needed medical attention, what needed to be done, and what was done to address the problems presented by the patient. Because it focuses on the ethics of clinical practice, clinical ethics strives for the richest possible descriptions of cases and their interpersonal dynamics and power differentials. In this vein, several anthologies of cases have appeared with well-informed clinical discussions (Pence; Crigger), including casebooks with cases drawn from ethics consultations (Kuczewski and Pinkus; Culver). Like the practice of clinical medicine, casuistry builds on the accumulated experience, both of the individual and of the professions, in dealing with a variety of cases. Comparing and contrasting related cases can reveal important ethical considerations that may not be apparent in isolated focus on a particular case.

Yet another response to critiques of earlier bioethics was to deepen and enrich the study of larger issues and themes in clinical practice, both by using cases and by drawing on knowledge available only through the intimacies of the clinician–patient encounter. Authors of such studies tend to be clinician-ethicists or ethicists who have adapted to the clinical setting sufficiently to share in such intimacies. Four examples among many are discussions of informed consent (Katz), life-and-death decision making (Brody, 1988), pain and suffering (Cassell), and the uses of power by clinicians (Brody, 1992). These studies draw on a variety of disciplines and experiential data obtained in clinical settings. As such, they encourage ethical scrutiny and reform of understandings and practices in the clinical encounters between patients and clinicians (Zaner). In this way, clinical ethics strengthens the conceptual underpinnings of bioethics with experiential data and helps motivate clinicians to reform their practices.

The continuing multidisciplinary growth in clinical ethics has, not surprisingly, created a great deal of methodological diversity in approaching clinical ethics issues. Methodological approaches characteristic of various health professions, the humanities, and the social sciences can be found in the literature (McGee; Charon and Montello; Kuczewski; Nelson; Bosk; Moreno). In practice, the approaches of different persons involved in clinical ethics efforts will, naturally, reflect, at least in part, their professional or disciplinary perspective. This is part of the great richness of clinical ethics.

In the face of this rich methodological diversity, clinical ethics, far from being fragmented, is held together by a profoundly practical aim: to make contributions to clinical practice and to policy governing clinical practice. To the extent that it is able to achieve this, clinical ethics must pay careful attention to and take into account certain features of the clinical context. As mentioned at the outset, these features include complex psychosocial, medical, legal, cultural, and political dimensions that have implications both for the types of ethical issues that arise and how these issues may be resolved (Society for Health and Human Values). For example, in the United States, the pluralistic societal context, the rights of individuals to live according to their values, and the value-laden nature of clinical practice make ethical conflict or uncertainty an inevitable feature of the clinical setting. Indeed, these features, in conjunction with advances in medical technology, arguably have created the need for formal efforts in clinical ethics. In the U.S. societal context, therefore, irrespective of the methodological approach employed by any particular person in working to address a given clinical ethics issue, the political rights of individuals must be taken into account if the approach is to make a contribution to actual clinical practice. Thus, in a very real sense, methodological approaches in clinical ethics and the theoretical commitments behind them are subordinated to the practical aim of this discipline.

II. CLINICAL ETHICS CONSULTATION

The dictionary defines consulting as "providing professional or expert advice." A clinical ethics consultant is defined here as a person who upon request provides expert advice to identify, analyze, and help resolve ethical questions or dilemmas that arise in the care of patients. Although the ethics consultant also may provide ethics education and help formulate policy, the bedside role is central to the definition of an ethics consultant (Jonsen).

In the United States, clinical ethics consultation began in some academic medical centers in the late 1960s and early 1970s (La Puma and Schiedermayer), and was given great impetus by the development of hospital ethics committees in the late 1970s and 1980s. During this period the rapid growth of medical technology confronted critically ill patients, their families, and health professionals with difficult ethical choices. At the same time, the traditional authority of the physician was challenged not only by the patient-rights and consumer-rights movements, but also by changes in the way medical care was delivered in tertiary-care hospitals, where patients were often treated by teams consisting of physicians, nurses, social workers, medical technicians, and others. Decisions about forgoing life-sustaining treatment for incompetent adults or premature infants were being made in a legal vacuum often filled by the fears of civil and even criminal litigation. In this atmosphere there was considerable uncertainty about the optimum process for resolving difficult ethical decisions without resorting to the public arena of the courts.

In its 1976 Quinlan decision, the New Jersey Supreme Court tentatively suggested the use of ethics committees to assist persons who faced difficult end-of-life decisions. In the early 1980s, the federal "Baby Doe" regulations spurred hospitals to develop internal mechanisms for dealing with decision making for severely handicapped infants. In 1983 the U.S. President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research endorsed the notion of shared decision making between patients and physicians. It suggested consultation with an ethics committee as a possible means for resolving disputes that arose in the clinical setting, but noted that the efficacy of such consultation had not been demonstrated (U.S. President's Commission).

In 1985 the National Institutes of Health and the University of California at San Francisco cosponsored a conference in Bethesda, Maryland, for persons designated by their institutions as ethics consultants. The conference was attended by fifty-three invitees, and fifty additional persons expressed interest in attending a future meeting of this group (Fletcher, 1986). By 1987 the Society for Bioethics Consultation was formed for the support and continuing education of clinical ethics consultants. In 1992 the Joint Commission for the Accreditation of Health Care Organizations (JCAHO) published a requirement for healthcare institution accreditation that all healthcare institutions must have in place a mechanism for resolving disputes concerning end-of-life decisions.

Structures of Clinical Ethics Consultation

Clinical ethics case consultation is provided in several ways: by an ethics consultative group as a whole (such as an ethics committee), by a subgroup of the consultative group, or by individual consultants. Clinical ethics case consultation by a large group has the potential for having diffused accountability and being depersonalized, bureaucratic, insensitive, closed-ended, and removed from the clinical setting. But it has the advantage of providing multiple perspectives and opportunities for queries from persons of diverse backgrounds, and for correcting the potential for narrow or idiosyncratic views of an individual consultant.

In contrast, clinical ethics case consultation by an individual consultant is an open-ended process that can extend over a period of time, and permit ongoing discussion and pursuit of issues that require clarification. The individual consultant can decide what information is necessary and obtain it firsthand. Interviews with patients, families, and health professionals can be scheduled flexibly and conducted in private settings more conducive to diminishing apprehension, establishing trust, sharing information, and allowing the kind of give-and-take that is so important to exploring emotionally powerful and intensely personal issues. Furthermore, an individual ethics consultant is more visible and accountable than a committee (Agich and Youngner). For

these reasons, many ethics consultative groups and healthcare professionals have found the individual clinical ethics consultant more effective than the committee. Many ethics consultative groups have created a middle ground that involves small teams who serve as an extension of the ethics consultation group or ethics committee.

Some see an advantage to a relationship between the ethics consultant and an ethics consultative group or committee because the large group regularly can review the individual consultant's activities. This arrangement provides peer review and quality assurance for the consultant as well as education for the larger group or committee. The ethics consultant or consultation team can ask the entire group to become involved in particularly controversial or complex cases.

The Role of the Clinical Ethics Consultant

Despite the growing interest in and practice of clinical ethics consultation, important questions remain about its purpose, requisite skills, methods, specific responsibilities, evaluation, and effect. Unlike traditional medical consultants, clinical ethics consultants are not subject to widely accepted standards and procedures for training, credentialing, maintaining accountability, charging fees, obtaining informed consent, or providing liability coverage (Purtilo; Agich).

While the role of the ethics consultant generally has been pragmatic, that is, to provide practical assistance with actual patient-care decisions (Cranford; Glover et al.; Siegler and Singer; Fletcher, 1986), there has been little consensus about how this role should be implemented. For example, although some see the ethics consultant, like the traditional medical consultant, as an expert who uses specific skills and knowledge to help "answer" ethical questions, exactly what constitutes the appropriate skills and knowledge base is a matter of debate. Does the expertise come from the wisdom of practical clinical experience (La Puma et al.), or is it derived from a knowledge of moral theory and ethical principles?

Others see the clinical ethics consultant's role not so much as an expert but as someone who facilitates decisions in a "community of reflective persons" (Glover et al., p. 24). This approach stresses the importance of involving all persons connected with the case—the patient, family members, physicians, nurses, medical students and residents, social workers, friends, and clergy. In this view, a shared decision-making process should extend beyond the physician–patient dyad so that a greater range of personal values and interests can be considered. This view is less compatible with the traditional model of medical consultation, which focuses more narrowly on the physician as decision maker.

Some commentators have worried that the individual ethics consultant, the ethics consultative group, or the ethics committee will act as moral "police" or "God Squad" (Siegler and Singer, p. 759), and erode the decision-making authority of the physician. Troyen Brennan has voiced a more subtle concern: that by turning increasingly to ethics consultants and ethics committees, we "run the risk of forcing the ethics of the caring relationship to the periphery of clinical practice as something that is best left to experts" (Brennan, p. 4). Furthermore, the role of the ethics consultant may be confused with other institutional roles, such as risk management, peer review, quality assurance, or resource allocation. Taking on these roles could create a conflict of interest for the ethics consultant.

Reasons for Ethics Consultation

Ethics consultations are requested for a variety of reasons that include prevention of litigation; mediation of disputes and resolution of conflicts between or among the patient, healthcare professional, and family; confirmation of or challenges to decisions already made; emotional support for difficult decisions; and identification of morally acceptable alternatives. For example, ethics consultation may be requested because physicians and family members disagree about how aggressively to treat a dying, incompetent cancer patient, or because there is difficulty interpreting a patient's living will. Ethics consultants may be called because there is disagreement about the acceptability of a family request to stop tube feeding an Alzheimer patient who refuses to eat. Requests for ethics consultation may come because nurses or house officers are concerned that competent patients are being left out of the decision-making process.

Goals of Ethics Consultation

There is disagreement about the appropriate goals of ethics consultation. John La Puma and E. Rush Priest have suggested that ethics consultations's primary goal should be "to effect ethical outcomes in particular cases and to teach physicians to construct their own frameworks for ethical decisions making" (La Puma and Priest, p. 17). Patient-rights advocates disagree. They argue that the primary goal of ethics consultation is the promotion of patient autonomy by encouraging shared decision making (Tulsky and Lo). John Fletcher takes a broader view. He identifies four goals of ethics consultation: (1) to protect and enhance shared decision making in the resolution of ethical problems; (2) to prevent poor outcomes; (3) to increase knowledge of clinical ethics; and (4) to increase knowledge of self and others through participation in resolving conflicts (Fletcher, 1992).

Contributions to the Practice of Ethics Consultation

While the general purpose of clinical ethics consultation is to help resolve ethical questions or dilemmas in patient care, persons who perform ethics consultation come from diverse professional backgrounds and do not share the same problem-solving methods or theoretical assumptions. This diversity has left its stamp on the way clinical ethics consultation is performed, and has profound implications not only for the practice of clinical ethics consultation but also for the training of its practitioners.

Despite this diversity, a common ground can be seen in the shared goal of identifying an ethically supportable solution to a clinical ethical question or dilemma, and in a recognition that the process of arriving at a solution requires knowledge of law, ethics, medicine, psychosocial issues, and at times, religion.

The legal tradition has influenced clinical ethics consultation by placing emphasis on rights and on formal mechanisms of decision making and arbitration, such as due process. The protection and nurturing of individual rights are central to this style (Wolf). Strict adherence to this style, however, may encourage adversarial rather than collaborative or nurturing relationships between patients and healthcare professionals (Agich and Youngner).

The medical tradition has contributed methods, assumptions, and traditions of clinical practice: a combination of technical knowledge and clinical experience (La Puma and Toulmin). Some argue that physicians are best suited to provide clinical ethics consultation because (1) their advice will be easily accepted by their medical colleagues, because they have clinical experience and speak the same language; and (2) only physicians can understand the ethos of physician-patient relationships. Critics caution that because they are "insiders," physicians may promote the values of medicine rather than those of their patients or the larger community. They argue that the ethics consultant should serve as a bridge between medical and other values, and cannot function properly from a position entirely within medicine (Glover et al.; Churchill).

Moral philosophy has offered three major approaches to clinical ethics consultation. The first is principle-based ethics, which argues that the answer to a given ethical question or dilemma may be discovered by applying the correct ethical theory (e.g., utilitarianism) or principle (e.g., autonomy) to the case. The second is virtue ethics, which emphasizes that the possession of certain virtues (e.g., honesty, loyalty, compassion) is essential to sound ethical decision making. The third is a case-based or casuistic ethic, which holds that by examining the particulars of a given case and comparing them with similar cases, a moral maxim that applies to the case can be discovered. An advantage of casuistry is that it sues a decision-making method already employed by clinicians (Jonsen and Toulmin). Casuistry relies upon teachable medical moral maxims that build upon experience. Because casuistry is not principle-based, it has been criticized as "situational," that is, pragmatically driven to solve individual problems without reference to a broader moral framework.

While principle-based clinical ethics reasoning has the advantage of providing a consistent moral reference point, its principles are necessarily abstract, often conflict with each other, and may create a rigid paradigm that is insensitive to differences in specific cases.

Theology and religion contribute to clinical ethics consultation by recognizing that specific religious positions may either facilitate the resolution of an ethical question or contribute to its intensity. For example, the Jehovah's Witness position on blood transfusions can create serious ethical dilemmas in the case of a Jehovah's Witness patient who is in urgent need of extensive, lifesaving surgery but refuses blood. One of the disadvantages of this perspective is that many physicians are suspicious of or even hostile to religious or theological interpretations of medical problems. However, insight into the religious morality of patients, family members, and healthcare professionals is useful in establishing communication and reaching understanding among physicians, patients, and family members.

Consultation liaison psychiatry and clinical psychology have influenced clinical ethics consultation by addressing dynamic and interpersonal elements of clinical ethics cases. This style involves using insight into the motivations and values of those involved in the ethics case to resolve conflicts among decision makers. The goal is to produce a consensus or compromise solution rather than to evoke rights language, ethical principles, or religious codes. A disadvantage of this approach is that a compromise solution is not always a just one. Its strength is that it skillfully manages confrontation and addresses the emotional needs of the participants.

Knowledge and Skills Needed for Ethics Consultation

While there is not unanimity about how rigorously schooled in specific academic disciplines or how proficient in specific skills the consultant should be, there is general agreement about the kind of skills, knowledge, and personal qualities ethics consultants require. These include knowledge of ethical language and ethical theory; skills of ethical analysis and reflective moral judgment; knowledge of clinical medicine (e.g., medical terminology, the natural history of disease

and its treatment); knowledge of and familiarity with hospital structure, sociology, and politics; knowledge of and familiarity with the professional ethos of physicians and nurses; knowledge of the law and legal reasoning; knowledge of psychological and social theories of behavior; communication and teaching skills; personal qualities such as the ability to establish rapport, empathy, and compassion; and professional attributes such as dedication, ability to maintain confidentiality, and comfort with cultural and ethical diversity.

Access to Ethics Consultation

Who should be able to request an ethics consultation? The answer to this question has political as well as moral implications. On the one hand, if only physicians have access to ethics consultation, many important ethical issues may never be examined (Tulsky and Lo). On the other hand, permitting patients, families, and other health professionals to request ethics consultation, especially without the physician's concurrence, might discourage more direct communication, disrupt physician-patient relationships, or undermine physician authority. The last possibility would be most threatening to authoritarian-minded physicians and very likely would challenge the traditional power structure of many hospitals. This may explain the gap between the argument in the literature for the ideal—that patients, families, and nurses should be able to request an ethics consultation—and the impression that many institutions do not permit, and almost none actively encourage, patient, family, or other health professional requests for ethics consultation.

The ability to ask for consultation is only one question concerning patient and family access to and control over the consultation process. Other questions include whether the patient or family should have authority to (1) call a consultation when the physician refuses to do so; (2) be informed routinely when consultations are requested by physicians; (3) veto physician-initiated consultation requests; (4) participate in all ethics consultations if they wish; and (5) receive verbal or written information about the consultant's findings and recommendations. Some argue that an insistence on a rights-based approach to these questions would doom ethics consultation services to failure in modern hospitals because of political considerations (Agich and Youngner).

Standards and Evaluation

The fact that standards and methods for evaluating clinical ethics consultation are not established comes as no surprise. The infancy of clinical ethics consultation and the disagreement about its goals, as well as the diverse academic and professional backgrounds of its practitioners, account for this lack. Most studies to date have employed physician satisfaction and usage as outcome measures. By this standard, ethics consultations have been judged to be helpful. Critics have pointed out, however, that by not including patient and surrogate satisfaction and reactions of house staff and nurses, an incomplete and perhaps inaccurate picture of ethics consultation is painted (Tulsky and Lo). For example, "it would be hard to argue that it is desirable for an ethics consultant to reject the choices of a competent and informed patient, even if the attending physician expresses satisfaction with such a consultation" (Tulsky and Lo, p. 591). More objective measures like changes in physician behavior, reduction in use of limited resources (Kanoti et al.), and decreased litigation are attractive, but could confuse matters if these goals were achieved at the expense of more traditional values, such as patient autonomy and well-being.

Credentialing and Accreditation

As ethics consultation becomes more widespread and perceived as part of the standard of medical care, society will hold accountable its practitioners and the institutions that employ them. Individual institutions and national accrediting bodies, such as the Joint Commission for the Accreditation of Health Care Organizations, will undoubtedly become more concerned with setting standards for clinical ethics consultation: consultation through traditional professional methods, such as standardized education and training, accreditation of training programs, and credentialing of ethics consultants. This process will be a major challenge to an interdisciplinary field that has yet to agree on its goals and how to evaluate them.

Fees

By and large, ethics consultants have not charged patients or third-party payers for their services. This may be explained by at least two factors. First, the efficacy of ethics consultations has not been clearly demonstrated; and second, ethics consultations are called as frequently to assist health professionals as they are to help patients. Generally, ethics consultants have been paid by the institutions where they practice, either directly for their consultations or indirectly, as part of their overall responsibility in directing ethics programs or committees.

As our healthcare system becomes increasingly constrained by economic factors, healthcare institutions may find it more difficult to support clinical ethics consultation.

This will put pressure on ethics consultants to charge patients or third-party payers or to demonstrate that their activities save money by decreasing litigation or reducing resource consumption.

Conclusion

Clinical ethics consultation arose in the United States in the latter half of the twentieth century amid the moral and legal uncertainty spawned by the rapid expansion of choices produced by medical advances, the emergence of the tertiary-care medical center, and the individual-rights movement that challenged traditional authority structures. Although it holds great promise, clinical ethics consultation remains a nascent profession. Many of the theoretical and practical questions about its goals, training, evaluation, accountability, and support remain unanswered. Nonetheless, clinical ethics consultation is growing and even flourishing. As the U.S. health system evolves over the coming years, the role and place of clinical ethics consultation in the healthcare system certainly will be addressed.

III. INSTITUTIONAL ETHICS COMMITTEES

Ethics committees have played clinically relevant roles in U.S. healthcare contexts since the 1960s. At that time, some hospitals established committees to approve requests for abortion and sterilization and to allocate scarce dialysis machines. Universities and hospitals created human subjects committees to scrutinize research protocols and consent forms; in the 1970s, these committees became federally mandated institutional review boards (IRBs).

In the 1976 *Quinlan* case, in which parents won the authority to remove a ventilator from an incompetent adult child, the New Jersey Supreme Court recommended that hospitals establish ethics committees to confirm prognoses in cases involving withdrawal of life support. The 1982 "Baby Doe" ruling that allowed parents to withhold a life-saving operation from an infant with Down syndrome led to the establishment of infant-care review committees in cases of withholding or withdrawing life support from disabled newborns. In 1983, a report from the U.S. President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research encouraged the formation of hospital ethics committees to review cases that raised ethical dilemmas and to resolve ethical conflict.

By the mid-1980s, a movement had begun to establish institutional ethics committees in healthcare facilities, especially in hospitals. In 1982, only 1 percent of all U.S. hospitals had ethics committees; by 1987, over 60 percent did (Fleetwood et al.). Ethics committees were endorsed in this period by leading professional groups, including the American Medical Association, the American Hospital Association, the American Academy of Pediatrics, and the American Academy of Neurologists. Growth in the number of institutional ethics committees continued into the 1990s and spread to nursing homes and hospices (Glaser). It is likely that the number and influence of these committees will grow as the length of stay in hospitals continues to decline and more patient days are spent outside hospitals. Moreover, with the shift of many kinds of care to alternative sites, it is likely that other institutional ethics committees will develop and spread—in home-healthcare agencies and managed-care networks, for example. Hospital ethics committees remain, however, the most common institutional ethics committees and the most closely analyzed in bioethics literature.

There is a paucity of empirical studies of hospital ethics committees. Committees have a "grass-roots" character, reflecting a variety of local circumstances and personalities. These factors make it hard to generalize. Nevertheless, some typical features have emerged. One of these features is interdisciplinary composition. Generally, committees are composed of doctors, nurses, social workers, pastoral-care professionals, and philosophers or theologians trained in ethics. Committee members can also include administrators, hospital attorneys, and consumer or community representatives. Committees are sometimes authorized by the medical staff; sometimes by the hospital governing board; sometimes by the administration.

Functions of Ethics Committees

Committee functions vary but generally include one, two, or all three of the following. First, institutional ethics committees create a vehicle for education on ethical dimensions of patient care. Committees typically have dual efforts in this respect: education of the committee itself, through discussion of current bioethics literature, for example; and education of the medical staff and hospital employees, by organizing periodic lectures, panel discussions, and "ethics grand rounds."

Second, committees draft institutional policies on ethical questions. This may arise through committee initiative. For example, a hospital panel discussion may reveal the need for a new policy on withholding resuscitation from dying

patients, and the ethics committee takes the lead by preparing a first draft. New policies or review of existing policies may also be requested from the ethics committee by the hospital administration, or other hospital committees may route drafts of proposed policies and revisions of existing policies to the committee for review and comment.

Third, many institutional ethics committees offer ethics consultations, prospectively or retrospectively, on difficult clinical cases, often those involving the withholding or withdrawal of life-support measures. This last function—ethics consultation, especially for ongoing cases—has been the main focus of discussion in the bioethics literature. Seven issues have dominated these discussions: questions of competence and authority; impact on the doctor-patient relationship; access to consultation; recordkeeping and charting; problems of evaluation; unsettled legal questions; and questions about the purpose or purposes of consultations.

COMPETENCE AND AUTHORITY. Some committees that offer consultation services, generally smaller committees, consult as a committee of the whole. Larger committees typically have a subcommittee that consults prospectively and reports to the committee as a whole for retrospective review of its work. Some committees offer consultation through a single ethics consultant who may be on the committee or have a formal relationship with it. Some critics have expressed concern that when committees consult, difficult ethical choices will be affected by compromise, hospital politics, professional rivalries, and conformism (Wikler). Concerns about competence have been raised when individuals provide consultations. Clinicians typically have few of the skills of trained ethicists and vice versa.

Continued spread of ethics committee consultation to more hospitals and nonhospital settings is indirect evidence that the challenges to competence and authority are being met successfully. Furthermore, most published concerns about the competence of committees or individuals are from the 1970s "first wave" of writing about institutional ethics committees, at a time when the idea of ethics consultation was new and controversial. The literature of the 1980s and 1990s displays a growing confidence about the concept of ethics consultation and more attention to resolving specific problems. Apparently, committees had learned to negotiate without conformism or loss of principle. Individuals have been acquiring the proper expertise: clinicians gaining the analytic techniques of ethicists, and ethicists learning to apply their analyses in clinically relevant ways.

Gender-related questions have not been raised directly in the bioethics literature on ethics committees. However, they are raised indirectly when the focus is on the role of nurses, given the fact that most nurses are women. Nurses have been excluded from some committees, could not access them for consultation, or have found their special ethical concerns omitted from consideration. In addition to the gender issue, this situation raises questions of professional status in relation to other healthcare providers. In some hospitals, these problems have been addressed by the formation of nursing ethics committees (Edwards and Haddad).

There has also been a suggestion in the literature that ethics committees, especially those that are or function as infant-care review committees, should include persons with disabilities on the committee (Mahowald). This step could help ensure that the quality of life of persons with disabilities is not undervalued in deliberations about treatment decisions.

DOCTOR-PATIENT RELATIONSHIP. Trust in the doctor-patient relationship is grounded in the doctor's professional obligation to the patient. Some have expressed concern that ethics consultations will undermine that obligation and trust by limiting doctors' authority to act for their patients or by encouraging abdication of the responsibility (Siegler). These concerns are addressed or attenuated by the fact that use of a committee's consulting service is generally optional and its findings are advisory (Fost and Cranford). It should be admitted, however, that when an ethics consultation is sought and its findings are received, a de facto "burden of proof" may be imposed on those doctors who choose to reject or ignore the ethics committee's advice. They will probably need to muster strong reasons for doing so.

ACCESS TO CONSULTATION. Who should have the authority to request an ethics consultation? Some committees use a medical model whereby only the attending physician can initiate a consultation; he or she alone joins in the deliberations and receives the advice. But many committees allow other physicians, nurses, other professionals, and the patient and family to initiate consultations.

There are two main reasons why ethics committees reject the medical model. First, ethical dilemmas in patient care, especially those surrounding withholding or withdrawing life support, are felt acutely by all professionals involved. Second, if the consulting process helps to delimit or set priorities for a patient's options, the patient's right of informed consent may require that he or she, or a surrogate, be able to participate in the consultation. There is no clear pattern for such participation in the literature. Some consulting teams interview competent patients; others do not. Some encourage the presence of patients or surrogates at consultations; others do not. While most committees that reject the medical model respond to patient requests for consultation, it is not clear generally whether objection by a

patient or surrogate can prevent an ethics consultation or stop one that has been initiated by others.

RECORDKEEPING AND CHARTING. Some committees and consultants keep no records in order to ensure patient confidentiality and to prevent the use of committee deliberations in legal proceedings. Plainly, all institutional ethics committees must carefully adhere to the norms of medical confidentiality, but the prevailing wisdom is that ethics committees should keep good records and should enter their advice and reasons for it into the patient's active chart (Cranford et al.). Such procedures build trust in the committee, educate the medical and nursing staffs on ethical issues, and provide accountability for committee advice in what are often literally life-and-death decisions.

EVALUATION. The brief history of most ethics committees, the confidential status of what they do, and the ambiguity many of them experience about their roles, especially in consultation, have made it difficult to conduct comprehensive evaluation of their effectiveness. Moreover, there is no independent standard of right and wrong against which the advice of these committees can be measured. However, committees can be evaluated by reference to their own mission statements, by written assessments of those who request consultations, and by the informal measures of success as an interdisciplinary forum: enhanced institutional sensitivity to ethical issues and increased requests for consultation (Van Allen et al.).

Some ethics committees use very explicit regulations or ethical guidelines for consulting. These documents could provide norms for more focused evaluation of consultation. Hospitals in the Veterans Administration system, for example, employ detailed national protocols on withholding and withdrawing life support. Catholic hospitals make explicit use of ethical guidelines contained in the Ethical and Religious Directives for Catholic Health Facilities (Craig et al.).

UNSETTLED LEGAL QUESTIONS. A number of legal questions about ethics committees remain unsettled for want of legislation and court decisions. Can an ethics committee and/or its members be sued and held accountable in civil or criminal actions? Are the records of an ethics committee discoverable? If used in court, what weight should they be given (Wolf)? There is also a widely held, but undocumented, view that the availability of an ethics committee can lessen the likelihood of litigation because it provides a forum for resolving conflict and because it allows for thorough examination of ethical issues that frequently have significant legal components.

THE PURPOSE OR PURPOSES OF CONSULTATIONS. Several authors have argued that protection of patients' interests should be the single purpose of an institutional ethics committee's consultation (Hoffmann). But it is also clear that consultations often serve other purposes: to assist caregivers, to support patients' families, to negotiate compromise when disputes arise, to protect the hospital, to offer the correct or best moral advice. Sometimes these other purposes can conflict with the purpose of protecting the patients' best interests. Moreover, in some cases a patient's apparent best interest is incompatible with what the patient demands. Clear strategies for dealing with such conflicts have not yet emerged in the bioethics literature, but they are plainly needed.

Conclusion

Much remains to be done to sharpen the focus of the work of institutional ethics committees and to evaluate the strengths and weaknesses of various committee and consultation models. This area is one of social experimentation and will remain so into the foreseeable future. Nevertheless, in a very short time, ethics committees have contributed greatly to the general bioethics agenda of creating dialogue on ethics issues in healthcare. Most acute-care hospitals in the United States, and many other settings where chronically ill and dying patients receive care, have an established institutional vehicle for explicit, interdisciplinary discussion of difficult ethical issues.

CLONING

I. SCIENTIFIC BACKGROUND

The term *cloning* has many meanings. Scientific meanings are reasonably clear, although they have become more complex since technologies for reproducing mammals by cloning from nuclei of somatic cells were demonstrated by Keith H. Campbell and colleagues (1996) and Ian Wilmut and colleagues (1997), the latter resulting in Dolly, the first sheep cloned from an adult somatic cell. Since then, there has been an explosion of research in this area, and the terminology has sometimes been controversial. This entry will cover scientific aspects of both reproductive and therapeutic cloning.

Definitions

Etymologically, *clone* is derived from the Greek word *klon* (twig). The ancient Greeks already knew that planting a twig from a tree or bush generally resulted in a new organism very similar to the parent tree. Hundreds of species of plants routinely reproduce by cloning, both at the hand of mankind (e.g., potatoes, asparagus) and naturally (e.g., aspen trees). So, what does "reproduction by cloning" mean?

There are two main approaches to biological reproduction: sexual and asexual. In almost all cases, sexual reproduction involves the processes of meiosis and fertilization. Asexual reproduction does not include these processes. For example, seeds are products of meiosis and fertilization by pollen, and planting these embryos results in sexual reproduction. This is fundamentally different from cutting a potato into several pieces and planting them. Thus, cloning can be broadly defined as asexual reproduction.

There is plenty of asexual reproduction in animals, too. If one appropriately bisects a planarian (a flatworm) or various other invertebrates, two normal copies eventually result. The situation becomes less flexible with vertebrates, particularly with mammals. Nevertheless, even in mammals, asexual reproduction occurs when identical twins or triplets (or quadruplets, etc.) are produced. The duplication that occurs when one embryo produces two individuals is asexual reproduction, albeit superimposed on sexual reproduction. The production of identical multiple offspring is the norm in at least two species of armadillos, and probably in several other mammalian species.

Cloning can also be defined as transplantation of a nucleus from a cell (see Figure 1) into an ovum (technically, an oocyte, or egg). To understand this process, a few biological principles will be reviewed. The billions of cells in bodies of animals can be classified into two kinds: somatic cells and germ-line cells. The germ-line cells have an element of immortality; certain early embryonic cells divide to form a lineage of cells that divide to form gametes (sperm or oocytes), which, after fertilization, form embryos of the next generation, and so on *ad infinitum* unless the species becomes extinct. Except for gametes, all cells in the body are diploid, that is they have two similar copies of genetic material, one copy inherited from the sperm, and one copy from the egg. Whenever cells divide, they first duplicate the genetic material so that *each* resulting daughter cell remains diploid. However, the cells that will form sperm divide twice after duplicating their genetic material, resulting in four haploid (one copy of genetic material) sperm, rather than two diploid cells; similar divisions occur to form haploid eggs.

With this background, the basic principle of nuclear transplantation is simple enough. Instead of fertilizing the haploid oocyte with a haploid sperm, one removes the chromosomal genetic information from the oocyte and "fertilizes" it with a diploid cell (see Figure 2).

The first mammals produced via nuclear transplantation were derived from nuclei of cells of early embryos (around the sixteen-cell stage) in the 1980s by Steen M. Willadsen in Cambridge, England. With this approach, one makes a number of genetic copies of an embryo, not an animal. This, of course, changed with Dolly, whose "parent" was a somatic cell derived from differentiated adult mammary tissue. Thus, cloning via nuclear transplantation is fundamentally different when using nuclei from embryonic cells than when using nuclei from adult cells, in that there is considerable uncertainty about the phenotype (visible characteristics) that will result from the embryo, whereas there will be more information about what will result with a nucleus taken from an adult animal, or even a newborn.

Cloning is often defined very broadly as simply making a genetic copy (or copying an organism)—sometimes with the implications of making many copies. Sometimes *clone* is used as a noun to indicate a genetic copy.

How Identical are Clones with Each Other?

Clonal, or asexual, reproduction, in nature results in nearly genetically identical individuals. This includes two categories of genetic identity: between parent and offspring, and among offspring. However, for numerous traits, genetic identity does not result in phenotypic identity, either due to epigenetic effects or to environmental effects. The environmental effects are well known, particularly from human identical-twin studies. Epigenetic effects are defined as effects due to genes that vary from organism to organism due to random chance, and therefore, cannot ever be predicted exactly. Epigenetic effects are less well known than environmental effects, but can be huge for some traits, such as different coat-color patterns among clones or identical twins. There is no genetic instruction specifying the color of each individual hair in animals with hair of different colors, but only genetic instructions for the general pattern of hair color. These instructions provide general guidelines about how melanoblasts, which differentiate into cells termed melanocytes, migrate and invade hair follicles during fetal development, but not an instruction whether or not to invade an individual hair follicle. Melanocytes reside in hair follicles and add packets of melanin to color each hair as it grows. Numerous other epigenetic phenomena occur during embryonic and fetal development such as random X-chromosome inactivation in female mammals, different methylation (addition of a carbon atom plus 3 hydrogen atoms) patterns of cytosines (see below), and lengths of telomeres, which make up the ends of chromosomes.

There also is considerable variability in embryonic development due to chance effects. Richard C. Lewontin has described how these effects interact with genotype, and with epigenetic and environmental effects, in complex ways so as to generate considerable differences among clonal sets.

One other potential source of differences among animals cloned from genetically identical nuclei is cytoplasmic (see Figure 1) inheritance, illustrated most clearly by mitochondria. Mitochondria are small cytoplasmic bodies located in all cells (with hundreds per cell). They have numerous functions, including generation of energy for such life processes as muscular movement. Mitochondria have their own genetic information in the form of small, circular chromosomes. These almost always are inherited exclusively from mother via the oocyte. Different maternal

lines have mitochondria of different genetic makeup, so it is the cytoplasm of the oocyte that determines the makeup of the mitochondrial genome, rather than the chromosomes in the nucleus. Thus, when cloning by nuclear transfer, the mitochondrial genetics will differ from clone to clone unless the oocytes are all derived from the same maternal line of females.

Another source of differences among clones is mutations in the DNA in nuclear chromosomes or mitochondria. DNA is composed of only four kinds of building blocks, known as adenine, thymine, guanine, and cytosine, or A, T, G, and C, respectively. The genetic makeup (DNA) of the nucleus of each mammalian diploid cell has around 12 billion of these building blocks, theoretically hooked together in precisely the same way when DNA is replicated, so that each daughter cell produced has the same genetic makeup, or order of the four building blocks as the "parent" cell that divided. As one might imagine, there is an occasional error when assembling 12 billion items in a specific sequence, and these errors are one source of mutations. Other causes of mutations include background radiation (with which we are constantly bombarded) and chemical reactions, such as peroxidation, which is a chemical process caused by oxygen that can be very detrimental.

The human body is loaded with antioxidants to prevent peroxidation, and its cells contain DNA proofreading and repair enzymes, but these are imperfect at preventing mutations. A common example of mutations is cancer cells, which no longer have true copies of the DNA of normal cells. Most mutations do not cause cancer or have any other noticeable effect, but some cause changes—such as blue rather than brown eyes. Differences among otherwise genetically identical clones due to mutations are usually minor, but nevertheless do occur frequently.

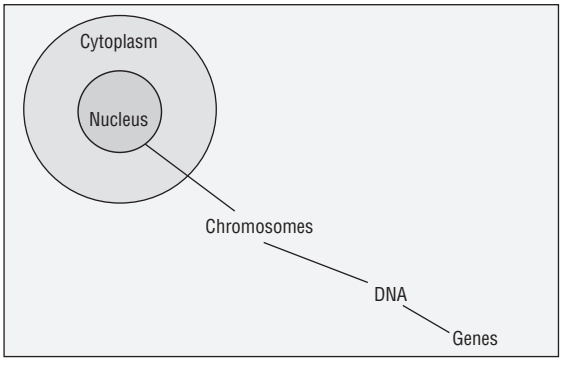
The "gold standard" for genetic identity of mammals is identical twins, triplets, etc. These at least start out with identical chromosomal and mitochondrial genetics and are gestated in the same environment. Even postnatally, identical twins usually grow up in a very similar environment. All man-made clones will be less identical than these, especially in phenotype. Since there are considerable differences between naturally occurring identical twins, such differences will also occur among manufactured clones, in addition to the other differences already discussed.

Procedures for Cloning Mammals

There are numerous procedures for cloning mammals, but two are the most common. The first concerns making identical copies of embryos from embryonic cells, and the second creates embryos (with identical nuclear DNA) from cells of embryos, fetuses, young animals, or adult cells.

FIGURE 1

The Arrangement of Genetic Units within Cells



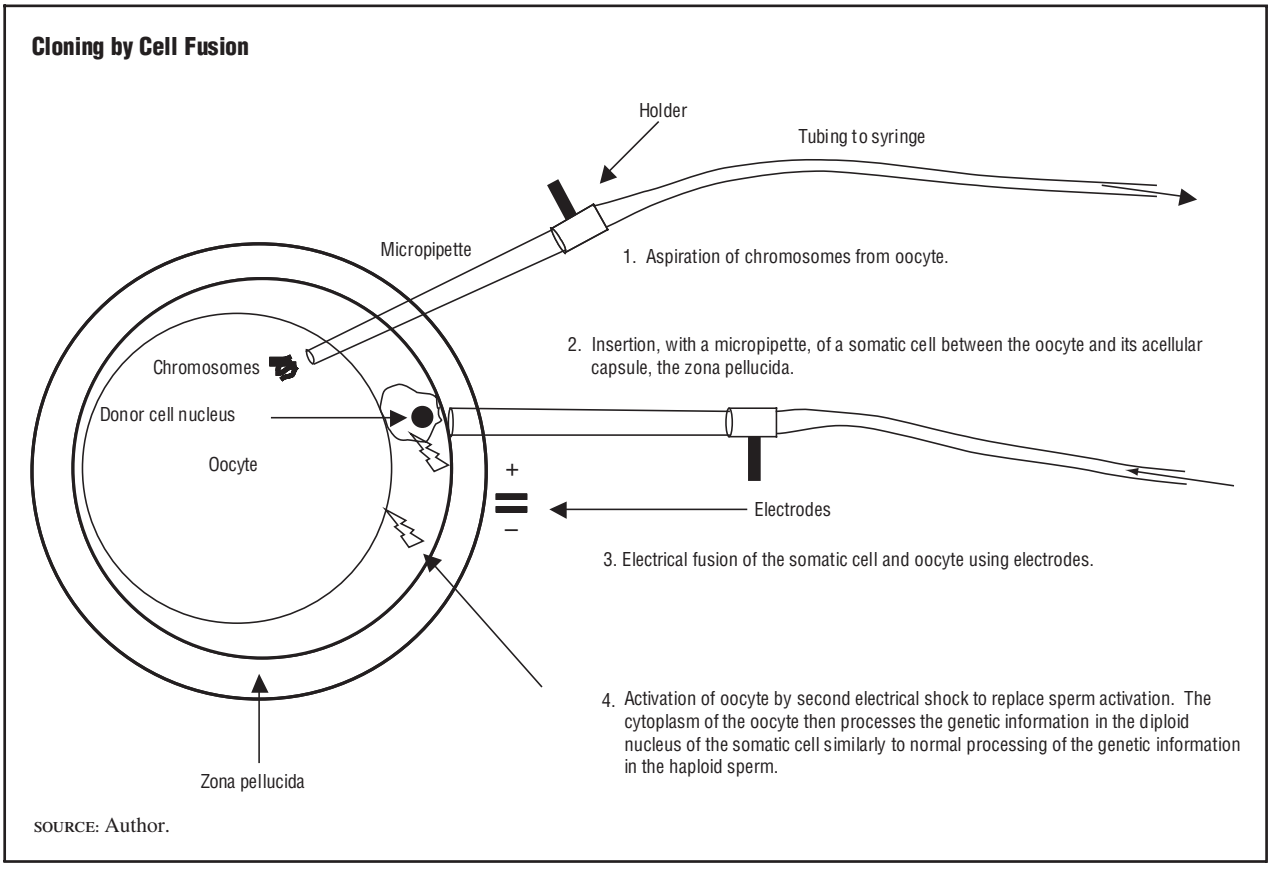
Note: The functional genetic units, genes, are composed of DNA that is arranged linearly on chromosomes located in the nuclei of cells.

SOURCE: Author.

Conceptually, the simplest approach would be to separate the two cells of a two-cell embryo so that two identical organisms form. This has been done repeatedly in one way or another, even occasionally resulting in identical quadruplets when dividing a four-cell embryo four ways. Success rates are quite high when aiming at identical twins, but become very low when dividing embryos into quadruplets, the practical limit of the technique. For technical reasons, this approach is much more practical at later stages of embryonic development—at the 100-cell stage, for example), when embryos can be bisected. This latter approach has been used to produce thousands of identical twins (and occasionally triplets) commercially, primarily with cattle (as illustrated by Timothy Williams and colleagues [1984]).

Surprisingly, the main reason for splitting embryos to produce demi-embryos is not to produce sets of identical copies, but rather because splitting embryos augments the general technology of embryo transfer, which is designed to increase the reproductive rates of agricultural (and other) females, much like artificial insemination increases the reproduction of males. To illustrate, pregnancy rates for whole bovine embryos are around 65 percent, whereas pregnancy rates for half embryos are around 50 percent. Thus, because there are twice as many demi-embryos after the splitting process, the net pregnancy rate is frequently over 100 percent. Identical twins and triplets produced by these methods make excellent experimental subjects because genetic variation can be controlled, and sometimes they are produced mainly for these purposes.

FIGURE 2



SOURCE: Author.

With nuclear transfer, the main principle is that the ovum, or oocyte is a minifactory designed to produce an embryo, which eventually develops into a term pregnancy. Half of the genetic instructions to make the conceptus normally come from the oocyte, and half from the sperm. With cloning, a complete set of genetic instructions is provided by the nucleus of one embryonic or somatic cell. Of course, those instructions originally were derived from the sperm and oocyte that resulted in the organism that provided the donor cell.

One problem is obtaining oocytes to use as recipients for the diploid nuclei. These cells, the largest in the body (about 1/200 inch in diameter), must be of the same species as the donor nucleus. Usually, they are aspirated from ovarian follicles (large blister-like, fluid-filled structures). In the case of farm animals, oocytes are often obtained from ovaries of slaughtered animals of unknown background. An alternative is to aspirate (remove by suction) oocytes through a large needle inserted into the ovaries in the body cavity of living animals—ultrasound is usually used to visualize the follicles so the needle can be guided into them after piercing the wall of the vagina. This method is used in women to obtain oocytes for routine in vitro fertilization. Oocytes from laboratory animals such as mice are usually obtained after the oocytes are ovulated (released from the follicles) naturally. The oocytes then are located in the part of the reproductive system called the oviduct, and the body cavity needs to be opened to get them out, either via surgery with anesthesia, or after euthanizing the animal.

After oocytes are obtained, they are cultured under specific conditions with specific chemicals until they have matured appropriately. The length of the maturation period may range from less than an hour to two days, depending on the species, the treatments, and the reproductive status of the animal providing the oocytes.

The next step is to remove or destroy the unwanted chromosomes of the oocyte. This usually is done by aspiration of this material with a micropipette (see Figure 2), although there are other options, such as destroying the chromosomes with a laser. Following this step comes transplantation of the nucleus. This can be done by removing the nucleus from the donor cell and injecting it into the cytoplasm of the oocyte. However, in the vast majority of cases the entire donor cell is simply fused with the oocyte using an electric pulse. This incorporates the nucleus into

the oocyte, but it also mixes the cytoplasm of the two cells, which also mixes the mitochondria. This is usually not a problem because the oocyte has more than 100 times the volume of the cytoplasm of the donor cell, so the donor cytoplasm essentially gets diluted out.

When a sperm fertilizes an oocyte, it not only adds its 50 percent contribution of genetic material, it also activates, or turns on, the oocyte. Prior to fertilization the oocyte is a large, slowly dying cell. The sperm adds a specific enzyme that chemically activates the ovum, so it comes to life, starts using more energy, and, among other things, duplicates the genetic material in preparation for division to the two-cell stage. This activation function must be duplicated during the nuclear transplantation process for successful embryonic development. It is accomplished in a variety of ways, depending on the species and other details, such as the degree of maturity of the oocyte. A common approach is to apply a strong electrical shock.

The final step is to allow the cloned embryo to develop *in vitro,* eventually growing from the two-cell stage to a suitable stage for transferring the embryo back to the reproductive tract of a recipient. The length of this culture is usually a few days to a week, depending on the species.

Potential Applications of Cloning Nonhuman Animals

Aside from splitting embryos to produce more offspring, the main application of cloning to date has been to obtain basic biological information that can be applied in other areas. This will continue to be the main value of cloning for some time, and will result in information about causes of birth defects, aging, cancer, and other disease states.

One obvious application of cloning by nuclear transplantation and cell fusion is to make genetic copies of outstanding agricultural animals. As discussed earlier, a genetic copy does not equal a phenotypic copy, so this is not nearly as attractive as most people surmise. For example, the genetic contribution (heritability) to differences between cattle (within breeds) in milk production is on the order of 30 percent, while other factors, mainly environment and random chance, explain the other 70 percent. Thus, if one cloned a cow producing 3,000 gallons of milk annually, selected from a herd averaging 2,000 gallons of milk, on the average only 30 percent of the difference between the production of the individual cow and the herd would show up in the clone. A herd of such clones might average 2,300 gallons of milk, a substantial improvement over the 2,000 gallons average, but not even close to the 3,000 gallons produced by the animal being cloned. (This example is an oversimplification, for a variety of reasons—including interactions between genotype and environment [see Lewontin]—but the broad idea is correct.)

There is an even more serious problem with using cloning to increase production of milk (or meat, fiber, etc.), which is that it is not economically viable. The value of the extra milk produced by such a cow would be less than $1,000 during her lifetime, and she might eat more feed than other cows because more nutrients are required to make more milk, further decreasing her economic value. Costs of cloning in 2003 are in excess of $10,000 per cow, and while this likely will decrease markedly, it is unlikely that costs will approach economic viability in the foreseeable future. Thus, herds of cloned cows are not likely any time soon. The situation for meat production is even less favorable economically. If one did use this strategy, there would be hundreds of different donor cows cloned due to wanting different optimal genotypes for different environments (e.g. the optimal Vermont cow would be different from the optimal cow for Georgia) not to mention the individual preferences of farmers).

One agricultural application that does make sense is to make copies of genetically (as opposed to phenotypically) outstanding individuals. A good example is a bull whose daughters, on the average, have excellent milk production and are not prone to mammary gland infections. Such a bull might have thousands of daughters demonstrated to be superior to the average population. This bull obviously is essentially worthless phenotypically—copies will not produce any milk—but cloned copies of the bull will produce essentially identical sperm that can be used to produce more daughters by artificial insemination. For this example, one or two clones would likely produce all the semen that could be sold, so large numbers of copies are not needed. In fact, the main application in this context is insurance. Such bulls are extremely valuable, and having one or two copies makes good economic sense. More copies, however, are redundant and expensive to feed and maintain.

Another popular potential application of somatic-cell cloning concerns companion animals, particularly dogs and horses. Again, one will not get a phenotypic copy, so this only makes marginal sense. The resulting cloned animal will often have somewhat similar coat-color patterns and be roughly the same size, but it may have a very different personality, since this is largely influenced by environment. One does not recreate the same animal by cloning, simply a chromosomal genetic copy.

There are myriad experimental uses of cloning, particularly in making transgenic technology more useful. Cloning

by nuclear transplantation is thus a powerful experimental tool.

Potential Applications of Human Cloning

In most cultures there would be huge ethical problems in making genetic copies of human beings—so-called reproductive cloning. Currently, this is ethically unacceptable because of the high incidence of congenital abnormalities in offspring derived from cloning by nuclear transfer. If there were no such problems—if cloned children would be as healthy as those produced naturally—one can concoct scenarios for which reproductive cloning might be ethically acceptable. The classic example is a couple whose baby dies within a day or two of birth due to an accident that also makes the mother incapable of reproducing due to damage to ovaries. One could theoretically take cells from the dead baby and clone them using a donated oocyte, which could then be transferred to the uterus (which is still functional) of the woman. The donor cells from the dead baby could also be frozen for later use, so timing would not be a problem.

Other (very improbable) scenarios could be envisioned that would make reproductive cloning ethically acceptable for most people. In any case, this technology for reproductive cloning of persons would likely work with a similar success rate as occurs in other species (extremely low, as of 2003). It is certainly possible that a century or more in the future this mode of reproduction will be used to some extent, and persons from that era may well consider our current collective thinking quaint. Since chromosomal genetic identity never results in phenotypic identity, one never recreates a person or animal, and even if phenotypic identity were possible, such individuals would still be individuals. Identical twins and triplets provide some guidance on potential problems. Such individuals usually lead fairly normal lives, and they are considerably more identical than manufactured clones will ever be.

Therapeutic Cloning

A second kind of cloning, therapeutic cloning, is intended to produce tissue and organ replacement parts. There are millions of people worldwide who suffer from debilitating diseases such as diabetes, heart disease, and cirrhosis of the liver. Similarly, millions suffer from accidents that severely damage tissues and organs, including burns, spinal cord damage, and crushed kidneys. In many of these cases, tissue or organ transplants will prolong life and greatly increase quality of life. There are two major problems with this approach: (1) There is a critical shortage of such tissues and organs, and (2) there is usually immunological incompatibility of donor and recipient, which requires immunosuppressive therapy that is debilitating and greatly increases the incidence of cancer.

A solution to this unfortunate situation is to use nuclei of somatic cells of the subject to make immunologically compatible tissues for replacement parts. This approach is not yet available for practical use, but likely will be developed in one form or another in the near future. What is envisioned is to take cells (e.g., from skin) of the person who needs the replacement tissue, and fuse them with donated oocytes from which original chromosomes are removed to form early embryos. Instead of transferring these to the uterus to form a fetus, they would be induced to develop into various tissues *in vitro*. No fetus would be formed, so there would be no brain, heart, leg, or face, but rather tissues that make up body parts. Quite a bit is known about how to induce the embryonic cells to make muscle, skin, or other tissues, but there is still much to be learned.

This approach likely cannot be used to produce a heart or a kidney, at least in the foreseeable future, but producing heart-muscle cells, nerve cells, pancreatic tissue, liver tissue, or skin does seem feasible. Liver, for example, has a remarkable regenerative capability, so only a small bit of liver may be needed—such as liver stem cells, which might regenerate a whole organ after transplantation. Producing pancreatic tissue to alleviate diabetes would likely be considerably simpler, while producing nerve cells to repair spinal cord damage would likely be more difficult.

It is possible that some tissues can be generated from adult stem cells, circumventing the need for cloning via embryos. However, the embryonic approach has several theoretical advantages—it is the way tissues develop naturally, for example—and it has some practical advantages as well. Furthermore, research into *in vitro* differentiation of tissue, much of which can be done in animal models with or without the cloning steps, will likely produce information that can eventually be used outside of the context of cloning to accomplish the numerous therapeutic objectives.

Characteristics of Cloned Animals and Related Ethical Consequences

If all goes well, a genetic copy of the animal being cloned is produced, but, again, one clone can vary considerably in phenotype from the donor for numerous traits. Unfortunately, natural reproduction does not go well in every case, and such problems are greatly exacerbated with cloning. In a 2002 summary of all available information on animals cloned from somatic cells (38 studies resulting in 335

subjects in 5 species), Jose B. Cibelli and colleagues found that 77 percent of the resulting animals were normal, while 23 percent were not. The normal subjects, though mostly adults, had not yet lived out their normal life spans, so additional problems (over and above those due to normal aging) could yet develop. Cloning from somatic cells has not resulted in monsters, but, in most cases, reasonably normal individuals.

However, 23 percent abnormalities, mostly neonatal death, is completely unacceptable ethically for producing children, and for most scientists working in this area that ends the ethical debate on human reproductive cloning. In the Cibelli survey it was noted that many of the animals produced represented the initial, or at least early, studies on cloning in respective laboratories, and that the incidence of abnormalities likely would decrease with more experience and improved techniques. This is already being borne out in the scientific literature, but it likely will be many years before the incidence of problems with somatic-cell cloning will decrease to acceptable levels for reproductive cloning of people. However, this ethical crutch will also likely disappear with time.

A complex ethical question is where to set the boundaries on acceptable levels of abnormalities. Interestingly, a 2002 study by Michèle Hansen and colleagues that looked at children produced via *in vitro* fertilization showed that congenital abnormalities were approximately double the 4 percent seen with natural reproduction. Most of these abnormalities were not extremely serious and could be circumvented or repaired. Nevertheless, the abnormalities were doubled, and some were serious. Thus, this ethical problem is already with us.

The question boils down to the right of people to reproduce given an increased risk of an abnormal child. Of course, these questions arise outside of the context of assisted reproductive technology, such as the increased risk of a child with Down's syndrome when older women reproduce. Modern science can minimize such suffering (e.g., by genotyping embryos before transfer back to the uterus, and eliminating those that will result in severely abnormal individuals). Another reality is that, in one sense or another, nearly all persons are abnormal. For example, essentially all humans have lethal or severely debilitating recessive alleles in their genetic makeup, which, if matched with another such allele in a gamete of a mate, will result in death of the conceptus or resulting child.

A frequent abnormality that occurs with cloning by nuclear transfer via embryonic or somatic donor cells is fetal overgrowth. It is not unusual for offspring to be 30 or 40 percent larger than normal at birth. In some studies, up to 30 percent of offspring have this condition, known as *large-offspring syndrome,* and some animals cloned from the same donor are large, some are normal, and some are small—which elegantly illustrates that identical chromosomal identity does not equal identical phenotype. Large-offspring syndrome is not a genetic trait, in that this problem is not transmitted to the next generation when the cloned animals reproduce naturally. Also, Michael Wilson and colleagues showed in 1995 that these excessively large neonates develop into only slightly larger adults. The scientific consensus is that large-offpsring syndrome can be summarized as a genetically normal fetus in an epigenetically abnormal placenta. That is, the placenta from cloned pregnancies is often abnormal, resulting in secondary problems in the fetus that largely correct themselves after birth. Unfortunately, with routine husbandry, the newborns often die because of being debilitated from gestating in an abnormal placenta. Fortunately, with a few days of intensive care starting at birth, such offspring survive reasonably well and develop normally, as shown by Frank B. Garry and colleagues in 1995.

As with human babies, animal offspring derived from *in vitro* fertilization or long-term *in vitro* culture of embryos have a much higher incidence of abnormalities than with normal reproduction, but a lower incidence than with cloning (see Kelley Tamashiro and colleagues). Clearly, some (but not all) *in vitro* manipulations, particularly when the *in vitro* period exceeds several days, lead to increased problems in resulting offspring. Thus, there is a baseline of problems with natural reproduction, which increases with the amount of *in vitro* manipulation (and reaches a higher level with somatic-cell cloning). It is likely that these problems will decrease or be circumvented with improved techniques, and also that the basic information obtained will be useful in decreasing birth defects and neonatal problems that occur with natural reproduction.

There are some special problems with a small percentage of pregnancies from somatic-cell cloning that are not just an increase in incidence of naturally occurring problems. In some cases, the immune system appears to be severely compromised, and there can be major problems with the heart, blood vessels, and kidneys that are extremely rare with normal reproduction. Furthermore, there is an unusual amount of embryonic death and fetal absorption or abortion with cloned pregnancies—over 80 percent embryonic and fetal attrition is not unusual (compared with around 30 percent with normal reproduction). Thus, the incidence of problem conceptuses is very high, and most of these die in early pregnancy. This is still another reason that, as practiced at the beginning of the twenty-first century, reproductive cloning should not be done with human embryos.

A final point is that cloning via nuclei from somatic cells is very inefficient, currently on the order of 2 percent success per oocyte. This is due to the multiplicative attrition (or success) of the various steps. For example, if there is 90 percent successful fusion of donor cell and oocyte, with 50 percent dividing into embryos suitable for transfer to recipients, 30 percent embryonic survival until pregnancy can be diagnosed, 20 percent of diagnosed pregnancies developing to term, and 85 percent surviving the neonatal period, the result is an overall success rate of around 2 percent. These are typical current values, and are one reason why the costs of cloning are so high. While success rates are improving, it will likely be some years until overall success even approaches 10 percent. For human reproductive cloning, dozens of women would need to be involved as donors of oocytes and recipients of embryos to produce even one baby—assuming the procedures worked as well as they do with animal models, which is unlikely. This illustrates another ethical issue, in that undue use of scarce and expensive medical resources would be required for clonal human reproduction.

Conclusion

The most important conclusions from this scientific overview are that, although cloning procedures for mammals are yielding huge amounts of important scientific information, current procedures are extremely inefficient and result in a high incidence of abnormalities in offspring. These problems severely limit immediate prospects for applications of cloning mammals due to both financial and ethical considerations. Furthermore, cloning does not and will not lead to reincarnation of an animal or person, but rather to a new individual with considerable phenotypic differences from the genetic donor.

II. REPRODUCTIVE

Reproductive cloning uses the technique of cloning to produce a child. Using technology to assist in "making babies" is nothing new. Artificial insemination has been available since the first part of the twentieth century. The first of many "test-tube babies" produced by *in vitro* fertilization (IVF) was born in England in 1978. Newer technologies include the injection of sperm directly into the egg and the use of frozen and donated eggs and embryos. In 1985 there were thirty fertility clinics in the United States alone, but by 2000 this number had grown to more than 350. More then 1 million couples in the United States seek fertility treatment each year, some of which includes the use of assisted reproductive technologies.

Only recently has producing a child through the technique of cloning become a real possibility. Since the birth of Dolly the sheep at the Roslin Institute near Edinburgh, Scotland in March, 1996, people have wondered whether it would also be possible to produce humans by this method. Dolly was a clone, a genetic copy, of a six-year-old ewe. Rather than coming into being by the joining of sperm and egg, Dolly was created by inserting the nucleus of a cell from the udder of this ewe into a sheep egg from which the

nucleus had been removed. After being stimulated to grow, the egg was implanted into the uterus of another sheep from which Dolly was born. Because Dolly was a mammal like humans, people concluded that it might be possible to clone human beings as well. Moreover, Dolly was produced from a body or somatic cell of an adult sheep with already determined characteristics. Because the cells of an adult are already differentiated, have taken on specialized roles, scientists had previously assumed that cloning from such cells would not be possible. After Dolly, it seemed, it might be possible to produce an identical, though younger, twin of an already existing human being.

Reactions to this possibility varied widely. Some hailed it as another marvel of science that could benefit many. Others were horrified at the prospect that this seeming science fiction might become reality. Some thought of it as just another form of assisted reproductive technology, while others viewed it as something radically different. This overview of cloning for the purpose of reproduction will address the following questions:

What is reproductive cloning?
What are the present capabilities in the area of cloning?
What are the proposed uses of this type of cloning?
What are the ethical considerations and objections to it?
What are the public policy implications?

Cloning: Its Nature and Capabilities

The type of cloning described above is called somatic cell nuclear transfer (SCNT) because it transfers the nucleus of a somatic or body cell into an egg from which the nucleus has been removed. A different type of cloning is achieved through fission or cutting of an early embryo. Through this method it may be possible to make identical human twins or triplets from one embryo. These genetically identical embryos could then be stored for further tries at conception, thus saving a woman from undergoing repeated ovulation during fertility treatment. Here, however, the concentration will be on cloning through SCNT. Also, this entry treats only cloning for reproductive purposes, not what has come to be called research or therapeutic cloning. In the latter, the same process occurs but is not intended to lead to the birth of a child. Rather it is oriented, for example, to the study of the process of development or to the producing of stem cells that might be useful in therapies for Parkinson's, diabetes, and other diseases.

How close are we to being able to produce a human being through cloning? As of the beginning of 2003, to researchers' knowledge there have been no human beings produced through cloning. Clonaid, a company founded by a religious sect called the Raelians, has claimed to have produced five cloned babies. However, no DNA or other evidence has so far been provided to substantiate this. In November 2001, Advanced Cell Technology, a small biotech company in Worcester, Massachusetts, said it had succeeded in producing a human embryo through cloning. Scientists extracted human eggs from seven volunteer women and replaced the nuclei of these eggs with cells from an adult donor, some skin cells and some cumulus cells (the cells surrounding a maturing egg). While none of the eggs that used the skin began the cell division process, three of the eight eggs that were re-nucleated with cumulus cells began dividing. One developed to the two-cell stage, one to the four-cell stage, and the third to the six-cell stage, at which point it too died.

One can also judge something of the potential for human cloning from the progress of animal cloning. In just the past two decades a number of higher animals have been produced through cloning, including cows, sheep, goats, mice, pigs, rabbits, and a cat called CC for carbon copy or copy cat. Cloned animals themselves have produced offspring of their own in the natural way. Dolly had six seemingly normal lambs. Several generations of mice have also been produced through SCNT. Clones have been derived not only from udder cells, but also from cells from embryos and fetuses, and from mice tails and cumulus cells.

However, these experiments have been neither efficient nor safe. In the case of Dolly, 277 eggs were used to produce only one lamb. In March 1996, the Roslin Institute also produced two lambs from mature embryo cells, Megan and Morag. However, they were only two out of five who were born and survived in a project that used over 200 embryos. Alan Coleman, research director of PPL Therapeutics, the company that produced Dolly, reported having cloned five female pigs who were genetically modified to lack a gene that makes pig organs incompatible with the human immune system. However, here the success rate was again quite low. Scientists implanted 300 embryos, producing twenty-eight sows that gave birth to seven live piglets, only four of which survived. In another project involving rabbits, 371 eggs were implanted, using twenty-seven rabbits as foster mothers, but only six rabbits were born and only five of these survived to the state of weaning. CC, the cat mentioned above, was one of eighty-seven embryos implanted in eight surrogate mother cats, and was the only one of two resulting pregnancies that survived.

Cloned animals also have shown various abnormalities. In one study all twelve cloned mice died between one and two years of age. Six of the cloned mice had pneumonia, four

had serious liver damage, and one had leukemia and lung cancer. On February 14, 2003, Dolly died. She was euthanized because she suffered from a lung disease that the owners feared would spread. At age five, Dolly had also been diagnosed with arthritis. Some suggest that this may be due to the fact that she was cloned from the cell of an already aged adult sheep. However, in late 2001 Advanced Cell Technology claimed to have cloned thirty cattle from skin cells, twenty-four of which were alive and healthy between one and four years later. Some say that the high failure rate and the prevalence of serious abnormalities in animals means that cloning humans is probably not possible. Others believe that with time the efficiency and safety of animal cloning will improve and then it may be possible to clone human beings as well.

Uses of Reproductive Cloning

What uses might there be, or what reasons might someone have, for producing a human being through cloning? What follows is a survey of a number of possible uses of this procedure, some of which are obviously more problematic than others. The ethical issues that have been or might be raised regarding the possible uses of reproductive cloning will then be discussed.

One of the probable primary uses, if cloning does become a reality, is for the treatment of fertility problems. For example, if the male or husband is sterile, or does not produce sperm, DNA from one of his cells could be inserted into a de-nucleated egg from the female or wife who would also bear the child. Both would then be contributing to the make up and birth of the child. Many have pointed out that there is a strong desire among people who want a child to have one that is biologically related to them. These parents also may wish to avoid the confusion that can result from the use of donor eggs or sperm. If the woman is infertile, another woman's egg could be used along with the DNA of the infertile woman or her husband or partner. Cloning might also be used to avoid genetic diseases.

Another possible use would be in the fertilization of a woman who wants to have children to whom she is related biologically, but who does not have a partner and does not wish to use donor sperm. The woman might be one who is single and who has not found a suitable partner, or who is divorced and still wants to have children. A cell from her body could be used. In this case the child would be a clone of the woman herself. Or in the case of a lesbian couple, a cell from the body of the other partner could be used. In this case both would have contributed to the make up of the child.

Someone might want to produce a child who is a clone of a much-loved spouse or child who has died. As noted below, while this would not bring back the loved one or duplicate them exactly, there would be some similarities and thus in a way the ability to keep some part of the person alive. One might even want to achieve a certain kind of immortality by cloning oneself. This would be similar in some way to living on through our children and their children.

Cloning could also be used to help ill family members. There have been cases in which parents have conceived a child in the hope that he or she could be a donor match for a sibling who had some serious disorder. A child who was the clone of such a sibling could also be a blood or bone marrow donor for the sibling. Although no one is suggesting that clones would be produced simply as the source of organs, some organ donation might not be objectionable.

Finally, cloned human beings could provide us with further information about the relationship between nature and nurture. A disabled person might want to show or see what he would have been like but for the disability, or someone might simply be curious to see how a clone of himself might grow to adulthood.

Ethical Objections and Arguments

Ethics judges or evaluates human choices and actions or policies as being, for example, good or bad, right or wrong, and just or unjust. Ethical or moral judgments (the terms being used synonymously here) require reasons that justify them. Many people have raised various ethical objections regarding human cloning. The arguments and the reasons given for them are summarized here as well as the responses of critics of the arguments. However, since what is presented is only a summary, it is not possible to give a full analysis of the kind of reasons that they exemplify and why these might or might not be well-grounded in generally-accepted values or in ethical theory.

It should also be noted at the outset that ethical evaluation is independent of social policy and law. Not everything that is morally bad or wrong ought to be illegal. It takes a separate set of reasons to conclude that because some instances of human cloning might be morally wrong that they should then also be illegal. Nevertheless many of our policies and laws do have ethical bases. First the ethical arguments will be treated and then finally some social policy issues related to them. Some suggestions regarding the relationship between these two domains will also be provided.

Playing God

One of the objections to human cloning most often raised is that it would be *Playing God.* While it is not always clear just what is meant by this, at least three or four overlapping

versions of this objection can be delineated. One is that only God can and should create a human life. This role is specifically reserved to God, such that when humans who try to do it take on a role that is improper for them to play.

Those who hold this view might use religious reasons and sources to support it. However, while this looks like a religious position, it is not necessarily so. For example, it might mean that the coming into being of a new person is a creation, not a making or production. A creation is the bringing into being of something the outcome of which is not known in advance. The coming into being of a human being or person is also a said to be a mysterious thing and something in the face of which humankind should be in awe. When producing a human being, as in cloning, people become instead makers or manipulators of a product that they control and over which they have power. Rather, this argument continues, those who bring a child into the world should do so with an attitude of respect for something wondrous, the coming into existence of a totally unique and new being.

A third version of this objection stresses the significance of nature and the natural. In producing a human being through cloning, scientists act against human nature. In humans, as in all higher animals, reproduction is sexual, not asexual. Cloning, however, is asexual reproduction. Leon Kass is one of the strongest proponents of this view. He alleges that in cloning a human being people wrongly seek to escape the bounds and dictates of their own sexual nature.

A fourth and related version of the "don't play God" argument holds that attempting to clone a human being would demonstrate hubris, thinking we are wise enough to know the effects of one's acts when in fact that is not the case. It is similar to the warning that it is dangerous to "mess with mother nature." When dealing with human beings one should be particularly careful. Above all each person should avoid doing what unknowingly may turn out to be seriously harmful to the individuals produced and to future generations.

Just as there are various possible interpretations of this objection, there are various responses to, or criticisms of, it. On the point that by interfering in nature people take on a role that belongs only to God, the response is to ask how this is any different from other ways that man interferes with or changes nature. One example is medicine. Here science fights off natural threats, disease, and disability, for example, with inoculations, insulin, blood transfusions and prostheses. Others argue that God gave us brains to use and God is honored by that use, especially if it is for the benefit of humans and society. Human intelligence, the argument continues, is in fact a part of nature, so that in using it people do not actually oppose nature but follow it. Critics also point out that in using technology to assist reproduction, one does not necessarily lose a sense of awe in the face of the coming into being, though with human help, of a unique new being. Objectors may point out, however, that cloning does not create a unique new being, but a copy of one that already exists or has existed. This objection thus overlaps with a second major objection, namely, that cloning is a threat to individuality.

Threats to Individuality

Some people object to the very idea of cloning a human being because they believe that the person cloned would not be a unique individual. He or she would be the genetic copy of the person from whom the somatic cell was transferred. He or she would be the equivalent of an identical twin of this person, though years younger. Moreover, since dignity and worth is attached to a person's uniqueness as an individual, cloned individuals would lose something that is the basis of the special value each person should have. Some go so far as to claim that each person has in fact a right to a unique identity. Others point out the difficulties that clones would have in maintaining their individuality. People often have difficulty distinguishing identical twins from one another. Sometimes they dress alike and often they are expected to act alike. The implication is that they do not have the freedom or ability to develop their own individual personalities.

This objection is sometimes expressed as the view that a cloned human being would not have a soul, that he or she would be a hollow shell of a person. This version of the objection is probably based on a religious belief that only God should be allowed to create a human being and in doing so directly acts to place a soul in that person. Thus if through cloning man produces a human being, God is prevented from placing a soul in that person.

Again, criticisms of these objections vary with the interpretation. One response is to review the facts about identical twins. Identical twins are more like each other than a clone would be to the person who was cloned. This is because identical twins shared the same nuclear environment as well as the same uterus. This would not be the case with clones. They would have had different mitochondria. This is important because the mitochondrial genes in the cytoplasm surrounding the re-nucleated cell do play a role in development. Clones would have developed in different uteruses and they would be raised in different circumstances and environments. Studies of plants and animals give dramatic evidence of how great a difference the environment makes. For example, plants and some animals vary significantly in structure and characteristics depending on the altitude of the land in which they develop. The genotype

does not fully determine the phenotype. CC, the cloned cat mentioned above, does not quite look like its mother, Rainbow, a calico tri-colored female. They have different coat patterns because genes are not the only factor that controls coat color. At one year CC also has a different personality from her mother, being much more playful and curious. Even in the science fiction stories of creation of groups of clones, for instance of Hitler in the movie, *The Boys from Brazil,* the creators try to duplicate the environment. While genes do matter, and thus there would be similarities between the clone and the person who was cloned, the two would not be identical. Furthermore, these critics note, even normally-produced children may look like one or both of their parents and this fact does not prevent them from being individuals.

On the matter of soul, critics wonder why could God not give each person, identical twin or clone, an individual soul. Consider when the soul is supposed to be implanted in an individual. Some medieval writers, for example, held that the soul appeared or was implanted in the fetus when it had developed sufficiently so that it was fit for a human soul. Previous to that point, some held, the developing fetus had a vegetable and then an animal soul. Aristotle held that the soul or psyche was simply the form of the being, that which gave it unity as a particular living being, whether it be a plant or animal or person. Like any living human being, a cloned human being would on this view be a distinct being and so would have a human psyche or soul.

A Right to an Open Future

Some have argued that cloning a human being is objectionable because the clone is expected to be like the person from whom he or she was cloned and thus would not be free to develop independently. Joel Feinberg has written about what he calls the "right to an open future" and Hans Jonas "the right to ignorance." The idea is that each person should be free to construct his or her own life and develop a unique self. However, a clone would be expected to use the person from whom he or she was cloned as a model. His or her future would already be given and known. Even if such expectations for the clone were not generally accepted, people would be hard pressed not to at least entertain such ideas. The argument also points out that an essential feature of having a child should include accepting whatever the child turns out to be. This would mean accepting the child as a unique being. Children are not objects to be controlled, nor to mold in a particular image. They have their own lives to lead. Parents may try to influence them and teach them while realizing that the children may decide to do or be different, which is their right as individual persons.

Critics of this argument may admit that there might be some inclination to have certain expectations for the clone. However, they argue, this undue influence is a possibility in the case of all parents and children, and not limited to clones. Parents decide on what schools to send their children and what sports or activities they will promote. The temptation or inclination may exist to unduly influence their children, but it is incumbent on parents to control the extent of that influence. The goal is to provide children with opportunities of various sorts from which the children themselves eventually choose. It is not cloning, these critics contend, that would cause a threat to an open future for a child, but the attitudes and character of parents and others.

Exploitation

Related to the previous objection is one that holds that cloned children or persons would tend to be exploited. If one looks at many of the reasons given for cloning a person, the objection goes, they tend to be cases in which the cloning is for the sake of others. For example, the cloned child could be a donor for someone else. We might make clones that are of a certain sort that could be used for doing menial work or fighting wars. We might want to clone certain valued individuals, stars of the screen or athletic arena. In all these cases the clone would not be valued for his or her own self nor respected as a unique person. He or she would be valued for what they can bring to others. German philosopher Immanuel Kant (1724–1804) is cited as the source of the moral principle that persons ought not simply be used but ought to be treated as ends in themselves.

Critics could agree with Kant, but still disagree that a cloned human being would be any more likely than anyone else to be used by others for their own purposes only. Just because a child was conceived to provide bone marrow for a sick sibling would not prevent her from also being loved for her own sake. Even a case in which a man would clone himself in order to see how such a being might grow could turn out to be a situation in which the clone would be much loved and respected for himself and his own unique characteristics. Furthermore, the idea that we would allow anyone to clone a whole group of individuals and imprison them while training them to be workers or soldiers is not living in the present world in which there are legal protections against such treatment of children or other individuals. So also, critics may contend, the possibility that some group might take over society and create a 'Brave New World' in which children were produced only through cloning is far-fetched and no more than fiction. So also is a world in which there would be widespread cloning of stars and pop idols. While eugenics as a social policy has not been unknown in modern

history, it is highly unlikely in open societies. Moreover, cloning is not the only way that eugenics could be practiced, as is demonstrated by the existence of (little-used) sperm banks of Nobel prize winners.

Effect on Families

Some people believe that if human cloning were a reality, it would only add to the confusion already generated by the use of some other reproductive technologies. When donated eggs and surrogate mothers are used, the genetic parents are different from the gestational parents and the rearing parents, and conflicts have arisen regarding who the *real* parents are. Cloning, objectors contend, would be even more of a problem. It would add to this confusion the blurring of lines between generations. The mother's child could be her twin, or a twin of her own mother or father.

According to Leon Kass in "The Wisdom of Repugnance," this would lead to a confusion of kinship relations. In natural reproduction, two lineages come together to form one new being. "The child is the parents' own commingled being externalized and given a separate and persisting existence" (p. 30). Genetically, the cloned child has only one parent, the provider of the somatic cell. The child is literally the child of only one of a couple. What happens, then, to the traditional relationships with the members of the other side of the family, grandparents, aunts, and uncles? Or to the relationship of the husband to the child who is the twin of the mother or the wife to the child who is the twin of her husband? The answer, according to this objection, is that normal and natural human family relationships would be seriously eroded and harmed.

Critics of these arguments respond that, although there is a traditional type of family that in fact varies from culture to culture, there are also many different kinds of nontraditional families. Among these are single-parent households, adopted families, blended families, and lesbian and gay families. It is not the type of family that makes for a good loving household, the argument goes, but the amount of love and care that exists there. Children can learn new or different ways of relating to others. For example, just as stepparents can find ways of being valued parts of their stepchildren's lives, so also the parent who is not a genetic parent of a cloned child could adapt.

The *Yuck* Factor

The argument that gives this section its title goes something as follows: Sometimes one has a gut reaction to something regarded as abhorrent. One is offended by the very thought of it and cannot always give reasons for this reaction. Yet instinctively one knows that what is abhorred is wrong. Many people seem to react to human cloning in this way. Such emotional reactions can be described as an expression of a kind of knowledge, as a kind of moral intuition. They could even be viewed as expressions of a kind of deep wisdom. The very idea of someone making a copy of themselves or many copies of a famous star is simply bizarre, revolting, and repulsive, and these emotional reactions tell us that there is something very wrong with it, even if there is no full explanation for what that is.

Any adequate response to this argument would entail an analysis of how ethical reasoning works when it works well. Emotional reactions or moral intuitions may indeed play a role in moral reasoning. However, most philosophers would agree that adequate moral reasoning should not rely on intuition or emotion alone. Reflections about why one might rightly have such gut reactions are in order. People have been known to have negative gut reactions to things that in fact were not wrong—interracial marriage, for example. It is incumbent on those who assert that something is wrong, most philosophers believe, that they provide rational argument and well-supported reasons to justify these beliefs and emotional reactions.

Rights

Some of the arguments about human reproductive cloning have relied on the use of the language of rights for their conclusions. For example, as noted above, some have objected to cloning on grounds that people have a "right to an open future." In contrast, some argue that human cloning should be allowed because people have a "right to reproduce." And again, because cloning is such a risky process, some argue that it ought to be prohibited because children have a "right to be born healthy." Some attention should be given here, then, to what is meant by a right and why and whether we have certain rights, including these particular rights.

A right is generally understood to be a strong and legitimate claim that people can make to certain things. If the assertion is based on moral grounds, we refer to the right as a moral right, whether or not it is reinforced by law. It is a negative right or claim if it is a claim not to be interfered with. This is sometimes called a liberty right. Thus a right to freedom of speech would be classified primarily as a negative or liberty right, that is, a right not to be prevented from speaking out. But a positive right is a claim to be given certain things. Thus a right to healthcare would be classified as a right to be given certain forms of healthcare. Since rights are legitimate claims, there must be serious reasons or grounds given for their assertion. One view is that only

persons have rights (not rocks or plants, while animals are a disputed case) for only persons are moral agents who can be held responsible for their actions. There are certain things that are essential in order for a person to function well as a human being, and these can be legitimately claimed as rights.

Given these clarifications about rights, which of the above mentioned claims might be legitimate claims and of what kind? Being able to produce a child of one's own might well be so important for a full human existence (with certain exceptions perhaps for celibates or others who serve higher or other causes) that one might well be said to have a legitimate claim or right to do so. It would first of all be classified as a negative or liberty right, in other words a right not to be prevented from producing children, and perhaps also producing them through cloning, at least when no one is harmed. Whether it is also so important that it could be considered a positive right such that society ought to provide the means or aids for those who are having trouble reproducing in the natural way due to infertility problems is another matter. While it may not at first seem reasonable to assert a right to reproduce in this or that way, it may make sense if one thinks of it as one thinks of eyeglasses or wheel chairs, namely as necessary aids to seeing and mobility, things that are essential for a satisfying human life and thus legitimate claims that people can make. A right to an open future could most reasonably be claimed as a negative right, namely a right not to be prevented from choosing a life for oneself. Things that would seriously interfere with this would then be morally problematic as threats to that right.

A right to be born healthy would most reasonably be thought of as a negative right. No one should deliberately do what will result in harm to a child, or do what poses an inordinate or undue risk to its life or health. It would be more problematic to claim that a being that does not exist in some requisite sense has a right to be given a life. However, if it is to have a life, then one might well argue that it should if possible have a life with decent chances for development and happiness. One might ground this in notions of equal opportunity and justice, that each person should have a fair chance to develop and to compete for access to life's goods. Given the risks that are associated with animal cloning, grave questions can be raised about human cloning in this regard.

Safety and Harms

Given the abnormalities so far associated with animal cloning, there is a high likelihood that similar risks would accompany human cloning, at least at present. As described above, animal clones are at a rather high risk for a short life and a life with various diseases and abnormalities. Some have argued that since the alternative for the cloned child is not to exist at all, one cannot claim that giving birth to a child with abnormalities harms that child. One could only say the child was harmed if it were brought into existence with such difficulties that its life with these conditions would be worse than having no life at all. However, others have questioned this sort of reasoning. They believe that it does make sense to say that doing what one knows will bring into existence a child whose life will be short and encumbered with serious ills is to harm that child. Since the harm is serious and the risk is high, they argue, one would be wrong to take it. However, this is not the same as arguing that the law ought to prevent people from taking such risks for others. This is discussed below.

Other harms to consider relate to the number of oocytes or human eggs that thus far must be used to achieve one cloning success. These eggs would presumably have to be obtained from women volunteers. Care would have to be taken that these donors are not coerced or simply used as egg providers. So also care would have to be taken, as in other cases, that women into whom the enucleated eggs were placed for gestation would not be harmed or unduly influenced into performing that service.

Some people have objected to human cloning on the grounds of possible harm to society. One argument is the possible threat human cloning might pose to genetic diversity. If the human gene pool were seriously restricted, we would be less able than otherwise to adapt or respond to environmental changes and threats. However, this would be a possible problem only if human cloning were widespread. Since the normal method of reproduction is so much more enjoyable and desired, this would be very unlikely.

Social Policy

Often, when the issue of human cloning is addressed, there is a confusion about whether what is being asserted is that human cloning is morally right or wrong or whether it ought to be legally permitted or prohibited. These two realms are distinct. In particular, not everything that is morally wrong ought to be legally prohibited. Many examples can be provided, such as spiteful thoughts about others. So also, where a particular case of cloning a human being might be morally objectionable, there may or may not be grounds for it to be legally prohibited. This is partially dependent on the relationship between the realms of morality and the law.

Although not all the views on this relationship can be analyzed here, the most generally accepted view is governed by what has been called the harm principle. This is the view that the law ought to restrict people's liberty only to prevent them from harming others. The purpose of law is not to see that people do the morally right thing or that they do not do

what causes harm only to themselves (if they are adults), for example. On the basis of the harm principle, the possible harm done to those cloned would be particularly relevant. This is why the safety aspect of human cloning is particularly important with regard to what the law should do. Both the degree and certainty of the harm would be important. If the risk were high and the harm serious, there would be grounds to restrict the cloning of human beings by law, at least until it were safe.

One could also argue that people can be harmed by having their basic liberties restricted (where they are not harming others) or their privacy invaded. Those arguing for procreative liberties may also use this principle in support of their views. However, there would still remain a provision that their liberty or privacy could be restricted to protect others from being seriously harmed.

Some have argued in favor of allowing human cloning to proceed on grounds that science cannot and should not be legally regulated or restricted. However, this view would surely need to be tempered at least by the harm principle. Many laws and policies do restrict science on this ground, including food and drug safety regulations. Moreover, while technology has many benefits, it can also be misused. Concerns regarding the misuse and dangers of technology have probably given rise to objections to human cloning of the "Frankenstein" type. Some fear that the results of human cloning could not be controlled. Why cloning would be less controllable than other technology is an open question. But some argue that it is better to permit certain practices and technologies to develop and even to fund them with public money because of the increased publicity and monitoring that this provides.

At present there are no U.S. federal laws prohibiting human cloning, though a few states have passed such legislation, among them California, Louisiana, Michigan, and Rhode Island. Internationally a number of countries and international groups have banned the cloning of humans, including Great Britain, the European Union, and the General Assembly of the United Nations. In early 2003, the recommendations of the U.S. National Bioethics Advisory Commission in their 1997 Report are still being considered by the U.S. Congress as it addresses the issue of human cloning, both reproductive and research/therapeutic. A key recommendation of this report was that at present human reproductive cloning ought to be prohibited because of the safety issues. Congress may also consider the July 2002 recommendations of a divided Presidential Council on Bioethics for a four-year moratorium on both therapeutic and reproductive cloning. The Council rejected these terms in its report, opting instead for "cloning-for-biomedical-research" and "cloning-to-produce-children." However, there are also more general existing laws that could govern human cloning such as those protecting human research subjects, especially non-consenting subjects.

This summary of the issues surrounding human reproductive cloning has considered the nature of human cloning, its present capabilities, and some possible uses for it. It has focused on the ethical objections to cloning, responses to them, and has concluded with some discussion of the relation between ethics and public policy.

III. RELIGIOUS PERSPECTIVES

In its 1997 report on human cloning, the National Bioethics Advisory Commission (NBAC) paid significant attention to the views and concerns of the world's religious communities and their traditions. The NBAC recognized that various religions have supported critical and sustained reflection on issues relevant to assessing human cloning, including the relation of humanity to the natural world, the significance of marriage and procreation in human life, the status of the embryo, and others. For that reason, the NBAC commissioned a report, "Cloning Human Beings: Religious Perspectives on Human Cloning," and took testimony from distinguished scholars of various religious traditions. Drawing on the NBAC report, the testimony given before the commission, and other sources, this entry offers a thumbnail sketch of how four world religions understand the issues raised by reproductive human cloning, for the most part ignoring matters of "therapeutic cloning." Of particular interest are the issues of how cloned children are likely to be valued in contrast to children born of "natural" means; the relevance of parental motives; the possibility of cloning for the purposes of securing biological material for therapeutic use, for example, bone marrow for ill siblings; the issue of destroying embryos; and the notions of "playing God" and "cheating death."

Judaism

Many of Judaism's basic beliefs about humans and God are rooted in the Genesis account of creation. Jewish scholars generally agree that the Biblical account accommodates two views of creation, namely, creation as a completed act, and creation as a transformative process. These disparate views can dramatically influence the way one understands human cloning and the roles of God, humans, and technology in procreation.

Viewing creation as a completed event has led some Jewish ethicists to argue against human cloning on grounds that it violates the structure of nature and impinges on God's sovereignty. According to this line of thought, given that God created the structure of the world, who are humans to tamper with it? Further, the Genesis description of humans created in the image of God begs the question of how that likeness could be improved. From this perspective, human cloning is wrong in that it attempts to improve upon the divine creation that God has called both "good" and "very good." Further, cloning alters and transgresses God's ordained method of human sexual reproduction.

A related argument is that cloning is worrisome in that it fuels a kind of narcissistic fascination with the idea of escaping or cheating death. As such, cloning holds out the promise of rebirth, a second chance for the self to live a better, fuller life. Yet this promise is illusory, and so the quest to clone is a self-deceptive journey and one that distracts humans from pressing moral commitments here and now—for example, the pursuit of justice in healthcare.

The more generally accepted Jewish view suggests that human beings are partners with God in the ongoing act of creation. As such, humans are commissioned with a divine mandate both to steward and to improve the earth through their own creativity and knowledge. Humans thus become responsible, creative agents, cocreators with God, endowed with God-given duties to promote health and healing. Given

that cloning may promote human well-being, it is, provisionally, an acceptable method of stewardship and improvement. In this view, humans do not usurp God's sovereignty in pursuing cloning because, if cloning changes the world for the better, this pursuit exercises their God-given freedom properly. Of course, the assumption that human cloning would actually improve the world is key to this view. Recognizing what a large assumption this is, Jewish scholars who endorse this view of creation also urge caution and recognize that cloning seems to possess inherent dangers for individuals, families, and cultures.

Jewish Biblical commentary traditionally recognizes two values with respect to human beings that are especially helpful in thinking about cloning: uniqueness and equality. Attending to these values may lead to important questions about cloning: Will human clones be more or less valuable than humans conceived through sexual reproduction? Are human clones more likely to be treated as commodities than humans conceived naturally?

Such concerns grow organically out of an understanding that humans are created in the image of God rather than as replications or images of an existing human. It is conceivable that human clones may be regarded as mere objects of production or genetically replaceable resources for our own uses and ends. That clones might be considered "made," may in some way devalue their existence. That clones may be replaceable may undermine their uniqueness. That clones may be used to breed genetic wonders may impinge upon the long-held value of human equality under God. That human cloning could jeopardize all of these values simultaneously and, in so doing, lead to a form of human slavery is a concern not taken lightly by Jewish thinkers.

While these cautions and concerns are taken seriously, Jewish thought also recognizes the transcendent character of the human person. Therefore, humans can never be fully controlled by human technology, will, or intervention. Furthermore, some Jewish scholars have argued that because cloning is a biologically natural process, whereby the clone would be born through a natural process of a human mother, cloning is an acceptable form of reproduction. It also follows that any cloned human being should be treated morally and legally as fully human. Indeed, there is rabbinic consensus that human clones would be fully human and have full moral status.

Finally, Jewish commentators have been concerned about public policy restrictions on cloning. Given the commitment of Jewish tradition to pursue scientific research for the betterment of humanity, many Jewish scholars have cautioned against restricting or prohibiting cloning as a matter of public policy. Also, because Jewish law does not grant full moral status to the embryo, Jewish scholars have not been among those advocating restriction on cloning because it will lead to the destruction of embryos.

Christianity

As with other religious traditions, Christian responses to cloning have been mixed. As early as the mid-1960s, Christian ethicists split sharply over whether cloning was "playing God." Supporting new biotechnologies, Joseph Fletcher famously claimed: "let's play God" (p. 126). Paul Ramsey's equally famous and oft-quoted response cautioned against advancing reproductive technologies: "Men ought not to play God before they learn to be men, and after they have learned to be men they will not play God" (p. 138). The contrast between such different Christian responses to interventions in reproduction continues into the twenty-first century. Some of the diversity in Christian responses to cloning is noted below.

PROTESTANTISM. Protestant Christianity shares a number of Judaism's intellectual and textual traditions. For example, some of the principal elements of the Protestant view of humanity are rooted in the biblical accounts of creation, taking seriously the *imago Dei* theme found in Genesis. Within the Protestant tradition, *imago Dei* is often discussed either in terms of "stewardship" or of "created cocreatorship," but unlike the Jewish thinking, the stewardship model understands creation as a completed process in which humans serve as God's appointed stewards overseeing a finished work, while the cocreatorship model sees creation itself as incomplete *creation continua,* a process in which humans are responsible to participate and improve. These two perspectives relate to human cloning when one asks whether cloning exceeds the limits of human createdness, and whether humans attempt to play God through the genetic manipulation of another human. Understood as stewards, humanity is restricted to conserving the created order. In this view, human cloning is problematic because it usurps God's role as creator; humans are not called to be creators but rather stewards of creation. By contrast, emphasizing the theme that humans are created cocreators tends to support the permissibility of cloning by highlighting the idea of creative freedom implied by this view of *imago Dei.*

In their analysis of human reproductive cloning, Protestant scholars also seriously consider the impact that asexual reproduction may have on the societal norms of marriage, childbearing, and how humans are likely to view and value human clones. Protestants often maintain a normative Biblical view of the child as a being conceived within marriage, a gift from God, and the result of a loving relationship

between a man and a woman. Human cloning raises Protestant concerns regarding the disjunction of marriage and childbearing, and the fear that such a separation will have a lasting and adverse affect on children and society. As representatives in some Protestant denominations have argued, human cloning allows humans to sever the connection between human reproduction and the marital relationship, a separation considered harmful both to child and culture.

Protestants also fear cloning's potential to change how humans view children, namely from a "gift from God" to a "project." Some scholars distinguish between what is "begotten" and what is "made," arguing that begetting is consistent with human dignity in a way that manufacturing is not. Similarly, some Protestant traditions caution against cloning on grounds that it reduces humanity to raw material to be fashioned in human image rather than the image of God.

It is in this light that some Protestants consider both the parental motives for cloning and some of the possible benefits of reproductive cloning. Sympathetic to suffering and the human condition in a fallen world, Protestants remain skeptical of cloning humans for utilitarian purposes such as cloning to replace a young child killed in an accident or cloning to gain access to biological material. Each of these instances of cloning may violate Protestantism's commitment to the inherent and non-instrumental value of human beings.

Indeed, all of these themes are nicely illustrated in a resolution condemning cloning passed by the Southern Baptist Convention in June 2001. According to the resolution, because cloning involves the "wanton destruction" of human embryos; because it is contrary to the "biblical witness" that children are a gift from God and "not the result of asexual replication"; because cloning "does not meet the biblical standards for procreation in which children are begotten, not made"; and because cloning represents "a decisive step toward substituting human procreation with biological manufacturing of humans," cloning is morally abhorrent.

CATHOLICISM. Perhaps the most consistent and vocal opposition to human cloning has come from the Catholic Church. Magisterial (authoritative teaching) documents of the church have regularly and vigorously rejected cloning. For example, in *Donum Vitae,* an "Instruction" issued in 1987, the Vatican examined cloning in the context of other reproductive interventions made possible by the advent of *in vitro* fertilization and concluded that cloning was categorically wrong. *Donum Vitae* is typical of Catholic teaching on topics of bioethics in that it appeals both to beliefs that are shared primarily by the community of the faithful and also to basic human values and experiences that it takes to be common to all humanity. Thus, according to Catholic tradition, it makes sense to note reasons why cloning is morally wrong both in explicitly religious terms and in more secular terms.

An example of the former is Catholic teaching that life is a gift from God and that humans therefore have a responsibility to appreciate and safeguard the inestimable value of human life. According to the Catholic Church, the embryo should be treated as a person from the moment of conception. It follows that cloning is deeply troubling, for embryos will inevitably be destroyed when human beings are cloned. Cloning thus fails to respect the fact that life is a gift from God that should be treasured. Moreover, Catholic tradition emphasizes the fact that humans are created by God as a union of body and soul, and, for that reason, the human person cannot be treated merely as a complex biological system. Thus, to the degree that cloning defines the human person genetically (that is, largely in bodily terms), it is not consistent with a Catholic vision of the spiritual and bodily union of the person and is problematic. Indeed, according to the Vatican, cloning fails to respect the fact that there are limits on human dominance over nature. According to Catholic teaching, it is one thing for reproductive medicine to study human reproduction to assist society in the good that is procreation, it is another thing to dominate the process of procreation. Cloning crosses that line.

In addition to this religiously-grounded argument, Catholic teaching also appeals to the notion of common human experiences. Thus, for example, in her testimony before the NBAC, Lisa Sowle Cahill noted that although autonomy has become a, if not the, central value in contemporary debates in bioethics, Catholic teaching has always emphasized the importance of the common good in addition to individual liberty. With regard to cloning, therefore, Catholic tradition asks not merely whether this technology might benefit individuals, but whether it will benefit society in the long run. In answering this question, Catholic tradition focuses on the importance of family to social good. According to Catholic teaching, the biological connection between parents and children is a manifestation of the natural connection between sex, marriage, and procreation. In traditional language, natural law requires that sex and procreation go together. Thus cloning is wrong in that it violates natural law by separating sex and procreation. This conclusion, says the Church, should be clear even to those who do not share a commitment to natural law. Careful reflection on the importance of families, historically and cross-culturally, along with an examination of how cloning might fundamentally change the notion of family is enough to show that cloning is deeply worrisome.

Islam

Just as Jewish and Christian scholars have drawn on accounts of creation in thinking about cloning, so, too, have Muslim scholars. For example, Chapter 23, verses 12–14 in the Qur'an, the Muslim scripture, are frequently cited as relevant to a discussion of cloning. The passage reads: "We created man of an extraction of clay, then We set him, a drop in a safe lodging, then We created of the drop a clot, then We created of the clot a tissue, then We created of the tissue bones, then We covered the bones in flesh; thereafter We produced it as another creature. So blessed be God, the Best of creators!" Supporters of cloning have understood this passage to mean that because humans participate in the act of creation with God, humans may intervene creatively in nature to promote human welfare. Thus, to undertake cloning in an effort to promote human flourishing may be acceptable.

In summarizing the response of Islam to reproductive cloning, it is also important to stress three themes from the *Shari'a* (Islamic law) that regulate individual and social morality for Muslims. First, Islamic law places a high value on the importance of scientific knowledge. Scientific research reveals the complexity of God's creation and for that reason can be understood as a kind of worship of God. Second, Islamic tradition has emphasized the importance of heterosexual marriage and the family to social and communal good. Third, although the tradition has no definitive position on the moral status of the early embryo, there is a well-known hadith (saying of the Prophet) that an angel comes to breathe spirit into a fetus at six weeks.

With these fundamental commitments supporting Islamic reflections on cloning, a number of positions can and have been developed. Consistent with the Qur'anic emphasis on the pursuit of knowledge, scientific research into reproduction that has led to the possibility of cloning is entirely legitimate. Indeed, some verses of the Qur'an have been interpreted to support the claim that God's will is manifest in so-called artificial reproduction because unless God wills the creation of life, there would be no life. Thus, assuming that the knowledge gained by pursuing cloning would be used to benefit humanity and not instead misused, cloning may be supported.

Nevertheless, there are aspects of cloning that give scholars of Islam pause. For example, the fact that cloning allows for reproduction without heterosexual pairing is problematic, for the Qu'ran is understood to be quite explicit about this: "And of everything We have created pairs that you may be mindful" (51:49). Thus, just as Catholicism is concerned about the threat cloning may pose to the traditional family, so, too, is Islam. Given the importance Islam places on the notion of a family that is founded upon heterosexual union, cloning has seemed very problematic to some Muslim jurists.

Finally, Islam also shares the concern raised by other religious traditions that cloning will lead to the reduction of children to commodities. Given the emphasis in Islam on the notion of spiritual equality, cloning may be problematic if it leads us to value some humans more highly than others because they have, or are free of, certain genetic traits. If cloning will lead us to place a market value on human beings, it will be opposed by Islam. Moreover, given the tradition that the moral status of the fetus changes approximately six weeks after conception, cloning will be problematic to the degree that it results in a substantial loss of fetal life after this point in gestation.

Buddhism

In order to understand Buddhist responses to cloning, it is important to note that Buddhist teaching generally emphasizes the centrality of individual judgment and discretion informed by reflection on Buddhist texts and the opinion of respected teachers. Thus, on cloning as on other issues, it is difficult to speak of a Buddhist position.

Nevertheless, the tradition clearly emphasizes a number of values that are helpful in framing a Buddhist response to cloning. First, in Buddhism, human existence is particularly valuable because only human beings can achieve enlightenment and thereby escape perpetual rebirth. The birth of a human being is therefore important because it affords a sentient being the possibility of release from suffering. Reproductive cloning may be viewed positively from a Buddhist perspective because it appears to facilitate the process of rebirth and liberation. The fact that such cloning would involve asexual reproduction does not appear to be significant in Buddhist tradition, which clearly contains stories of other kinds of asexual generation.

In contrast to several Protestant, Catholic, and Islamic objections to human cloning, Buddhists do not argue that asexual reproduction and cloning are human attempts to play God, or that they in any way infringe upon God's sovereignty as creator. Nor do Buddhists fear that human cloning, through genetic manipulation, might deprive cloned individuals of their right to an open future. Buddhism rejects the kind of physical reductionism that such genetic determinism implies, and scholars have been careful to note that human cloning does not determine or control the life of another being. The Buddhist conception of human life maintains that while cloning does determine the genotype of an individual, one's genetic construction does not and

cannot determine the complete life of the human being, usually thought to comprise the body, sensation, thought, dispositions, and consciousness.

Buddhism does look upon cloning with skepticism and caution for other reasons. The universal value shared by all Buddhist traditions remains ego-transcending thought and behavior. Egocentric conduct and its motives are considered great moral wrongs. Buddhism is likely to analyze the morality of human cloning in terms of the motives, intentions, and desires of those engaged in genetic engineering and cloning. Should the motives behind cloning in general, or cloning in a specific instance, be found to be purely self-centered or self-gratifying, then the practice would be immoral and contrary to Buddhist values. This point is nicely illustrated by the classic Buddhist narrative, the "Parable of the Mustard Seed." According to the parable, a mother who is grieving over the death of her child approaches the Buddha to ask that he bring her dead child back to life. The Buddha instructs the woman that she will be able to accomplish her goal if she prepares tea from mustard seeds that have come from a house not touched by death. Of course, the woman is unable to find such seeds, and that is indeed the point; all life is impermanent. In the face of this fact, the woman needs to reflect on her desires and attachments to things that are necessarily impermanent.

Given this parable, Buddhist tradition raises serious questions about the wisdom of one form of reproductive cloning, namely, cloning to replace a lost loved one. Such cloning might be acceptable if one can find a physician whose family has not been touched by death, but seeking to replace a loved one appears to interfere with a Buddhist commitment to seek enlightenment through freedom from bondage to the self and its attachments. The parable thus points to the significance of attending to the motives or desires for cloning in rendering a Buddhist assessment of the practice. Many of the reasons that have been advanced for reproductive cloning, for example, to resolve infertility, to replace a lost child, to replicate oneself, appear to be profoundly egocentric. As such, they would be morally problematic according to Buddhist teaching.

Nevertheless, scholars remain divided on this line of thinking. Some have argued that should cloning benefit the couple wishing for a child, and provided it does not cause pain or suffering, then such cloning should be supported. Others have noted, however, that even the least objectionable motivations for cloning, such as the desire to avoid passing down hereditary disease, remain egocentric and self-serving. In this view, the decision to clone instead of using donor cells or adopting a child in need of a family, for example, seems rooted in a desire to have a genetically related child and does not truly look to ease the suffering of another, but has a self-gratifying aim. Accordingly, the argument goes, virtually all rationales for reproductive cloning stem from this desire.

While the motivation behind cloning is of primary significance in assessing its moral value, there is some concern among Buddhists that the inevitable destruction of early human embryos in cloning's experimental phases and in the successful process itself runs contrary to Buddhism's objection to the taking of human life. Although as a non-sentient being the early embryo would not suffer, Buddhism does view the early embryo as a human being and, as previously noted, the human is highly valued for its role in one's attainment of nirvana and the release from suffering. Thus, destroying human life, however early or insentient, may violate one of Buddhism's highest values.

Conclusion

This survey of religious responses to cloning suggests that there is significant misunderstanding of how major religious traditions have reacted to the possibility of reproductive cloning, at least in the popular media. For example, when the story broke that the British House of Lords had legalized therapeutic cloning for the purpose of deriving stem cells in 2001, the Reuters news service described Parliament as "turning a deaf ear to religious leaders from across the spectrum who had urged them to oppose the measures." Reuters's characterization of religious leaders as uniformly opposed to cloning is fairly typical. The reality is quite different. As this survey attests, Judaism, Christianity, Islam, and Buddhism take subtly different positions on the status of the embryo, on the appropriate motives for even considering cloning, on the notion of "playing God" and manipulating nature, and other matters.

Add to this the fact that, within each tradition, there are disagreements about these matters and the picture becomes very complex. What can safely be said is that none of these traditions appears to embrace cloning as an unqualified good, and, with the exception of official Catholic teaching and that of some evangelical Protestant groups, none appears to condemn cloning as intrinsically and unqualifiedly wrong.

COERCION

• • •

Is it ever acceptable for the government to coerce someone into receiving healthcare? Is it acceptable for healthcare professionals to do so? Equally important, if an individual is coerced to do something including, for example, consenting to treatment, does the coercion invalidate responsibility for the act? Are prisoners and other institutionalized persons able to freely decide whether to enroll as subjects in experiments, or should they be seen as coerced, and, if so, does that invalidate their consent? Is paying research subjects to participate in research acceptable, or is that practice coercive?

These questions are basic to many of the ethical dilemmas faced in healthcare and healthcare research. To answer them, it is necessary to answer a number of more general questions. What is coercion? Are coercive acts ever morally legitimate? If so, how can they be distinguished from illegitimate coercion? Are there types of coercive acts that are always illegitimate, or do their moral natures vary with the context in which they occur? This entry aims to answer these and other related questions. A clear definition of coercion is a mandatory first step.

What Is Coercion?

In their 4th edition of *Principles of Biomedical Ethics,* published in 1994, Tom L. Beauchamp and James F. Childress provided a definition of coercion that is consistent with common usage: "Coercion … occurs if and only if one person intentionally uses a credible and severe threat of harm or force to control another" (Beauchamp and Childress, p. 164). This definition has three critical elements: a person

acting intentionally, a threat of harm, and an effort to control another. Perhaps the prototype of this image of coercion is the robber who approaches a victim and says, "Your money or your life." Note that the robber is not forcing the victim to hand over the money. The victim still has options, but the robber has manipulated the options in such a manner that most people would agree to hand over the money.

If Beauchamp and Childress's definition is correct, most constraints on freedom should not be thought of as coercion. In their definition only other people can coerce. Someone who lacks resources should not be thought of as being coerced by the lack of resources. The poor are not coerced into homelessness no matter how much their situation may be out of their control. A nation that lacks oil is not coerced into trading with a country that has oil simply because of its need. Similarly, an environment, such as a prison, cannot be thought to be coercive. Thus the regulatory restrictions on research with prisoners cannot be justified by limitations on coercion.

Similarly, threats are a fundamental feature of this definition; other pressures do not produce coercion. This position is controversial. In his 1986 volume, *Harm to Self,* Joel Feinberg, like Beauchamp and Childress, used the term *compulsion* rather than *coercion* to refer to the actual use of force, because compulsion reduces options and coercion only changes the attractiveness of the options. Michael D. Bayles, like others, however, did not consider this distinction important (Bayles).

Force is not the only type of pressure that is sometimes included in coercion. Positive pressures such as inducements and persuasion may be seen as "excessive." Many commentators on research ethics have suggested that excessive inducements may well constitute a form of coercion (Macklin; Levine; Ackerman; Dickert and Grady). For example, in his 1986 book, *Ethics and the Regulation of Clinical Research,* Robert J. Levine suggested that almost all bioethics support this view. The U.S. Food and Drug Administration's (FDA) information sheets require institutional review boards to ensure that payments not be "unduly influential" (FDA). Indeed, Neal Dickert and Christine Grady suggested in a 1999 article that whether or not a payment is unduly influential is largely determined by the strategy used to establish the amounts to be paid. Several others, including Beauchamp and Childress and Robert Nozick (1969), exclude positive incentives from the concept of coercion.

It should also follow from Beauchamp and Childress's definition that if the threatener has no intention of controlling the behavior of the other party, there is no coercion. Thus a physician who tells an individual seeking help for what might be a gunshot wound that he must report any gunshot wounds to the authorities is not coercing the potential patient, because there is no attempt to alter that person's behavior.

The question of coercion can be stated as follows: If *A* proposes to do something to *B*, what are the conditions that make the act coercive or not? Several commentators have suggested that the relevant question is whether the proposed act leaves *B* better off or worse off. If better off, it is a legitimate offer; if worse off, it is coercive (Zimmerman). Nevertheless, this does not entirely solve the problem. Consider a physician who tells a sick patient that she will provide treatment but only with the payment of $100 (or some other reasonable fee). This is an entirely reasonable offer and not coercive at all. If, however, the patient belongs to an HMO to which the physician belongs and which forbids this sort of co-pay, this "offer" might be coercive. Put more generally, whether an act is a legitimate offer or coercion depends on the right of the offerer to make the offer.

Such problems can be handled better by what Alan Wertheimer, in his 1987 book, *Coercion* called a "moralized theory" of coercion. Wertheimer objected to views suggesting that what is coercive can be determined simply by looking at the pressure applied to the individual. In his view, coercion is an inherently moralized judgment. One cannot determine whether or not an act is coercive except on the basis of understanding the normative context of the actions. Wertheimer argued that coercion judgments come down to whether the possible coercer has the right to make the proposal and whether the possible coercee has the obligation to resist it.

Coercion and Autonomy

The view in Western culture that coercion is a bad thing reflects a deep commitment to the principle of autonomy. Starting with the German philosopher Immanuel Kant (1724–1804) and his 1785 work, *Groundwork of the Metaphysics of Morals,* secular ethics has taken the respect for the autonomous actions of others as a primary point of orientation. In this context, coercion is wrong because it interferes with autonomy. Thus the nineteenth-century English philosopher and economist John Stuart Mill argued in *On Liberty* (1859) that there were inherent limitations on the power that the state or other authorities should exercise over individuals:

> [T]he sole end for which mankind are warranted, individually or collectively, in interfering with the

> liberty of action of any of their number, is self-protection.… the only purpose for which power can be rightfully exercised over any member of a civilized community, against his will, is to prevent harm to others. His own good, either physical or moral, is not a sufficient warrant. (Mill, p. 494)

Although this often quoted passage seems to prohibit many coercive actions that Western society accepts routinely today, it is worth noting that Mill made exceptions for children and for adults not of sound mind. His vision of autonomy is so rationalistic that there appears to be no basis for respecting the autonomy of those who are lacking in reasoning ability.

Is Coercion Always Wrong?

At least in the context of Western values, it is hard to defend coercive behaviors per se. Nonetheless, there are many examples of coercive behaviors that are generally accepted. Indeed, political scientists general acknowledge that the governmental monopoly on the use of force is a fundamental feature of civil order. The ability of the authorities to threaten the use of force seems essential. There are innumerable examples, both in and out of medicine, in which coercion is accepted. The courts routinely tell people who are thought to have a mental illness that they can either take their prescribed medicine or be involuntarily committed to a hospital. In this case, the courts are still consistent with Mill's viewpoint. But when parents are told that if they want their children to attend public schools, the children must have certain vaccinations, this appears to go beyond Mill's limits on coercion.

The viewpoint that coercion is sometimes justified is referred to as *paternalism.* Here the authority, be it the state or the medical professional, justifies the use of threats and force based on the best interests of the individual. Although few ethicists have expressly focused on justifying paternalism per se, there has been considerable discussion of the circumstances under which paternalism might be acceptable.

Feinberg (1971) distinguished between weak paternalism and strong paternalism. The former depends for its legitimacy on an individual's compromised ability to decide, based on, for example, the influence of psychotropic drugs, some forms of mental illness, severe acute pain, or acute neurological injuries. Strong paternalism, by contrast, justifies actions that are simply intended to benefit a competent rational individual who is, in the view of the paternalist, making the wrong decision. Strong paternalism may take the form of either restricting what is disclosed to an individual or simply overriding the person's autonomous choices.

Empirical Findings: The Example of Psychiatric Admission

Empirical data cannot resolve ethical issues, but experience in bioethics has shown that ethical issues often look quite different when they are embedded in complex situations. Likewise, empirical data can render problematic assumptions about the nature of the ethical decisions that occur in healthcare contexts.

There have not been very many efforts to study coercion in healthcare. The exception is psychiatric care. There has been considerable research into coercion in psychiatric admissions and in other aspects of psychiatric care that are mandated by courts or other legally constituted authorities. Precisely because such situations use the coercive power of the state and yet occur within the context of medical care, they have been of special interest to ethicists and policymakers. For this reason, research on coercion in psychiatry can also be helpful in understanding some of the general issues concerning coercion in healthcare.

Research on coercion in psychiatry was relatively unorganized until the MacArthur Foundation funded a series of studies in the 1990s. These studies contributed a number of important empirical findings, but their most important contribution was to create a measure of perceived coercion that has been widely adopted and that has allowed comparisons across international boundaries and among different types of psychiatric care. It is important to recognize, however, that this scale measures *perceived* coercion and that it is based on an understanding of coercion as a restriction on the ability to make decisions for oneself (Gardner et al., 1993).

Among its findings, the MacArthur group reported several that have important implications for understanding coercion in healthcare. First, there is surprising agreement among the participants in hospitalization decisions (patients, family, and clinicians) about what happened (Hoge et al., 1998; Lidz et al., 1998). The differences are in how the events are evaluated. Thus the different participants often disagreed about the level of coercion even when they agreed about the acts involved.

Perhaps the most surprising MacArthur finding was that being legally involuntarily committed is not necessarily perceived by patients as coercive. Indeed, almost a third of the people who were legally committed reported that they did not feel coerced. Conversely, more than 10 percent of those who were admitted "voluntarily" felt coerced (Hoge et al., 1997). These finding have been confirmed by other investigators (Nicholson, Ekenstam, and Norwood; Hiday et al.). Similar findings have been found in different countries (McKenna, Simpson, and Laidlaw), in involuntary

outpatient treatment (Swartz et al.), and in drug treatment (Wild, Newton-Taylor, and Alletto).

Perhaps the most interesting of the MacArthur group's findings involved the issue of moralized versus nonmoralized concepts of coercion. In a 1993 study, Nancy S. Bennett and her colleagues examined the transcripts of interviews with admitted patients and noted that the patients' descriptions of their experiences with admission and their perceptions of coercion appeared to be substantially related to their perception of what came to be called procedural justice. This concept included the sense that patients had a chance to express their own thoughts on the hospitalization, that they were listened to, and that the motives of others involved in the hospitalization decision were benign (Bennett et al.). Subsequent follow-up studies, both from the MacArthur group (Lidz et al., 1995) and others (Hiday et al.), showed that both procedural justice and what the researchers called negative pressures (force and threats) were strongly related to perceived coercion but that "positive pressures" such as inducements were not.

Conclusion

Coercion may be defined in a purely behavioral manner as the use of a threat to control the behavior of another. Other thinkers have argued that coercion is inherently a moralized judgment that can be understood only in the normative context in which it is made. From this perspective, there can be no such thing as approved coercion. Indeed, coercion is almost universally condemned in the abstract, but there are many instances in which actions that fit behavioral definitions of coercion are approved. The empirical studies of coercion appear to support a view of coercion that involves both behavioral and moral components. There appears to be little empirical support, however, for the idea that offers or other inducements are experienced as coercive.

COMMERCIALISM IN SCIENTIFIC RESEARCH

• • •

Scientific research has never been entirely insulated from the incentives provided by the profit motive and the need to secure financial support. Scientists have always required funding, whether it be from personal funds, patrons, universities, or industry. Similarly, opportunities for scientific entrepreneurship have always existed. Since the early 1800s, however, scientific research has both required increasing amounts of capital investment and promised progressively greater financial returns. Consequently, scientists have been forced to rely on a broader range of funding sources and have become more willing to involve themselves in the financial implications of their work. This incremental "commercialization" of science has increased markedly since the early 1980s and poses challenges for both society and the research community.

Well into the early nineteenth century most scientists were indifferent to the commercial potential of their work and typically did not pursue large-scale or external financial support. Research then did not require huge expenditures, and many researchers believed that scientific research was the work of disinterested amateurs devoted to the pursuit of truth. In the mid- to late nineteenth century the development of the large-scale laboratory in Europe and ultimately in the United States increased the costs of research and foreshadowed the decline of the solitary, amateur researcher. At the same time, a variety of connections between industry and science developed. Many businesses employed their own scientists, but an increasing number established relationships with universities and employed academic scientists as consultants and researchers. While this trend continued in the early twentieth century, industry-sponsored research typically focused on applied-science projects. Basic research areas had yet to be viewed as fruitful areas of investment (Etzkowitz).

In the last half of the twentieth century, several developments enhanced the commercial aspects of science. The cost of basic science research continued to soar, requiring sophisticated equipment and resources, larger laboratories, and more staff. Basic research therefore has become increasingly dependent on financial support from either the government or the private sector. Scientific research, especially in the biomedical fields, promises to generate tremendous profits for those who control new discoveries. Moreover, the gap between basic and applied science has narrowed, so that discoveries can be translated into usable and profitable products with less energy and over a shorter span of time (Etzkowitz).

Commercialization, the Ideals of Science, and the Public Good

Despite the need for broad-based and generous funding and the right of scientists to reap rewards for their efforts and ingenuity, financial incentives may create conflicts of interest that can undermine and corrupt the ideal of disinterested scientific inquiry. A conflict of interest exists when any professional judgment or activity relating to a primary interest (e.g., intellectual honesty, validity, openness, or objectivity), equivalent to the scientific norms articulated by Robert K. Merton and others, may be influenced by secondary interests (e.g., financial gain, profit, position, or fame). The mere existence of a conflict of interest does not mean that unethical behavior has occurred; the scientist may honor the primary interests and refuse to be influenced by the secondary interests. Conflicts of interest instead signal cases in which the danger of unethical behavior is increased. In some cases the conflicts can be managed by restricting the secondary interests; in more extreme cases ethical outcomes can be assured only if the secondary interests are entirely removed (Thompson; Merton; Cournand).

Conflict of interest may exist at an individual or at an institutional level. For example, one primary interest of a university is to serve the public good. Financial incentives may induce researchers and institutions to behave in ways

detrimental to society (Angell). For example, a scientist may forgo research on an important project in favor of another that is more profitable. Comprehensive ethical policies would ideally address both possible levels of conflict, though they require different forms of remedies.

Industry Investment in Academic Research

Private investment in university research may take a number of forms. Companies may offer universities large grants in exchange for patent rights to anticipated discoveries or establish lucrative consulting arrangements with faculty members who provide sponsoring corporations with priority access to valuable research. Faculty members sometimes own equity interests in biotechnology firms related to their work, or they may found their own corporations. And in what is so far a rare agreement, a corporation may provide an academic research institute generous payments in exchange for the right to market all the institution's discoveries. These secondary—financial—interests threaten to undermine the university's primary interests of advancing basic knowledge, promoting the open exchange of ideas, providing a source of expertise for society, and training future scientists (Etzkowitz; Ashford).

In 2003 Justin E. Bekelman, Yan Li, and Cary P. Gross provided a systematic review of the extent and nature of commercial influence on biomedical research. The researchers found that about one-fourth of biomedical scientists at academic institutions receive research funding from industry, while two-thirds of academic institutions hold equity interests in biotechnology firms. According to the survey findings, it is likely that such relationships bias scientific outcomes because published studies sponsored by industry are substantially more likely than nonindustry studies to reach conclusions favorable to the sale of the sponsors' products. Faculty sponsored by industry are more likely than other faculty to report that publication of their research results was delayed, and more than half of the firms surveyed reported that their contracts typically demand delays in publication of more than six months. Between 12 percent and 34 percent of investigators reported that they had tried to obtain and had been denied access to research results by industry sponsors.

If free exchange through traditional scholarly mediums of conferences and publications is blunted, scientists will be unable to examine and replicate experiments, and scientific progress may be endangered. Some contractual agreements with industries specifically require scientists to withhold submission of their findings to professional journals until the corporation has determined if the information warrants patent protection. After patent protection is secured, the findings can be released to the general scientific community. The propriety of these arrangements depends in part on the length and impact of the delay of release of scientifically important information and varies from contract to contract. It is possible that much of the research that is withheld from the scientific community as trade secrets has little intrinsic scientific value or applicability and is limited to information such as scientifically unimportant formulas for products, scientific instrument calibrations, or engineering tolerances (Snapper).

Commercial considerations can distort academic life in other respects. Researchers may be tempted to devote time earmarked for the university to their commercial projects and to use university resources, including graduate assistants and laboratory staff, for their own financial benefit. Graduate students are particularly vulnerable to the availability of funds; the entire course of their careers may be guided by the source of their mentors' grants (Porter 1992a; Blumenthal). The prospect of large infusions of money into a cash-starved university might make an institution less scrupulous when evaluating potential research projects. For example, an institutional review board (IRB) might be less likely to point out problematic aspects of an experimental study if they believe that the corporate sponsor will withdraw its funds and go elsewhere with the proposal. An existing or potential grant might influence a university's decision on the composition of its faculty, the structure of a department, and the granting of tenure (Nelkin and Nelson). Financial incentives have encouraged some university researchers to redirect their work toward projects that are more likely to yield financial rewards. Such a redirection of research might encourage researchers to value applied projects with clear commercial ends and patentable uses over basic science projects whose practical applications are uncertain. While society benefits from applied research, fundamental breakthroughs and scientific progress are predicated on a strong commitment to basic research.

Despite these caveats, private funding of university research serves as an effective and essential supplement to government funding. Some reports demonstrate that, in general, industry-funded scientists publish more, produce more patentable discoveries, and still manage to teach as much and to serve as many administrative roles as colleagues without corporate financial support (Blumenthal). Industrial subsidies allow universities to support a more talented and larger faculty and to improve their facilities. Therefore, some authors argue that the danger of increased commercial presence in universities must be weighed against the positive contributions made by industry funding (Blake).

Conflicts and Scientists' Social Duties

Professional researchers are the public's and policymakers' most important source of scientific expertise. Government agencies that evaluate biomedical proposals and projects must rely on scientists to analyze the safety and efficacy of research and products. Scientists also serve as reviewers for governmental grant applications and as authors, editors, and referees for professional publications. Conflicts of interest arise when industry, regulatory agencies, government committees, and editors all seek out the same individuals—a likely prospect when many of the most talented researchers have already-established commercial interests (Culliton).

Few scientists will purposely present biased conclusions, but researchers' commercial interests may influence their professional life in other respects. Scientists might be hesitant to participate in the evaluation of an industry with which they maintain a financial connection. Following a large oil spill on the California coast in the late 1960s, for example, government investigators found it difficult to recruit scientists willing to testify against the oil companies. Most qualified scientists had commercial ties to the industry (Kenney). When a medical journal sought independent reviewers to judge the quality of a research study showing the lack of benefits of a popular drug—a study whose publication the company manufacturing the drug was attempting to suppress on the grounds that the study was badly designed—the editors discovered that virtually all scientific experts in that field had existing financial ties to the company (Rennie). Corporations frequently employ researchers as consultants to determine if their facilities meet governmental health standards or if their new product induces disease. A researcher's desire to please the employer and to preserve the potential of future affiliations may influence the study design and methodology selected for the investigation. A study that monitors employee health for only a short time, for example, would be less likely to uncover an occupation-related disease with a long latency period. A corporation facing liability for a suspect drug would prefer its researchers to find that the product presented no danger and was not responsible for the maladies suffered by current users (Ashford; Porter, 1992a, 1992b).

Similarly, reviewers of grant applications may have commercial interests that unconsciously lead them to undervalue a potential competitor's proposal. Journal referees may denigrate articles or reports that threaten their commercial interests or their industry employer. A researcher with a consulting arrangement or an equity interest in a new development might tend toward findings that would laud the benefits of the innovation. In one egregious case, a researcher who owned over 500,000 shares of biomedical stock altered a study design to delay the release of negative findings until he could sell his holdings for a tremendous profit (American Medical Association). Physician-researchers with commercial interests in innovative treatments or research protocols bear additional responsibilities. A central tenet of medical professionalism holds that the welfare of the patient be placed before any benefit to the physician. If a physician-researcher is testing an experimental therapy, the patient must be protected from risks of undue harm from either the experimental drug itself or from withholding standard therapy. Physician-researchers with financial interests in their protocol might tend to recruit subjects aggressively, playing down the risks and exaggerating the benefits associated with the research. In a highly publicized case in which a young man died during experimental gene therapy, both the investigator and the university had financial interests in the biotechnology firm that planned to market the drug if it proved successful, and it was charged that substantial, known risks were not disclosed to the subject (2001).

During the 1990s a considerable change in pharmaceutical research funding occurred in the United States. Companies began to shift research grants away from universities and toward for-profit contract-research organizations (CROs). The CROs promised quicker research results and hence faster licensing of new drugs, compared to the more cumbersome, bureaucratic university system. Between 1991 and 1998, the portion of pharmaceutical industry research funds going to academic medical centers fell from 80 percent to 40 percent (2000). For-profit commercial IRBs sprang up to service the CROs, creating questions as to the adequacy of ethical review when both the IRB and the investigating organization had such strong financial incentives to speed the progress of research and to produce positive results (Lemmens and Freedman). As research funds were shifted to the private sector, university investigators had to compete more vigorously for the remaining funds, increasing the likelihood that both institutions and individuals would ignore serious conflicts of interest in their eagerness to secure funding.

Remedies and Safeguards

The integrity of individual researchers is clearly the most important guard against the malevolent potential of conflicts of interest. But honesty alone may sometimes be insufficient, as damage can occur from unconscious bias and error as well as from conscious falsification. While all conflicts of interest have the potential to undermine a scientist's or an institution's primary goals of truth, objectivity, and openness, all conflicts do not pose the same degree of danger or require the same response. The danger of a particular conflict of interest depends both on how likely the

arrangement is to corrupt the scientist's professional duty and on how much damage that corruption is likely to cause. Larger financial payments, and longer and closer relationships between researchers and business, will typically pose greater dangers than small financial incentives and one-time contacts with corporations (Thompson). While supervisory and regulatory measures can usually be tailored to the degree of the risk, there may be some situations in which the danger of harm to scientific integrity and society is so high that no protective measure can remedy it.

Universities might limit the amount of support they accept from industry, limit the amount of time that faculty may devote to outside endeavors, or prohibit particularly suspicious arrangements. In addition, research institutes can require the disclosure of all commercial links and interests and establish prospective administrative review of all proposals for outside funding (Varrin and Kukich; AAMC, 1990). Disclosure rules not only assist university officials and peers in policing conflicts of interest but may also make researchers more scrupulous in evaluating the potential bias in their own work. Researchers sometimes end or eschew questionable relationships rather than disclose them to the academic community. Some have argued, however, that today's institutional policies tend to advocate, inappropriately, disclosure alone, treating it as if it were a panacea. A number of prestigious universities and organizations in the United States proposed stringent conflict of interest policies in the early 2000s (Kelch; Kassirer). Many focus on individual conflicts of interest to the exclusion of institutional-level conflicts. By contrast, a group of Canadian authors, stimulated by widely publicized cases in their country of egregious institutional violations of academic freedom, have proposed elements of a conflict of interest policy that offers remedies for both levels of conflict (Lewis et al.). A policy on institutional conflicts of interest proposed in 2002 by the Association of American Medical Colleges (AAMC) locates responsibility for policing potential conflicts of interest within each university, whereas the Canadian group suggested that an appellate process involving a national group independent of any one university would be desirable (Lewis et al.; AAMC 2002). After developing a policy considered one of the most stringent in the nation, Harvard Medical School came under pressure to loosen its requirements, lest some of its most prestigious researchers move elsewhere (Angell). Bioethics programs in universities are part of the research enterprise and, according to some, should have policies to prevent conflicts of interest. Concerns have been expressed about paid consulting relationships between bioethics faculty and industry (Brody et al.).

Government agencies and professional publications also institute policies to guard against conflicts of interest. The U.S. Food and Drug Administration and the National Institutes of Health require extensive disclosure of all advisers' commercial interests. Some professional journals demand that authors and reviewers disclose any commercial relationships that might be construed as creating conflicts of interest. According to this view, conflicts of interest should not automatically disqualify a reviewer or author, but the revelation will allow readers, editors, and administrators to scrutinize conclusions more carefully (Koshland). Other publications have adopted somewhat more stringent guidelines. The *New England Journal of Medicine,* for example, has required that authors disclose their financial conflicts, that its editors have no financial interest in any business related to clinical medicine, and that authors of review articles and editorials have no financial connection to their topics (Relman). The *Journal* was later forced to admit, however, that many of its authors of review articles had evaded these requirements (Angell, Utiger, and Wood). A few observers warn that excessive concern over conflicts of interest and safeguards may hinder scientific progress and undermine the scientific objectivity that they are designed to preserve. These writers claim that focusing reviewers' and readers' attention on potential outside influences instead of the content of the data, findings, and ideas generates a subjective skepticism unrelated to the objective merit of the work (Rothman). In 2001, however, the editors of thirteen major medical journals decided that the problem was serious enough to demand a unified and even more stringent disclosure policy (Davidoff et al.).

Some observers argue that the physician-researcher's commercial ties should be revealed to the patient-subject through the mechanism of informed consent and to the investigator's institution through a formal reporting mechanism (Finkel). Finally, IRBs can scrutinize protocols that promise great financial rewards for physician-investigators.

Patents and the Public Interest

Patenting is another commercially motivated practice that may create conflicts between the primary interests of good science and the secondary interests created by the profit motive. Patenting is based on the theory that innovators will be more likely to share their knowledge because they know that they will receive remuneration and credit and that entrepreneurs will be more willing to invest in the development of discoveries because they know that they have exclusive or protected access and will recoup their expenditures in profits. Patenting's skeptics, however, argue that the very nature of patenting undermines the traditional scientific norm of openness. Researchers may be tempted to withhold socially valuable information until they are certain

that their pecuniary interests are protected by a patent (Kass; Wiener). Especially in the biomedical fields, a delay in the release of information can lead to postponed development and dissemination and the loss of lives. Others speculate that potentially patentable, lucrative discoveries will lead researchers away from less profitable yet socially important projects. Finally, some critics claim that entrepreneurs who purchase rights to a basic discovery often do not use or develop it in a socially responsible way. Furthermore, their monopoly advantage makes it impossible for the market to force them to distribute the breakthrough in an equitable and useful manner (Goldman).

The federal Bayh-Dole Act of 1980 provided the legal basis for universities to patent genetic and other biotechnology products and discoveries. When passed by Congress, the act seemed uncontroversial, because the public would benefit both from the quicker marketing of the fruits of new research and also from a lower tax burden as universities made more money from patents and licenses. In retrospect, some provisions of the act appear to have had undesirable consequences. Besides the dangers of turning so big a percentage of research funding over to corporate interests, some fear that the ease with which one can patent each separate step of a complex sequence needed to create genetic tests or therapies will actually pose a barrier to future advances, because the manufacture of any gene product may require negotiating license fees with the owners of dozens of patents (Nelkin and Andrews; Merz et al.).

The government can also provide patentlike incentives to encourage the development of products with marginal profitability that are intended to treat a small patient population or that are ineligible for normal patent protection—so-called orphan drugs. Orphan-drug programs might include research grants, investment tax credits, expedited approval processes, and exclusive licenses to produce and distribute the drug. Critics of orphan-drug programs argue that the policy excessively favors drug manufacturers, inflates the costs of lifesaving medications, and delays the development of lower-cost alternatives. Private corporations sometimes reap profits far in excess of their expectations and effort while effectively denying life-sustaining remedies to patients through monopoly pricing practices (Ackiron). Incentives are sometimes overgenerous, and corporations are able to enrich themselves on drugs that serve only a small number of patients and occasionally produce limited benefits (Wagner). It is important to scrutinize the incentive structure of the orphan-drug policy in an attempt to eliminate unnecessary windfall profits for drug manufacturers. Policymakers must balance the cost of the incentives, including monopoly pricing practices and tax abatements, against the benefits provided by the new drug (i.e., the number of people served and the efficacy of the remedy).

Marketable Products from Human Sources

Another challenging problem arises when an individual's body parts or cells are transformed into valuable commodities. In one such case, a patient's removed spleen contained unique cells that a physician-researcher cultured into a patented cell line. Should the patient have been apprised, as part of the informed-consent procedure, that the cells had potential commercial value? Fully informed consent would have allowed the patient to evaluate the physician's potential conflict of interests and choice of treatments more effectively. Because society and the law have typically been hesitant to "commodify" the body and do not allow the sale of organs, it might seem inappropriate to grant the patient a share of the profits based on the theory that the tissue is his or her "property." In contrast, the system appears to allow the biomedical entrepreneur to benefit from the sale of body parts. Developers of such innovative products might argue that the resulting cell line is not a body part but rather the result of their labor and ingenuity and that these efforts deserve to be rewarded and encouraged by traditional patents. Even granting this argument, it may be unjust to allow others to benefit from an innovation while the person upon whose existence the development rests receives nothing. Consequently, it seems fair and equitable that individuals receive some benefit from their unique physical characteristics that have been used to create great profits. The amount of remuneration could depend upon the nature of the informed-consent agreement, the degree to which the body tissue contribution was changed by the researcher before it was offered as a product, and the uniqueness of the physical material used (Murray).

Conclusion

It would be unrealistic to expect modern capital-intensive scientific research to thrive entirely without the support and influence of commercial interests and incentives. Similarly, it would be unwise and impractical to suggest that scientists who maintain commercial connections, and therefore have potential conflicts of interest, should disqualify themselves from all advisory duties. The trend toward adoption of explicit and stringent conflict of interest policies suggests a growing consensus that individuals, institutions, and professional groups have all been too tolerant in the past of ethically questionable but lucrative practices. It remains to be seen how effective these new policies will prove in policing the problem. The U.S. public, moreover, may be forced to reexamine the wisdom of allowing so great a

percentage of the total research endeavor to be governed by private commercial interests.

COMMUNITARIANISM AND BIOETHICS

• • •

In the 1990s, communitarian approaches to bioethics became increasingly common and explicit in the literature. This evolution was the result of the prominence of the communitarian philosophical critiques of liberalism that occurred in the 1980s, particularly works by Alasdair MacIntyre, Michael Sandel, Charles Taylor, and Michael Walzer.

Communitarianism is a neo-Aristotelian philosophy that focuses on the common good and is concerned with the relationship between the good person or good citizen and the good of the community or society. As would be expected, it has much in common with other neo-Aristotelian approaches, such as casuistry and virtue ethics. Communitarianism is both a critique of the dominant Western ideology of liberal individualism and an orientation to ethical problem solving.

Communitarians often argue that the notion of human nature and the concept of the self behind liberalism are insufficient to make possible a shared common understanding of values among members of society. Similarly, communitarians sometimes argue that liberal society is committed to neutrality toward all notions of the good life, and thereby cannot adequately address ethical issues. As a result, communitarians often stress an orientation toward ethical questions that relies on the establishment, or re-establishment, of a shared common understanding, a shared notion of the good life, or a shared notion of the self.

Only a few bioethicists have openly embraced the communitarian label in their writings (Emanuel; Brennan; Loewy; Nelson; Callahan, 1996; Kuczewski, 1997). However, much work in bioethics shares community-oriented assumptions—that healthcare is special and different from market commodities, for example (Daniels), and may be seen as a good that is part of the common good (even by those who do not embrace communitarianism in other spheres of distributive justice) (Jecker and Jonsen). Similarly, many writers take relationships as the starting point of their ethic, rather than the individual (Murray).

Furthermore, even if society tries to remain neutral toward visions of the good life, ethical issues arise within the context of healthcare and require that the public institutions that provide medical treatment and conduct biomedical research somehow address such ethical dilemmas. As a result, pragmatists such as Jonathan Moreno embrace communitarian strands of thought in an effort to resolve such questions through the production of consensus (e.g., the creation of shared common understandings) (Moreno).

Communitarian Critiques of Liberalism

Communitarian critiques of liberalism have an intuitive appeal, and the nature of the critiques determine the kind of solutions that communitarians seek. It is again important to note that these critiques were developed mainly in the philosophical and political-theory literature and then imported to bioethics, often in a compressed fashion. Two different, but related, starting points form the basis of the communitarian criticisms.

LOSS OF SHARED COMMON UNDERSTANDING. Some communitarians, most notably the philosopher Alasdair MacIntyre, claim that liberalism will always fail to settle

ethical disagreements because of the loss of a shared common understanding, or of a shared view of the good life (MacIntyre, 1981). According to this view, ethical and moral concepts are only understandable within the framework of the traditions within which the concepts developed. Such traditions are marked by a shared vision of the good life. This vision is thought to contain a shared hierarchy of goods, and ethical disagreements are supposed to be resolved by reference to this hierarchy.

Such communitarians see the contemporary moral situation as dire. Because there is no shared vision of the good life within a liberal democratic society, they claim, there is no such thing as moral discourse. Although there may be the appearance of moral debate, such arguments tend to have a back-and-forth nature, mostly between rival conceptions that share few common assumptions. MacIntyre characterizes such discussions within our society as "shrill" and "interminable" (MacIntyre, 1981, pp. 8–12) The debates are shrill because, lacking the rational basis of a shared hierarchy of goods, rival conceptions can only advance their conclusions by the force of emotion. The debates are interminable because the force of emotion can produce no enduring consensus.

Societal discussion regarding bioethical issues is characterized as essentially being in bad faith. That is, bioethics must put forth public policy and some point to the developing of widespread consensus on several issues, but such consenses are said to be forced and sociological in nature (MacIntyre, 1984; 1990, pp. 226–227). For MacIntyre, the solution to the contemporary moral fragmentation is to build up from particular communities that share a vision of the good life, perhaps through sectarian universities, to the restoration of a shared common understanding of the good life (MacIntyre, pp. 220–223).

Similarly, a number of communitarians echo MacIntyre's criticism by highlighting the fact that liberal political theory embraces the *neutrality thesis* toward views of the good life. It is not that visions of the good life have mysteriously been lost from moral discourse. Rather they are, in principle, not allowed to form the basis of ethical quandaries or social policies (Larmore, 1987, pp. 42–55). The neutrality thesis can be illustrated by the suspicion with which religion is treated in the public sphere. Policy positions that are seen to emanate mainly from religious sentiments, sentiments that are expressions of a particular vision of the good life, are generally not considered viable options within public policy debates. Similarly, such positions, should they become the law of the land, can and are sometimes struck down by courts if they infringe on the liberty interests of the nonreligious.

Communitarians note that the state cannot remain neutral toward all elements of the good life. It is the role of the state to protect the life and liberty of its citizens and to foster opportunity among them (i.e., to foster the "pursuit of happiness"). Although safeguarding life, liberty, and the pursuit of happiness does not logically entail a vision of the good life, questions of what kind of life a society wishes to foster can be unavoidable in practice. Simply providing and mandating a specific minimum amount of such a value neutral commodity as education can be more conducive to some visions of the good life than to others. Given the inevitability of impacting on visions of the good life, communitarians often seek ways to produce consensus regarding the values to be fostered, or to create policy solutions that balance widely shared values.

LIBERALISM'S IMPOVERISHED VIEW OF THE PERSON. Communitarians can also begin by showing that liberal democracy is based on a certain view of human nature, and that this view is inadequate even for the purpose of establishing the moral aspirations that liberal democratic theorists hold dear.

Liberal theorists do not wish to set forth a vision of the good life. Nevertheless, thinkers such as John Rawls posit a view of what is essential to human nature. Rawls puts forward such a vision in order to provide support for the rationality of the choice of certain principles of justice to govern the basic institutions of society (Rawls, 1971, pp. 54–60). In other words, although no vision of the good life is essential to humans, *choosing* a vision of the good is what is essential to human beings. This self that is defined by choice and will, i.e., this *volitional self* is the justification for a view of society as fostering opportunity to pursue one's vision of the good life.

The communitarian critique of the volitional self points to the fact that this concept fails on its own terms. The political theorist Michael Sandel argues that this vision of human beings is too thin to actually justify the kind of contractarian liberalism that rests upon it. Liberalism typically includes a distributive or redistributive role for government to assist the least advantaged, an aspiration that is viewed as not justifiable when based on such a thin concept of the self. Justifying such an aspiration requires a view of human beings as deliberative and interrelational, not merely volitional and contractual. People are not static and fixed entities who mysteriously have a set vision of the good life that they pursue; they develop and refine values and preferences in social processes. As a result, political processes should be arranged to foster the deliberative capacities of citizens, not to count the preferences in a voting procedure (Emanuel, p. 232).

Liberalism includes a principle of sharing. John Rawls expresses this as the "difference principle" (Rawls, 1971, pp. 75–83). According to this principle, inequalities are allowed as long as they work to benefit the least advantaged. Because liberal theorists wish for a sharing principle to follow from the description of the volitional self, Rawls argues that citizens would choose this principle if they did not know which arbitrary advantages or disadvantages they would have by accident of birth or luck. This derivation of the difference principle follows deductively only if we assume that persons are highly risk-averse creatures and will go to great lengths to avoid being in the worst position, even if such an outcome would be unlikely. This is the position Rawls took in his early development of the "maximin principle" (Rawls, 1971, pp. 152–157).

One could also say that that the choice of the difference principle reflects the kind of choice that persons in a certain kind of historical community would make in virtue of their self-understanding. This is the position toward which Rawls moved in his later work. But, if reflection on the ideals of a community's self-understanding can be the basis for ethics, ethics can be based on more contentful concepts of the self, such as the communitarian's ideal of the self as deliberative and rational.

The Communitarian Concept of the Self

For the communitarian self, the pursuit and choice of the good life is a process that is interpretive and deliberative. Persons are born into, or thrown into, situations that contain fragments of traditions, values, customs, norms, and habits. However, these raw materials are continuously reinterpreted and reappropriated as circumstances evolve and change. Similarly, persons make choices, accumulate experience, and receive a variety of kinds of feedback. They modify, refine, or change their ends, or the means to those ends, based upon these life processes. In so doing, they come to know who they are. Being a "self" is therefore a process of self-discovery.

Being a person is also a process of mutual self-discovery (Kuczewski, 1997, pp. 51–56, 108–112). That is, a person not only makes his or her own plans and gathers feedback, but is also shaped by his or her response to, and participation in, the process of self-discovery of others. A person's identity is thereby inseparable from the life of the communities and societies in which the person participates. Of course, this is not the mere alignment of the projects and values of the person with the community. The person's identity is partially constituted by his or her community, even in the person's rejection of the community's values.

The essence of a person comes from the person's participation in the process of mutual self-discovery. Thus, for the communitarian, the ultimate question is always how to foster the development of a person's deliberative powers and create appropriate opportunities for exercising meaningful participation in communal deliberation. This heuristic applies to deliberation on levels of interpersonal encounters such as clinical decision making as well as societal decisions regarding the use of common resources.

Communitarian thought is obviously closely related to another neo-Aristotelian ethic, virtue theory. Communitarians hold that the concept of the person includes the notion of capacities that need to be developed to be a good citizen and good person. Virtue ethics takes the development of excellence of character as its end-point, its *telos*. That is, the virtuous person is what the community and social practices should aim to produce. There are few obvious points of tension between communitarianism and virtue ethics, and disputes would seem to be a matter of emphasis and tone. Communitarians are generally oriented to process, virtue theorists to outcome (i.e., character). But both emphasize the relationship and interdependence of the community and the deliberative capacities of its members.

The Methods of Communitarianism: Consensus from Fragmentation

Communitarianism is probably best characterized as a philosophy of public deliberation that tries to produce consensus on public matters—matters that include the topics typically considered in the field of bioethics. Of course, the important question is how to actually produce that consensus. Three general approaches predominate: the whole-tradition method, liberal communitarianism, and consensus in public judgment.

THE "WHOLE-TRADITION" METHOD: REVIVAL AND REVITALIZATION OF PARTICULAR TRADITIONS. The "whole tradition" method of communitarianism sees the fragmentation of values and traditions as an almost insurmountable problem. Communitarians such as the philosopher Alasdair MacIntyre and the Christian theologian Stanley Hauerwas view moral concepts as only intelligible within the traditions in which they originated. Moral traditions, therefore, contain concepts that are incommensurable with those of other traditions, and that are untranslatable because they only make sense within their respective traditions. As a result, moral method must take the form of reviving particular traditions.

MacIntyre proposes that moral discourse take the form of a competition among revitalized traditions. Each tradition would express itself through a university in which the tradition would express and develop its worldview across the disciplines. The ultimate test of a tradition is the degree to which it can create a comprehensive worldview that accounts for the facts of the contemporary world and can respond to new challenges and crises that arise. MacIntyre also holds open the possibility that one worldview may simply be developed that is comprehensive enough to encompass the truths and strengths of other traditions. He clearly believes that the Aristotelian-Thomistic tradition is the most promising in this regard (MacIntyre, 1990, p. 81).

The whole-tradition movement in communitarianism is the most radical and pessimistic form of communitarianism. It holds that there is (and can be) no genuine moral discourse in a pluralistic liberal society—and that the revival of whole traditions in toto is the only possible solution. Once such traditions are developed, people can choose among the views of the good life that are contained therein. The work required to bring this about is described by MacIntyre as being akin to the service that Saint Benedict and the monastic orders provided in keeping civilization alive during the medieval period.

LIBERAL COMMUNITARIANISM. Communal deliberation is intrinsic to communitarianism. So it is natural that some communitarians should propose that community members gather and deliberate to develop consensus. In bioethics, this approach is notably associated with the early work of Ezekiel J. Emanuel.

In his highly regarded book, *The Ends of Human Life: Medical Ethics in a Liberal Polity* (1991), Emanuel suggests that ethical decisions regarding medical care are best handled by the members of small cooperatives called Community Health Plans (CHPs). Members would have a choice of a variety of CHPs in their geographic area. In the early stages of the founding of the plan, members would articulate the fundamental value assumptions behind the plan. For instance, some CHPs could have a philosophy that is strongly geared toward preservation of biological life, while others might maximize palliative care options. Similarly, some might strongly favor choice in reproductive and contraceptive options, while others would promote religious approaches to family life. By organizing the CHPs according to nonnegotiable value choices, the CHP progresses easily beyond the shrill and interminable debates to the more subtle choices involved in developing a health plan.

In Emanuel's plan, each person would have a voucher that would be brought to the plan. As a result, the deliberation about values and coverage of treatments is also a resource-allocation process. Each member must think not only about his or her values in the abstract, but must consider how to balance the fiscal implications of those commitments against other values and potential needs. This discussion takes place within a communal dialogue among the approximately 10,000 members of the plan. In such a dialogue, a person comes to develop his or her deliberative capacities and refine and clarify his or her values.

The strength of such a proposal is that it embodies the virtues of a genuine deliberative democracy. Such a plan brings together the rights and responsibilities of each person, granting each the right to be true to his or her most fundamental value commitments, and to be self-determining in devising a health plan to meet those commitments. But, more importantly, it demands personal responsibility in accepting the allocation consequences of one's choices. One may choose to be part of a plan that explicitly provides a maximum amount of some services and minimizes other services, and one must live with the minimal services provided should he or she develop an illness that might benefit from a higher level of services. Because the plan respects the rights of each within a communal framework, it is sometimes called *liberal communitarianism.*

Of course, the proposal for CHPs suffers from the practical difficulties of any community-based initiative. Although our best selves may develop in a context of dialogue and deliberation, many persons will simply not wish to devote the time and energy needed to participate meaningfully. Emanuel acknowledges that the model of the New England town meeting (the model on which the CHP is based) usually becomes dominated by a small, highly participatory group in whom the silent majority comes to have confidence (Emanuel, pp. 231–232). However, if stable communal consensus can be developed in ways that do not require the direct participation of most citizens, such approaches may recommend themselves to communitarians.

CONSENSUS IN PUBLIC JUDGMENT. ***Proxy dialogue and balancing values.*** One of the striking facts concerning bioethics is that public debate has produced areas of stable consensus, most notably in the United States, concerning informed consent to treatment and the principles concerning end-of-life decision making. Similarly, some studies have suggested that the American people may, in general, be less fragmented in reference to their values than is usually thought to be the case. Contrary to the radical communitarians such as MacIntyre, there may be empirical reason to be optimistic that a society can achieve stable consensus on moral problems that occur within public and quasi-public institutions.

The public debate concerning informed consent and end-of-life decisions has not been one with a clearly identifiable locus, but has taken a variety of forms, including court decisions, state referenda, and the policy deliberations of institutions such as professional societies and accreditation agencies. The public has been informed in a variety of ways, including media coverage of court decisions, public education efforts when referenda are introduced, and portrayal of these issues in entertainment programming such as television medical dramas. Somehow, over time, a consensus has taken shape.

Consensus, in this context, has tended to mean a set of principles that are widely accepted. It does not mean unanimity, for a large pluralistic society will always include those who disagree. Similarly, the interpretation and application of the principles will constantly require refinement because of the wide variety of possible circumstances in which they may be needed. As a result, debate may seem to be ceaseless, but the object of the debates actually becomes more refined. For instance, the consensus on forgoing life-sustaining treatment includes a distinction between forgoing treatment and assisted suicide (though the state of Oregon does not adhere to this distinction in a substantive way). The consensus also holds that patients who have lost their decision-making capacity (i.e., they have been deemed "incompetent") have the same rights as other patients. While all U.S. states adhere to this general principle, the evidentiary standards regarding the incapacitated patient's prior wishes can differ substantially among states (Meisel, Snyder, and Quill). Although these are important disputes, they do not undermine the widely shared areas of agreement.

Of course, identifying that a society has achieved a stable consensus is not always a simple task. Public opinion polls can measure the public's views, but it is not always obvious when the data reflect a stable consensus. It is often the case that responses to poll questions reflect mere fleeting preferences. Although communitarianism is premised on the idea that people must come to discover their wishes, or how their values translate into preferences, how this happens on a grand scale is somewhat mysterious. However, some suggestions have been made.

First, a consensus is probably more stable if it is able to balance several competing values that are important to a society. For instance, the consensus on forgoing life-sustaining treatment has been relatively stable for more than a decade because it reflects the balancing of important values and considerations (Kuczewski, 2002). A patient's ability to participate in the decisions regarding his or her medical care, especially as one nears death, is fostered and balanced against the duty of society and the medical profession to protect patients, especially those who are vulnerable due to lack of decisional capacity. Policy proposals that tip the balance heavily in favor of patient self-determination, such as those for legalizing assisted suicide, have met with limited success. Similarly, proposals that eschew patient autonomy in favor of the physician's duty to do no harm, such as futility policies, continue to remain outside the consensus (Helft, Siegler, and Lantos).

Second, in situations in which the content of consensus gains widely shared acceptance without direct participation by the citizenry, some sort of "proxy dialogue" might have served as a substitute for direct participation (Yankelovich, 1999, p. 167). That is, representatives of various positions and interests might achieve recognition, and their interaction might forge a position that accommodates the major values at stake. By having the process play out publicly, the solution is internalized by much of the citizenry. Furthermore, consensus is semiperformative (Moreno, p. 52).

A consensus is furthered when an announcement is made that there is a consensus on certain points. People generally do not wish to overturn consensus for its own sake. Thus, when one announces consensus and proceeds to state the specific points, people will probably prefer to assent. This assent would seem more likely to be freely given if the citizens are able to recognize their values as being respected in the points of consensus. Dissent would seem more likely to follow if the consensus is ideological in the sense that it traces all its points to only one value or principle, rather than representing the array of values that are relevant to the issues under consideration. These values may be identified *a priori* by surveying the goods generally considered characteristic of a particular sphere of human activity (Walzer, pp. 6–10), or by empirical approaches that assess the values of the community involved.

Relationships, casuistry, and pragmatism. On the most pragmatic level, communitarians often approach ethical issues by beginning with the norms of the relationships involved, rather than the rights of the individual. In this way, communitarianism provides the foundational philosophical assumptions for the customary workings of popular methods in bioethics, such as casuistry, pragmatism, and the four-principles method. Bioethics, especially clinical bioethics, has often proceeded as if a number of persons have a stake in the outcome of the case, and that dialogue and negotiation leading to consensus are better than a simple assertion of one person's rights. These practices are more easily justified within a communitarian conception of the person as being essentially related to those around him or her than on the liberal conception of the individual. However, this does not necessarily result in a tyranny of the interests of the majority,

as there may be spheres of being in which individual rights are more authoritative, and irreconcilable conflicts may have to be resolved in favor of certain individuals no matter in which sphere of endeavor it takes place.

Casuists such as Albert Jonsen and Stephen Toulmin assert that that the kinds of norms that predominate in various types of cases result from the nature of the relationships involved in the particular case under examination. Cases in which the relationships are intimate are more generally decided in favor of values such as beneficence and caring. In these kinds of cases the boundaries between persons are fluid, and looking out for the good of the other is often called for by the situation. In impersonal situations, in which persons are more likely to be strangers, solutions are more often found in the direction of autonomy and individual rights. Nevertheless, specific circumstances can render these generalizations inapplicable, and some spheres of interaction (e.g., healthcare) can embody elements of both an ethics of strangers and an ethics of intimacy. As a result, paradigm cases for each kind of bioethical issue must be sought and taxonomies of paradigms and variations established (Jonsen and Toulmin, pp. 291–292).

Similarly, the famed *four principles* approach, also known as principlism, takes the physician-patient relationship as the starting point of medical ethics (Beauchamp and Childress, pp. 12–13). Principlists argue that ethical problems arise when any of the four main obligations of physicians to patients (respect for autonomy, nonmaleficence, beneficence, and justice) come into conflict with another of the principles. The goal then becomes to resolve this conflict of principles. This method assumes that members of society share a common morality, and that it is interpretable within the confines of the healthcare system (Beauchamp and Childress, pp. 401–405). These same assumptions are shared by many communitarian bioethicists. However, communitarian philosophers have made advances on the static understanding of the moral principles of the principlists. For instance, Emanuel's communitarianism includes a theory of the physician-patient relationship. This relationship, in its highest expression, focuses on helping the patient to interpret and discover his or her health-related values and how they apply to the choices before the patient (Emanuel and Emanuel). In this framework, patient autonomy is an essential element, but in many situations it is seen as the outcome of an interpersonal process rather than as the starting point of the interaction. Others with communitarian leanings focus on familial relationships as the starting point of an ethic.

Thomas Murray, a sociologist by training, argues that bioethics will make more progress toward consensus on controversial issues by starting with a tapestry of relationships that are prized by persons in a society. He notes that familial relationships are often among those that give distinctiveness to life. By creating such a tapestry, and describing the goods fostered therein, he believes that some of the so-called unending debates in bioethics can be defused. For instance, Murray asserts that conclusions in the abortion debate often exceed the premises and are inconsistent with other practices of adherents of the conclusions. Murray believes that the strength of the conclusions is probably a derivative from perceived threats to valued relationships (Murray, pp.173–174).

James and Hilde Nelson have begun the work of developing an ethics of intimate relationships that takes familial relationships as the starting point. This kind of work exemplifies the nuances of contemporary communitarian bioethics in that it results in generalizations about specific spheres of relationships. Furthermore, the kinds of generalizations that are developed give moral weight to those whose interests are most affected by situations, rather than invoking individual rights.

Applications

Radical whole-tradition communitarianism results in the most radical prescriptions, since it nullifies all rights claims and counsels a return to separate communities to work out a shared ethic. As we have seen, most communitarians have far more subtle prescriptions for facilitating the kind of public deliberation that they seek.

There are few attempts in the literature by communitarians to directly deduce conclusions from communitarian premises. One might expect that communitarians will be more sympathetic to the common good in weighing solutions to ethical problems. It is true that some communitarians have favored aggressive approaches to organ procurement for transplantation (Nelson), mandatory rationing to resolve resource-allocation problems (Callahan, 1990), and public health concerns over individual privacy and choice (Etzioni). However, none of these positions are necessarily entailed by communitarian sympathies as one can easily argue that these same policies foster values the community should reject. As a result, communitarianism continues to be an approach to bioethics that is more about process than particular outcomes.

COMPASSIONATE LOVE

• • •

Compassionate love describes attitudes toward and service for others, motivated by a desire for the good of the other. It includes caring for, valuing, and respecting the person so loved. The combination of the two words "compassionate" and "love" highlights features in both words: this combination describes sympathy towards the other, in a way that is

caring, respectful, and appropriately emotionally engaged, which leads to appropriate action in service of the other person. Compassionate love can operate through the relief of suffering, but also through acknowledging life's full possibilities and making space for each human being to reach his or her potential. Compassionate love encourages fullness of life in the other. By the early twenty-first century, compassionate love was also bolstered by scientific research and incorporated into a social science model. It provides a sound concept to guide action benefiting those who are in need, in various situations. Compassionate love is a valuable quality to bring to the care of those who are sick, and would be beneficial to include in treatment, care, and decision making.

Definitional Issues

Some of the most noble human actions are those that express compassionate love. A person acting with compassionate love perceives the suffering, needs, or potential of another, and chooses to act in ways that can better the condition of the other, placing the other's needs in higher priority. There are other moments when one sets aside selfish needs for those of others, when one expresses to others, by words or actions, that they are of value. This occurs in both professional and personal relationships. To contribute to a better understanding of the concept, some definitional points are helpful. Important features of compassionate love include:

(1) free choice;
(2) some degree of cognitive understanding of the situation;
(3) some understanding of self;
(4) fundamentally valuing the other;
(5) openness and receptivity; and
(6) a response of the heart (heart is here defined as "core," where emotions and cognition integrate).

The particular nature of individual personalities, social setting, cultural setting, genetic predisposition, and other factors limit the freedom of individuals. This makes up the substrate, the basic starting situation, in which individuals begin to act with compassionate love. This starting point is different for each person, and situations in which action takes place differ as well.

The full expression of compassionate love towards those who are ill relies on appropriate motive. Although helpful behaviors are good and useful, and can contribute to the well-being of another, motives focused more on the self than on the other can decrease the positive effect on the person being served, as well as on the moral growth of the individual giving the love. There are many attitudes that can diminish motives, such that they are less likely to result in compassionate love being fully expressed. These include a variety of possible needs or wants for the self: guilt, fear, needs for love and success, fears of failure, desire to claim the upper hand, reputation. Motives are usually mixed, but when self-centered needs predominate, compassionate love cannot be fully expressed.

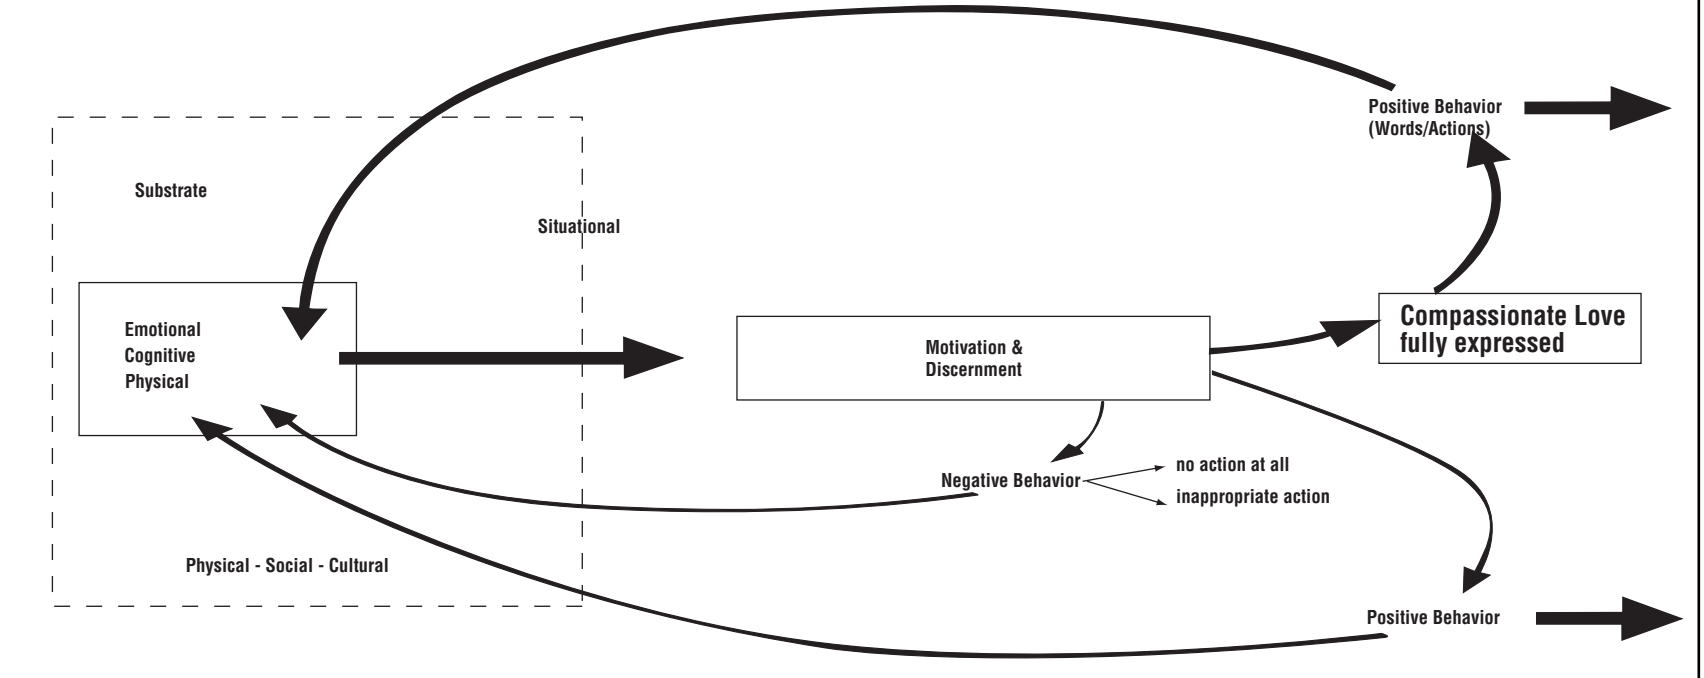
Research Model

Research specifically on compassionate love is needed in order to determine how best to foster this quality in people's lives, and to assess the particular impact of this quality in the care of the sick. Results from research can help to give appropriate priority to this quality in the training of healthcare providers, and in the settings and circumstances provided for those who are sick. In order to do adequate research on compassionate love, it is important to clearly articulate the various essential components, the conditions that might foster and those that might impede its expression, and to develop methodologies for assessment. There are over fifty large research projects specifically gathering data on this topic, some in healthcare settings.

Figure 1 illustrates a research model that has shown promise in this area. It starts with the substrates discussed previously. Given those starting points, as one encounters a specific person in a specific situation, one must make a decision to act (shown centrally in the figure), and a motive drives that decision. Motive is particularly hard to research, but there are some ways to begin to investigate it, such as experimental models (especially those from economics and social psychology), implicit-explicit models, observational studies with multiple actions, insightful self-report, and neural imaging. When motives for self outweigh those for others, or there is an inappropriate action given the various factors to be considered, the result is frequently negative for the person being served. Good actions can also emerge from motives not full of compassionate love, such as the motive to look good in the eyes of others or to feel needed, but ultimately the feedback of repeating these kinds of behaviors on the moral development of the healthcare provider can be detrimental. It is also possible that the more self-centered, condescending, or less respectful motive is noticed by the sick person, and care is not as effective. These kinds of motives can also adversely affect discernment of appropriate care for the sick person.

In the center of the model is both motive and discernment. Compassionate love fully expressed is not just good intentions, but doing what is really good for the other. This kind of discernment occurs continually in healthcare settings. Short-term distress may be necessary to serve the longer-term interests of a sick person. Weighing the relative

FIGURE 1



SOURCE: Underwood, 2002.

needs of others, including appropriate care for self, is also critical to good discernment leading to effective actions.

Revised "Professional Distance"

Compassionate love is not the same as romantic love, familial love, or affection, although it can accompany these other forms of love and blend with them. The professional in a healthcare setting needs to avoid becoming too attached to the patient, and compassionate love allows for this. In fact, one critical aspect of compassionate love is that it is not a "need love," the kind of love that focuses on the needs of the person giving love. In its focus on the needs of the other, compassionate love's non-attachment is very harmonious with the concept of "professional distance," but actually can be more satisfying to both the patient and healthcare provider: it enables an emotional component to be appropriately engaged, if that is called for in the specific setting.

Improving Well-Being and Health

In the United States and many other medical healthcare systems, a fee for service operating basis, or fee for time, results primarily in action from duty and obligation. However, there is leeway even within this operating system that provides opportunity to "go the extra mile for the patient," or engage in compassionate caring for the sick person.

Initial research has shown that empathy, valuing the patient, and giving the patient a sense that he or she is understood can be powerful factors in contributing to improvements in health outcomes, both through increases in adherence to regimens and more direct effects. Ongoing research is exploring whether increasing compassionate love on the part of the healthcare provider can improve patient outcomes.

It is generally acknowledged that there exists a placebo effect in medical treatments, such that placebos, usually inert substances, are included in most major clinical trials; the various constituents of this effect are currently unknown. Conditioning, optimism, improved self-efficacy, and natural regression to the mean are some of the most frequently cited mechanisms, but the role of the patient-provider relationship on outcomes is just beginning to be explored fully as a part of the placebo effect. Compassionate love is one of the components patients report as being important to them: being valued, feeling understood, feeling cared for, having a provider that goes beyond mere duty. This attitude of the healthcare provider can encourage the sick person to better adhere to medication regimes, and with a more positive attitude toward themselves, exert better efforts towards self-care and preventive measures. There may also be additional effects on health.

The therapeutic relationship is important for the person who is ill, as has long been asserted in psychotherapy. From the ill person's point of view, feeling valued, cared about, and understood is important, and this works synergistically with the actual treatment—even in treatment for physical illness. This kind of care also can contribute significantly to the well-being of the ill person in areas where health cannot be significantly improved, such as chronic progressive illness and end of life care. This is not a minor issue for healthcare in the twenty-first century context of a continually aging population, and extensive chronic diseases.

Effects on the Healthcare Provider or Administrator

As described in the model (Figure 1), various substrate factors affect the ability to give compassionate love. Supportive factors can be provided by the healthcare organizational structure, cultural setting, family, religious background, relationships, and others in the healthcare organization. Support from these sources helps to avoid the burnout problem that can occur when one's work focuses continually on those in need. Supportive elements can provide the strength needed to sustain those who care for others.

Outside of the work setting, social relationships, community involvement, family, and religious institutions encourage the healthcare provider's ability and desire to act with compassionate love. Many religions and particular social micro-cultures value this quality, and the nesting of the impetus to act within a religious or social context is useful, as it can provide an infrastructure and additional reinforcement for attitudes and actions.

One who gives compassionate love is also significantly affected by feedback from the one helped. When a good balance (see Figure 2) exists as decisions are made, and the motivation is well grounded, giving compassionate love fully can be satisfying and strengthening to the one who gives it. Feedback from patients can provide a real, positive input for this kind of work, and the ability to express this quality and engage the self more fully in care can be satisfying and add to one's own well-being. This can enable the healthcare provider or administrator to gain more joy from their job.

Compassionate Love within the Social Network

Social support can contribute positively to a person's health. Compassionate love is nested within social relationships,

and it is not only the healthcare provider who improves health and quality of life, but also people within the sick person's social support network. This idea is central to providing healthcare systems and healthcare that value and nurture supportive relationships. Although material support in and of itself is important, scientific literature continually illustrates the value of emotional support. The concept of compassionate love as a contribution to quality of life and well-being can be particularly powerful, and in 2003 is being studied in a variety of social contexts, including a World Health Organization study of contributors to quality of life.

Both the giving and receiving of support can improve well-being and quality of life. Those who are sick generally do not want pity; they want others to help them and understand them and care about them, but also, unless totally incapacitated, they want to give to others, and want to feel of use. One study of pain patients conducted by Frank Keefe, Ph.D at Duke University, is examining the use of a "loving kindness meditation," a Buddhist-inspired practice that has patients dwell on compassionate love for themselves, close friends, those they have trouble with, and the whole world, to help those with pain experience less suffering. When sick people are enabled and encouraged to have good relationships with those around them, they can give to others within the constraints of their situation and this can be an additional positive outcome.

Making Healthcare Decisions

During a National Institutes of Health conference with the goal of setting a research agenda for end of life care in November of 2001, the physicians and nurses involved in care for patients and their families, the qualitative researchers, the economists, and those representing hospice and nursing homes identified a central theme: the importance of what the patient values, and what society values, as decisions needed to be made. Compassionate love, which includes valuing the other fully, action and attitude driven by other-centered motivations, and clear discernment as to the most caring action, can effectively guide healthcare decisions and policies. In a study of over four thousand people from various cultures and religions worldwide, conducted by the World Health Organization, and presented by Kate O'Connell at the International Quality of Life meeting in Amsterdam in November of 2001, it was found that issues of being loved, cared for, and accepted contribute significantly to overall qualtiy of life, over and above basic health indicators.

Compassionate love requires that decisions be considered through a lens that views the other as having significant value. Decision-making based in compassionate love also can include various more consciously-articulated ways of weighing competing factors (Figure 2). For example, the immediate desires of the patient may not be in the patient's long term interest, and therefore immediate relief of suffering is not always the most compassionately loving act. Decision-making that incorporates these qualities and complexities into the process can result in better decisions for both the cared-for and the caregiver. By including compassionate love in decision-making, the caregiver can better address the needs of the patient and enable a fuller expression of the humanity of the healthcare provider.

Conclusion

As a guide for action in healthcare settings, compassionate love can lift the care of the sick from a duty to be carried out to satisfying caring with joy. Attitudes toward and care for those who are ill are enriched by taking a respectful, caring, understanding approach that values each individual. The sick person can benefit substantially from this, and various social and behavioral sciences are contributing to a body of literature demonstrating how compassionate love positively affects health. Structural changes in healthcare environments and payment models need to adopt the value of compassionate love in order to improve care.

COMPETENCE

• • •

Competence is a necessary condition before a physician can accept a patient's treatment consent or refusal. Competence confers decision-making authority on those who are competent, while disenfranchising those who are not (Beauchamp). A determination of patient competence promotes respect for self-determination as well as patient participation in healthcare and other decision making. In most nonemergency situations, those who are legally competent may consent to or refuse healthcare. A patient maintained for years on outpatient hemodialysis, for example, may be allowed to terminate hemodialysis, resulting in death, if the patient decides that he or she can no longer tolerate the stress of the

procedure (Neu and Kjellstrand). And based upon religious reasons, a Jehovah's Witness may even refuse a blood transfusion that would otherwise save his or her life. In contrast, the consent or refusal of those who are legally incompetent or clinically incapacitated need not be respected. A psychotic woman who refuses to have a cardiac pacemaker inserted because she believes that others could then monitor and control her activities would not be permitted to refuse this lifesustaining surgical procedure. Competence is usually not a relevant issue in healthcare emergencies, when treatment delay would be substantially harmful to the patient.

Competence and autonomy are often conflated, although their meanings are quite distinguishable (Beauchamp). Competence allows a person to exercise his or her autonomy. One must be autonomous to be competent, yet competent persons may act nonautonomously when, for example, compelled to do so by another person. Further, an autonomous person may act incompetently (e.g., a professional negligent at work).

This entry considers some of the issues in defining, determining, and assessing competence, as well as some of the applications of competence to the field of mental healthcare.

Definitions

Generically, "competence" means simply the ability to perform a particular task (Beauchamp), although it has often been used loosely in several senses. In healthcare contexts, competence is the capacity to make autonomous healthcare decisions (Morreim). In most accounts of competence, competence is specific to the task or issue, since a person may be able to perform one task but not another. Few people are globally competent or incompetent. Since one's abilities change over time, in either direction, competence is also specific to time. Abilities may also be a function of the conditions or the situation in which they are tested or the person who tests them.

Competencies, of course, relate to all areas of function (Grisso). While competence to consent to healthcare or research is of primary concern in the present context, issues are often raised about a person's ability to work, manage personal finances, make a contract, write a will, live independently, drive a car, marry and divorce, parent a child, or testify in court. In legal contexts, competence questions arise in civil actions as well as in criminal litigation (competence to stand trial, commit a crime, enter a plea, or be sentenced) (Bonnie). Legal competencies implicate past decision making (e.g., competence to write a will), present decision making (e.g., competence to stand trial), or future decision making (e.g., competence to manage one's financial affairs).

A person's competence may be questioned in more than one area. In the case of a mother with cancer and a psychotic depressive disorder who is separated from her husband, for example, questions may arise about her capacity to parent her children, manage her finances, and consent to medical or psychiatric care. If she were employed, questions may arise about her ability to function at work if she failed to meet deadlines or otherwise fulfill her job duties due to a medical or psychiatric disorder. Her or her husband's attorney may question her ability to consult with her attorney and participate in the divorce litigation.

This contextualized, decision-specific notion of competence may be contrasted with a more generalized conception that reflects the general legal and moral autonomy enjoyed by most adults in contemporary Western cultures (Wear). Many more adults are considered competent under the general conception than the task-specific one; therefore, establishing that a person is incompetent is more difficult under the former than the latter.

"Incompetence" has come to mean the loss in court of a person's legal right to function in some particular area. Such a narrow legal definition of competence or incompetence contrasts with the more common clinical use of incompetence according to which a person has a legal right to function but is unable to do so. Clinical and legal competence may not correspond. An elderly, demented person, for example, may have the legal right to drive a car or make his or her own healthcare decisions but may no longer be substantially able to do so. Similarly, an adolescent may not be legally competent to consent to healthcare but may be clinically or functionally able to do so.

The increasingly prevalent view is that individuals have various specific abilities or capacities as well as incapacities, each along a continuum. A person is considered incapacitated when the person is no longer able to perform that specific function and incompetent when a court has so ruled. Legally, there is a presumption of competence, which may be overcome when the court is presented with adequate evidence of incapacitation. In the clinical literature, however, competence refers either to an individual's capacities (a descriptive definition) or to whether that individual's particular capacities are sufficient to render legal decision-making authority to him or her (a threshold definition).

Finally, although competence usually refers to a person's abilities, it may also refer to his or her actions or behavior (Beauchamp). For example, a person of general competence may autonomously choose to act incompetently in a given situation (e.g., intentionally fail an examination).

Managing Incompetence

Because functional or decision-making capacities occur on a continuum and because a person's capacities can be expected to fluctuate over time, in most cases a clinician need not be resigned to accept a patient as permanently incapacitated. The clinician frequently has opportunities to enhance the person's functional or decision-making capacity. Hearing aids, eyeglasses, psychotropic medication, counseling and psychotherapy, and specific behavioral training in the area of incapacity are examples of remedial efforts that can be made to improve a person's capacity. When such efforts fail, disposition of those who are incapacitated is a complex matter and varies with the context in question. In a case where life-saving treatment may be needed, the clinician may have to obtain an adjudication of legal incompetence in order to treat an incompetent refusing patient.

Although competence is a necessary precondition to respecting patient choice, incompetence is not a sufficient condition to overriding it, contrary to much clinical and lay understanding. The clinician may wish to, and often should, respect a person's preferences even if the person is legally incompetent or functionally incapacitated. The clinician may ask a young boy with which parent he prefers to live following his parents' divorce; the clinician probably will ask an elderly, demented woman whom she prefers to manage her estate should the appointment of a legal guardian be authorized.

Before intervening over the person's objection, the clinician needs to specifically assess the risks, benefits, and alternatives; this includes an evaluation of the potential harms of a proposed intervention to the person. Overriding treatment refusals, whether by a healthcare professional, family member, or court, ethically and legally requires evidence that (1) such treatment would benefit the patient (the "best interests" test); (2) such treatment would have been the decision of the patient had he or she been able to make the decision (the "substituted judgment" test); or (3) the patient had provided some previous direction or instruction about the treatment in question ("expressed interest" test). The test of substitute decision making varies with the decision, the decision maker, and the legal jurisdiction. Use of the substituted-judgment or the expressed interest test, in contrast to the best-interests test, better respects the person's autonomy and self-determination.

Competence Criteria

There is no international clinical, legal, philosophical, or ethical consensus about competence criteria or standards, and many are in use. In other words, there is no agreement about the threshold of decision-making or functional capacity necessary to consider a person legally or morally competent. In a given case, there may be wide consensus among clinicians, legal professionals, and ethicists that a particular person is, or is not, competent in some respect; however, disagreement is likely in many cases. In part, this derives from the fact that competence determinations are not essentially factual, objective, or empirical matters but rather are value-laden judgments about the relative importance of autonomy and beneficence to the person, as assessed by the clinician or others. Competence is typically inferred from the person's behavior and thinking rather than observed directly, and evaluators may differ in their judgment of the person's competence. Such differences about the person's competence occur in part due to evaluators' varying perceptions of the person's values or of the person's rationality. Under the most common view, competence is not a fixed property of an individual applicable to all decisions and all potential risks; rather, competence is a context-dependent, decision-specific, interpersonal process (Buchanan and Brock; Drane).

Criteria for competence involve whether the person can make a choice, communicate that choice, understand relevant information about the choice and its alternatives, and rationally manipulate information about the choice and its alternatives (Appelbaum and Grisso). The person must be able to apply the relevant information about a prospective decision to his or her own case rather than in the abstract or as applied to someone else.

The influential U.S. President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research adopted a standard of capacity that requires (1) possession of a set of values and goals; (2) the ability to communicate and to understand information; and (3) the ability to reason and to deliberate about one's choices (U.S. President's Commission). This standard emphasizes the process of reasoning or decision making rather than the particular outcome of the decision. A competence standard that focuses upon the outcome of the decision can be faulted for granting greater priority to the values of the person assessing the patient's competence than to the values of the patient.

A similar definition of competence is offered by the Canadian province of Ontario: "Mentally competent means having the ability to understand the subject-matter in respect of which consent is requested and able to appreciate the consequences of giving or withholding consent" (Ontario Ministry of Health). This "appreciation" component,

however, involves emotional rather than strictly cognitive considerations, and broadens the competence standard.

As noted by the U.S. President's Commission, assessment of the individual's current and previous personal values is an essential component of evaluating competence. Obtaining a values history for the individual provides critical information about the person's past major life decisions relevant to the present decision making. Judgments about a person's competence must be individualized according to his or her attitudes and values history rather than reflect only the person's knowledge, skills, and cognitive capacities.

It is unrealistic to expect that competence criteria are, or will remain, fixed over time. Competence criteria are likely to evolve as society seeks to resolve the conflict between the competing principles of respect for autonomy and concern for the person's well-being.

SLIDING SCALE OF COMPETENCE CRITERIA. The predominant approach to selecting competence criteria, at least with regard to competence to consent to healthcare, depends on the actual decision at issue. In this scheme, named the "sliding scale," the criteria for competence vary with the particular decision and its risks and benefits. As the risks of the proposed healthcare increase or as the benefits to the proposed healthcare decrease, more capacity is required for the patient to be considered competent to consent to the healthcare (Drane; Roth et al.). For example, it is less difficult to decide to consent to a course of conventional antibiotic medication for a urinary tract infection than a course of experimental chemotherapy for stomach cancer, and less capacity should be required to do so. Likewise, more capacity is required for the patient to be considered competent to refuse healthcare when its risks decrease or its benefits increase.

Although the sliding-scale approach to competence criteria is commonly used in healthcare decision making, some problems accompany its use. Given the strong bias of healthcare professionals—and society—in favor of treatment, one concern is that professionals will manipulate or selectively use those competence criteria that result in labeling competent someone who consents to healthcare, while labeling incompetent someone who refuses care. Another concern of the variable standard approach is that, counterintuitively, a patient could be considered competent to consent to a particular intervention but incompetent to refuse that same intervention (Buchanan and Brock). This may occur because refusing healthcare is more complicated than consenting to it, but here too a protreatment bias is evident.

Competence Assessments

Clinicians frequently make informal judgments about a patient's competence in their daily work; but some cases, such as treatment refusals or consents by questionably competent patients, necessitate formal, detailed assessments. Competence assessments should focus on the specific area of function in question. Assessments of global or general competence are unlikely to adequately respond to the presenting question. Among the procedural considerations in conducting competence assessments, the time and place of examination and the need for reexamination are especially important (Weiner and Wettstein). These assessments sometimes use written structured or formal assessment inventories of functioning, observational functional assessments (e.g., observing a patient grocery shopping and preparing a meal), psychological testing, or formal psychiatric interviews. History taking and collateral reports from third-party informants such as family, friends, and other healthcare personnel can be valuable additions to individual contact with the person being assessed. The examiner pays particular attention to eliciting information about the patient's decision-making history and the values he or she has placed on personal autonomy, healthcare, disability, and death. Consultations with colleagues or second opinions may also be helpful to the examiner in difficult cases. In general medical hospitals, competence assessments are conducted initially by nonpsychiatric physicians; if necessary, psychiatric consultants are called to assist in the evaluation.

Competence assessments raise many problematic clinical issues including denial of illness; subtle forms of incapacity; impact of elevated or depressed mood on decision-making capacity; fluctuating mental status (due to intermittent treatment compliance, the natural course of the disorder, or side effects of treatment); treatment refusals based on religious reasons; lack of information about the patient, including personal values and goals or history of treatment refusals; lack of formal staff training to do competence assessments; and disagreements among staff about the appropriate competence criteria or threshold. Typically, competence is not challenged, investigated, or formally assessed in clinical practice until a patient refuses treatment or is noncompliant with it.

Competence and Mental Healthcare

The presence of a mental disorder does not automatically negate the presumption of a person's competence. Although some severely mental ill persons are indeed incapacitated in many areas of their functioning, most mentally ill persons

have only some discrete areas of decision-making incapacity, often confined to episodes of their illness. A paranoid delusional patient who denies that he is mentally ill, for example, may be unable to rationally decide whether or not to consent to antipsychotic medication while he is mentally ill but may have adequate decision-making ability to consent to treatment for diabetes and heart disease. In such a case, the content of the patient's paranoid delusions would be irrelevant to the patient's diabetes and heart disease, and the patient would not deny the fact of his medical illnesses. A patient in a manic episode may be unable to manage his finances because he will rapidly dissipate them, but his decision-making capacity will return as the episode ends. Subtle forms of decision-making incapacity can also arise from mildly altered mood states (depression, hopelessness, anxiety, euphoria), from cognitive dysfunction (impairment in memory or attention from head injury), or from personality traits (guilt, self-punishment, feelings of worthlessness).

COMPETENCE TO REFUSE PSYCHOTROPIC MEDICATION. In contrast to admission to a medical-surgical hospital, admission to a psychiatric hospital may be accomplished by voluntary or involuntary means. In either facility, however, there may be uncertainty about the patient's ability to consent to voluntary hospitalization. Patients who are demented or seriously depressed or psychotic often have difficulty understanding that they are ill, need treatment, or should be hospitalized. They may have difficulty comprehending the risks and benefits of treatment and hospitalization. Nevertheless, decisions about the person's ability to consent to voluntary hospitalization precede, and differ from, decisions about the person's ability, once hospitalized, to consent to treatment with medication.

Managing a person's refusal of psychotropic medication (e.g., antipsychotic or antidepressant medication), once he or she has been hospitalized, has been one of the most controversial issues in mental healthcare in recent years. Before the 1980s, many rejected the notion of a psychiatric patient's right to refuse medication, suggesting that the purpose of psychiatric hospitalization would be defeated if patients were permitted to refuse treatment with medication (Appelbaum, 1988). In part, the controversy about involuntary treatment of psychiatric inpatients with medication arose from the nature and effects of psychotropic medication. Psychotropic medications have been viewed somewhat inaccurately as powerful and dangerous substances whose use is akin to "mind control." Their risks, whether short-term dry mouth and constipation or long-term involuntary movement disorders, relative to their benefits, the treatment of the mental disorder, have been greatly exaggerated, at least by many attorneys and courts (Gutheil and Appelbaum).

Once patients enter psychiatric hospitals, especially on an involuntary basis by court order, they sometimes refuse recommended treatment with psychotropic medication, particularly antipsychotic medication. Patients refuse treatment based on problems in the physician-patient relationship, such as rebelliousness towards authority figures and reality-based side effects of medication (e.g., dry mouth, constipation, weight gain, restlessness), or most relevant in the present context, symptoms of the patient's illness, such as a delusional belief that the medication is poison. Decisions about hospitalizing a person involuntarily differ from those about medicating that person involuntarily once hospitalized; the former are largely a function of the person's future risk of violence to self or others due to a mental disorder, while the latter usually depend upon the person's ability to make decisions about accepting medication or his or her best interests. An involuntarily hospitalized patient, even one committed by a court, is not necessarily deemed unable to consent to medication. In most cases, a person who has been involuntarily hospitalized does not lose the legal right to object to or to refuse medication.

Voluntarily hospitalized patients who refuse medication for whatever reason may not be medicated involuntarily, except briefly in emergency situations. It is argued that patient autonomy regarding treatment refusal should be respected despite the consequences of continued illness, hospitalization, and incapacity. This legal right to refuse medication is based on the patient's right to free speech and thought, to freedom from bodily intrusion, the right to bodily integrity, a ban on cruel punishment, and the right to autonomy and self-determination.

Nevertheless, involuntarily hospitalized patients who refuse medication may sometimes be medicated involuntarily in nonemergency situations, as well as briefly in emergencies. Many states in the United States use a judicial model for these cases in which forced medication of involuntarily hospitalized patients may be accomplished only after a judicial hearing and court determination that the patient is incompetent to refuse the mediation because of the mental illness (Weiner and Wettstein). A substitute decision maker is sometimes appointed by the court to determine whether the patient should be compelled to take medication. This is the same procedure that would be followed if the physician sought involuntary surgery (e.g., amputation of a gangrenous extremity) on the patient. In contrast, in some U.S. states and in some Canadian provinces, the attending physician or a medical or administrative review panel decides whether or not to override the patient's refusal; the patient may then appeal the physician or panel's decision to involuntarily medicate to a court (Weiner and Wettstein; Ontario

Ministry of Health). In England, the Mental Health Act of 1983 permits the treating physician to authorize medication for up to three months to an incompetently refusing, involuntarily hospitalized patient (section 56); after that, a second physician opinion is needed to continue the involuntary treatment (section 58) (Appelbaum, 1985). In this nonjudicial model, the patient's decision-making capacity about medication as assessed by the attending physician may still be the most important factor in the disposition of the case. However, the U.S. Supreme Court has held that decision-making capacity is not relevant to determining whether prisoners should be medicated involuntarily with psychotropic drugs (*Washington v. Harper*).

According to empirical data about the right to refuse psychotropic medication, the judicial-review model, using a formal incompetence declaration, carries substantial fiscal costs, given the delays inherent in obtaining the required court hearing. It also involves prolonged periods of nontreatment pending the hearing, which often results in injuries to the patient, other patients, and staff (Ciccone et al.; Hoge et al.). Few courts ultimately grant the patient a right to refuse medication.

COMPETENCE FOR EXECUTION. According to U.S. law civil or criminal litigants must be legally competent before they can bring suit or have suit brought against them. In criminal law, defendants must be competent to stand trial, plead guilty, be sentenced, or be executed before those proceedings can occur.

Executing a person who is considered incompetent (i.e., "insane") at the time of execution, as opposed to at the time of the crime, has been ruled unconstitutional by the U.S. Supreme Court (*Ford* v. *Wainwright*). Execution in such cases offends humanity, has no deterrent value to others, and offers no retribution to the condemned person. The courts, however, have yet to articulate a competence standard by which to adjudicate a death-row inmate as incompetent (Winick).

The courts have not yet decided whether, once death-row inmates have been found incompetent, the state may involuntarily medicate them to restore competence and then execute them (*Louisiana* v. *Perry*). Such an eventuality places the treating psychiatrist, who ethically must not participate in an execution, in a difficult dilemma: Medicate the inmate to relieve suffering, which leads to the inmate's death, or do not medicate the inmate, which spares the inmate's life but fails to reduce suffering (Heilbrun et al.). Only automatic commutation of an incompetent death-row inmate to life in prison would definitively resolve the matter.

Conclusion

Whether in healthcare, financial, legal, or any other area of decision making, the stakes for both persons and professionals in competence definitions are substantial. Identifying and labeling someone as incompetent can be stigmatizing and deprives the person of self-determination. Legal and healthcare delivery systems are then confronted with, and disrupted by, the need for surrogate decision making for the incapacitated or incompetent person. On the other hand, failure to protect the incapacitated person from making erroneous and harmful decisions (e.g., refusing necessary medical care) may not honor the person's best interests. The question then is when and how to respect people's choices and maximize their decision-making autonomy while protecting them from their own harmful choices (Drane). In most cases in the healthcare system, clinicians agree that the person should, or should not, be considered competent, even if there is no universal consensus on how much rationality and understanding are sufficient for the person to be considered legally competent and granted authority to decide for him- or herself. Still, there are other cases in which judgments about the person's decision-making capacity are problematic, and clinicians, administrators, patients, families, and the courts become involved in emotionally charged disputes about how to manage the person's medical care. Such cases are unlikely to abate in the future as long as our society continues to value, and attempts to balance, autonomy and beneficence.

CONFIDENTIALITY

• • •

Confidentiality has its roots in the human practice of sharing and keeping secrets (Bok). For children, the desire to keep a secret is a manifestation of an emerging sense of self; the desire to share a secret stems from a need to retain or establish intimate relationships with others (Ekstein and Caruth). The willingness to share secrets presupposes an implicit trust or an explicit promise that they will be dept. Keeping and sharing secrets is a more complex social practice among adults. Some adults keep secrets simply to preserve their personal privacy; others may have something illegal or immoral to hide. Some persons do not reveal private thoughts, feelings, or behavior for fear of embarrassment, exploitation, stigmatization, or discrimination. Still others feel a need to disclose secrets to others to help resolve emotional conflicts or seek solutions to problems arising out of interpersonal

relationships. The sharing and keeping of secrets among friends, for instance, creates a context in which ethical issues concerning promises, trust, loyalty, and interests of others may come into conflict. For example, I may promise a friend to keep a secret that she feels an urgent need to tell me. She trusts me not to tell anyone else about her revelation. Out of loyalty to my friend, I promise in advance to keep her secret. But I am thrown into a moral conflict when she unexpectedly discloses her impulse and plan to kill a family member who she believes is plotting against her. I realize that my obligations to keep my promise and preserve loyalty and trust conflict with a desire, if not a responsibility, to prevent my friend's harm to herself as well as serious harm to another. Do I preserve confidentiality or protect others? Similar ethical conflicts arise for health professionals and their clients or patients.

The following discussion clarifies the concept of confidentiality and the related ideas of privacy and privileged communication in healthcare settings. The rights of clients/patients and the responsibilities of health professionals to their clients, their professions, and society bring out key ethical issues. Legal regulations both protect and limit confidentiality, sometimes in ways that create ethical conflicts for clients as well as professionals. In healthcare contexts neither absolute protection nor total abandonment of confidentiality is plausible. Yet sometimes it is uncertain where boundaries should be drawn because legitimate interests come into conflict. Personal privacy, professional integrity, effective care, economic considerations, and public health and safety influence both general policies and specific practices concerning confidentiality.

Conceptual Analysis

Confidentiality is closely related to the broad concept of privacy and the narrower concept of privileged communications. All three concepts share the idea of limiting access of others in certain respects (Gavison; Allen). Privacy refers to limiting access of others to one's body or mind, such as through physical contact or disclosure of thoughts or feelings. The idea of limited access describes privacy in a neutral way. But privacy is closely linked to normative values. Privacy is usually thought to be good; it is something that individuals typically desire to preserve, protect, and control. Thus privacy and a right to privacy are sometimes not clearly distinguished. In law and ethics "privacy" usually refers to privacy rights as well as limited access. Thus, privacy in law is linked to freedom from intrusion by the state or third persons. It may designate a domain of personal decision, usually about important matters such as personal associations, abortion, or bodily integrity.

Confidentiality concerns the communication of private and personal information from one person to another where it is expected that the recipient of the information, such as a health professional, will not ordinarily disclose the confidential information to third persons. In other words, other persons, unless properly authorized, have limited access to confidential information. Confidentiality, like privacy, is valued because it protects individual preferences and rights.

Privileged communications are those confidential communications that the law protects against disclosure in legal settings. Once again, others have limited access to confidential information. A person who has disclosed private information to a spouse or certain professionals (doctor, lawyer, priest, psychotherapist) may restrict his or her testimony in a legal context, subject to certain exceptions (Smith-Bell and Winslade; Weiner and Wettstein).

Privacy and confidentiality are alike in that each stands as a polar opposite to the idea of "public": what is private and confidential is not public. Yet privacy and confidentiality are not the same. Privacy can refer to singular features of persons, such as privacy of thoughts, feelings, or fantasies. Confidentiality always refers to relational contexts involving two or more persons. Privacy can also refer to relational contexts, such as privacy of personal associations or private records. Thus, in this respect the concepts overlap. In many relational contexts the terms "privacy" and "confidentiality" are used interchangeably and sometimes loosely. Professional codes of ethics, for example, often use these terms in this way (Winslade and Ross).

It should be noted, however, that privacy and confidentiality are significantly different in one important respect. Relinquishing personal privacy is a precondition for establishing confidentiality. Confidentiality requires a relationship of at least two persons, one of whom exposes or discloses private data to the other. An expectation of confidentiality arises out of a special relationship between the parties created by their respective roles (doctor-patient, lawyer-client) or by an explicit promise. Confidentiality, as with its linguistic origins (*con* and *fides:* with fidelity), assumes a relationship based on trust or fidelity< Between strangers there is no expectation of trust. Privacy is given up because confidentiality is assured; unauthorized persons are excluded.

Yet confidentiality does not flow simply from the fact that personal or private information is divulged to another. If persons choose to announce their sexual preferences in street-corner speeches, in books, or on billboards, this information, though private in its origin, is not confidential. Confidentiality depends not only on the information, but also on the context of the disclosure as well as on the

relationship between the discloser and the recipient of the information. Confidentiality applies to personal, sensitive, sometimes potentially harmful or embarrassing private information disclosed within the confines of a special relationship. It should be noted, however, that the disclosure of private information from client to professional is one-way, unlike other interpersonal confidentiality contexts (Winslade and Ross).

Rights of Patients/Clients

When clients enter into a healthcare relationship, they relinquish some personal privacy in permitting physical examinations, taking tests, or giving social and medical histories. Usually this information is documented in a medical record, often stored electronically and held by the health professional or an institution. In exchange for the loss of privacy, clients expect and are promised some degree of confidentiality. In general, all personal medical information is confidential unless the client requests disclosure to third parties or a specific exception permits or requires disclosure. For example, clients may request disclosure to obtain insurance coverage or permit disclosure to a scientific researcher. The law requires health professionals to report certain infectious diseases to public-health departments or to report suspected child abuse to appropriate agencies. Unilateral disclosure of otherwise confidential information to third parties by health professionals or institutions is unethical unless it is authorized by the client or by law.

In the United States and other Western societies, the values of privacy, confidentiality, and privileged communications are closely tied to the values of personal rights and self-determination. These rights include freedom from the intrusion of others into one's private life, thoughts, conduct, or relationships. Interest in protection of personal rights has grown in response to public and private surveillance of individuals through the use of data bases to collect, store, and transmit information about individuals (Flaherty). In the United States the ideas of privacy and confidentiality have generated much legal and philosophical scholarship, influenced important judicial decisions, and prompted federal and state legislation (Winslade and Ross). The legal doctrine and ethical ideal of informed consent in healthcare reinforces the importance of personal autonomy (Beauchamp and Childress). The right to informed consent, applied specifically to confidentiality, gives patients/clients the right to control disclosure of confidential information. Other countries with less individualistic traditions do not place such high ethical value on privacy or personal rights. Even persons in cultures where privacy is not a prominent value can be harmed, however, by revelations of personal information (Macklin).

Traditional ethical theories can be interpreted to provide additional support for the values of privacy and confidentiality. Deontology stresses the rights of persons and the duties of others to respect persons as ends in themselves, to respect especially their personal rights. To the extent that the social practices tied to privacy and confidentiality enhance the welfare of all, utilitarianism may also be invoked on behalf of individuals. Virtue theory advocates personal moral aspiration and achievement. Privacy and confidentiality provide a context and an opportunity for cultivation of virtues without outside interference.

Despite the value of privacy and confidentiality to individuals, however, other values—such as collective need for information or public health and safety—limit individual rights. Confidentiality conflicts often arise about information contained in medical records. Clients usually want information to remain confidential. Others—such as employers, insurers, family members, researchers, and litigants—exert pressure to limit confidentiality and to gain access to personal information. Health professionals are often pulled in both directions by their professional loyalty to patients/clients and their broader social responsibilities.

Responsibilities of Health Professionals

The responsibilities of health professionals, as articulated in codes of professional ethics, reinforce the value of confidentiality. For example, the Hippocratic oath states:

> What I may see or hear in the course of the treatment or even outside of the treatment in regard to the life of men, which on no account one must spread abroad, I will keep to myself, holding such things shameful to be spoken about. (see Appendix)

Modern codes of professional ethics, like the Principles of Ethics of the American Medical Association, instruct physicians to "safeguard patient confidences within the constraints of the law" (see Appendix). Similarly, ethics codes for psychotherapists, nurses, and other allied health professionals make general, though not always coherent, reference to protection of professional-client confidentiality (Winslade and Ross). The American Psychiatric Association, however, has also issued detailed official Guidelines on Confidentiality pertaining to special situations, records, special settings, and the legal process (Committee on Confidentiality). The American Bar Association has offered a handbook, *AIDS/HIV and Confidentiality Model Policy and*

Procedures, that addresses the value of confidentiality, consent to disclosures, third-party access to information, and penalties for unauthorized disclosures (Rennert). The Council on Ethical and Judicial Affairs of the American Medical Association (1992) outlines the scope and value of confidentiality and addresses in detail confidentiality in the context of computerized medical records. These documents stress individual rights and specify professional responsibilities concerning confidentiality.

Despite the explicit attention given to confidentiality in oaths and codes, practical ethical problems arise, occasionally causing heated controversy. For instance, in 1991 an authorized biography of the deceased poet Anne Sexton relied in part upon audiotapes of psychotherapy sessions. One of Sexton's psychiatrists permitted the biographer to listen to some 300 hours of psychotherapy tapes. Prior to the publication of the biography, a front-page story in the *New York Times* about the disclosure of the tapes to the biographer generated a furious ethical debate. On the one hand, some critics believed that release of the tapes violated the deceased patient's privacy. Others pointed out the harm to surviving family members. Still others stressed the duty of the psychiatrist not to reveal anything about the content of therapy. Unless the therapist was required by law to release the information on the tapes, these critics argued, confidentiality should have been preserved. On the other hand, the psychiatrist claimed that his duty was primarily to protect his patient's interests—including her interest in self-revelation, in being understood, and in helping others. The psychiatrist believed that the patient, when competent, had specifically authorized him to use his own best judgment about what to do with the tapes. He also believed that he should cooperate with the request of the patient's literary executor—her daughter—to help make the biography accurate and complete. None of the relevant ethics codes sufficiently clarified or specifically addressed a case of this kind. Although charges were brought that the psychiatrist violated the code of ethics of the American Psychiatric Association, eventually a decision was reached that no ethics violation occurred. But a still-unsettled controversy swirls around these issues.

Professionals are often more aware of confidentiality issues than patients or clients. Professionals realize that privacy and confidentiality may give way to the institutional, governmental, and other third-party pressures for specific information about patients or clients. Health professionals desire to protect the integrity and special value of the professional-client relationship itself. Confidentiality is one basis of professionals' reciprocity with clients who reveal private information. (Other aspects of reciprocity include the clients' payment for the professionals' services in response to the professionals' expertise to meet the clients' needs.)

It should be emphasized that the primary justification for confidentiality is derived from the individual rights of clients and is supplemented by the responsibilities of professionals and the benefits of the healthcare relationship. This is why the client, rather than the health professional, determines what information is to remain confidential. Except where laws or other rules limit clients' rights to confidentiality, the client may not only request but require professionals to disclose otherwise confidential information. It is, after all, the client's private information that has been revealed to the professional.

Some recent critics, including feminist theorists, have questioned the adequacy of rights-based approaches. They argue that an ethics of care or caring must take account of a web of relationships, emotions, and values that include but go beyond individual rights. A care-based ethics stresses the interactive relationships, not only of patients and clinicians, but also families and society. Within the context of caring, humans—especially those who experience special suffering or discrimination—need more than just protection of their legal rights. In the specific context of privacy and confidentiality in medical genetics, for example, an ethics of care rather than rights may better explain the moral reasoning of geneticists (Wertz and Fletcher). This is discussed further in the later section on genetic and other medical screening.

Other critics think that the preservation of confidentiality should take priority over clients' and professionals' autonomy. This idea is based on the idea that total confidentiality is essential to protect both the integrity and the effectiveness of the professional-client relationship. No third parties should ever be permitted to penetrate the boundaries of a protected professional relationship. Neither the client nor the professional, according to this view, should be required or even permitted to disclose confidential information. Something close to this extreme position was considered but rejected by the California Supreme Court in *Lifshutz* (1970). Neither professional organizations nor their ethics codes endorse this idea, but it does highlight the importance that can be ascribed to confidentiality.

Even if the ideal of complete confidentiality cannot be justified in theory, it can sometimes be achieved in practice. A dyadic, exclusive relationship between client and health professional can sometimes fully preserve confidentiality. For example, a client establishes a relationship with a psychotherapist to explore the meaning of a significant personal loss. The client may not want others to know about the consultation. It is nobody else's business.

The therapist's office may have a separate entrance and exit to decrease the likelihood that clients will encounter

each other. The therapist may answer personally all phone calls. The therapist may keep no client-specific records and take no notes. The client may pay cash, not file a claim for insurance coverage, explicitly request that all discussions be kept confidential, and take other precautions to prevent others from learning even that the relationship with the therapist exists at all. The client reveals his or her feelings, fantasies, thoughts, or dreams only to the therapist, who seeks to understand and help interpret their meaning only to the client.

If client confidentiality and professional secrecy were always as unambiguous as the foregoing scenario, there would be little more to say. However, professionals as well as clients have widely divergent attitudes, beliefs, expectations, and values concerning confidentiality (Wettstein). A few professionals espouse the absolute value of confidentiality in dyadic therapeutic relationships while many others acknowledge only its limited and relative value. Others lament the declining value of confidentiality while accepting the encroachment of legal, economic, public-health and safety, or research interests. A few others view confidentiality as an inflated value that some professionals or clients use as a shield to conceal fraud, malpractice, or even criminal activity.

Rather than a simple dyadic relationship, a more complex, polycentric model is necessary to capture the nuances of confidentiality in healthcare. Clients, health professionals, and third parties may have varying claims on ethical grounds to protection of or access to confidential information. Clients may waive their rights to confidentiality to obtain other benefits such as insurance coverage or employment. Professionals may discern a conflict between ethical obligations to their clients and legally required reports. Third parties may have a legitimate need to know otherwise confidential information to assess quality of healthcare services, uncover fraud, or determine appropriate allocations of healthcare resources. Loss of confidentiality may result not only from ethical, legal, or economic factors, but also because of client ignorance or misunderstanding, professional or institutional carelessness, or third-party overreaching. The interplay of those various factors can best be understood by examining in more detail selected problem areas where confidentiality comes into conflict with competing ethical and social interests.

AIDS

The acquired immunodeficiency syndrome (AIDS) epidemic brings with it a full range of confidentiality issues. Patients who think that they might be HIV-positive are reluctant to be tested for fear that disclosure of such sensitive information may cause them to lose employment or insurance coverage or may make them subject to other types of discrimination. Yet if they are not tested, the benefits of clinical care to diminish the damage of the disease are not available. Patients who know that they are HIV-positive may not want others to know of their status to prevent discrimination. But third parties, such as sexual partners, who are at risk of being infected with a lethal virus, have a legitimate interest in access to otherwise confidential information. If the infected person is unwilling to inform others who may be at risk of getting AIDS, health professionals may be permitted or even required to warn persons who have been or may be put at risk of being infected. Family members may want to know why their relative is sick; they may need to know if they become caretakers. But patients may not be willing to disclose their diagnosis. Healthcare workers want to know their patients' HIV status just as patients want to know if their caretakers are infected. Both desire to avoid becoming infected themselves. Those who are at risk of infection may have a justifiable need to know; others may not.

Confidentiality is not the only value at stake, but it does impose substantial burdens on others. For example, in institutional settings, confidentiality of personal information, such as a patient's diagnosis, must be protected by written policies and actual practices. In a recent court case in Maryland, a hospital failed to protect adequately a patient's medical record that included a diagnosis of AIDS. It is not sufficient to state a policy that access to medical records is limited. It is also necessary to have and implement policies that actually restrict physical access to the records (Brannigan). The hospital was negligent because it did not go far enough to limit physical access of unauthorized persons to the records.

Required Reporting

Legal rules that require health professionals to report child or elder abuse, infectious diseases, or gunshot wounds preempt many of the specific ethical conflicts between confidentiality and public health or safety. However, not all ethical issues are resolved by legal rules. For example, some child-abuse-reporting laws are overly broad; health professionals may fail to make mandated reports in part because of the value ascribed to client confidentiality. Other reporting laws are so narrow that protection of threatened victims is undermined by confidentiality rules and practices (Miller and Weinstock). Some commentators have pointed out, for example, the conflicts created by statutes that require the reporting of not only actual but also suspected child abusers. Some parents

alleged to have abused their children have been required to undergo therapy; but to require them to admit abuse before conducting therapy conflicts with the constitutional privilege against self-incrimination.

Professionals, caught between the need for confidentiality in therapy and the legal demand for reporting abuse, sometimes underreport abuse; they protect therapeutic relationships at the risk of legal liability. Other professionals may overreport child abuse because of their concerns about legal liability, strained therapeutic relationships, vulnerability of potential victims, or uncertainty about the value of confidentiality. Some commentators have suggested that child-abuse statutes should be revised to be more specific and limited, requiring professionals to report only when their patients are victims of child abuse, but to give professionals greater discretion about whether to report abusers who are in treatment (Smith-Bell and Winslade).

Another ethical problem for health professionals that arises in connection with legally required disclosures of otherwise confidential information is what to tell clients prior to or near the outset of therapy. If clients are inadequately apprised about the limits of confidentiality, their trust in health professionals is damaged and their relationship may be ruptured. If clients are fully advised of the legal limits placed on confidentiality, they may withhold essential information, terminate therapy, or not even start it. A further problem is that professionals may not know precisely where legal lines have been drawn. For example, a therapist may know that notification must be made to authorities but may not know how much, if any, of the content of therapy must he disclosed.

Genetic and Other Medical Screening

Genetic and other types of medical screening by epidemiologists, physicians, employers, schools, and other public and private agencies give rise to situations in which confidentiality is threatened by a demand for personal medical information. Individuals who are screened want to control information about themselves to prevent stigma, loss of insurance or employment, or other forms of discrimination. Screeners desire access to such information to promote their interests in knowledge, scientific discovery, publication, or economic considerations as well as therapeutic purposes. Control over the information raises moral issues as well as practical problems. These values must be balanced against individuals' rights to preserve their informational privacy. Blood tests, family medical histories, personal medical histories, DNA assays, and data banking, for instance, all raise questions about confidentiality, access, and control of personal information (De Gorgey). Lack of consensus about ethical priorities, gaps in legal policies and remedies to individuals, and political uncertainty about jurisdiction and control over medical screening combine to create controversy. Protection of individual rights of privacy and confidentiality requires careful monitoring of the use of data banks to store information obtained by the Human Genome Project (Macklin).

Health professionals in genetics differ in their beliefs about the value of privacy and confidentiality. Considerable disagreement has been documented, for example, in an international study in nineteen countries of the attitudes of geneticists toward privacy and disclosure. These health professionals were asked to respond to vignettes concerning disclosure of false paternity; of a patient's genetic makeup to a spouse; to relatives at genetic risk; of ambiguous test results; and to institutional third parties, such as employers and insurers (Wertz and Fletcher). Some consensus as well as numerous differences were discovered among the geneticists' opinions about what disclosures are appropriate. Dorothy Wertz and John Fletcher also found that geneticists' reasoning was more likely to be based on the complex needs and relationships of the various parties rather than the rights of individuals. A care-based ethics approach poses a theoretical and practical alternative to a rights-based approach.

Legal Protections and Limitations

Legal protection of confidentiality in the United States has been sporadic and uneven. The 1974 Federal Privacy Act (P.L. 93–579) included some medical information and records; its passage signaled heightened congressional awareness of threats to privacy and confidentiality. The National Privacy Commission's report (U.S. Domestic Council, 1976) seemed to set the stage for further protective federal legislation. Several subsequent attempts to pass comprehensive federal laws to protect medical information failed; a patchwork of state statutes provides only limited protection of patients' confidentiality. The reason is that patients' interests in confidentiality are balanced against powerful interests of third parties, such as healthcare payers, governmental agencies, researchers, and law-enforcement agencies, who wish to have access to otherwise confidential medical information (Hendricks et al.).

Courts have been as hesitant as federal and state legislatures to provide stringent protection of patient confidentiality. The U. S. Supreme Court considered but rejected the idea that patients enjoy a constitutional right to "informational privacy" with regard to treatment records (*Whalen* v. *Roe*). This decision was rendered when the rhetoric of privacy was prominent in Supreme Court opinions; in the

1980s the right to privacy was restricted, and the rhetoric of privacy diminished. State courts, such as those in Florida and California, whose constitutions make explicit reference to a right to privacy, have been more inclined to protect confidentiality of medical information. But state laws provide infrequently enforced bureaucratic protections or opportunities for recovery of damages only after confidentiality has been violated. Even then, litigation is rare because patients are reluctant to further expose confidential matters, damages are difficult to prove, and awards are often limited by statute (Winslade).

In some settings, such as substance-abuse treatment programs, the federal government has established special rules to protect confidentiality. To encourage persons in need of treatment to enter substance-abuse programs, records are not disclosed to law-enforcement agencies that might otherwise seek to prosecute substance abusers. In sensitive human subject research, special "privacy certificates" can be obtained by researchers from the federal government to give added protection to confidential information. Similarly, coded and locked files, limited access even to authorized personnel, and other precautionary measures against leakage further enhance confidentiality (McCarthy and Porter).

Public concern about confidentiality surfaces periodically, especially concerning the potential evils of misuses of patient-identifiable information. For example, implications of the Human Genome Project and healthcare reform have most recently evoked anxiety about discrimination, violation of personal rights, and commerce in patient information. The potential for a new healthcare information infrastructure that relies heavily on computer technology to facilitate the flow of medical information dramatically increases the threat to confidentiality of medical records (Brannigan). Recent commentaries remind us that current legal policies are inadequate to protect individuals against unwarranted disclosure, to provide security for complex medical-information systems, and to preserve individuals' rights to consent and control the uses of personal medical information (Alpert; Gostin et al.).

A specific area of law that directly affects confidentiality concerns the obligations of psychotherapists whose potentially violent patients place other individuals at risk of harm. The California Supreme Court, in the case of *Tarasoff* v. *Regents of the University of California* (1974), ruled that psychotherapists of dangerous patients have a duty to use reasonable care to protect threatened victims from harm. To do so may require the disclosure of otherwise confidential patient information. In balancing public safety and confidentiality, the Court observed that "the protective privilege ends where the public peril begins."

In the *Tarasoff* case, a psychotherapist believed that his patient was potentially dangerous to a young woman who had rejected his interest in her. The patient was obsessed with her at the expense of his studies, his work, and his friends. When the patient talked of revenge and was thought to have a gun, the therapist sought to have his patient evaluated for involuntary hospitalization. But the police declined to bring the patient in for an assessment of his mental status. The patient, angry with his therapist, abruptly terminated treatment. A couple of months later the former patient killed the young woman. Her parents sued the therapists and their employer for failing to warn the victim or her family about the dangerous patient. Although this case was settled out of court without a trial, the reasonable-protection rule was articulated by the court for future cases.

Subsequently, a series of judicial decisions have elaborated the duty of psychotherapists to third parties. Some courts have restricted the duty to situations in which there is an imminent threat of serious violence toward an identifiable victim. Others have focused on the broader duty of health professionals to control the conduct of the dangerous patient. Still others have applied the *Tarasoff* standard even when the risk to others is neither serious nor specific. And a few courts have protected confidentiality rather than endorse the *Tarasoff* standard (Felthous).

The complexity of particular cases and the variability of judicial interpretations of facts and laws inevitably cause some uncertainty. In this context, as in many others, confidentiality is limited by other important values. For example, suppose a voluntary psychotic in-patient with no history of violence leaves the hospital against medical advice. He leaves behind some written notes that include violent fantasies about a family member. His therapist discovers the notes (which were left unsealed). Assume the therapist consults the patient, who demands confidentiality; but the therapist is concerned that the patient may be dangerous. The therapist must assess the probability of harm to the patient or the potential victim, consider alternatives to revealing confidential information, and decide what, if anything, to tell the patient, the threatened victim, or others. This delicate balancing inevitably occurs in contexts where information is incomplete, contextual nuances are elusive, and human behavior is notoriously difficult to predict. Nevertheless, decisions must be made and actions taken that will affect the scope of confidentiality as well as bring about other consequences.

Information about Limits of Confidentiality

When entering into a professional-client relationship, clients have a right to receive explicit information about the

scope and limits of confidentiality. Most nonprofessionals assume that disclosures made in the context of healthcare are confidential (Weiss). Most clients are uninformed about the limits of confidentiality and pressures to reveal presumably confidential information to third parties. Some clients realize that there are legal and ethical restrictions on confidentiality in healthcare, but others learn of them only after an undesired disclosure (Siegler).

Clients for whom confidentiality is especially important may take steps to preserve it. For example, a medical patient who chooses to file an insurance claim may request the right to review all documents released to the insurance carrier. Or the patient may pay privately rather than file an insurance claim. Other clients may be less concerned with confidentiality. Clients have a responsibility to inform themselves about what expectations about confidentiality are reasonable; then they will not be surprised or dismayed because of false assumptions about confidentiality.

Professionals have a responsibility to inform themselves as well as their clients about legal, ethical, and practical aspects of confidentiality. For example, neither patients nor health professionals usually are familiar with the practices of insurance companies concerning redisclosure of confidential information. Patients often sign a blanket waiver of confidentiality in order to obtain insurance benefits. This information may then be sold by the insurer to the Medical Information Bureau, a clearinghouse to protect against insurance fraud. This goal is laudable, but the data-banking process may include erroneous information that is difficult to detect or correct. In addition, many other interests outside healthcare—such as employers, government agencies, educational institutions, and the media—may gain access to information contained in these data bases (Linowes; Alpert).

At the very least, professionals should ask their clients what they want to know about confidentiality. Some professionals prepare a disclosure statement to give each new client, that is, a document that outlines confidentiality practices the particular professional follows. Policies and procedures concerning written medical records might be given to each new client. Further conversation, including clients' questions and professionals' answers, can clarify details that written statements may not address. Because professionals, like their clients, may differ in their attitudes toward confidentiality, it is important that disclosures about confidentiality be particularized. For example, the values of a psychoanalyst in private practice who never publishes patient case reports significantly differs from those of a research-oriented psychoanalyst who tapes and transcribes every session and publishes detailed case reports. Each should fully inform clients about the nature of his or her practice (Stoller).

Professionals have an obligation to take precautionary measures to protect confidentiality even if their clients have not requested it. Professionals should assume that all client information (including the very existence of the professional-client relationship as well as personal and private information revealed is strictly personal and private information revealed) is strictly confidential unless the client has requested or waived disclosure or unless the law requires it. Professionals should advise their clients of required disclosures, inform them of waivers, explore with them the consequences of disclosing or not disclosing information, and examine the reasons for and against disclosure. But clients retain the authority to decide what voluntary disclosures are to be made to third parties (Winslade and Ross).

Professionals also have a special responsibility to protect confidential client information from leakage through lax office procedures, professional or personal gossip, or the inappropriate inquiries of unauthorized persons. This is particularly problematic in institutional settings, where many individuals may have routine access to patient information contained in medical records (Siegler). As computerization of medical records expands further and information storage, retrieval, and distribution technologies become more sophisticated, the need for professionals' vigilance increases.

Many third parties—government officials and agencies, insurance interests, employers, family members, researchers, and others—seek specific information about particular patients. Third parties should not assume, however, that mere interest gives them legitimate authority to have access to confidential information. Third parties have a responsibility to justify to patients and professionals their need for access to confidential information. In some instances, this may require only a routine inquiry and documentation, but in other situations, professionals may find it necessary to confirm that their patients have requested, waived, or forfeited their rights to confidentiality. Too often, professionals, especially in an institutional setting, capitulate to pressure to disclose more information than necessary to third parties. At the very least, third parties as well as professionals should notify patients when access is sought, how it will be used, and whether the information will be redisclosed to anyone else. If appropriate disclosures are made to patients before access to confidential information is granted to third parties, not only will confidentiality be better preserved, but patients will also be better served.

CONFLICT OF INTEREST

• • •

In a conflict of interest, one's obligations to a particular person or group conflict with one's self-interest. A physician, for example, is ordinarily obligated to provide his or her patients with only the care that is reasonable and medically necessary, even if the physician may earn more money through unnecessary interventions. Conflicts of interest should be distinguished from conflicts of obligation, in which one's obligations to one person or group conflict with one's obligations to some other person or group. The latter need not necessarily involve any threat to the agent's own interests. For example, a physician is normally obligated to keep patients' medical problems confidential; however, when a patient poses a danger to others (by transmitting AIDS to a spouse, for example) the physician may have an obligation to protect that third party by violating the confidentiality that would otherwise be owed to the patient. In a healthcare context, conflicts of interest can arise for individual providers, such as physicians, dentists, nurses, or physical therapists, or for institutions, such as hospitals, health maintenance organizations (HMOs), insurers, or pharmaceutical companies.

Conflicts of interest can be found in any human endeavor; indeed, the clash between self-interest and altruism lies at the heart of morality. However, conflicts of interest in healthcare are especially serious because of the patient's vulnerability. Illness can impair a patient physically, emotionally, and rationally. To secure treatment, patients must expose physical and emotional intimacies normally reserved for loved ones, and they frequently face further risks from invasive diagnostic and therapeutic technologies. Patients usually have no choice but to submit to such exposure and risk, because typically they lack the knowledge and skill to identify and treat the illness or to ascertain whether care is being rendered appropriately. This vulnerability creates ample opportunities for providers to exploit patients for personal gain. Physicians or dentists might recommend costly, unnecessary care, or an insurer or an HMO might attempt to lure subscribers by promising more than it can deliver.

Accordingly, providers such as physicians and dentists are often regarded as fiduciaries, in both a moral and a legal sense. Fiduciaries hold beneficiaries' (the patients') interests in trust and are obligated to promote the latter's interests, even above their own hospitals, insurance companies and HMOs. Nursing and allied health professions are not ordinarily considered fiduciaries in the legal sense, but they do share a strong ethic of dedication to patients' interests.

For many years, a serious commitment to professionalism and an effacement of self-interest seemed sufficient to manage conflicts of interest. The traditional fee-for-service system admittedly encouraged unnecessary services, but prior to the mid-twentieth century providers had relatively few interventions to offer, beyond their own care and concern. As technologies emerged, a relative shortage of providers meant that each had more than enough to do. Furthermore, in the long-term relationships that characterized most healthcare, providers had to live with the consequences of their decisions, right alongside their patients. Exploitive or abusive practices thus carried strong disincentives.

Since about the mid-1960s, however, healthcare has become high cost and big business. Providers now face a plethora of conflicts of interest, ranging from the traditional but much-exacerbated conflicts implicit in fee-for-service to powerful pressures to cut the cost of care by doing less for patients.

Conflicts of Interest for Physicians

For physicians, conflicts of interest can arise in two distinct realms: the clinical setting, where medical care is primarily designed to help the patient, and the research setting, where physicians seek scientific knowledge that will only sometimes benefit the patient or research subject.

THE CLINICAL SETTING. In the clinical setting, a number of factors could encourage a physician to alter a patient's optimal care, whether it be to secure a personal gain or to avoid a loss. Conflicts can be posed by third-party payers, institutional healthcare providers, private industry, the legal system, and physician investment.

Third-party payers. Traditional fee-for-service reimbursement encourages physicians to deliver as many services as possible and, in a maneuver called "unbundling," to break down each service into as many separately billable small interventions as possible. Maximizing income may thus mean excessive care, which in turn threatens needless inconvenience, expense, and iatrogenic injury for patients.

Partly because fee-for-service is an inflationary reimbursement system, healthcare costs grew at an alarming rate from the mid-1960s through the early 1990s. In response, those who pay directly for healthcare—government, businesses, and insurers—placed powerful pressures on physicians to do less for their patients. Payers sometimes offered bonuses to physicians to discharge patients earlier than normal, and they often refused to pay for various tests and treatments unless they were performed in an outpatient setting. Through extensive *utilization review* (UR), many payers reimbursed only hospitalizations or medical interventions that met their criteria of medical necessity. Physicians therefore spent large amounts of time (usually uncompensated) justifying their plans of care to payers in order to secure reimbursement.

As a supplement, or sometimes an alternative, to such controls, many health plans instituted financial incentives. Capitation systems, for instance, attempt to save money by paying a single fee for a large unit of care, thereby creating an incentive to avoid rendering care beyond the budgeted fee. Medicare inaugurated its *diagnosis related group* (DRG) system in the early 1980s, paying hospitals a set amount for a specific episode of illness, based on such factors as the patient's diagnosis, age, and coexisting illnesses.

HMOs, in a broader capitation concept, began to provide all necessary healthcare for each subscriber in exchange for a single annual premium. In order to ensure that their physicians delivered services within the year's budget, most HMOs, in turn, applied downstream financial incentives to their physicians, often withholding 20 percent or more of the physician's salary or fees until the end of the year, when they would be paid (or not) depending on the HMO's financial health. HMOs also have commonly set aside a special fund for diagnostic tests, consultants, and hospitalization. Primary-care physicians, acting as gatekeepers whose permission is required for the patient to gain access to these services, would share any surplus funds (or debts) remaining at the end of the year. Other HMOs placed physicians under subcapitation systems in which the physician provided a range of services for a set fee per patient. These arrangements could make a substantial difference in a physician's year-end income, thereby providing a powerful incentive for physicians to economize on the level of care they provide or authorize for patients.

The mid-1990s saw a brief reprieve from healthcare cost inflation, which, combined with a booming economy and widespread horror stories about the abuses of managed care, prompted most health plans to scale back these cost controls and incentive arrangements. However, as healthcare costs began rising rapidly again in the early twenty-first century, health plans and providers again struggled to keep them in check through a variety of mechanisms.

Although these mechanisms have evolved, certain features have remained constant. Ultimately, all payment systems create conflicts of interest by creating an incentive to provide more of the services that are most profitably reimbursed, and less of those that generate less income. However, the challenge is markedly exacerbated in the healthcare setting. Every medical decision is a spending decision, yet payers ordinarily cannot control their costs by directly dictating what care the physician will and will not provide. To do so would be to practice medicine in the physician's stead. Rather, payers attempt to influence physicians, who control up to 80 percent of healthcare costs through their power of prescription and their professional influence over patients. That influence is almost always gained by placing physicians' personal interests in peril as they are rewarded or penalized for fiscally (im)prudent healthcare decisions.

Institutional providers. Institutional healthcare providers, such as hospitals and clinics, can establish incentives to encourage physicians to do more (or less), depending on the institution's economic status (proprietary or charitable) and the patient's financial status (well-insured or not). A for-profit walk-in clinic, for instance, makes its money through the tests and treatments its physician-employees order. Hence, high-profit physicians may be praised and invited to share profits, or even to own a share of the business, while low-profit physicians may receive administrative warnings or lose their jobs if they do not improve . In other cases, physicians and proprietary hospitals may enter into joint ventures to share both the profits and risks of running the facility.

Whether proprietary or charitable, all institutional providers need to contain costs. Monthly printouts comparing the costs of each physician's care may be shared with medical staff in an attempt to shame the high spenders into delivering more conservative care. And those whose patients consistently leave too many unpaid bills may lose their staff privileges in a strategy called *economic credentialing.*

Such incentives systematically place physicians in conflicts of interest. The potential loss of income, peer esteem, staff privileges, or even one's job creates powerful pressures to align one's judgment with the institution's interests, even at some cost to patients' interests.

Private industry. Many medical drugs and devices are sold only with the prescription of a licensed physician and, notwithstanding some notable exceptions, are often not readily advertised to the general public. Therefore, manufacturers' marketing typically targets physicians. Because physicians tend to be busy people with substantial incomes,

pharmaceutical companies can go to great lengths to get their attention. Promotions over the years have included all-expense-paid trips to exotic locations, ostensibly to hear a lecture on a new product; cash payments to physicians who agree to read literature describing nonapproved uses of a drug; "frequent prescriber" programs that award frequent-flyer points with the physician's preferred airline for every prescription of the company's drug; lavish parties and tickets to entertainment events; costly gifts such as luggage and decorative arts; inexpensive gifts such as pens and notepads; and subsidies for local educational colloquiums and travel to professional meetings.

The conflicts of interest are obvious. Such gifts reward physicians for prescribing drugs and devices whether or not they are necessary, and whether or not that particular product choice is most appropriate and least costly for the patient. Acceptance of gifts can engender a sense of personal gratitude and indebtedness that can put corporate loyalty above patients' interests. Furthermore, patients ultimately bear the costs of such promotions and gifts, whether through higher costs of the drugs and devices, higher costs for health insurance, or by forgoing higher salaries or fringe benefits because their employers are paying higher insurance premiums.

Legal system. Parallel to the escalation of healthcare costs, both the frequency and cost of medical malpractice litigation have increased. Physicians fearful of lawsuits may order extra diagnostic tests and more potent therapies to ensure that no one can accuse them of missing a diagnosis or doing too little for their patients. The cost of such "defensive medicine" has been estimated at up to 15 percent of the total cost of physicians' services. When physicians order procedures that are not medically necessary in order to protect their actual or imagined legal interests, they expose patients to extra inconvenience and iatrogenesis—at the patient's expense and usually without the patient's knowledge. It is a clear conflict of interest.

Physician investment. In some cases physicians create their own conflicts of interest by investing in facilities to which they refer their patients. Examples include freestanding diagnostic imaging centers, home health services, clinical laboratories, and physical therapy services. Although such investments can enhance the availability and quality of healthcare facilities in a particular locale, the physician owners of such facilities nevertheless have an incentive to refer patients there, even when the care is unnecessary, costly, or of poor quality. In the 1990s a series of federal laws and administrative regulations forbade many, but not all, of these arrangements.

The conflicts embedded in investments are not limited to freestanding facilities. One study found that physicians who owned radiographic equipment in their own offices tended to use it four times more often (generating costs seven times higher) than physicians who referred patients to independent radiologists for those services.

THE RESEARCH SETTING. The research context sometimes involves testing new treatments on ill patients, but it can also involve healthy volunteers when researchers look for toxicities of the very newest drugs. In many instances there is no expectation that participation in research will benefit the patient at all, whether because the subject is a normal control subject, because many people in the study will receive a placebo instead of active medication, or because the patient is too hopelessly ill to benefit from any treatment. Whatever the research protocol, however, the physician must respect the research subject's rights and interests.

Physicians can enjoy many personal rewards for successful research. Private companies such as drug manufacturers commonly sponsor research, in some cases paying the physician-investigator a fixed fee of several thousand dollars per person enrolled. The sum is intended to cover the costs of each subject's participation in the study, but in fact can result in a considerable surplus of money pocketed by the investigator. The more patients one enters in a study, the higher one's rewards, and an overzealous recruiter may be tempted to understate the inconvenience, discomfort, or risk that research participation may present for the patient, or to compromise the integrity of the study by signing up patients who are not truly eligible for the protocol.

Research that is funded by the government or other nonprofit sources can mitigate some, but not all, of the conflicts of privately sponsored research. Physician researchers still have strong incentives to gain the prestige, larger laboratory, increased technical support, academic promotion, science awards, and institutional power that come with securing grants and producing publishable research. In addition, some research projects have paid finders' fees to those who recruit patients for studies. As a result, investigators have powerful incentives to recruit patients into studies without necessarily taking full account of the patients' best interests.

Physicians can also create their own conflicts of interest. Sometimes physicians invest in corporations that are sponsoring their research, or they may serve as the corporations' paid spokespersons when research is completed. They may earn money from producing a valuable commodity, such as a cell line, by using tissues that patients either knowingly or unwittingly donate (see *Moore v. Regents of the University of California*). In a few cases physicians performing for-profit scientific research have charged subjects a fee to participate. Although such entrepreneurial research is controversial, the

conflicts embedded in for-profit research are not necessarily worse than those found throughout the high-pressure world of medical research.

Other Health Professionals

Whereas physicians and dentists often are private practitioners or independent contractors, nurses, physical therapists, dietitians, and allied health professionals usually are employees of hospitals, HMOs, clinics, home health services, or public health agencies. These professionals' conflicts of interest most often arise where their contractual duty to administer the therapies ordered by a physician or to follow established institutional rules clash with their own beliefs about what is best for a patient. Such health professionals may suffer personal retaliation if they violate institutional mandates in order to do what they deem best for the patient.

In these cases the problem begins with a conflict of obligation in which one's obligations to the institution do not match one's obligations to the patient. The conflict of interest arises as one faces a personal price, perhaps in the form of retaliation, for favoring the patient over the institution. Thus, though conflicts of obligation are not the same thing as conflicts of interest, in these cases they are connected. For example, in one instance a nurse was fired for informing a patient about alternative cancer treatments (the dismissal was later vacated on procedural grounds (see *Tuma v. Board of Nursing*). In another case a nurse was discharged for refusing to dialyse a patient for whom she believed the treatment was pointless and inhumane (see *Warthen v. Toms River Community Memorial Hospital*). Such clashes between administrative requirements and one's professional judgment are probably the greatest, though not the sole, source of conflicts for allied health professions.

Institutions

The interests of institutions and their administrators, like those of individual professionals, often mesh with patients' best interests. Ideally, in a competitive market where consumers seek quality and value for their dollars, a healthcare institution will prosper by serving patients well. However, such a happy match does not always occur, partly because ill patients are often not equipped to appraise and challenge the quality of their care, and because generous insurance policies insulate many patients from caring about the costs of care. Accordingly, the financial best interests of a hospital might prompt excessive charges, inadequate staffing and equipment, bloated advertising, or the premature "dumping" of uninsured patients into public institutions. Similarly, a pharmaceutical company may be financially rewarded for producing and marketing new drugs as early and as vigorously as possible, even if the drugs and their production methods are not as refined as they could be. As a result, some drugs may have more side effects, or cost more, than is necessary.

Managing Conflicts of Interest

The existence of a conflict of interest does not mean that a provider has done anything wrong, or has mistreated or will mistreat any patient. It means only that while there is a mandate to promote the patient's (or someone else's) best interest, there are self-interested reasons to do otherwise. To be tempted is not necessarily to succumb.

Providers cannot escape conflicts of interest. If they are paid according to how many services they provide, their interest is to provide more services, with the concomitant dangers of excessive interventions, costs, and risks of iatrogenesis. If they are paid according to how many patients they care for, their financial advantage lies in taking on too many patients. Physicians who are strictly on a salary have an adverse incentive to minimize their own labor, even if they cannot increase their income, by seeing fewer and less-needy patients.

Formal protections can help. Regulatory agencies, such as state boards of medicine, nursing, and dentistry and the Joint Commission on Accreditation of Healthcare Organizations, can establish standards of performance for individuals and institutions, and the legal system can redress individual cases where providers' self-interest injures patients. Fiduciary law, for example, requires a fiduciary in a conflict of interest to disclose that conflict fully to the beneficiary (here, the patient) and also empowers the latter to determine how the conflict should be resolved (see *Fulton National Bank v. Tate*). Patients thus can have common-law remedies for breach of fiduciary duty, lack of informed consent, and other causes.

Although regulation and litigation can thus provide important protections, they cannot supplant personal integrity. The prospective employee of an HMO, a hospital, or other institutional provider should check carefully into its incentive structure and refuse to join any organization that links financial consequences too closely to individual patient-care decisions. The physician in private practice can refuse to accept costly gifts from drug company representatives. Those who would invest in ancillary facilities within or outside of their offices can ensure that there is a genuine need for the facility, and they can empower their patients with information and freedom to make their own choices regarding their ancillary healthcare providers. Researchers can refrain from investing in corporations sponsoring their research, and they

can work with other research-sponsoring institutions to minimize conflicts. Where private industry pays university-based physicians a large per-patient fee, for example, that fee can be put into a general fund to benefit the institution after research costs are paid. Nurses and allied health professionals can work individually or collectively for contract terms that protect their right to exercise professional integrity.

Institutions must ensure that they do not create inordinate conflicts of interest for the professionals they employ. HMOs, for instance, should refrain from instituting incentive systems that unduly influence individual patient-care decisions. They and other payers should likewise disclose to current and potential subscribers any such incentives or limits on care. Informed subscribers are better empowered to guard their own interests. Institutions can also ameliorate their conflicts by pursuing ongoing quality improvement as a way of promoting quality care while economizing on costs. A focus on the success that comes from long-term quality should replace any preoccupation with short-term profitability.

Conflicts of interest affect providers pervasively, powerfully, and personally. Where fiduciary duty once consisted mainly of refraining from vulgar exploitation, the obligation to place the patient's interests before one's own can no longer be an unlimited obligation. Providers must exercise great care to avoid conflicts where possible, and to uphold a strong fiduciary presumption to favor patients' interests over their own. However, they cannot be expected to commit professional self-sacrifice in what may be a futile unilateral attempt to battle economic forces beyond their control. Therefore, one of the most important and difficult moral challenges of medicine's new economics is to consider not just what providers owe their patients but also the limits of those obligations. As healthcare systems continue to evolve, one important remedy will be to provide patients with greater choice and control over the content of their healthcare benefits, and thereby with more power to make their own trade-offs between the cost and quality of care. This will alleviate at least some of the conflicts of interest that arise as providers attempt to make these trade-offs on their patients' behalf.

CONFUCIANISM, BIOETHICS IN

• • •

Confucianism draws its name from the latinized honorific title of its founder, Kong Chiu or *Kong fuzi* (562–479 B.C.E.), an independent scholar and unsuccessful political advisor who believed moral self-cultivation and the practice of ritual were the cornerstones of an ideal society. Initially espoused by no more than a few dozen students, Confucius's teachings—expanded and significantly elaborated over time—ultimately became the dominant sociopolitical ideology of much of East, Northeast, and Southeast Asia.

Other traditions, notably Mahayana Buddhism and Taoism, successfully rivaled Confucianism for state support over the centuries, but none—not even Maoist atheism in China—ever seriously threatened the Confucian tradition's pervasive cultural dominance. Carried beyond its historical Asian boundaries by merchants, laborers, and refugees, Confucianism also maintains a strong hold on diasporic Chinese, Korean, Japanese, and South-Vietnamese populations the world over.

In considering the complexities of the Confucian tradition, the following must be borne in mind:

1. the tradition is not monolithic, that is, historical era, regional variation, and differential class appropriation inform Confucian practice;
2. the tradition does not exist in conceptual isolation, that is, within any given local culture at any particular historical moment, Confucianism has always been practiced by individuals as part of a constellation of personal practice, including Mahayana Buddhism and local folk religions;
3. although there is a sense of authority residing in the canonical texts and commentaries of the Confucian classics, there is no central governing body, no clergy, and no history of religious jurisprudence within the tradition to dictate orthodoxy or legislate orthopraxy;
4. there is neither a concept of evil nor an absolute dichotomy between right and wrong as understood in Western monotheisms; rather, it is ignorance, self-delusion, and a tendency to gratify selfish desires that pose the greatest obstacles to moral improvement;
5. Comparative discussion of certain contemporary topics, for example, human rights and abortion, is

complicated by the absence of notions of individual "rights"; in the Confucian view, humans are defined by their capacity to fulfill duties and responsibilities rather than by any sense of inherent possession of rights.

Origins of the Classical Tradition

Core concepts are found in brief statements attributed to the Master himself, recorded by others in the verses of the *Analects,* the *Great Learning,* and the *Doctrine of the Mean.* Modern scholars, notably E. Bruce Brooks and A. Taeko Brooks in their *The Original Analects,* have shown these texts to contain significant interpolations and emendations. As received tradition, however, the aphorisms ascribed to Confucius and his early followers continue to exert considerable authority. At the heart of Confucius's vision was the sense that an individual can become truly human only through a deliberate process of moral education. The cultivation of virtues and their expression in ritual forms yields a *gentleman* (or, in current terminology, a *perfected person*) who stands ready to fulfill the responsibilities of living in concert with others and of establishing a peaceful, just, and aesthetically pleasing society. Ritual without virtue is ornament without substance; virtue without ritual can lead to unbounded good intentions that may ultimately do harm.

Confucian society is built upon a set of five reciprocal relationships, each of which is characterized by particular virtues and specific responsibilities:

1. ruler-subject;
2. parent-child;
3. husband-wife;
4. older-younger (brothers); and
5. friends.

Confucius's primary concern was with the creation of a stable and prosperous state, but he understood that it was the family that would ultimately produce the individuals dedicated to establishing his ideal society. Of the five relationships, therefore, three are located within the family; of these, by far the most important is that between parent and child. For having given life, one's parents are owed an enduring debt of gratitude—an obligation that extends even beyond the temporal boundaries of this lifetime. The practice of filiality, or filial piety, is therefore the starting point for Confucian moral cultivation, and the family is the foremost focus of religious practice.

An individual's relationship with people outside the family is determined by interlocking considerations of age, social and educational position, gender, and degree of professional and personal connection—all of which determine relative seniority and significance, and thus the degree of deference and potential obligation owed. However, how one acts within the resulting relationship is far more flexible and less hierarchical than might be assumed. Much has been made in Western philosophical literature about the Golden Rule found in *Analects* 5:12 and 12:2, but Confucius himself indicated another *single thread* that bound his ethical teachings (*Analects* 4:15). Two strands comprise the single thread, namely, *chung* and *shu,* usually translated as *loyalty* and *reciprocity.* These terms refer to a dialectical process that requires that one first center oneself in the relationship at hand, clearly understanding its attendant responsibilities and privileges. One then imaginatively takes the other's position in the relationship. Then—and only then, from this enlarged and empathetic perspective—one acts, in full awareness of the consequences for the other of one's actions.

In the centuries after Confucius's death, new questions arose to challenge the tradition. A particularly vexatious problem was how to account for people's varying capacities to learn (or even to want to learn) to become truly human. The ensuing debate was ultimately settled in favor of the view espoused by Mengzi (also latinized as Mencius, 372–289 B.C.E.). According to Mengzi, all people possess the four seeds of humaneness, righteousness or duty, propriety, and wisdom. If nourished properly through environment and education, these seeds mature into the moral attitudes and ritual behavior of true humanity. It is worth noting, however, that extrapolation from this claim yields the conclusion that those who do not exhibit these seeds or their outgrowth are not entirely human—a conclusion with potentially troubling ramifications in discussions of capital punishment, euthanasia, and human rights.

The Han Synthesis

After China was united under the relatively stable administration of the Han dynasty in 206 B.C.E., training in Confucian principles was established as the basis for participation in the state's meritocracy. Over the course of the Han rule (through 221 C.E.), Confucianism's purview expanded beyond philosophical-political discussions of virtue and ritual to encompass cosmological theories derived from ancient divination forms, and from *yin-yang* and the so-called Five Elements systems. The goals were to discern macrocosmic and microcosmic correspondences and then to regulate human actions to ensure harmony with heaven and earth. Although many of the theories incorporated into this syncretic Confucian cosmology are frequently associated with Taoism, they are more accurately described as belonging to a

pre-sectarian worldview that underlies all Chinese religio-philosophical traditions.

The hexagrams of the *I Ching* (*Book of Changes*) provided glimpses of the flow of natural processes, especially *qi,* the animating *breath* of the cosmos. The alternation of *yin* (darkness, passivity, decay, emotionality, and femininity) and *yang* (light, activity, growth, rationality, and masculinity) underscored notions of complementarity. The Five Elements (fire, water, wood, metal, and earth) explained a thing's inherent characteristics as well as its patterns of growth and decline. Elaborate correspondences were constructed among these classificatory systems, such that hours of the day, seasons of the year, foods and tastes, colors, sounds, organs of the body, stages of life, heavenly constellations, and virtually all human activities could be mapped and harmonized. A dislocation or inappropriate item in any one part of the schema would lead to disharmony and inauspiciousness elsewhere. In the political realm, disharmony breeds revolution; in the personal realm, disharmony breeds illness. The goal of Chinese medicine is to restore the natural balance of one's internal environment and to harmonize it with external environmental circumstances. This requires that a patient's food, medicines, and therapies be dictated not only by symptoms, but also by individual psychophysiology and local environmental factors such as season of the year. In the Confucian view, maintaining one's good health is dictated by filial responsibility, as one's parents should have no cause for worry.

Neo-Confucianism

After the collapse of the Han, China fragmented into several smaller kingdoms and parts of north China fell under non-Chinese rule. During the following centuries of disunion, the Confucian tradition was somewhat eclipsed by Taoist sectarian traditions and by the rise of Buddhism. Beginning in the Song dynasty (960–1279), a Confucian revitalization movement gathered momentum. Meditation, visualization, and other interior spiritual techniques were borrowed from Buddhism and Taoism, and traditional Confucian ethical concerns were now linked formally to a notion of the cosmos as inherently inclined toward moral good. Mengzi's view that human nature is essentially good was reaffirmed by the great Neo-Confucian, Zhu Xi (1130–1200). Together with the *Analects,* the *Great Learning,* and the *Doctrine of the Mean,* Zhu Xi promoted the *Mengzi* as comprising the Four Books, the basic course of education in Confucian ideology. Indeed it was Zhu Xi's editions of these and other classical Confucian texts that formed the basis for the imperial Chinese civil service examinations.

Zhu Xi further contributed to the development of Confucian practice through his preparation of detailed *jiaxun,* or family regulations. In addition to providing minute descriptions of ritual preparations, he admonished would-be filial sons and daughters-in-law to acquire medical knowledge adequate to the care of their parents (-in-law). Not only should they know how to prepare certain medicines, but they should also be able to select reputable physicians—practitioners who, in Zhu Xi's day, were viewed as little different from barbers and masseurs. Filial duty also entailed assumption of the primary burden of care. Down to the present, the sense that eldercare is the responsibility of the family remains deeply ingrained in Confucian societies, but with the decline of the extended family, reports of abandoned seniors are increasingly common.

New Confucianism

After the fall of the Qing dynasty in 1911, Confucianism was widely derided by Chinese intellectuals as a remnant of a feudal past that hindered China's rightful advancement into the modern world. Much of the blame for women's oppression, for example, was allocated to *Confucius and Sons,* and study of the canon was replaced by scientific and technical training. Nonetheless there were some scholars who believed that Confucianism, freed from its feudal origins and centuries of accreted (and erroneous) practice, could be rehabilitated. An international revitalization movement, known as *New Confucianism,* arose in the 1920s at Peking University under the intellectual leadership of Xiong Shili and continued to develop through the 1940s at New Asia College in Hong Kong under Tang Junyi. During the 1960s, the movement gained added momentum by the efforts of Mou Zongsan and Xu Fuguan at Tunghai University in Taiwan. These New Confucians asserted that the tradition holds spiritual resources sufficient to meet the challenges of industrialization, urbanization, and bureaucratization, and to combat the depersonalization of the modern world.

Contemporary New Confucians draw inspiration from Lee Sang-eun (South Korea), Okada Takehiko (Japan), and, especially, Tu Weiming at Harvard University. Following his teacher Mou Zongsan, Tu Weiming has championed Confucianism as a world religious tradition—its ideals and practices open not only to those of East- and Southeast-Asian ethnic background, but to anyone who shares its anthropocosmic vision. And there are many who do. Robert C. Neville, author of *Boston Confucianism,* is a prominent example of those who claim a dual religious orientation and who write persuasively on the significance of Confucian tradition for the West.

Women

There is nothing in the Confucian tradition inimical to women. Confucius had little to say about women other than, like uneducated men, they "were difficult to deal with" (*Analects* 17: 25). It was only later, with the Han dynasty grafting of cosmological speculation onto the tradition, that women became ineluctably identified with yin and its associated qualities in a negative way. Mengzi, for example, accepted the social mores of his day but did not see women as disposable or unworthy of regard:

> Chunyu Kuan asked, "In giving and receiving things, is it not the rule that men and women should not touch?"
>
> Mengzi repled, "That is the rule."
>
> "If my sister-in-law is drowning, then should I use my hand to save her?"
>
> "Anyone who wouldn't is a wolf. That men and women shouldn't touch in giving and receiving things is the rule; to use your hand to save your sister-in-law transcends rules." (4A17)

Yet it was Mengzi who underscored the filial necessity of producing an heir in order to ensure the care of elderly parents and the maintenance of ancestral veneration. He said, "There are three ways to be unfilial, and the greatest of these is to be without posterity" (4A26). In the premodern world, posterity meant a son or, preferably, sons. The resultant pressures on a woman were great. She was to bear children early and often; to continue bearing children until at least one son was born; and, in cases where she failed in this requirement or seemed likely to do so, to accept divorce or the introduction of concubines into the household.

The imperative to produce a son remains strong and has had a profound impact on the growth of certain reproductive technologies. The desire for male offspring, coupled with restrictive population control measures in China, and with trends toward smaller nuclear families in the industrialized nations of Japan, Taiwan, Korea, and Singapore, has led to increased use of sonograms for fetal sex determination, often followed by elective abortion if the fetus is female. Of course, to describe abortion as *elective* in this context is to gloss over the many pressures—economic, spousal and familial, societal—that may accompany the decision; use of the term here indicates only that the procedure is not medically necessary.

Abortion itself is condemned within the Confucian tradition as a mutilation of familial flesh. Buddhist notions of karma and the Buddhist prohibition against the taking of life compound the sense that a fetus should be protected. However, there is widespread ambiguity in the popular imagination about the ontological status of the fetus, as noted in studies of fetus-ghost appeasement rituals in Japan and Taiwan, conducted by William LaFleur, Helen Hardacre, and Marc Moskowitz. Most people believe the fetus to have a soul at conception, yet there is also the belief that this soul is not solidly anchored, meaning that it is extremely susceptible to fright—and flight—during the first 100 days of infancy. A soul that escapes its body in this way will likely make its way to another, but the specter of a free-floating vengeful spirit has fueled a lucrative fetal-ghost appeasement industry.

It must also be noted that nominally Confucian cultures have long embraced a pragmatic ethical relativism, sometimes attributed to Taoism, which seeks to maximize personal and familial benefit while avoiding inauspicious residual effects. In late-twentieth-century China, an alternative to abortion and female infanticide has emerged: After birth unwanted infant females are anonymously left at local orphanages or social welfare offices, or else they are quickly sold to baby brokers who then deliver them to state facilities. In this way, the state has found itself with a seemingly inexhaustible supply of a highly desirable commodity: infant girls for the international adoption market.

In some areas the male-female sex ratio of recorded live births is severely and increasingly skewed in favor of males. In Korea use of ultrasound screening to determine fetal sex is illegal but widely practiced. In China the overall male-female ratio of recorded births is between 117:100 and 120:100, whereas the average should be 105:100. In certain rural areas, the ratio rises to 144:100, the highest imbalance in the world. It is impossible to know with certainty the exact percentages of the *missing girls* who were aborted or were victims of infanticide, or the number of girls who were born and kept by their families but whose births were not recorded on official rosters. What is known is that decades of increasingly unbalanced male-female ratios have given rise to kidnappings, mail order marriages of children, and wholesale trafficking in women (Rosenthal, Eckholm).

Ownership of the Body

Of particular relevance to bioethics is the Confucian understanding of ownership of the body. Confucian tradition holds that one's body is not truly one's own; rather, it is held in custody for one's parents and ancestors. In a particularly gendered illustration of this notion, the historical records contain many examples of filial daughters and daughters-in-law who, charged with the care and feeding of parents and parents-in-law, cut flesh from their arms or legs in order to make nourishing broth in times of war or famine. In other circumstances, however, to harm or mutilate one's body

might render it insufficient to its purpose of care for preceding generations. To a Confucian, therefore, preserving the integrity of the body is of great importance. This holds true even after death, for although the deceased becomes an ancestor him- or herself, he or she remains at the service of still earlier generations.

Here too, the complexity of Confucian interaction with other traditions becomes apparent: Internal organs are only valued for their functions, and thus the donation of a sample of bone marrow or of a single kidney would seem permissible. However, the general Confucian sense of the body remaining intact in order to serve one's family is compounded by the popular Buddhist notion that a body must be complete in order to move through its karmic destiny. For many people in Confucian cultures, therefore, the combination of these beliefs has precluded acceptance of organ donation and transplantation up until quite recently.

One organization that has been working to change this view is the Tzu Chi Buddhist Compassion Foundation, a lay organization that claims 4 million members worldwide. Founded in rural Taiwan in 1966 by Dharma Master Cheng Yen, a self-ordained nun, the Tzu Chi Foundation exhorts women to fulfill their traditional Confucian role of dutiful wife and mother—even as it promotes women's volunteer efforts outside the home, particularly in medical care and disaster relief. In 1994 Tzu Chi established a bone marrow registry, the third largest in the world in 2003. Tzu Chi encourages organ and tissue donation (and even body donation for the training of medical students) as examples of Buddhist compassion. Although these teachings are at odds with traditional Confucian-Buddhist attitudes toward the body, Master Cheng Yen emphasizes the interconnectedness of all beings and the importance of practicing compassion to save lives. At Tzu Chi hospitals, hospices, free clinics, and medical and nursing schools, healthcare workers are trained to view patients holistically and humanely, seeing them as teachers and as providers of opportunities to serve.

Current Directions of Contemporary Scholarship

For scholars *of* Confucianism, the implications of studying Confucianism as a world religion are that its texts and interpretive traditions are open to literary critical study; its history is scrutinized for gender, class, and other biases; its ideal figures are analyzed with historical, sociological, and psychological tools; and its entire ethos is set in a comparative framework. The profoundly transformative aspects of its humanistic project can be appreciated as overtly religious, and discussions of Confucian spirituality are increasingly common.

For scholars *in* the tradition, new questions abound. What is the Confucian response to environmental degradation? Can traditional relationships be recast to address new configurations of the nuclear family, for example, same-sex unions, one (female)-child households, or blended families? What is the nature of lateral relationships, that is, what is one's relationship to other members of a civil society? What is the Confucian perspective on various reproductive technologies, or on genetic screening? Such issues are fraught with ambiguity.

For people in cultural China, Korea, Japan, and Vietnam, Confucianism is perhaps best understood as providing a substratum of belief, complementing or complicating other beliefs and values, whether sectarian or secular. Although scholars can debate Confucian responses to any issue, a single Confucian judgment is probably impossible to construct. In the syncretic and diasporic world of Confucian cultures, a Korean Christian Confucian may hold one opinion, a Japanese Buddhist Confucian another, and a *Boston Confucian* may hold yet another view altogether.

CONSCIENCE

• • •

Matters of conscience arise with some frequency in bioethics. A health professional may cite considerations of conscience in declining to perform or participate in a certain procedure. A patient may refuse a particular treatment on grounds of conscience. And new or unanticipated circumstances may create conflicts of conscience for patients and health professionals alike. What do we mean by "conscience" in these and related contexts? Is conscience an internal moral sense sufficient for distinguishing right from wrong? Is the "voice" of conscience simply the echo of parental and social prohibitions? Or does conscience differ in important ways from either of these? How much weight should be given in ethical reflection to claims of conscience? To what extent and for what reasons should health professionals compromise personal convenience, institutional efficiency, or medical effectiveness in order to respect individual conscience, their own or their patients'?

Three Conceptions of Conscience

The idea of conscience has a long and complex history (D'Arcy, 1961; Mount). The word "conscience" derives from the Latin *conscientia,* introduced by Christian Scholastics. Most generally, it refers to conscious awareness of the moral quality of some past or contemplated action and the disposition to be so aware (conscientiousness). In what follows we consider three main conceptions: (1) conscience as an inner sense that distinguishes right acts from wrong; (2) conscience as the internalization of parental and social norms; and (3) conscience as the exercise and expression of a reflective sense of integrity.

MORAL SENSE. Conscience is sometimes conceived as an internal moral sense sufficient for distinguishing right from wrong. The reliability of this inner sense is usually attributed to its divine origin, its reflection of our true nature, or some combination of the two. There are, however, difficulties with this conception.

Consider, first, a variation of an argument developed by Plato in his *Euthyphro.* Is what makes an act right the fact that it is endorsed by one's conscience? Or does conscience recommend a certain course of conduct because it is right? If the former, the promptings of conscience appear to be arbitrary. Whatever is urged by a person's conscience would, in this view, be right. There would be no way to assess the deliverances of conscience or to compare the consciences of, say, Hitler and Mother Teresa. If, on the other hand, conscience directs us to perform certain acts because they are right, it cannot be the principal source of moral knowledge. We must, in this event, have prior, independent criteria of rightness and wrongness that allow us to distinguish those acts that should be recommended by conscience from those that should not—in which case conscience is not sufficient to guide conduct.

A related difficulty is the prevalence of conflicts of conscience, both within persons and between them. Such conflicts are especially pronounced in bioethics, where advances in knowledge and technology confront us with unprecedented, consequential choices ranging well beyond our ethical traditions. The limitations of conscience, if it is conceived as a sufficient guide to moral decision making, may not be so noticeable in static, homogenous, insular cultures and subcultures. But where new circumstances require members of pluralistic societies to come to some agreement on bioethical questions, appeals to an internal, self-validating sense of right and wrong are apt to generate more heat than light.

INTERNALIZED SOCIAL NORMS. The most plausible explanation for the limitations of conscience in resolving ethical conflicts is that the "voice" of conscience is simply the echo of social and parental admonitions impressed upon the developing psyches of young children (i.e., the Freudian superego). Whatever its psychological and developmental significance, conscience so conceived has little normative import. That we have certain moral compunctions as a result

of our socialization does little to establish their validity. We are bound by the voice of conscience only if we can provide independent justification of its dictates. It is the adequacy of the justification, not the persistence of the voice, that carries moral authority. Conceived as internalized social norms, then, conscience plays no direct role in ethical deliberation.

SENSE OF INTEGRITY. "I couldn't live with myself if I were [or were not] to perform the abortion in these circumstances." "I can no longer participate in this treatment plan in good conscience." "How could I continue to think of myself as a Jehovah's Witness if I were to consent to the blood transfusion?" Each of these sentences expresses an appeal to conscience that is neither a deliverance of an internal moral sense nor an internalization of an external social norm. What is expressed in each case is the culmination of conscientious reflection about the relationship between a certain course of action and a particular conception of the self. So understood, appeals to conscience are closely connected to reflective concern with one's integrity. The focus is not so much on the objective or universal rightness or wrongness of a particular act as on the consequences for the self of one's performing it.

There is something absurd, Gilbert Ryle has observed, in saying "My conscience says that *you* ought to do this or ought not to have done that" (Ryle, p. 31). I may be troubled by your wrongdoing, but unless I have advised or assisted you, or culpably failed to prevent you from performing the act in question, my conscience will be clear. The same is not true, however, about those of my acts that I have determined, for one reason or another, were or would be morally wrong. Having judged a certain act to be wrong, an appeal to conscience stresses the added wrongness of my performing it. Appeals to conscience therefore presuppose a prior determination of the rightness or wrongness of an act (Childress, 1979). Moreover, one may or may not extend the standards one employs in making this assessment to others in similar situations. If, for example, the standards are universalizable principles of respect for persons, justice, or beneficence, one will maintain that anyone would do wrong in performing the act in question. But if one's standards are grounded in religious convictions, personal ideals, or a particular worldview and way of life, one may not hold everyone else to them. What is at stake in all such appeals is one's wholeness or integrity as a person.

Integrity

"It would be better for me," Socrates says in the *Gorgias,* "that my lyre or a chorus I directed should be out of tune and loud with discord, and that multitudes of men should disagree with me rather than that I, *being one,* should be out of harmony with myself and contradict me" (Arendt, 1971, p. 439). One cannot lead a good and meaningful life, Socrates suggests, unless the self is reasonably unified or integrated—unless, that is, one's words and deeds cohere with one's basic, identity-conferring, moral, religious, and philosophical convictions. Hence the importance of critical reflection on one's life as a whole. The words, deeds, and convictions of an unexamined life are unlikely to be sufficiently integrated to constitute a singular life—let alone one worth living.

Conscience should not, therefore, be conceived as a faculty or component of the self. It is, rather, the voice of one's self as a whole, understood temporally—as having a beginning, a middle, and an end—as well as at a particular moment. Operating retrospectively, what Christian tradition calls "judicial" conscience makes judgments about past conduct. Operating prospectively, what the same tradition calls "legislative" conscience anticipates whether a prospective utterance or course of action is likely to be at odds with one's most basic ethical convictions (D'Arcy, 1961). In each case, the signal that something is wrong—that one's integrity has been, is currently, or would be compromised—is an actual or anticipatory feeling of guilt, shame, or remorse.

Consider, in this connection, the words of Aleksandr N. Chikunov, a veteran of the 1968 Soviet invasion of Czechoslovakia, as he explains sharing his experience with young soldiers called to Moscow to suppress democratic reforms during the abortive coup of August 1991: "I entered Prague in 1968 and I still have an ill conscience about it. I was a soldier then, like these guys. We were also sent like they are now, to defend the achievements of socialism. Twenty-three years have passed, and I still have an ill conscience" (*New York Times,* August 20, 1991, p. A13). Here Chikunov draws upon the lessons of his "ill" judicial conscience to inform and alert the legislative consciences of the young soldiers. His motivation, it seems, is not only to spare them the pangs of an ill conscience but also to help heal his own (and thus to heal himself).

The authority and sanctions of conscience are, Mr. Chikunov suggests, self-imposed. No external source can create or directly relieve a troubled conscience. Nor may we easily rationalize or evade its judgments. "Other judges," as D'Arcy points out, "may be venal or partial or fallible; not so the verdict of conscience" (D'Arcy, 1961, p. 8). The oppressiveness of a guilty conscience is due in part to its identity with the self.

Conscience in Bioethics

Three factors contribute to the prevalence of appeals to conscience in bioethics: (1) bioethical decision making often

involves our deepest identity-conferring convictions about the nature and meaning of creating, sustaining, and ending life; (2) healthcare professionals and patients and their families will occasionally have radically differing beliefs about such matters; and (3) the complexity of modern healthcare often requires agreement and cooperation on a single course of action.

CONFLICTS OF CONSCIENCE. Conflicts of conscience arise not only between individuals but also within them. Consider a physician whose patient, suffering greatly from the ravages of the last stages of a terminal illness, is also a longtime friend. The patient requests the physician to provide both the substance and the instruction for taking his own life. The physician finds herself torn. On the one hand, her conception of medicine and professional identity is incompatible with what appears to be physician-assisted suicide. On the other hand, the bonds of friendship and her natural sympathies strongly incline her to accede to her patient's request. The situation has, as a result, precipitated a crisis of conscience, and the physician must engage in what Charles Taylor has called "strong evaluation"—reflection about the self by the self in ways that engage and attempt to restructure one's deepest and most fundamental convictions (Taylor). Such reflection manifests an admirable concern for wholeness or integrity.

CONSCIENTIOUS REFUSAL. From Socrates to Sir Thomas More to Henry David Thoreau, individuals have appealed to conscience in refusing to comply with a wide range of legal or socially mandated directives. In some cases such noncompliance may be covert and evasive—for example, a physician's providing contraceptive information to married couples in Connecticut before that state's anticontraceptive law was declared unconstitutional (Childress, 1985). In most cases, however, health professionals and patients give reasons of conscience in openly seeking personal exemption from certain standard practices.

Physicians may appeal to conscience in refusing to do procedures that are both legal and performed by their colleagues. Consider an obstetrician's refusal to perform a legal abortion or a pediatrician's refusal to prescribe human growth hormone for short, but normal, children at the behest of their anxious parents. In each case the physician's decision may be based on moral convictions or personal ideals. The obstetrician need not believe that abortion ought to be illegal or that women who request, or physicians who perform, abortions are deeply immoral. The pediatrician may neither urge the legal prohibition of administering human growth hormone to short, but normal, children nor regard parents who request this treatment, or other pediatricians who administer it, as unethical. Both agree, however, that it would be a violation of conscience—a betrayal of their deepest personal convictions about life or the nature of medicine—if they were to perform the act in question.

Similarly, nurses appeal to conscience in seeking exemption from procedures or care plans that threaten their sense of integrity. For example, a nurse may conscientiously refuse to follow a physician's directive to remove medically administered hydration and nutrition from a patient in a persistent vegetative state. Regardless of the act's legality, the family's concurrence, and the physician's directive, given her deepest identity-conferring convictions about the nature and value of life, the nurse may be unable to carry out the action. Her reasoning, she might add, is not strong enough to condemn others who believe differently; but as for herself, she must refrain.

Patients, too, may appeal to conscience in refusing forms of medical treatment. When informed, mentally competent Jehovah's Witnesses refuse blood transfusions on religious grounds, they do not at the same time urge that blood transfusions be legally prohibited, nor do they condemn those who gratefully accept blood transfusions. What they want is not so much respect for the content of their particular convictions as much as respect for their consciences. The same is true of other patients who refuse or request certain forms of treatment on the basis of fundamental moral and religious convictions.

Respect for Conscience

Respect for conscience is a corollary of the principle of respect for persons. To respect another as a person is, insofar as possible, to respect the expression and exercise, if not the content, of a person's most fundamental convictions. A society's respect for individual conscience may extend not only to religious toleration but also, for example, to exempting conscripted pacifists from direct participation in war.

In the biomedical context, respect for conscience may be inconvenient, inefficient, or detrimental to medical outcomes. Still, it must always be taken seriously and often should prevail. In some cases, respect for conscience may be balanced with biomedical goals. At a certain level of abstraction, the purpose of healthcare is strikingly similar to that of protecting individual conscience. Although healthcare is usually focused on the body, emphasis on informed consent implies that the principal function of medicine is the health or wholeness of the patient as a person. Yet a person's sense of health or wholeness may also be threatened by what the former Soviet soldier, Aleksandr Chikunov, revealingly called

an "ill" conscience. The values underlying appeals to conscience within the healthcare system are not, therefore, radically at odds with the values underlying medical and nursing care. In each case the aim is to preserve or restore personal wholeness. Insofar, then, as appeals to conscience and the healthcare system share a fundamental commitment to preserving and restoring personal wholeness or integrity, we ought in cases of conflict to seek some sort of balance or accommodation between them.

Health professionals who refuse, withdraw, or dissociate themselves from certain practices or procedures on grounds of conscience may well be among the more thoughtful and effective members of a healthcare team. Thus a healthcare institution intent on retaining such nurses and physicians has prudential as well as ethical grounds for accommodating their claims of conscience even at the cost of some inconvenience or expense. Respect for conscience requires going to greater lengths for patients, however, than it does for healthcare professionals. This is in part because an individual's role as a healthcare professional is voluntary in a way that being a patient is not. It is one thing, for example, to respect a Jehovah's Witness patient's conscientious refusal of a blood transfusion; it is quite another to respect the conscientious refusal of a physician who is a Jehovah's Witness to administer blood transfusions. An individual whose moral or religious convictions are incompatible with a common, essential type of healthcare has no business seeking a position in which such care is a routine expectation.

Problems and Limits

At least two important questions remain. First, how do we distinguish genuine claims of conscience from claims serving as smoke screens for laziness, cowardice, distaste for certain procedures, or dislike or prejudice toward certain patients? Second, given that a genuine act of conscience may be morally wrong, should individuals always (or always be permitted to) follow their conscience?

GENUINENESS. Understanding the nature and justification of conscientious refusal allows us to distinguish genuine from spurious or self-deceived appeals to conscience. In assessing the authenticity of such appeals we may, for example, inquire into (1) the underlying values and the extent to which they constitute a core component of the individual's identity; (2) the depth of the individual's reflective consideration of the issue; and (3) the likelihood that he or she will experience guilt, shame, or a loss of self-respect by performing the act in question. Such criteria have been employed with reasonable success by the U.S. Selective Service System in identifying those whose deep and long-standing moral convictions forbid direct participation in war. They can be used with similar success in identifying genuine appeals to conscience in the healthcare setting (Benjamin and Curtis).

CONSCIENTIOUS BUT WRONG. Conscience is not an infallible guide to conduct. Even those who attend carefully to matters of integrity and who critically examine their basic convictions may, at a later date, judge some of their conscientious acts as wrong. Should one, then, always follow one's conscience? If by "conscience" we mean the exercise and expression of good-faith efforts to integrate conduct with reflective ethical conviction, the answer is "yes." Following conscience is obligatory, even if one's act turns out to be wrong, because one is doing what one reflectively believes to be right. Conversely, deliberately acting contrary to conscience is blameworthy, even if one's act turns out to be right, because one is doing what one reflectively believes to be wrong.

We must therefore distinguish the character of an agent from the rightness of a particular act. That an act is required by conscience entails neither that it is right nor that others must endorse the agent's convictions or permit the act to occur. It is difficult, for example, to question the character of Jehovah's Witness parents when they conscientiously refuse to consent to a life-saving blood transfusion for a young child. Yet if we have good reasons for believing that withholding the transfusion would be seriously wrong, we may try to persuade the parents to consent and, if necessary, seek a court order mandating treatment. Distinguishing the conscientiousness of the parents from our judgment of the act, though not eliminating the difficult question of whether, and if so, how, to intervene, enables us to attend more adequately to its complexity.

CONSCIENCE, RIGHTS OF

• • •

The phenomenon of a *right of conscience* arises only in a society that takes seriously the autonomy of individual persons. Philosopher James Childress has described appeals to conscience as "a person's consciousness of and reflection on his own acts in relation to his standards of judgment." (Childress, 1979) Rights of conscience are political rights that protect people's ability to do what they believe is morally best: they are political *autonomy rights.* Common scenarios for the exercise of a right of conscience in healthcare include seeking an exemption from mandatory vaccination and, for physicians, refusing to participate in morally controversial procedures like abortion.

Political Significance

To understand the political role of rights of conscience, it helps to think of the activities a person might engage in as falling into one of three political categories: (1) prohibited, (2) permitted, or (3) required. In Western societies, the vast majority of possible activities are permitted, meaning people may engage in that activity if they wish (it is not prohibited), but they do not have to engage in that activity (it is not required). A person may exercise autonomy, then, in deciding whether to engage in the activity. Likewise, some activities (e.g., murder, robbery) may be prohibited, and some activities (e.g., military service in times of war) may be required.

An autonomy right ensures that protected activities are not unduly prohibited or required. For example, one prominent autonomy right protects the practice of religion: the autonomy right of freedom of religion means that a person's religious practice cannot be unduly prohibited or required. This allows a person to practice religion, but also allows a person to decide not to practice a religion. Thus, the practice of religion is neither prohibited nor required, allowing a person to exercise autonomy in the practice of religion. Other examples of autonomy rights include freedom of speech (which protects against state prohibition of the expression of opinions, but does not require a person to express their opinion), freedom of assembly (which protects against state prohibition of people's ability to assemble), and, in the United States, the right to own firearms (which protects a person's ability to own a gun).

The Focus of Autonomy Rights

In Western societies, most political autonomy rights focus on ensuring that certain activities are not unduly prohibited (thus protecting a people's ability to engage in that activity if they should choose). This can be seen in the way such rights are normally phrased:

> Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof; or abridging the freedom of speech, or of the press; or the right of the people peaceably to assemble, and to petition the Government for a redress of grievances. (Bill of Rights, U.S. Constitution, Amendment I)

Rights of conscience, however, protect a person from mandatory participation in an activity if the activity in question threatens the fundamental values of an individual person. This focus can be seen in the way conscience clauses are typically phrased: "No person shall be required to …" In a clinical context, rights of conscience are exercised against a backdrop of a professional duty to treat a patient once a provider-patient relationship is established. Thus, rights of conscience claim an exemption to participation in activities that one would otherwise be expected to undertake. The most common example is a claim to be exempt from participation in abortion procedures.

Conditions of a Right of Conscience

The primary conditions necessary for the legitimate exercise of a right of conscience consist of: (1) the lack of harm posed to others by the exercise of a right of conscience; and (2) strength and sincerity of beliefs that are the basis for a claim of conscience. The exercise of a right of conscience does *not* require a demonstration of the truth of beliefs that are the basis of a right-of-conscience claim, as requiring the truth of a belief to be demonstrated would trivialize the right itself. The first of these conditions represents a straightforward balancing of the rights of individuals through recognition that autonomy rights must be restricted when significant harm is posed to others. Thus, for example, a right to freedom of speech does not include a right to shout "Fire!" in a crowded theater. Similarly, seeking an exemption from mandatory vaccination is restricted in circumstances of epidemic disease, where failure to be vaccinated could pose a threat of harm to others.

Such a balancing of autonomy rights and social harm was clearly recognized in the U.S. Supreme Court case of *Jacobson v. Massachusetts.* Henning Jacobson argued that he should not be forced to receive a vaccination during a smallpox epidemic because "compulsory vaccination is … hostile to the inherent right of every free man to care for his own body and health in such a way as to him seems best." The Supreme Court rejected this argument in the context of an epidemic, however, stating, "The liberty secured by the Constitution of the United States does not import an absolute right.… There are manifold restraints to which every person is necessarily subject for the common good" (*Jacobson v. Massachusetts*).

The second condition listed above is less commonly required for the exercise of an autonomy right. It requires that rights of conscience only be exercised on the basis of values that are central to one's life. As Childress describes it, "In appealing to conscience I indicate that I am trying to preserve a sense of myself, my wholeness or integrity … and that I cannot preserve these qualities if I submit to certain requirements of the state or society" (Childress, p. 327). To legitimately exercise a right of conscience, one must show that participation in the required activity would threaten values that play a central role in the way one has chosen to live.

Because the majority of people in Western societies are religious, and their religious convictions normally represent their most fundamental values, claims to rights of conscience most commonly arise in the context of religious convictions, though rights-of-conscience claims need not be based upon religion. The most prominent example is conscientious objection to participation in war. During the Vietnam War era, the U.S. Supreme Court ruled that a person may qualify for an exemption to participation in war if the person's opposition stems from "moral, ethical, or religious beliefs about what is right and wrong, and that these beliefs be held with strength of traditional religious convictions" (*Welsh v. U.S.*).

The type and significance of harm to others that might negate the ability to exercise a right of conscience, as well as the abstract notion of *strength of conviction* necessary to qualify for a right of conscience, represent the key points of contention in how to distinguish legitimate from illegitimate claims to a right of conscience. The most prominent debate in the literature concerns the consequences of recognizing rights of conscience relevant to access to abortion services. In some areas, conscientious refusal by physicians to participate in abortion services has limited access to abortion services, or made them unavailable. Use of this type of harm to negate rights of conscience, however, is met with substantial skepticism. The argument requires that the conscience of a woman seeking access to abortion takes precedence over that of a physician, and also assumes that a right to not be prohibited from having an abortion is tantamount to a right of access to abortion services. These issues remain at the center of this ongoing debate.

A second type of harm that is discussed in the literature consists of psychological and moral harms associated with the necessity of transfer of care from a provider a patient has chosen, due to that provider's refusal to participate in a particular treatment plan. The significance of this should

not be overlooked: while transfer of care leaves a patient with continued access to care in the abstract, the patient may not feel as comfortable with the caregivers to whom he or she is transferred. Thus, one should only necessitate such a transfer if the values threatened are significant.

The Exercise of Rights

Recognition of the types of harms described above is closely tied to attempts to outline the scenarios in which a right of conscience should (and should not) be exercised. While it is desirable to recognize rights of conscience in matters of central moral importance to a person, rights of conscience should not be used, for example, to discriminate against a racial or ethnic group by refusing services to that group, or to undermine informed consent by pressuring a patient to agree to a treatment plan through threat of transfer of care. Conscience clauses that offer blanket protection and simply require transfer of care fail to address these concerns, so criteria to distinguish when a right of conscience is appropriately exercised become important.

Most of the literature recognizes that entering into a profession imposes some level of moral duty that may at times conflict with a person's own judgment. While it is important to recognize moral diversity within a profession, and thus allow for some cases of conscientious objection, it is also important to recognize the weight of professional obligations, such as respect for patient autonomy and informed consent. Because professional obligations to respect informed consent do carry moral weight, rights of conscience are, in general, more appropriately exercised over patient requests for services than over patient refusals, since objection to a patient's refusal fails to respect that patient's evaluation that the treatment does not offer desired benefits (this is a general guideline, however, and may admit of exceptions). So, for example, a physician's right of conscience (for refusal of services) is appropriately exercised over a patient's request for an abortion or for assistance in committing suicide (physician-assisted suicide). A right of conscience is not appropriately exercised, however, over a patient's refusal of a ventilator. Similarly, it is widely recognized that rights of conscience should not be exercised over simple disagreement with a patient's treatment choice. These general guidelines still leave a lot of gray area, however. For example, does a request by a Jehovah's Witness for surgery without blood products constitute a refusal of blood products or a request for a specific surgical procedure (one that does not involve the use of blood products)?

Professional obligations of nondiscrimination are also important in formulating criteria for the legitimate exercise of a right of conscience. The conscientious objection in question should not be based on *who* is to receive the treatment or procedure. Instead, conscientious refusal should be based on the *type* of treatment or procedure in question, rather than, for example, provision of this treatment or procedure to members of a particular racial or ethnic group. Here, too, the general guidelines leave room for debate; such as when an objection is based on the fact that a procedure is particularly dangerous for a certain segment of the population (e.g., organ transplant recipients, elderly patients).

Summary

While several points of debate continue to remain contentious, some general observations can be made concerning the appropriate exercise of a right of conscience. First, such rights should only be exercised if doing so does not pose a threat of significant harm to others. Second, the exercise of a right of conscience should be based upon values that play a central role in the life of the person claiming a right of conscience. Related to this, rights of conscience should not be exercised on the basis of simple disagreement about a treatment plan. Third, conscientious objection to patient requests will be, in general, more appropriate than objection to patient refusals. Finally, professional obligations to respect patient autonomy and to avoid discriminatory practices should be weighed against the exercise of a right of conscience. In this context, conscientious objection should be exercised only when based upon an objection to the *type* of activity in question.

CONSENSUS, ROLE AND AUTHORITY OF

• • •

Consensus plays a paradoxical role in bioethics: Although the weight of opinion is traditionally thought to have little or no merit in the resolution of moral problems, practical moral problems beg for a modus operandi that enables activity to proceed. Upon analysis, consensus also reveals a complex conceptual structure as well as a murky etiology in the history of ideas. Yet it seems difficult, if not impossible, to avoid the pursuit of consensus in the face of a morally troubling situation, however obscure the object of that pursuit might be. The impetus for a consensus is acute in a field like bioethics, which often expresses itself in such settings as clinical or research ethics committees (Moreno, 1988) and governmental policy commissions (Walters).

The History of Consensus

It is not easy to get clear on the idea of consensus, and particularly the idea of moral consensus. One reason is that relevant discussions in the history of philosophy do not always use those terms. For example, Plato's political philosophy can be taken as a treatise on consensus, but he would understand a consensus (a Latin term, of course), as a common or shared opinion. Thus the findings of the jury in Socrates's trial represent a shared opinion, and to Plato a deeply flawed one, that led to the death of his beloved teacher and seems to have inspired his elaboration and extension of Socratic philosophy in the *Republic.*

Literary and philosophical references to consensus seem first to have appeared with some frequency only since the nineteenth century. By then the political conception of consent of the governed had of course been subjected to close examination prior to the American and French revolutions and played a key role in those epochal events. Consensus might be regarded as the sociological cousin of political consent, not always as explicit in its manifestation nor as definitive, but nevertheless a key element in a well-functioning society. In contrast to the philosophical notion of consensus exemplified in social contract theories, sociological understandings of consensus emphasize acquiescence to extant norms.

For social scientists consensus emerged as an important category of analysis in the era of industrialization, as it helped account for the social harmony required of complex bureaucracies in the private and public sectors. Increasingly, societies in the process of pluralizing also had reason to be more aware of consensus as they encountered an unaccustomed diversity of basic values. By the late twentieth century consensus had become very nearly an end in itself among policy makers intent on finding common ground in postmodern societies rent by divisive issues, such as abortion.

Bioethics is certainly a result of this emerging process. In the early 1960s, when dialysis machines were developed to the point that they could extend life indefinitely but remained in short supply, the need to formulate an acceptable allocation arrangement was acute. Other matters of concern followed rapidly, including organ transplants, genetic engineering, human experimentation, and discontinuing life-sustaining treatment. In each case bioethics gained social standing through its participation in the formulation of a consensus. Conspicuous in its absence from this list is abortion, and it may be significant that this is the only one of these topics that was resolved almost solely in the legal system. Although the law is often an excellent instrument for consolidating a moral consensus, this is evidently not always the case.

The Paradox of Consensus in Bioethics

The emergence of consensus as a category of moral discourse flies in the face of some deeply held cultural assumptions, at least in the West. Plato's version of consensus as shared opinion was intimately related to his devastating critique of democracy as mob rule, a view that arguably required more than a millennium to overcome. His philosopher-kings knew the Good, they did not have a mere opinion about it. The great moral heroes of Western culture, from Moses to Jesus to St. Joan to Gandhi and Martin Luther King, Jr., embodied the Platonic ideal of the individual who knows the Good, confronting the mob, possessed only of an opinion.

Although one can hardly gainsay the salutary societal effects of moral heroism, the confidence it implies has its pitfalls. What American philosopher and educator John Dewey (1859–1952) so penetratingly labeled a quest for certainty characterizes much of subsequent thought, philosophical and scientific, as well as theological, all under the sway of Platonism. With the emergence of modernity, moral certainty in particular has been in tension with what another American philosopher, Charles Sander Peirce (1839–1914), called fallibilism: the doctrine that assertions must be revisable in light of further evidence, and that in the final analysis belief statements are certified as true by a community, not an individual. Fallibilism is the underlying philosophy of experimental science. Dewey especially argued that there is an experimental quality to the moral life, and that longstanding moral values have proven themselves over long experience and cross-culturally. On this view, the adaptation of values to new circumstances requires literal re-evaluation, much as scientific communities revise hypotheses in light of new evidence. In direct contrast to Platonism, this position valorizes community opinion, or consensus.

As bioethics both draws from traditional moral values and concerns itself with emerging and often quite novel problems, this tension between Platonic and Deweyan views of moral consensus underlies all bioethical discourse. It is perhaps especially well illustrated in the contrasting outcomes of two early bioethics debates. In the recombinant DNA controversy of the 1970s, the first generation of bioethicists allied with scientists to undermine theological critiques of science unleashed on unique human qualities (Evans). By contrast, at the same time bioethicists added their voices to those protesting the high degree of discretion permitted medical scientists in human experiments (Moreno, 2001).

Modes of Consensus

The moral paradox of consensus in bioethics may therefore work itself out in surprising ways, but on the whole, and especially when it engages in developing public policy, bioethics is largely a consensus-oriented field (Moreno, 1995). These consensus processes may occur in various contexts and may be more or less self-conscious. Patient management conferences often involve ethical issues that may not be acknowledged as such, in contrast to the more formal setting of an ethics committee. The most formalized and public context for moral consensus is the governmental ethics commission. Lying somewhere in between are ethics advisory boards for private entities.

Whatever the context, insofar as consensus is the preferred outcome it can be distinguished from compromise, in which the parties seek to defend and retain certain underlying principles though they may be willing to modify elements of their viewpoints that are less central (Benjamin). In a truly consensus-oriented situation the members of the group do not arrive with fixed positions but each appreciates a genuine puzzlement at the problem and the optimal solution. They then work together to find what seems to be the most ethically justifiable way to manage the problem. Although the common language refers to *seeking* and *achieving* consensus, these terms imply a static series of events while in fact consensus is more accurately described as a process through which a certain shared sense emerges.

Considering that the problems addressed in bioethics tend to be novel in at least some important ways and are often controversial, it may be surprising that consensus is ever realized. In this respect a focus on particular cases or rather highly specified issues can be critical. Frequently consensus characterizes a group discussion of a specific moral problem though the members of the same group may harbor substantial differences concerning general moral views. One may therefore contrast deep with superficial consensus, where the latter is not dependent on the former. Various moral systems may lead to the same conclusion in particular cases. Efforts to reach a deep consensus may even backfire if they fail and the group's solidarity is thereby undermined. The somewhat counter-intuitive conclusion is that, when consensus is the concern, superficial agreement is often quite adequate and efforts to resolve deeper differences should be approached with caution.

Because bioethics is a social institution that often expresses itself in appointed or self-appointed committees, panels, task forces, commissions or some other small group, an important question arises about the relation between that group and its stakeholders. Many ethics panels include members of the community, apparently in contrast to the experts who generally make up the majority of the group. The presence of community members is presumably intended to help ensure that the views of the wider society are

represented. But the precise sense of representation at work here raises further questions. One way of modeling this activity is that of democratic deliberation, in which those actually engaged in the discourse are taken to be stand-ins for all those who do not have the resources or opportunity to immerse themselves in the issues at hand.

Consensus and Its Critics

The rapid growth of the bioethics profession and its close association with consensus processes expose it to the Platonic critique of shared opinion, particularly as these opinions are often received as a kind of moral expertise (Tong). The notion of expertise suggests that there is a certain body of information available to those who have certain training and experience, but not to others. If this information is taken to be at least partly factual in nature, then the consensus of moral experts must be limited to description rather than prescription. That is, on pain of violating the fact-value distinction, moral expertise can do no more than identify what is and has in fact been valued, not what ought to be valued.

Descriptive moral consensus is a form of social science, perhaps of survey research, that leaves little room for the dynamic public and professional discourse that characterizes bioethics. Without running afoul of the fact-value distinction, it appears that bioethicists must reconstruct their activity as a kind of social reform movement (Moreno, 1995). Their expertise lies not in the privileged status of their recommendations but in the arguments they put forward in support of these recommendations. Within these arguments is evidence drawn from many sources and principles derived from various sources, secular and theological, that are viewed as more or less authoritative.

Defenders of the role of consensus in bioethics, such as D. Micah Hester and Bruce Jennings, develop the notion of the individual as inherently a member of a community, so that values are embedded in social life. Rarely does any group speak with a single voice, however, and bioethicists themselves have diverse moral understandings regarding central moral issues. Even among these ethics experts there is often no common moral vision. In fact, it may be argued that this diversity is often ideological in nature, and therefore as suspect as any assertions about morality delivered by anyone with a partisan purpose (Engelhardt, 2002).

Similarly, no professional group can hope to speak for all moral viewpoints. Bioethicists have both adopted and helped articulate a certain ethical framework that valorizes individual self-determination. But many cultural subgroups, both in the developing world and within the developed world, do not accept the standard bioethical doctrines of truth telling and informed consent. Thus even if bioethicists as a professional class share some very broad consensus, they can hardly claim to speak for those groups that do not share their liberal sentiments with respect to individualism. Even a weak consensus seems hard to achieve across the board in a pluralistic society, and it is an impoverished morality that imposes self-determination on those who reject it (Trotter).

Yet a consensus among bioethical experts, however the latter term is defined, is not guaranteed to influence social policy. As Mark Kuczewski has pointed out, in the areas of foregoing life-sustaining treatment and the conduct of biomedical research, bioethicists have had extraordinary success in helping to develop a social consensus. But, as he notes, the same cannot be said for the questions concerning universal health insurance, even though many bioethicists are on record as supportive of such a program. This fact suggests that a bioethical consensus is perhaps not as weighty in public life as the critics of consensus may fear, nor as bioethicists may wish were the case.

Constraining Consensus

Considering both the moral hazards inherent in consensus and its practical inevitability in a field of ethics oriented toward practice and group decision making, careful attention must be given to the conditions under which consensus processes take place. As Kuczewski notes, in itself agreement among bioethicists means nothing. Acquiescence to expertise for its own sake would be an instance of the naturalistic fallacy, the derivation of a normative statement from a descriptive one. At the extreme, the widespread adoption of a collective bioethical soundbite that moves the public owing to its rhetoric would be emotivism in the guise of reflection.

What does count is the quality of arguments provided. These can and should be formulated, evaluated and revised by a community of bioethical inquirers. The environment must be one that fosters the exchange of reasoned views, further presupposing the peaceful resolution of moral controversy (Engelhardt, 1995). What emerges is a set of side constraints on moral consensus processes. Besides peaceable and reasoned argument there are also elements of democratic deliberation, such as a willingness to entertain unpopular points of view, mutual respect among the protagonists, and the assurance that the voices of all stakeholders have an opportunity to be heard. Strict attention must therefore be paid to the quality of the process. A self-critical consensus process should worry not about whether the outcome approximates an objectively right solution but

whether the proceedings have satisfied the requirements of fairness and accuracy.

The Future of Consensus in Bioethics

If consensus is an intrinsic part of bioethics as a social institution, especially in its capacity as a forum for the development of institutional and public policy, then there will be a continuing need to examine the way consensus processes operate both within bioethics and in the larger society that incorporates the views offered by bioethicists. A field concerned with the construction of moral standards should not be ignorant of the ways its procedures and products may be distorted, whether intentionally or not. This conclusion argues not only for a degree of self-consciousness about bioethical discourse. It also commends the need to develop a sophisticated understanding about those social psychological and political processes that set bioethics apart from other forms of moral inquiry.

CONTRACTARIANISM AND BIOETHICS

• • •

The idea of the social contract has been a central feature of Western moral and political thought since the seventeenth century. Theories that follow that tradition claim that the legitimate source of moral or political authority is mutual agreement. Contractarianism had widespread influence through the writings of Thomas Hobbes, Jean-Jacques Rousseau (1973 [1762]), Immanuel Kant (1965 [1797]), and John Locke (1960 [1706]) and has had a recent revival in the work of John Rawls (1971, 1993), David Gauthier (1986), and Thomas Scanlon (1998). Contemporary contractarians continue to drive discussions about topics such as the nature of democratic principles, the distribution of scarce resources in healthcare, the provision of public goods and services, the current generation's duties to future generations, and the current generation's obligation to preserve and protect the environment.

The Tenets of Contractarianism

Contractarianism includes a diverse family of theories that share a basic understanding about the nature of normative

justification: When faced with questions such as the following—What is just? What is right? What should I do?—contractarianism seeks an answer rooted in agreement. The motivating force behind the contract approach is the idea that consent confers legitimacy on particular moral decisions, the policies and laws of a particular society, and the basic principles of a just society.

The metaphor of the social contract represents people's willingness to enter into a society or a system of moral rules for mutual benefit, agreeing to bind themselves to the rules that make cooperative life possible. The social contract sometimes is characterized as a general agreement to keep more specific agreements. This idea is rooted in a form of skepticism about competing sources of normative authority, such as theories about human nature, theories of natural law, perfectionist theories, virtue theory, and other theories that attempt to offer more objective or foundational support for the content of moral principles and theories of justice.

Within the family of theories contractarians tend to be divided over questions about how to characterize agreement and the mechanisms of choice. For example, does moral justification stem from actual historical agreement, or is it more appropriate to reason hypothetically about what people would have reason to agree to in certain ideal conditions? The former approach to moral questions traces moral justification to actual agreements. The latter approach reflects on the hypothetical agreements of imagined agents in idealized circumstances. Both variants posit a starting point or initial position from which people have historically or hypothetically emerged to contract with one another for the sake of mutual benefit. Both mechanisms make it possible to evaluate current conditions in society or current moral practices by reference to a more ideal historical or hypothetical situation. For the contractarian, social and political institutions are human conventions that are open to criticism, rejection, revision, and ultimately acceptance.

Both the actual and the hypothetical contractarian approaches to moral and political theory have played a central role in bioethics. People who are interested in carrying on the contractarian tradition within bioethics must contend with some of the problems inherited by the more general theory as it has been developed in moral and political philosophy. What follows is an overview of contractarian approaches to the special problems of bioethics, including consideration of the strengths and weaknesses of those approaches.

Contractarian Approaches to Bioethics

If morality and politics are understood as joint enterprises that are entered into for mutual advantage, as contractarians understand them, one can begin to see a natural affinity between bioethics and contract theory. The patient-physician relationship, the practice of informed consent, the use of advance directives, the conducting of medical and scientific research, the obligation to take care of the elderly, systems of medical insurance and national healthcare, and many other aspects of health policy are central issues in bioethical debates. In an important way contractarianism attempts to make health policy, scientific institutions, and individual practitioners answerable to the individuals they serve.

Howard Brody (1989) has drawn a parallel between the rise of contractarianism in political philosophy and the rise of contractarianism in medical ethics. Just as Enlightenment philosophers challenged the idea of the divine right of kings to rule over subjects without consent, bioethicists from the early 1960s through the 1970s challenged the idea of paternalism in medicine. If patients are viewed in the way Enlightenment philosophers viewed the citizens of a state—as being autonomous and worthy of respect—treating patients paternalistically—considering them as being ignorant and inherently dependent on physicians—violates patients' autonomy.

THE PATIENT-PHYSICIAN RELATIONSHIP. Robert Veatch (1991), one of the earliest proponents of contract theory in bioethics, posed the following question: What type of patient-physician relationship would the parties to that relationship rationally consent to, assuming they were placed in a starting position of equal power? The resulting contractual model allows for important differences in knowledge and decision-making capacities between a patient and a physician but requires that equal respect be given to the interests and goals of both parties. The model grants physicians control over technical decisions and grants patients control over the aspects of a decision that involve personal values. If a patient in renal failure is faced with the options of ongoing renal dialysis and kidney transplant surgery, it is the physician's responsibility to present the risks and benefits of those options and explain the relevant medical information. It is up to the patient to decide what degree of risk she or he is willing to accept with either option and weigh the options in light of his or her own values.

The contractual model of medical ethics views the patient-physician relationship as one of respectful communication and negotiation. The specific list of rights and duties is arrived at through the hypothetical contract mechanism. If physicians and patients were negotiating the terms of the patient-physician contract, what terms would all the interested parties include in the contract? Certain rights, such as the patient's right of self-determination, and certain

corresponding duties, such as the physician's duty to disclose all the information needed by the patient to make a fully informed choice, would make up the content of the contractual model. Consistent with this model is the idea that a patient may willingly delegate his or her choices to a physician.

Norman Daniels (1981), following the political philosopher John Rawls (1971), relies on a Rawlsian model of the hypothetical social contract to construct a specific theory of healthcare needs. In the classic Rawlsian model it is imagined that a number of impartial observers are charged with the task of choosing basic principles of justice that will shape the constitution and laws of the society into which the observers will be born. These hypothetical agents do not know what place they will occupy within the society or even the generation to which they will belong. The thought is that the resulting principles of justice will be fairly chosen, unlike principles chosen by actual, biased, and self-interested parties in a real society. Rawls (1971) argues that rational agents in the original position will want to increase the amount of primary social goods available to them, consistent with an equal share of liberty. He assumes that such agents would be risk-aversive in a certain sense: They would not be willing to risk losing a certain basic amount of primary social goods in exchange for the possibility of seeking greater amounts of those primary goods.

HEALTHCARE NEEDS. Expanding on Rawls's general theory of justice, Daniels (1988) places healthcare goods under the principle of fair equality of opportunity, including healthcare needs among the primary needs of a society's members. One of the most interesting results of the theory as it is applied to health policy is the way in which Daniels attempts to solve the problem of age-group bias. In attempting to determine a just allocation of scarce health resources most real agents are deeply biased in favor of the scheme that will maximize the resources of their age group, heavily discounting the present over the future. If, however, people place themselves behind a Rawlsian veil of ignorance and imagine that they are blind to their particular generation, they will arrive at fair principles of healthcare distribution. The hope is that the resulting principles of resource allocation will ensure the well-being of all persons as they pass through various health institutions through the course of their lives. A healthcare system designed in accordance with the principle of equal opportunity will attempt to balance, for example, the need for services in critical care, preventive care, and long-term care. If the institutions at each stage are designed prudently, the hope is that all generations will benefit from the overall health system.

THE REQUIREMENT FOR PERMISSION. Against the Rawlsian contractrarian approach to bioethics, Tristram Engelhardt (1996) has offered a theory of bioethics rooted in the Kantian philosophical tradition, which relies centrally on the requirement of permission between persons. Engelhardt's approach to the specific problems of bioethics stems from deep skepticism about the possibility of achieving consensus about the substantive questions in morality and politics. He argues that all competing approaches to bioethics rely in some way on prior substantive assumptions about what is good or right. Such assumptions, he claims, cannot reasonably be made in a pluralistic world filled with competing ideas of justice and fairness, understandings of rationality, and visions of the good life.

Engelhardt offers an alternative model of bioethics that rests on a very minimal assumption salvaged from the Enlightenment project and the contractarian tradition. The basic assumption is that the only justifiable ground for dealing with moral controversies in a world of moral diversity is to appeal to actual agreement as the source of moral authority; any other appeal is illegitimate because it involves acceptance through force or coercion. To avoid imposing substantive moral views on those who are strangers to a group of people's views, Engelhardt urges people to appeal to consent as the mark of legitimate moral authority.

Rather than design a healthcare system that is based on the hypothetical agreement of hypothetical agents who must be assumed to have certain substantive views about what is just or good, Enghelhardt proposes that decisions about the allocation of health-resources be made directly by real parties to real agreements. In this model market mechanisms generally will guide decisions about the allocation of health resources on the national level, with the assumption that those who participate in the market implicitly if not explicitly consent to the practice and its outcomes.

Engelhardt leaves open the possibility that smaller groups and communities will agree to set up health institutions, such as private hospitals and long-term-care facilities, that are governed by more substantive goals of justice or visions of the good life. A Catholic hospital, for example, might have an internal policy against performing abortions and also might have a policy of offering a certain amount of charity care to indigent patients. In this model the relationship between the patient and the physician is characterized fundamentally in terms of permission and consent. Agreements between patients and their caregivers, such as those struck through the process of filling out advance directives, play a central role in ensuring that the minimal moral requirement of permission is secured. Similar to Veatch's account, the relationship between patient and physician is,

in Engelhardt's model, understood as one of respectful negotiation between the different parties to the decision-making process.

Critiques of Contractarian Approaches to Bioethics

Several important criticisms have been lodged against contractarian approaches to bioethics. Those criticisms have a common theme: The moral relationships and contexts that characterize the healthcare and research settings are too complex and subtle to be understood solely in terms of a contract. The general concern is that contract theory is too minimal in its approach to the rich and complicated moral terrain of bioethics.

Critics have objected that the physician-patient relationship rarely begins with an agreement or involves explicit negotiating. More often the beginning of the relationship is characterized by surprise, stress, a lack of time, fear, hope, an imbalance of knowledge, and a great need for trust. It is not typically a calm encounter between equal partners in a negotiation. This objection speaks primarily against the actual-contract model offered by Engelhardt because the hypothetical model is attempting to ask what principles should guide this stressful, complex encounter, and these principles are chosen in a calmer hour by philosophers, bioethicists, and health-policy makers.

This objection can be extended to the hypothetical model, however, by pointing out the disparity between the ideal situation in which principles of bioethics are hypothetically chosen and the real world. If the disparity is significant, it is not clear what binding force hypothetically chosen principles should have in actual practice. A great deal depends on the content of the hypothetical situation of choice and the substantive principles of rationality that will guide choice. If too much is packed into the descriptions of the initial position, the resulting choice will be biased and arbitrary, exactly the pitfall the contract tradition was designed to avoid. If one provides no structure and content to the nature of rationality guiding choosers in the initial position, the resulting principles will be empty and meaningless. This is a serious problem for contract theory in general that has been inherited by those hoping to apply that model to bioethics.

The unique relationship between patient and physician, others have argued, is not best characterized by the economic-political metaphor of the contract because the contract model relies too narrowly on rights and permission and overlooks other important goals and duties, such as compassion and trust. From the perspective of virtue theory, for example, the contractarian model of bioethics fails to address important issues about the character of physicians and other healthcare workers. What does it mean to be a good physician or a good nurse? Certainly there is more to being a good health professional or a good researcher than making sure that one negotiates the permission of one's patients and research subjects thoroughly. William May (1996), for example, suggests that the religious idea of a covenant compared with the secular metaphor of the contract is better able to capture the rich sense of duty and obligation inherent in the physician-patient relationship.

What drives this objection is a deeper concern that the minimal moral requirements of the contract model will not encourage a lasting and dedicated relationship with patients but instead will encourage physicians to ask, "Has the consent form been signed?" Although beneficence and compassion are clearly compatible with contractarian requirements in bioethics, there is a sense in which such moral goals remain "optional" because they are not the central focus of the theory.

Along a similar line communitarians have argued that the contract model is too individualistic in its focus. Moral issues in bioethics, even in the narrower domain of medical ethics, involve complicated social systems, shared and unspoken understandings, deep-seated cultural beliefs, and common expectations. Explicit contracts account for only a small part of the moral dealings in this context. Especially in areas such as public health, many decisions are best made in terms of what is best for the community or what maximizes the overall health of the community over and above the desires and preferences of individuals. Sometimes the only way to stem the immediate threat of an infectious disease such as tuberculosis may require practices, such as reporting and quarantine, that infringe on principles of individual consent and permission.

A final objection to the contractarian model, especially as it is applied to bioethics, is that it is centrally a theory about persons, whereas bioethics involves important ethical issues about nonpersons or semipersons, including animals, embryos, fetuses, children, adults with serious mental deficits, brain-dead patients, and the dead. Some of the most interesting and challenging issues in bioethics involve subjects one does not easily imagine sitting at the negotiating table. Because the contract model focuses on what rational, conscious agents would choose, there is concern that the focus on rational agreement excludes the moral concerns of more vulnerable members of society.

A morality based on mutuality and rational consent certainly can deliver principles for addressing the needs of

children, the mentally ill, and animals, but only insofar as the agents to the agreement deem those more vulnerable subjects worthy of consideration. Because moral duties and obligations emerge from mutual agreement, any duties that people have toward research animals, for example, could result only from the agreement of the human parties involved. The obligation is indirect: If animals and other vulnerable subjects are thought by human parties to an agreement to be worthy of care and respectful treatment, people will have indirect duties toward those animals. For some critics indirect consideration is too unstable a moral requirement, especially for subjects that cannot be parties to the agreement and are particularly susceptible to being overlooked in the moral calculus of rational consent.

Conclusion

Despite these objections the metaphor of the contract remains a powerful heuristic tool for reflecting on the existing conventions and practices of medicine and science. The lasting insight of contract theory is that the willingness of individuals, rather than force or rigid appeals to human nature, is a powerful legitimating force in morality and politics in a world where individuals disagree deeply about foundational moral issues. Thus, contract theory remains a particularly useful insight and starting point in the diverse field of contemporary bioethics.

CORPORATE COMPLIANCE

• • •

The word compliance can be defined as the act of adhering to or conforming with a law, rule, demand, or request. In a business environment, conforming to the laws, regulations, rules and policies is the part of business operations often referred to as "corporate compliance." Corporate compliance involves keeping a watchful eye on an ever-changing legal and regulatory climate, and making the changes necessary for the business to continue operating in good standing within its industry, community, and customer base. In a broader sense, corporate compliance extends beyond mere legal and regulatory conformity into the realm of promoting organizational ethics and corporate integrity.

The roots of corporate compliance efforts are found in the government contracting scandals of the 1980s. During those years, the Department of Defense received extraordinary charges for commonplace equipment. Investigations led to criminal convictions and monetary settlements for a number of companies providing equipment and supplies under contract to the U.S. government. In response to these events, defense industry companies wishing to contract with the government were required to develop corporate compliance programs to prevent such abuses in the future. Shortly thereafter, the U.S. Sentencing Commission established Organizational Sentencing Guidelines that offered more lenient fines and penalties for corporate violators that created voluntary programs to prevent and remedy violations of law and regulation.

Leniency under the Sentencing Guidelines is calculated. Upon a finding of guilt, the court considers the company's compliance efforts. This is done through the use of a culpability scoring formula set forth in the Sentencing Guidelines and applied to corporate conduct. Documented evidence of compliance efforts such as monitoring, auditing, corrective actions, and system modifications or redesign to prevent future problem behavior reduces the culpability score or degree of "guiltiness." Fines and penalties are then assessed based upon this score.

Beyond the Sentencing Guidelines, indirect incentives exist for businesses to create compliance programs. A company's intolerance for wrongdoing, evidenced by corporate action taken consistent with its corporate compliance effort, can speak volumes to federal prosecutors conducting an investigation of alleged wrongdoing. Where prosecutors determine that a company has high standards of conduct demanding employee compliance with law and regulation, it may be inferred there was minimal or no criminal intent by the organization to commit a wrongful act. The absence or reduction of evidence of intent then translates into a lesser charge or citation, particularly in a case where intent is a critical element of the crime or offense. Corresponding to the reduced charge, the fines and level of penalty are less than would be associated if a more serious (in degree) offense were claimed.

Compliance programs may also impact civil enforcement fines or penalties. If a company is found liable for wrongdoing (rather than guilty as in a criminal action), the existence of a compliance program may reduce the risk of a full-scale government investigation of the company. Short of a civil trial seeking monetary recovery, the existence of an effective compliance program often prompts government agency auditors to find human error rather than conscious misconduct led to a failure to comply with a set of rules. In these instances, leniency can be granted in the form of more favorable repayment terms and interest rates, and reduced civil fines and penalties.

A well-developed, established compliance program also helps a company avoid the imposition of probation or a corporate integrity agreement (CIA). The CIA is a mandated type of compliance program where timeframes for achieving targeted performance are aggressively short. Components of a CIA include staff education on general and specific compliance issues, establishing specific policy and procedures to minimize recurrence of the misconduct, auditing, and monitoring activities. Quite often these mandatory compliance programs call for the use of outside consultants to support business operations and/or provide objective documentation of progress toward fulfillment of the terms set forth in the agreement. CIA implementation is often expensive. Aggressive deadlines for achieving compliance milestones, multiple compliance targets, complexity of compliance issues, and the use of government-approved outside agencies are factors influencing cost.

Healthcare Compliance

With the decade of the 1990s came a warning from the Office of the Inspector General (OIG) for the U.S. Department of Health and Human Services (HHS). The healthcare industry was not immune from prosecution and liability for fraudulent and abusive practices. OIG audits demonstrated that as much as 10 percent of U.S. government-funded healthcare expenditures were related to care that was not

billed correctly, was not medically necessary, or was never delivered to the patient. There were additional concerns about the adequacy of care being delivered in the United States and concern about the reporting of health organization costs. Fraud and abuse are the terms often used in reference to these types of practices.

HHS and the OIG projected savings to be billions of dollars per year if concerted efforts were made to minimize such practices. Several initiatives were considered. One was a curative approach, whereby fraudulent or abusive practices would be investigated and prosecuted. Another was enlisting the voluntary aid of the healthcare industry to implement prevention programs. Given the magnitude of the problem, and the high cost of investigating and prosecuting fraud, the OIG determined that a cost-effective solution to minimize fraud and abuse was to emphasize prevention over law enforcement investigation and prosecution. With this thought, HHS and the OIG embraced the defense industry's compliance concept along with the Sentencing Guidelines and established the first government healthcare compliance guidance in 1997.

The initial guidance was written for laboratories. OIG compliance guidance is available for other care delivery settings such as hospitals, long-term care, home healthcare, hospice, physician offices, and support services such as medical coding and billing companies. On April 23, 2003, the OIG issued compliance program guidance for pharmaceutical manufacturers.

Early Healthcare Compliance Efforts

Initial OIG-written commentary for healthcare compliance programs focused on internal controls. Healthcare organizations were encouraged, for example, to develop protocols for insurance claim processing and billing, to properly use codes (e.g., diagnosis related group assignments for inpatient hospital service classification and payment), and to ensure patient freedom of choice. Hospital contracts with physicians that encouraged over-utilization of services prohibited by anti-kickback law were also high on the regulatory list of concerns. Yet other compliance efforts focused on provider or entity compliance with governmental and private insurer documentation guidelines, medical need for service, timely refunding of overpayments for services (e.g., refunding credit balanceS), and document retention and destruction policy.

By 2003, it was not unusual to find defined compliance departments within healthcare organizations. The actual name of the department may vary from simply the "corporate compliance department" to the "business practices office." In some organizations, corporate compliance, internal audit, and corporate ethics are combined or maintain close working relations. Independence of review and periodic reporting to senior company officials are two key aspects of any compliance function. Some compliance offices also have advisory committees to assist in various compliance endeavors. At least one organization is known to have a combined compliance and corporate ethics advisory committee. Consistent with the OIG guidance, compliance officers are instrumental in developing or assisting to develop comprehensive policy on OIG target areas, staff training, monitoring, and auditing.

Effective Healthcare Compliance Programs

Little has been published as to what constitutes an "effective" healthcare compliance program. The OIG initiative broadly encourages healthcare providers and entities to conduct business in a manner that conforms to federal and state law and regulations. Similarly, regulatory agency expectations of compliance initiatives vary with the size and complexity of the entity and monies available to fund compliance efforts. For example, a small family practice physician operating an office in a rural location is not expected to have the same size, scope, and sophistication in terms of a compliance program as a healthcare organization with 1,000 or more beds spread over multiple care delivery sites in a highly populated urban setting. Recent enforcement activities, however, demonstrate that staff compliance education and an entity's ongoing commitment to "following the rules" are key components to proving effectiveness, regardless of the entity's size and complexity. Ineffective programs may not provide the same leniency and opportunities as have been discussed above.

Development of an effective program includes ongoing review and revision of the program based on the emphasis found in the annual OIG work plan. A review of current and prior work plans reveals a continuing focus on payment, billing, and claims processing issues. The OIG also releases a number of publications and opinions throughout the year that advise healthcare providers and entities such as hospitals, home health agencies, extended care facilities, etc., on prevention, detection, and resolution methods for suspect practices. Other OIG publications and opinions clarify subject areas to better enable compliant conduct by health organizations.

Consistent with the expansion of regulatory agency focus, areas of compliance concern have expanded to include issues such as quality of care, maintaining patient privacy, eliminating healthcare errors, maintaining occupational safety,

enhancing staff understanding of clinical and business ethics, and eliminating or minimizing conflicts of interest. Specialty areas of the law that were topics for compliance discussion in the early twenty-first century encompass employment law, environmental law, tax law, and intellectual property law. This broadened scope has prompted many organizations to revise and reprioritize compliance programs to incorporate standards of behavior that address organization expectations on existing as well as new focal areas.

Essential Elements of a Healthcare Compliance Program

Common elements of any healthcare compliance program incorporate the following:

1. designation of a high-level entity officer to lead the compliance program;
2. documented standards of behavior that are described in more detail in the entity's policies and procedures;
3. compliance training for staff with regular updates to maintain awareness;
4. establishment and maintenance of a readily available anonymous communication process for receiving complaints and concerns (i.e. telephone hotline, suggestion boxes);
5. procedures for protecting healthcare whistleblowers;
6. maintenance of a system for responding to complaints in a timely manner;
7. documented disciplinary action procedures for violations of law, regulation, or compliance policies of the entity;
8. planned auditing and monitoring activities to reveal areas where compliance issues exist, and to monitor correction actions for effectiveness;
9. defined investigation processes;
10. a procedure for initiating the entity's process improvement procedure to correct system process problems;
11. a process to address employment decisions for persons who are temporarily or permanently barred from participating in the care of patients who are beneficiaries of a federally-funded healthcare program.

Operating a Healthcare Compliance Program

Using OIG guidance materials, the compliance officer and compliance committee members develop and direct activities based on governmental and organizational identified areas of concern. The compliance officer should have direct access to both the chief executive officer and the governing board of the organization whenever necessary to ensure timely communication of pertinent issues.

It is important for the organization leadership to grant oversight authority to the compliance officer and committee members for monitoring, auditing, and corrective action activities of the corporate compliance program. Additionally, leadership should support the compliance officer's establishment of alternate methods of communicating with employees to encourage anonymous reporting of compliance issues. It is essential for employees to view the compliance officer as a non-threatening source of education and empowerment, a person they may seek out to resolve concerns without fear of discipline, retaliation, or retribution for reporting a concern.

Establishing a Corporate Culture of Compliance

An organization must be committed to compliance efforts in order for the program to be effective. Establishing written standards, policies, and procedures demonstrates acceptance by senior leadership and delineates behavioral expectations for all employees, governing body members, officers, management, physicians, contractors, and business associates of the organization. Beginning with a statement describing the organization's mission and vision (goals for the future), the organization guides conduct by defining a potential compliance issue along with the conduct standard and examples of appropriate behavior. An illustration of this concept:

- Mission statement: To provide excellent healthcare for our patients and the communities we serve.
- Vision statement: We are committed to the highest level of organizational and professional excellence and will serve others with respect for individual dignity.
- Performance Standards: Greet everyone with direct eye contact and a smile; At the end of an interaction, "ask is there anything else I can do for you?"; Provide information and give updates at specific intervals as promised.

It is important to write components of a compliance program at a reading level that the majority of staff can understand. It is also important to make the conduct requirements accessible to employees so they can be easily referenced. Since laws and regulations change and the OIG, HHS, professional review agencies, fiscal intermediaries,

and carriers identify different areas of concern over time, compliance requirements must be updated to reflect behaviors required for the organization to remain in compliance.

A significant portion of the compliance officer and committee members' roles involve establishing and maintaining positive relationships with others in the organization. In maintaining a level of visibility and collegiality, the compliance officer is more likely to be in a position where opportunities for improvement can be identified and ethical behaviors can be positively reinforced. Likewise, visible, approachable committee members are likely to find less resistance to monitoring and auditing activities. Without these positive relationships, compliance activities may be impeded by efforts to thwart data access and collection for fear of poor audit results and the demand for time-consuming responsive action plans by management. While the compliance officer and committee members are often the most visible leaders of corporate compliance efforts, it remains important for organization leadership and management to mentor employees, encouraging responsible and ethical behavior in the workplace.

Strategies for Maintaining a Compliance Program with Limited Resources

The number of personnel assigned to the compliance department or to assist with compliance functions varies from organization to organization. The size of the compliance department and level of sophistication of the compliance program is not directly proportionate to organizational size and complexity. Given the limited size of many departments, a compliance officer must often utilize a variety of strategies to maintain the continuity of compliance program activities.

One strategy involves enlisting managers and supervisors of other departments to join in conducting and evaluating daily monitoring activities, and participate in development and implementation of solutions to issues raised. Compliance department staff or internal audit personnel may check on these efforts through quarterly or annual audits. If needed, in-depth analysis may be conducted by outside consultants.

Another strategy involves using work groups or task forces to assist with monitoring and auditing functions. The groups are formed from members of departments with specific but related functions (i.e. patient registration, patient accounts, collections, and coding). By doing this, members are exposed to the compliance program in action. Work group members engaged in program activities often become ambassadors and assist in enhancing the compliance culture within the organization.

Improved organizational performance can be a practical result from compliance work group efforts. Compliance initiatives may reduce payment collection times and rejections rates. Compliance initiatives may also resolve long-festering issues that impede work completion and flow. With the compliance officer acting as a mentor, information resource, and support person, multiple work groups may simultaneously be engaged in compliance activities, thus improving organizational compliance effectiveness in an efficient, thoughtful manner.

Providers Excluded from Federal Health Programs

Compliance initiatives must also implement steps to ensure practitioners and entities excluded from federal health program participation are not employed or used by the company. By partnering with numerous departments in an organization, a small compliance program can coordinate the monitoring of governmental databases to ensure excluded persons or entities rules are followed. If a monitoring process is ineffective, the organization is likely to realize a significant financial impact because federal programs such as Medicare, Medicaid, or Tri-Care will not reimburse services ordered or performed by these excluded providers.

The monitoring requires that the compliance officer or designee review the Health and Human Services Office of the OIG Excluded Provider database and the General Services Administration database at periodic intervals. The review process and subsequent response activities incorporate human resource, medical staff credentialing, materials management vendor selection, and contractor selection functions within the organization. Legal counsel must be included in these compliance activities to ensure that organization contracts incorporate provisions that impose an affirmative duty on contracting parties to communicate anticipated or actual government action that may result in the party becoming an excluded provider. Action in response to a finding of exclusion may involve, for example, contract termination, termination of employment, or loss of medical staff membership and privileges at the organization.

Corporate Compliance Programs and Organizational Ethics

Partnering within and among organization departments and functions appears consistent with OIG commentary on

effective compliance plans. OIG writings suggest that organizations create and foster compliance efforts that conform to legal and regulatory directives as well as enhance the commitment to ethical clinical and business practices within the corporate culture. Though some similarities exist, ethicists caution that corporate compliance must be viewed as distinct from organizational ethics; each has a unique focus.

Corporate compliance programs focus on establishing a floor or minimum level of appropriate behavior for the organization in order for the organization to conform to legal and regulatory requirements for a given industry. The appropriate behaviors are communicated through the compliance program's conduct standards, policies, and procedures. In behaving appropriately, the organization avoids sanctions and maintains its reputation within the community.

Alternatively, organizational ethics focuses on the realm of behavior where no legal or regulatory requirements exist; where equal priorities compete and where individual values, interests, and beliefs differ to the extent that no "right" answer is readily available. In healthcare entities, organizational ethics faces the additional challenges of reconciling priorities often at the level of life and death seriousness. Individual, professional, and societal values and beliefs; competing interests among parties involved in a controversy; the rights of the patient, other individuals, and the organization must be considered in organizational ethics activities.

Unlike corporate compliance programs, organizational ethics is not a new concept in the business world. The curriculum in secondary education and beyond has included courses in business ethics and corporate responsibility, and coursework in these areas has existed for decades. There are, however, few healthcare industry examples of formal organizational ethics functions. Organizational ethics programs should not to be confused with clinical ethics functions.

Healthcare Clinical Ethics and Institutional Review Boards

In contrast with organizational ethics efforts, a number of healthcare organizations established clinical ethics programs within their organizations in the 1970s and 1980s. These efforts were often driven by the need to address ethical and legal dilemmas associated with patients or families seeking to terminate care or refuse care associated with the end of life, often in the absence of state law. In other cases, there was a need to address differing family and patient perspectives on what care should be given outside terminal illness settings. Even with greater clarity on the patient's right to refuse treatment, organizations still needed a defined, deliberate process to address the bioethical and legal issues associated with such decisions.

Another catalyst for establishing a clinical ethics program was the Federal Drug Administration requirement that called for creating an institutional review board (IRB) to protect the patient's rights in clinical research activities. For example, IRB members review research proposals to ensure the patient receives pertinent information about a study prior to agreeing to participate in it, and that adequate safeguards are in place to protect the patient.

Unscrupulous Activities Toll

In 2002, a number of U.S. corporations were fraught with business practice scandals. The "ripple effect" caused people across the country to watch helplessly as their retirement plans and stock portfolios withered after an international accounting firm and several major corporations ceased operations. Senior executive interest in the business practices of their industries and their organizations was heightened. A nationwide focus developed whereby corporations looked to ensure that their staff understood that compliance with industry-specific accepted business practices was an expectation. Likewise, staff were to conduct themselves in an ethically responsible manner in workplace activities.

It is clear that the federal and state governments were alarmed by these business scandals and the subsequent effects felt by the citizenry. Consequently, government began scrutinizing corporate business practices in an unprecedented manner. Thus, it may be prudent for all organizations, for-profit and nonprofit alike, to expand compliance programs to include an organizational ethics function as well.

Single Purpose

For one healthcare organization, the foregoing concerns coupled with a discussion of other real-life scenarios and case studies prompted senior leadership and the governing board to encourage the development of a coordinated approach to these issues. By expanding the scope of corporate compliance activities to incorporate organizational ethics and responsible business practices, the organization hopes to operate compliant with law, regulation, and ethical principles (Oakwood Healthcare Inc.). By 2003, a committee had been formed including compliance, ethics, finance, legal, religious, human resource, operations, and internal audit representatives. By appointing members with different perspectives, the committee provides a balanced approach to complex legal, regulatory, and ethical issues. Uniting ethics

and compliance supports the effort to do the "right thing," and that, as many say, is the essence of ethics and compliance.

CYBERNETICS

• • •

Cybernetics, in its purest definition, is the science of control and communication in the animal and the machine. The word was devised by Norbert Wiener in the 1940s and is derived from the Greek word *kybernetes*, meaning "steersman." In his book *The Human Use of Human Beings* (1950), Wiener wrote that "society can only be understood through a study of the messages and the communication facilities which belong to it; and that in the future development of these messages and communication facilities, messages between man and machines, between machines and man, and between machine and machine, are destined to play an ever-increasing part" (Wiener, p. 16). In 1957, W. Ross Ashby described the focus of this theory of machines as focusing not on what a thing is, but on what it does: "Cybernetics deals with all forms of behavior in so far as they are regular, or determinate, or reproducible. The materiality is irrelevant" (Ashby, p.1). Recognizing that there are significant similarities in biological and mechanical systems, subsequent researchers have pursued the ideal of merging biological and mechanical/electrical systems into what Manfred Clynes and Nathan Kline termed *cyborgs* or *cybernetic organisms.* In this sense, cybernetics has taken on the meaning of adding prostheses to the human or animal body to either replace lost function or augment biological activity.

Humans have long used tools to augment various functions, and for centuries have attached some of these tools to their bodies. Filled or artificial teeth, glasses and contact lenses, hearing aids, pacemakers, and artificial limbs are all examples of this phenomenon. By the late twentieth century, significant advances in the fields of neuroscience and computer technologies allowed the direct interface of animal or human nervous systems with electromechanical devices. Examples of this evolving field include the creation of neural-silicon junctions involving transistors and neurons to prepare neuronal circuits, the re-creation of visual images from signals transmitted in the optical pathways of a cat, the remote control of mechanical manipulator arms by implants inserted into the motor cortex of owl monkeys, and a remote control that can move rats over a directed path via implanted electrodes.

While the above are examples of direct internal interfaces between a nervous system and a cybernetic prosthesis, another approach to cybernetic augmentation is through the use of external or wearable computing devices. In this approach, prosthetic enhancement is achieved via miniaturization of traditional computing devices, interface mechanisms, and optical projection devices, and then seamlessly incorporating these devices into clothing, glasses, and jewelry. This form of cybernetic enhancement has moved from the academic to the commercial stage. Aside from allowing the user/wearer of such devices wireless access to the Internet and other databases on a continuous basis, they may also be

used for *augmented reality,* which is the concept of supplementing traditional sensory input with augmented senses or new types of sensory data. Examples include retrograde vision (seeing to one's rear), distant or projected hearing, and infrared vision. Further visual input may be analyzed and correlated with other information such as Global Positioning System (GPS) location identification. Buildings and streets could be labeled, hours of business accessed, and people visually identified (with demographic information provided), with all of this information directly projected on the user's retina.

While these developments may sound like something out of a Star Trek episode, cybernetic technology has developed at a rapid pace, and will no doubt continue to be a growing field of investigation, therapeutic intervention, and commercial development. In June 2002, the National Science Foundation and the U.S. Department of Commerce issued a report recommending substantial U.S. government investment in the development of cybernetic technologies, with the specific goal of augmenting human performance. These technologies will be produced by the synergistic convergence of biotechnology, nanotechnology, information technology, cognitive science, and neurotechnology through a proposed Human Cognome Project.

Healing versus Augmentation

As has already been indicated, the mechanical or prosthetic manipulation of human beings is not a new idea or practice. In the past, however, such interventions have almost always been in the context of repair or replacement of absent, diseased, or disordered function. The goal of visual lenses is to restore vision to biological norms, not to augment or improve function beyond normal. Similarly, prosthetic limbs replace those congenitally absent, malformed, or traumatically severed or injured. Pacemakers replace the electrical pacing of heart contractions lost through injury, aging, or disease. In this context, new tools to restore sight to the blind, hearing to the deaf, and movement and normal function to the lame or paralyzed are tremendous advances fully in keeping with the traditional goals of medicine (healing, restoring, palliation, and prevention of injury). Yet humans also use telescopes, microscopes, night vision, and other means of augmenting visual function for specific purposes. The difference is that these tools are not permanent fixtures of the body. Wearable computing devices and implantable brain chips, however, are being produced and marketed to enhance the normal, not necessarily heal the afflicted. This raises a number of challenging ethical questions, including whether or not human augmentation should even be permitted, let alone pursued?

Before the question of whether augmentation should be permitted, promoted, or prohibited can be addressed, a more basic issue must be considered: Can a distinction between healing and augmentation be delineated? This question poses equal challenges to a variety of areas in addition to cybernetics, particularly the more immediate possibilities of genetic therapy or enhancement and pharmacotherapy for behavior control, mood enhancement, and cognitive enhancement.

The difficulty lies in trying to define a clear line of demarcation between a disease state and normal structure and function. It is sometimes easy to pick out extremes of phenotype, particularly if an underlying pathophysiological mechanism for the deviation can be demonstrated. Examples include hemophilia, congenital dwarfism, and impaired vision. Other situations raise difficulties, illustrating that many times the definition of disease or abnormality can be socially, rather than objectively or scientifically determined. How much deviation from ideal body weight is within the bounds of normal variation, and when does the deviation become pathologic? While anorexia nervosa and morbid obesity are clearly pathologic in that they can influence survival and other health issues, a significant number of individuals are on the edges of the norms, where the threshold of pathology is unclear.

A striking example of the cultural variation in the definition of disease is the response of many congenitally deaf individuals to the suggestion that they are afflicted and in need of therapy. Many deaf parents of deaf children have refused to allow their children to receive cochlear implants to correct the deafness because this would remove the children from the deaf community. At a 1997 conference of deaf individuals, 16 percent of the delegates were interested in prenatal diagnosis for deafness, but, of that group, 29 percent indicated that they would use these techniques to select for deafness in the child (see Middleton, et al.).

Cognitive and neurological function, the areas most impacted by cybernetics, are particularly fraught with difficulty, in part because certain deviations from the norm may impart certain functional advantages in addition to social or behavioral liabilities. For instance, while attention-deficit/hyperactivity disorder (ADHD) and autism are diseases, many of the individuals who have these conditions also manifest significant brilliance and creativity in mathematics, music, art, science and engineering. Both the positive and negative manifestations are part of the same disease entity, and what degree of negative manifestation requires treatment becomes subjective. The treatments employed may suppress the undesired manifestation, but they may also

impair the desirable expressions. The situation becomes even more complex when these challenges are extended to a measure of cognitive function such as memory, mathematical calculation, musical ability or language processing. Who doesn't think of himself or herself as being deficient in cognitive abilities or able to benefit from enhancement of cognitive function?

In addition, necessary cognitive function may be very task or profession specific. Should individuals who would be considered cognitively normal be allowed to receive enhancing technologies to permit them to pursue a career otherwise beyond their intrinsic ability? And, as these technologies become available, should professions that demand high levels of cognitive excellence be allowed to require the use of enhancing technologies? Given that books and computers are forms of information exchange enhancement that are currently required for education in the professions, one could argue that the only thing that has changed is the intimacy of the enhancing method. Because, these technologies may intrinsically carry certain risks that are absent from current information technologies, however, many believe that such means should never be mandated, but only available by free choice. The reality, however, is that competition with peers will serve as a strong coercive force to pursue enhancement.

Safety Questions

The answers to these questions require the consideration of additional issues. At the most basic, cybernetic technologies, both implantable and wearable, must demonstrate physical, emotional, and cognitive safety. While physical safety will, in general, be the most easily addressed, there are still new challenges beyond those typically encountered by medical devices. Traditional medical-device safety issues include the risk of infection, local reaction, tissue injury, and involuntary or undesired neural or muscular stimulation. Current devices, however, tend to function in isolation in the specific local environment of the recipient body. Cybernetic devices, on the other hand, will often be connected to a shifting network environment, dependent upon software and the exchange of external information as well as hardware. As such, viral code could potentially disrupt function of the device, and possibly injure the user. Even wearable devices could potentially be turned into weapons, and so need to be strongly regulated, with proof of software and hardware safeguards against injury by rogue software agents.

The issues of emotional and cognitive safety will be more challenging to understand and regulate. In the era of the Internet there is a growing literature addressing problems with personality fragmentation, breakdown of direct personal interaction in favor of cyber relationships, increasing dissatisfaction with reality, addiction to cybersex and pornography, and other psychosocial concerns. These concerns can only increase when individuals are cybernetically connected most, if not all, of the time. The long-term consequences of virtual environments are unknown. The variability of involvement and susceptibility to dysfunctional utilization will vary tremendously between individuals, making generalized regulation difficult. However, some form of registered informed consent as to potential negative consequences, with mandatory, periodic, and long-term follow-up, may be helpful.

The Nature of Medicine

The issue of safety introduces yet another question: What sorts of individuals should be involved in implanting devices for internal cybernetic enhancements or for fitting wearable devices with optical interfaces? Because of the invasive nature of the implants, it would seem a logical requirement that physicians, particularly neurosurgeons, place these devices in humans. This certainly would be necessary for cybernetic devices of a therapeutic nature, but what about devices that are solely for enhancement purposes? Placing devices for nonmedical indications leads the physician into participating in interventions that are potentially harmful, have no therapeutic necessity, and thus are outside the traditional goals of medicine. A strong argument could be made that physicians should not participate in applying these technologies for other than therapeutic purposes. Yet few would want someone with less training than a neurosurgeon to invade their nervous system.

An analogy can be made to cosmetic surgery. Some ethicists, such as Franklin Miller and Howard Brody, contend that such interventions are outside the bounds of appropriate goals of medicine and should not be performed. Others counter that an individual should have the freedom to manipulate his or her own body, and, if a physician is willing to provide the service, restriction would be wrong and counter to the cherished goals of autonomy. Anders Sandberg takes the argument further, stating that each person has the fundamental right to pursue whatever means are available that might enhance or prolong life. The implications of this approach for medicine, however, are to change the profession from a group committed to healing (with a dominant ethos of beneficence in trust and nonmaleficence) to individuals skilled in surgical technique who are merely technicians providing whatever service may be requested.

Justice and Social Values

In the end, safety considerations may mandate that physicians and healthcare resources be used to implant cybernetic devices for nontherapeutic purposes, but justice may require that third-party healthcare dollars not be used to cover the costs of the devices or resources utilized. This raises concerns that access to enhancement technologies will be accessible only to those who already possess economic, educational, and technical advantages, further widening the gap between the haves and have-nots. As some members of society become incrementally enhanced and plugged in to cybernetic communities, these individuals will share less and less in common with the unenhanced, fragmenting society; potentially generating decreasingly compatible, or even competing, separate societies.

This is not necessarily a new phenomenon, for technologies have created boundaries between social groups in the past, the Amish and some Native Americans being notable examples. The difference is that the Amish have always wished to remain a distinct society, while some individuals who wish to reject personal enhancement may still desire participation in and access to the goods of the larger social structure. Deliberate efforts to maintain tolerance of individuals and groups who choose to forgo the use of certain technologies must be pursued if democratic-republican ideals are to be preserved, and inclusive means of communication must remain available to all members of society.

Cognitive cybernetic devices must also be equipped with reliable means of filtering incoming information, especially against information that might be designed for repetitive or subliminal influence. Privacy is a similar critical issue, and must be deliberately and prospectively defended in the cybernetic age. Technologies such as functional magnetic-resonance imaging are being proposed to sense, process, and interpret thought patterns. Not only is the accuracy of such technology a critical requirement, but the concept of invading the mind is at issue.

To Prohibit, Permit, or Pursue?

Cybernetics offers wonderful devises of healing for significant, age-old disabilities, and it can be welcomed when utilized in that context. It is likely that using such tools to enhance normal function will be possible, but great caution is needed, as well as a commitment to the preservation of privacy and justice. Rigorous safeguards for demonstrating the safety of cybernetics devices, and requirements for government approval and licensing, need to be set in place. The government, the academy, and industry should commit significant resources to the exploration of the ethical and social implications of these technologies, and to the development of appropriate analysis and preparation of guidelines for implementation.

DAOISM, BIOETHICS IN

• • •

Daoism is an ancient and multifaceted element of traditional Chinese culture. Its origins and scope are debated by modern scholars, Chinese and Western alike. Most understand "Daoism" in terms of the naturalistic thought seen in ancient texts like those of Lao-tzu (the *Dao te ching*) and Chuang-tzu (see Lau, 1982; Graham, 1981). But to others, "Daoism" denotes primarily a religious tradition that emerged around the second century C.E. and has endured to the present (Seidel, 1990; Robinet, 1991, 1993). Specialists today generally employ a comprehensive approach, interpreting both of those elements as aspects of a broad and inclusive cultural tradition, interwoven both historically and thematically (Schipper).

Daoism may be characterized as a holistic worldview and ethos, including a variety of interrelated moral and religious values and practices. Daoism lacks any coherent conceptual structure, so there have never been any "Daoist positions" regarding ethics or any other issues. Yet, most segments of the tradition share certain assumptions and concerns. One is an assumption that human reality is ultimately grounded in deeper realities; humans are components of a cosmos, a harmonious universe in which all things are subtly but profoundly interrelated (Kirkland, 1993). Daoism is devoted to the pursuit of greater integration with the cosmos, in social as well as individual terms. Daoists vary widely in their understandings of how that integration is best expressed and pursued.

The first section of this entry outlines the elements of classical "Lao-Chuang" Daoism, and the history, teachings, and practices of the much-misunderstood "Daoist religion." The subsequent exploration of the Daoist moral life focuses upon (1) the ideals of refinement (*lien*) and "fostering life"; (2) the ideals of balance and harmony; and (3) the issue of death. Throughout, one should bear clearly in mind that many issues that are considered central in contemporary bioethical debate are completely alien to the traditional Daoist worldview. Daoists not only lacked the concepts of "good" and "evil," but they were simply never interested in arguments over "right or wrong" on any terms. One should thus beware assuming that contemporary issues could ever be translatable into Daoist terms.

The Daoist Heritage

CLASSICAL THEMES. In the ancient texts *Lao-tzu* and *Chuang-tzu,* integration with the cosmos is generally expressed in terms of returning to the natural rhythm or flow of life—to the Dao, an impersonal reality that constitutes simultaneously the source of the cosmos, the subtle structures of the cosmos in its pristine state, and the salutary natural forces that—in that pristine state—maintain all things in a natural and healthy alignment. In "Lao-Chuang" Daoism, all the world's problems are attributed to humanity's digression from the Dao, particularly to a loss of proper perspective upon the nature of reality. The goal of Lao-Chuang Daoism is to regain that perspective and thereby return to the original integration with the natural world and its constituent forces and processes. The eponymous Lao-Chuang texts are vague about the means to be employed in achieving that end. Later Lao-Chuang writings (e.g., in texts like the *Kuan-tzu* and *Huai-nan-tzu*) present a more detailed analysis of the human constitution, and suggest specific spiritual and physiological practices to reintegrate the individual and realign him or her with the natural forces of the

cosmos (Roth). Suffice it to note that all such theory assumes none of the dichotomies of mindmatter or body/spirit that underlie much of Western medicine and moral theory. Moreover, it is a mistake to assume (as do most in twentieth-century Asia and the West) that Daoism was essentially individualistic: the basic Lao-Chuang writings (most notably the *Dao te ching*) often addressed broader problems of human society in both moral and political terms. The later Daoist tradition is generally an extension of the ideals and values seen in these earlier writings.

THE DAOIST RELIGIOUS TRADITION: NEW PERSPECTIVES. Until recently, virtually all educated people dismissed postclassical Daoism (often misnamed "popular Daoism") as a mass of disreputable superstitions created and perpetuated by the ignorant masses. Such was certainly not the case. The problem is that before the 1970s, few intellectuals, Chinese or Western, had any firsthand knowledge of later Daoism, in terms of either its modern practice or its historical tradition. As scholars began serious analysis of the Daoist texts preserved in the massive collection known as the *Dao-tsang,* and researched the roles that Daoism played in traditional Chinese history and society, they started to develop a far different perspective, though this new perspective has yet to reach the educated public.

Until the 1980s, religious Daoism was often said to have been focused on individual practices intended to confer longevity and/or physical immortality. The pursuit of physical longevity did exist in China from early times, but it is wrong to associate such pursuits with "religious Daoism."

Western scholars generally have placed emphasis on certain practices or crafts that they suppose have been particularly "Daoist," notably the quest for physical immortality, breath control, techniques of sexual union, herbalism, dietetics, and alchemy. In such a view, though, as in the question of doctrine in general, there is some ambiguity between what is specifically Daoist and what is simply Chinese (Strickman, pp. 1044–1045).

Extensive research has generally demonstrated that such practices have little or no intrinsic connection to the traditions of religious Daoism.

THE EVOLUTION OF THE DAOIST RELIGION. The Daoist religion has been compared to a river formed by the confluence of many streams. Its origins lie in the Han dynasty (206 B.C.E.–221 C.E.). During that period, Chinese intellectuals (like the Confucian theorist Tung Chung-shu) were seeking a comprehensive explanation for worldly events. From such roots, imperial advisers called *fang-shih* produced a series of sacred texts that culminated in the *T'ai-p'ing ching,* which is generally regarded as the first Daoist scripture. According to the *T'ai-p'ing ching,* ancient rulers had maintained an "ambience of Grand Tranquillity" (*t'ai-p'ing*) by observing *wu-wei* (nonaction)—a behavioral ideal of avoiding purposive action and trusting instead to the world's natural order (the Dao). When later rulers meddled with the world, the "Grand Tranquillity" was disrupted. Now, the scripture says, one must return to the Dao by looking within oneself. The text provides specific directions for pursuing union with the Dao, including moral injunctions and instructions for meditation, as well as recommendations for enhancing one's health and longevity through hygienic practices (such as breath control), medicine, acupuncture, and even music therapy. The focus of the *T'ai-p'ing ching* is thus upon providing the people with practical advice for reintegrating with the natural order (Kaltenmark).

In late Han times, the *T'ai-p'ing ching* helped inspire several social movements. One was led by Chang Dao-ling, who claimed to have received a divine mandate to replace the now-effete Han government with a new social order. Claiming the mantle of "Celestial Master," Chang and his heirs oversaw a religious organization in which male and female priests healed the sick by performing expiatory rituals. This organization, generally called "Celestial Master Daoism," was based on the idea that a healthy society depended upon the moral, physical, and spiritual health of all its members.

In the fourth century C.E., northern China was invaded by peoples from the northern steppes, and the leaders of the Celestial Master movement fled south. There they found a rich indigenous religious culture centered upon the pursuit of personal perfection through ritual activity. Unlike the Celestial Master tradition, the religion of southern China took little interest in ideals of a healthy society: its focus was almost exclusively upon the individual. Modern writers, Chinese and Western, have often mistakenly cited certain of its texts (like the *Pao-p'u-tzu* of the maverick Confucian Ko Hung) as representative of religious Daoism. In so doing, they have completely neglected the rich heritage of the *T'ai-p'ing ching* and most of the subsequent Daoist tradition.

The fourth century C.E. was a period of rich interaction among such diverse traditions, and there were two new developments, both of which occurred as the result of revelations from celestial beings. The first, known as the Shang-ch'ing (Supreme Purity) revelation, was received from angelic beings called "Perfected Ones" who dwelt in distant heavens of that name. The Perfected Ones revealed methods by which the diligent practitioner could ascend to their heavens, particularly visualizational meditation (Robinet,

1993). But Shang-ch'ing Daoism also subsumed the older southern pursuit of personal perfection through alchemy, a transformative spiritual process expressed in chemical terms. Alchemy, often misrepresented as a "typical" element of religious Daoism, actually arose quite independently, though it was embraced by certain Shang-ch'ing Daoists as a practice thought to elevate the aspirant's spiritual state for eventual ascent to the heavens (Strickmann). What the alchemical tradition shared with Daoism was a vital concern with self-perfection based on an assumption that the individual's being is a unified whole. For exceptional aspirants, alchemy provided secret knowledge that permitted control of the forces of the cosmos that inhere within the constitution of the individual. Outsiders often misunderstood the whole undertaking as a pursuit of physical longevity. But within Daoism, alchemy was actually a method of moral and spiritual self-refinement: through proper knowledge and action, one could pare away the grosser elements of one's being and eventually ascend to a higher plane of existence. Nonetheless, alchemy was, for most, a purely theoretical interest. The "average" Daoist practiced meditation and morality, and in later ages Daoists discarded the theory of "external alchemy" in favor of "inner alchemy"—a meditative pursuit of reunion with the Dao that employed the language of alchemy metaphorically.

The Shang-ch'ing revelations were immediately followed by a quite different set of revelations, known by the term *Ling-pao* (Numinous Treasure). *Ling-pao* Daoism is distinguished by (1) elements influenced by Mahayana Buddhism, and (2) a renewed concern with the human community. *Ling-pao* scriptures (such as the *Tu-jen ching,* "Scripture for Human Salvation") tell of a great cosmic deity—a personification of the Dao—who is concerned to save humanity. By ritual recitation of the scripture, one may participate in its salvific power. In the fifth century, the *Ling-pao* tradition was refocused by Lu Hsiu-ching, who reconfigured its ritual activities and formulated a new set of liturgies that continue to influence contemporary Daoist practice. A central liturgy is the *chiao,* a lengthy series of rituals that renew the local community by reintegrating it with the heavenly order. Other liturgies, called *chai,* had diverse aims. One was designed to prevent disease by expiating moral transgressions through communal confession. Another labored for the salvation of deceased ancestors. A third was intended to forestall natural disasters and reintegrate the sociopolitical order with the cosmos. Through these liturgies, Daoism incorporated ritual frameworks from all segments of society, from the imperial court to the local village, and unified them through the activity of priests (*Dao-shih*), some of whom were women (Kirkland, 1991a).

"Liturgical Daoism" soon became central to life at all levels of Chinese society. Admiring emperors sought to bolster their legitimacy by associating with Daoist masters, and by having them perform liturgies for the sake of state and society. During the T'ang dynasty (618–906 C.E.), cultural leaders in every field associated with such masters, and were deeply influenced by Daoist religious, artistic, and literary traditions. Prominent Daoists like Ssu-ma Ch'eng-chen not only maintained the liturgical tradition but also refined the meditative practices that had always been central to the Daoist spiritual life (Engelhardt, 1987). In addition, certain Daoists became known for their achievements as physicians. The social prominence of liturgical Daoism changed drastically during the twelfth and thirteenth centuries C.E., when China was again invaded by northern peoples. The foreign rulers often suspected religious organizations of fostering rebellious activities, so Chinese who sought social or political advancement began to dissociate themselves from such organizations. Hence, in late imperial China, liturgical Daoism became divorced from the elite segments of society, and endured primarily among the less affluent and less educated (Kirkland, 1992). The broadly based, ecumenical Daoist tradition of T'ang times dissipated, to be replaced by new, smaller sects. One of the earliest examples was Ch'ing-wei Daoism: founded by a young woman about 900, it introduced "thunder rites," by which a priest internalized the spiritual power of thunder to gain union with the Dao, then healed illnesses. In T'ien-hsin Daoism, founded by a twelfth-century scholar, priests healed mental illness by drawing spiritual power from stars. The most traditional of the new sects was T'ai-i Daoism, which stressed ritual healing and social responsibility, and was popular with some rulers, including the Mongol Khubilai Khan. None of those sects had much lasting influence. One that did endure was Cheng-i (Orthodox Unity) Daoism, which flourished under imperial patronage from the eleventh to eighteenth centuries and is still practiced in Taiwan. It preserves traditional liturgies, adding rituals for exorcism and personal protection. None of the new sects that arose during the "Daoist reformation" was in any way concerned with the pursuit of immortality. Rather, priests of all those sects ministered to the community by healing and performing other ritual services.

Modern Daoism has maintained the pursuit of individual self-perfection through meditation. Earlier Daoist meditation took a variety of forms. But from the eleventh century on, most Daoist meditation was couched in terms of "inner alchemy." Employing terminology from ancient Lao-Chuang texts, "inner alchemy" aims at self-perfection through cultivating "spirit" (*shen*) and "vital force" (*ch'i*) (Robinet, 1989).

These practices were embraced in Ch'üan-chen (Complete Perfection) Daoism, a monastic movement founded in the twelfth century. Ch'üan-chen institutions flourished into the twentieth century, as did some of its teachings on self-perfection through meditation.

The Ethical Dimensions of Daoism

Many accounts of Daoism lead one to question whether there is—or could be—such a thing as a Daoist ethic, suggesting quite incorrectly that Daoist values were intrinsically egocentric. In fact, all segments of the Daoist tradition fostered a personal ethic, and most segments taught a social ethic as well. At times, in fact, it is clear that Daoism assumed a universalistic ethic that extended not only to all humanity but also to the wider domain of all living things (Kirkland, 1986). These values were not borrowings from Confucianism or Buddhism, but a natural extension of fundamental elements of the Daoist worldview, rooted in the ancient heritage of the *Dao te ching* and the *T'ai-p'ing ching*. That worldview was interwoven with an ethos that encouraged individuals and groups to engage in activities intended to promote the healthy integration of the individual, society, nature, and cosmos.

THE MORAL LIFE: IDEALS OF REFINEMENT AND "FOSTERING LIFE." The Daoist view of personal identity and human values contrasts sharply with that of Confucianism. Confucians understand humans to be innately distinct from and superior to all other forms of life, because of humans' social inclinations and moral consciousness. Daoism, by contrast, locates the value of humanity not in what separates it from the rest of the natural world but in what humans share with the rest of the world. A constant if not universal goal of Daoism is to propel the individual's attention to ever higher and broader perspectives, to move as far as possible not only beyond the isolated concerns of the individual but also beyond the socioculturally defined concerns of the unreflective. The Daoist goal is not to ignore socioculturally defined concerns but to transcend them.

For that reason, despite all its insistence upon restoring harmony with the natural order, Daoism is not consistent with the activist tendencies of modern environmentalism. No Daoist of any persuasion ever embraced goal-directed action as a legitimate agency for solving problems. The *Dao te ching* in fact implies that, contrary to appearances, nature is ultimately more powerful than all human endeavor, and that if humans will refrain from taking any action, however well-intentioned, nature itself will inevitably rectify any problems.

Daoists insist that we must focus our concern upon ourselves, seeking (re)integration with the deeper realities of the cosmos through a process of personal refinement (*lien*). In some of Lao-Chuang Daoism, that process at times appears so rarefied that it involves no more than altered perceptions: one learns to reject conventional "truths" in pursuit of a deeper state of awareness. But most later Daoists understand the process of refinement as a more comprehensive undertaking, involving a transformation or sublimation of one's physical reality as well. Such "biospiritual" ideals are often couched in terms of the imperative of "fostering life" (*yang-sheng*). Some writers have identified *yang-sheng* with physiological practices designed to enhance individual health and prolong physical life. But in the Daoist context, at least, the term connotes much more:

> Indeed, the very idea of life or health, including as it does both physical and spiritual dimensions, evokes an archaic aura of religious meaning—that the fullness of life is supranormal by conventional standards—and symbolically is closely linked with a generalized Daoist notion of the mystic and religious, individual and social, salvational goal of reestablishing harmony with the cosmic life principle of the Dao. (Girardot, p. 1631)

Within the Daoist worldview, *yang-sheng* presupposed a personal ethic of moral and spiritual cultivation (Kirkland, 1991b). That ethic, moreover, assumed a dedication not only to the perfection of the individual self but also to reestablishment of a broader, universal harmony.

The term *yang* means "to foster, nourish, or care for." Thus the *Dao te ching* sometimes presents the Dao in imagery that suggests a loving parent who exerts no control, and oft-overlooked passages encourage altruistic attention to the needs and interests of others (Kirkland, 1986). In that context, *yang-sheng* can be interpreted as selfless concern with fostering others' lives as well as one's own.

In fact, rather than being promoted by a Confucian sense of social service, hospitals, orphan care, and community quarantine procedures were linked to the activities of the Daoist and Buddhist monasteries during the Six Dynasties period.… The root of this concern for community healthcare would seem to be most strongly influenced by the Buddhist idea of universal compassion (*karuna*), but in Daoism this idea could be interpreted as an aspect of the selfless kindness and concern for human health extended to all persons in the practice of *wu-wei.* (Girardot, p. 1636)

Medieval Daoist literature abounds in stories of exemplary men and women who earned recognition—and, on occasion, the boon of immortality—by secretly performing

compassionate acts, particularly for people and animals disdained by others (Kirkland, 1986; Cahill). Such values have sometimes been attributed to Buddhist influence, but they are actually rooted in elements of the ancient Daoist worldview. The Daoist ethos started with the individual, and redirected his or her attention to a broader life context: from body to spirit, from self to community, from humanity to nature. In addition, it presented the would-be Daoist with a moral responsibility to live for a purpose greater than oneself.

Daoist conceptions of history, humanity, and cosmos also undercut some of the paternalistic tendencies so common in other traditions, including Confucianism. Human lives are to mirror the operation of the Dao, which contrasts markedly with Western images of God as creator, father, ruler, or judge. The Dao is not an external authority, nor a being assumed to possess a moral right to control or intervene in the lives of others. Moreover, the *Dao te ching* commends "feminine" behaviors like yielding, as explicitly opposed to "masculine" behaviors of assertion, intervention, or control. There is thus little temptation for a Daoist to "play God," whether in medicine, government, or law.

THE MORAL LIFE: IDEALS OF BALANCE AND HARMONY. While Daoism did not create the ideals of balance and harmony, it embraced them to an extent unequaled by other traditions. A fundamental Daoist assumption, applicable to any facet of life, was that disorder is a result of imbalance, whether physical or spiritual, individual or social. Physical illness was generally understood as an indicator of what might be called a biospiritual imbalance within the individual. In many presentations of Chinese medicine, disease is explained as a result of a misalignment of *ch'i,* the natural life force (which eludes the distinction of "body" from "spirit"). In the minds of the peasantry, such misalignment was often understood as the result of moral misdeeds, and some Daoists who were anxious to involve the common people incorporated such ideas into their writings and practices. But in a broader theoretical context, the imbalances that result in disease might better be attributed to a kind of natural entropy. Ancient Chinese thought assumed that the present state of the world represents a degeneration from an earlier state of universal peace and harmony. The goal of life for Confucians and Daoists alike was to restore that original harmony. Certain Daoists took a profound interest in the problem of restoring the harmony of individuals through treating physical maladies (Girardot). But disease and healing were never understood in purely materialistic terms, and the goal of medicine was never simply the alleviation of physical suffering. Like healers in many traditional cultures, Daoists of most periods assumed that all physical symptoms remit when one restores the biospiritual integrity of the individual and reestablishes a state of balance and harmony with the deeper realities of life. Consequently, some Daoists worked to restore health through therapeutic ritual activity (Strickmann).

Restoring harmony, however, was never a purely individual matter, for the Daoist any more than for the Confucian. Just as a physical disorder was understood as resulting from a biospiritual imbalance within the individual, so sociopolitical disorder was generally understood as resulting from a biospiritual imbalance on a larger scale. Daoists and Confucians of classical times and the later imperial period felt a responsibility to rectify that imbalance, to play a managerial role in restoring *T'ai-p'ing,* "Grand Tranquillity." *T'ai-p'ing* connoted a well-ordered society, both in universal terms and in terms of the local community. But it was not merely a political concept:

> It was a state in which all the concentric spheres of the organic Chinese universe, which contained nature as well as society, were perfectly attuned, communicated with each other in a balanced rhythm of timeliness, and brought maximum fulfillment to each living being. (Seidel, 1987a, p. 251)

Daoist priests of all periods assumed a special responsibility to tend to the spiritual dimensions of upholding *T'ai-p'ing,* complementing the real and symbolic activities of the emperor and local magistrate. Until Mongol times, that understanding of the role of the Daoist priest was accepted at all levels of society, and emperors frequently relied upon Daoist priests to provide both advice and ritual support in keeping state and society in harmony with the cosmos.

The Daoist concern with balance and harmony extended to participation in religious activities. While the *Dao te ching* had commended "feminine" behavioral models, the early Daoist religious community offered participation to women, apparently on an equal basis with men. Though it is not clear how often women performed the same priestly functions as men, medieval texts describe women's spirituality in terms that make it only subtly distinguishable from that of men (Cahill; Kirkland, 1991a). The marginalization of liturgical Daoism after the twelfth century coincided with a more general diminution of opportunities for women throughout Chinese life, and from then on, few women appear in the Daoist tradition.

Daoist attitudes toward sexuality were quite vague. Daoists never articulated any specific sexual ethic. Aside from Confucian moralists, few Chinese regarded sexuality as morally problematic, and most regarded it as a valuable component of human life. Some Daoists took an interest in

reproductive forces as the most readily accessible manifestation of the natural forces of the cosmos. The imagery of "inner alchemy" was sometimes applied to those forces, resulting in biospiritual practices aimed at total sublimation and concomitant personal perfection. Particularly in later centuries, some men and women focused their efforts at self-transformation upon the physical or metaphorical transformation of sexual forces. But once again, it is questionable whether such activities ought to be called specifically "Daoist," for they have little in common with the activities of any of the liturgical Daoist organizations.

DAOIST ATTITUDES TOWARD DEATH. One of the most intensely debated issues in modern discussions of Daoism is that of its attitude(s) toward death. The controversy stems from some interpreters' insistence that religious Daoists struggled to *avert* death, while the earlier Lao-Chuang Daoists had espoused an *acceptance* of death as a natural conclusion to the cycle of life. There is evidence to support that interpretation, but there are also passages in the *Dao te ching* and other Lao-Chuang texts that suggest the possibility of obviating death and the desirability of attaining a deathless state. A natural conclusion would be that "religious Daoism" focused upon those passages, and set about devising practical methods of attaining such a state. But while none can dispute the commonness of texts describing such methods, it is again questionable whether they can be considered representative of "religious Daoism." It should be noted that the most famous proponent of the pursuit of immortality—the fourth-century Ko Hung—actually repudiated the Daoist tradition. On the other hand, the architects of the Daoist liturgical tradition seldom even alluded to immortality as a desirable goal.

Daoists of all periods would be puzzled by the insistence of modern Western medicine that the prevention of human death transcends all other concerns. To Daoists, the reality of one's life extends far beyond the biological activity of one's body, and extending the latter *for its own sake* would hardly seem even desirable. The Daoist goal is always harmony with the deeper dimensions of life, and in those terms a medical model that defines "life" in strictly biological terms seems perverted.

In reality, Daoist attitudes toward death are hardly reducible to any clear, unequivocal proposition. But one may safely affirm that a pursuit of immortality for its own sake—that is, a search for some trick that would obviate the death event—was never a Daoist goal (Kirkland, 1991b). Rather, Daoists consistently pursued a state of spiritual perfection. Frequently, they expressed that state of perfection as a state that was not subject to death. Chinese literature (by no means specifically Daoist) is replete with stories of *hsien*—wondrous male and female beings who live outside the realm of ordinary life and death. Daoist writers sometimes employed such imagery to suggest the final fruits of spiritual development. Some writings suggest that rare individuals underwent a transformation that merely simulated death (Robinet, 1979). But one must beware mistaking metaphor for reality (Bokenkamp). When read carefully, most Daoist writings actually present a "postmortem immortality"; that is, a deathless state can indeed be achieved, but biological death remains a necessity (Strickmann; Seidel, 1987b). Daoist attitudes toward death thus remain a paradox.

Conclusion

Though some Daoist writings do present moral injunctions, Daoism never developed any real ethical code, for such an idea makes little sense in a Daoist context. For instance, since there was no divine Lawgiver, Daoists never developed an ethic conceived as obedience to divine authority. Daoists of various periods did accept the existence of divinities, and some Daoist writings incorporated popular concepts of a heavenly hierarchy that dispenses posthumous rewards and punishments. But acceptance of such beliefs was never considered mandatory, and most Daoist literature lacks such ideas.

Similarly, Daoists lacked the notion that the individual—or even the human species—is an independent locus of moral value. In fact, Lao-Chuang Daoism can easily be read as a concerted effort to disabuse humans of the absurd notions of self-importance that most people tacitly embrace as natural and normal. Hence, the very concept of "rights"—for individuals or groups, humans or animals—makes no sense in Daoist terms.

Daoism might appear to embody a virtue ethic. Indeed, the term te in the title of the *Dao te ching* is generally translated "virtue." But the Daoist perspective is quite distinct from the virtue ethic developed by Confucians like Mencius. Mencius clearly articulated virtues like *jen* (benevolence), and insisted that proper cultivation of such virtues would result in the perfection of individual, family, society, and state. Much of Daoism seems to suggest a similar model, with the substitution of *te* for *jen.* But though Mencius attributed human moral impulses to a natural inheritance from "Heaven," Lao-Chuang Daoists frequently criticized most Confucians as seeking answers to life's issues in terms that were excessively humanistic. Confucians often seem ambivalent concerning the relevance or even the existence of transhuman realities. And it was upon precisely such realities that Daoism centered itself.

To understand the moral dimensions of Daoism, one must understand the "vague and elusive" concept of the Dao—transcendent yet immanent, divine yet inherent in humanity and all of nature. Most important, since the Dao never acts by design, Lao-Chuang Daoists ridicule the notion that good could result from conscious evaluation of possible courses of action. Such deliberate "ethical reflection," they argue, blinds one to the natural course of action, which is the course that one follows when living spontaneously, without the arrogant and destructive imposition of rationality and intentionality. The ethical dimensions of Daoism are thus real but subtle. Since Daoists never embraced normative expressions of any kind, to perceive the ethical dimensions of Daoism, one must peer deeply and carefully into the entire tradition, extrapolating from a plethora of sources from different segments of a highly diverse tradition. In doing so, one forms the impression that to live a proper Daoist life is to live in such a way that one restores and maintains the world's holistic unity. The Daoist life involves dedication to a process of self-refinement, which is considered one's natural contribution to the health and well-being of both nature and society. In a sense, to be a Daoist is to accept personal responsibility for taking part in a universal healing, doing one's part to restore the health and wholeness of the individual, society, nature, and cosmos.

DEATH

I. CULTURAL PERSPECTIVES

What is death? How do we understand its meaning? Since death cannot be directly apprehended by straightforward scientific means, culture provides the key medium for comprehending the final boundary between our existence as living beings and the eventual end of that existence. Death is a fact of life, but awareness of mortality is a social, not a biological reality. Knowledge about death and its meaning and value is socially constructed. How should we account for profound differences across the world and throughout history? In some societies, elders choose to end their own life via exposure to the elements, to avoid being a burden to the wider community—the perhaps apocryphal Eskimo on an ice floe narrative—which provides a powerful image whether supported by the ethnographic evidence or not. Or mothers may withdraw their love and attention from an infant deemed unlikely to survive in an impoverished environment like the slums of northeastern Brazil.

In contemporary U.S. society, through a combination of technical prowess, institutional arrangements, and bioethics-governed procedures and practices, we elect to maintain the liminal—betwixt and between—existence of patients suffering from persistent coma, maintaining their biological lives in specialized ventilatory-care units. Others may decide to have their brains or bodies "cryopreserved" after the moment of physical, cardiopulmonary death, in response to internet advertisements. The native inhabitants of the Amazon, called the Wari, respect their dead, and assuage their grief, by engaging in ritual mortuary cannibalism. How might the profound range of cultural variability in organizing death inform bioethics debates about the morally right management of death and the end of life?

This entry examines the intersection of death, culture, and bioethics, taking the disciplinary perspective of anthropology, the field most associated with the analysis of culture. The scope is both broad, examining conceptually the ways in which the experience of death is culturally constructed within particular social and historical moments, and narrow, detailing the growing body of knowledge about the influence of an increasingly globalized biomedicine (and "the ethics" of that medicine, bioethics) on the experience of death and dying in multi-cultural societies (Kaufman; Conklin; Scheper-Hughes).

Intersections of Death, Culture and Bioethics

When *cultural* difference is considered, we generally think of differences among people from varied ethnic backgrounds in a diverse society, or of clashes emerging in the face of immigration or forced migration of populations. In homogenous societies, for example, when healers', patients', and broad social expectations about death are concordant, cultural difference may be transparent and cultural conflicts rare. In diverse societies, ethnic and cultural background influences all aspects of healthcare, nowhere more profoundly than when death is near. Even patients and families who appear well integrated into a diverse society such as the United States may draw heavily on the resources of cultural background (particularly spirituality) when experiencing and responding to death. When cultural gaps between families and healthcare providers are profound, accentuated by language barriers and varied experience shaped by social class, negotiating the difficult transitions on the path from life to death, always a daunting challenge, becomes even more difficult.

We argue that all domains of end-of-life care are shaped by culture, including:

- the meaning ascribed to illness;
- the actual language used to discuss sickness and death (including whether death may be openly acknowledged);
- the symbolic value placed on an individual's life (and death);
- the lived experience of pain and suffering;
- the appropriate expression of pain;
- the styles and background assumptions about family decision making;
- the correct role for a healer to assume,
- the care of the body after death, and
- appropriate expressions of grief.

When the patient's family and healthcare providers do not share fundamental assumptions and goals, the challenges are daunting. Even with excellent and open communication—the foremost goal of culturally, and ethically, appropriate

care—barriers remain. Differences in social class and religious background may further accentuate the profound challenge of defining and implementing "good" end-of-life care in healthcare systems serving increasingly diverse societies. The conceptual challenge for bioethics is defining the good in such situations, and making certain that recommendations for respecting cultural difference serve both pragmatic and principled goals (Sprio, McCrea Curnen, and Wandel).

When dealing with concepts as totalizing, but slippery as culture, and as seemingly precise as death, it is useful to begin by considering the definitions and basic concepts used by other disciplines.

Anthropological vs. Philosophical Approaches to Death

It is helpful to consider how taking an anthropological or cultural approach to the study of death differs from the approaches taken within philosophy, where the mystery of death has been a topic of debate and discussion for thousands of years. Philosophy has attempted to account for death conceptually, and more recently in terms of developing criteria for judging when death has occurred. Death is a state following upon the end of life; it is the absence of life. Death is a mystery, but is it more mysterious than other phenomena that we do not understand? Philosophers have tried to ask what death is, and in general have encountered serious definitional difficulties, stemming primarily from the problem of how one defines *life*.

A question of key philosophical interest was posed by the Epicurean philosophers, and most clearly articulated by Lucretius, who asked, "Is death bad for you?" His basic argument, that since the dead person no longer exists, death cannot be "bad" for the individual who dies, has been influential in the subsequent philosophical discourse on death. By contrast, cultural critiques begin with a set of *social* questions that move beyond the individual: How do different societies manage the existential fact that all members will eventually die, and the practical implications of the death of individuals, including the reintegration of survivors of a death? What role do healers and healing systems play, if any. Ethnographers, whether of tribal and hunter-gatherer societies or of a contemporary intensive care units, have a quite different task than the philosopher: describing the range of culturally patterned responses to the existential realities of eventual human frailty and death.

Death and the Birth of Bioethics

Death has been an essential focus of bioethics since the inception of the field nearly four decades ago (Jonsen). Dealing with the challenges of a dramatically changed biomedical landscape was, in fact, one of the main driving forces in the field's birth. One could argue that bioethics in its current form exists partly in relationship to its encounters with death, to birth pains peculiar to the unique cultural environment of the United States, where the field first crystallized into a new discipline. Following the successes of post-World War II clinical medicine, in particular the development of the mechanical ventilator, and its increasing use outside of its original site—in operating theaters and post-anesthesia recovery—the question arose: When is a patient beyond hope for a meaningful recovery and when is a patient whose heart and lungs are being continued by artificial means actually dead? (Veatch). The first heart transplant in 1968 added the complexity of figuring out when someone was "dead enough" for their organs to be harvested for transplant recipients.

A series of seminal legal cases, many receiving widespread attention, such as the cases of Baby Doe and Karen Ann Quinlan, revealed the fundamental ambiguities of medicine's power to combat death. Recognition of these ambiguities lead to the creation of a series of presidential commissions to debate and reflect on topics such as criteria for establishing brain death, and appropriate procedures for withholding or withdrawing potentially life-sustaining technologies.

Cultural analysis takes account of developments in technology but does not require a determinist position. The argument is *not* that new medical technologies transform cultural understandings of death in a straightforward, linear way. Rather, the meaning of any new medical procedure to forestall death will be developed and gain significance against a specific cultural background. Since understandings of technologies are inevitably culturally shaped, they are never *neutral* but their development is affected by the existing cultural milieu and once in use, cultural context affects how they are used. Thus, most researchers in science studies accept a view that the meanings of new medical technologies are *co-constructed,* rather than determined, they are in a way amalgams of social practices and technical objects; one must understand both in order to have the full picture. A totally implantable defibrillator to save patients from sudden death will not have a specific meaning in an environment where medicine's goal is to intervene in every death. Another society might question the use of certain procedures, such as resuscitation, in the situation of an expected death. The same dynamic affects "low tech" interventions like feeding tubes. Against the background of a long-standing cultural adage that "dying on an empty stomach" is a horrific fate, the surgically-implanted feeding tube will take on one sort of meaning. In another environment, where freedom from

tubes and bodily interventions is highly valued, another outcome is likely. As the use of technologies intensifies, indeed, as patients begin to be defined as dying only after they have failed all readily available interventions, we might speak of death occurring in technological time (Muller and Koenig 1988).

Cultural Perspectives on Death

Exact definitions of culture are elusive, like the concept itself. At the most general level, culture is defined as those aspects of human activity that are socially rather than genetically transmitted. Thus culture is patterns of life passed among humans. Definitions are often so broad as to be meaningless, applying to every domain in society: religious beliefs, folk practices, language use, material objects, worldview, artistic expression, etc. According to pioneering anthropologist Robert Lowie, culture "is, indeed, the sole and exclusive subject-matter of ethnology [anthropology], as consciousness is the subject matter of psychology, life of biology, electricity as a branch of physics" (orig. 1917). "In explanatory importance and in generality of application it is comparable to such categories as gravity in physics, disease in medicine, evolution in biology," Alfred Kroeber and Clyde Kluckhohn wrote in 1952 (see Kuper for an overview).

With a category this broad, boundaries are difficult to delineate. Anthropologists have become critical of the application of the culture concept (Kuper). The work of Clifford Geertz moved the field of anthropology in the direction of interpretation, transforming culture from a passive noun to an active verb. "Man is an animal suspended in webs of significance he himself has spun; I take culture to be those webs, and the analysis of it to be, therefore, not an experimental science in search of law, but an interpretive one in search of meaning (p. 5)." In biomedicine the dangers of an essential view of culture are clear. We cannot simply *read* culture in patients facing death or indeed any clinical encounter, discerning their views, desires, and needs with false security based on knowledge that culture *A* holds view *B* about disclosing a terminal prognosis to a patient, and culture *C* holds view *D*.

The origins of the culture concept date back to the work of early post-Enlightenment folklorists, such as Herder, who made use of the concept to avoid the uniform, totalizing theories of human capabilities that were characteristic of the late eighteenth century. The modern concept of culture developed much later, partly in response to racist (and biological determinist) ideologies of the nineteenth century, most incorporating an evolutionary framework based on social Darwinism. The species *homo sapiens* was viewed as divided into separate sub-species or races, each with engrained, essential characteristics, a system that included a hierarchy of moral worth.

Philosophers maintain that a general problem with the culture concept is that it is often linked with a naïve relativism which precludes judgments about the unique cultural practices found around the world. Indeed, in some instances this criticism is warranted; attention to the diversity of cultures and the need to judge each on its own terms is central to the field. However such attention to cultural relativism at the empirical level does not necessarily lead to a stance of ethical relativism. Often practices dealing with death that were unsettling to Europeans, such as head hunting and cannibalism, were the focus of disproportionate attention, supporting efforts to justify and document a radically different "other" (Conklin).

The history of anthropological engagement with mortality dates back to the origins of the discipline, and is bound up with concerns about the origins of religion. Early theorists focused on small scale societies where magic, science, and religion are not separate cultural domains. For example the nineteenth century anthropologist Edward Tyler, who worked from an evolutionary paradigm of explanation, saw the origins of human society and culture in efforts to explain mortality, and in particular, in the recurrence of dreams and other visions about deceased close kin. The "savage philosopher" reflected on everyday experience and developed the notion of the soul. In *Magic, Science and Religion* Malinowski wrote,

> Of all sources of religion, the supreme and final crisis of life—death—is of the greatest importance. Death is the gateway to the other world in more than the most literal sense. According to most theories of early religion, a great deal, if not all, of religious inspiration has been derived from it.… Man has to live his life in the shadow of death, and he who clings to life and enjoys its fullness must dread the menace of its end. Death and its denial—immortality—have always formed, as they form today, the most poignant theme of man's forebodings. [Experience] at life's end condensed into one crisis which provokes a violent and complex outburst of religious manifestations. (p. 47)

Social theorists influential to the development of anthropology, such as Émile Durkheim, and later Robert Hertz, argued that all societies exert institutional controls to protect and preserve the lives of members, including rules governing appropriate and inappropriate killing. Many actions that appear to be individual choices, such as suicide or the expression of emotion during grieving, are actually

socially patterned, as studies such as Durkheim's comparative analysis of suicide rates, one of the first uses of statistics in social science, illustrate (1951 [1897]). Hertz used cross cultural comparisons of mourning rituals to suggest that the human expression of grief can also be best understood as a *social fact,* particular to each society (1960 [1907]).

For reasons that have been the subject of extensive internal critique within anthropology (Rosaldo; Behar), until fairly recently the field concerned itself primarily with the rituals following death. This included ceremonies that focus on the disposal of the dead body and occur *after* cardiopulmonary death generally, although not always. This concern with ritual practices and symbolic meaning precluded a full engagement with the profound emotional significance of the process of dying, grief, and loss. Scholars focused on the recurrence throughout the world of death rituals that expressed fertility and rebirth (Bloch and Parry). The emphasis on sexuality, and the connection between sex and death, fit well with interpretations of ritual behavior that emphasized function. Death rituals serve the function of reintegration of society following a death, focusing on reproduction.

In some societies this symbolic link between death and regeneration is expressed explicitly; funerary practices incorporate the abandonment off usual standards of sexual propriety for a confined time period, or allow and encourage sexual relationships between categories of kin where such contact was generally excluded (Barley). These *rites de passage* seemed designed to guide the passage of humans through dangerous, liminal transitions, marking the boundary between life and death. Thus van Gennep (1960 [1909]) saw associations between funerals and other rites of transition, such as initiation ceremonies. In contemporary U.S. hospitals, the practices of bioethics developed in the last decades have become the *new* rituals guiding these transitions between life and death. A number of studies in anthropology (and medical sociology) examine contemporary death practices in biomedical settings, such as Bluebond-Langner's 1978 account of disclosure of a terminal diagnosis to children under treatment for leukemia, or Sudnow's 1967 account of dying in a public hospital. Christakis examines contemporary practices in foretelling death (1999). Other recent ethnographies chronicle the experience of death and extreme old age for specific populations, for example elderly Jewish immigrants (Myerhoff).

Defining the Boundary Between Life and Death

The concept of "social death" has been of considerable utility in describing the varied boundaries between life and death throughout the world. Nigel Barley, who has written an accessible account of the range of cultural practices surrounding death, describes his alarm and confusion when an African informant tells him casually that his wife "died" that morning, in the midst of a conversation asking him for a cigarette. In reality, she had been, in western terms "unconscious," but the Dowayo make no distinction, either linguistically or conceptually, between death-like states that are reversible (what we might call coma, persistent vegetative state or perhaps suspended animation) and that which continues permanently. This view of death provides a sharp contrast to biomedical definitions that assume irreversibility. (Although it is important to remember that even in the West, belief in resurrection calls the finality of death into question for many, and forms a core of religious belief.)

Studying ideas of death, of course, also reveals views on life and what it means to be human. The idea of social death is intimately tied up with notions of personhood, and who counts as a person within a society. Social death has utility in analyses at both ends of the human lifespan. Anthropologists have observed and documented societies in which full term infants are not considered fully alive, and thus members of the social group, until they have survived the first month of life (perhaps not by chance the period of highest vulnerability for a newborn) and received a name in a formal naming ceremony. Those who die before naming are not considered fully human—we might say that the social group does not recognize the infant' *personhood*—and thus do not warrant ritual attention, such as funerals or elaborate mourning rituals. Such practices are in sharp contrast with contemporary obstetrics practices in the first world, where developing fetuses are named and ultrasound images are exchanged prior to birth. Indeed, the very survival of extremely premature infants in neonatal intensive care units is best understood as an artifact of culture. In other societies specific kinds of birth—such as twins—or certain infants may be judged as incompatible with life, and thus viewed as already dead or infanticide may be allowed. In Bariba society (in Africa), certain infants are understood to be witches, and thus mothers are not allowed to grieve the loss because the infant is defined as not human (Sargent).

Social death is also a useful concept for describing practices near the end of life. In some societies, ritual mourning practices may begin before cardiopulmonary death occurs, since the ill or extremely aged person is viewed as meeting cultural criteria for social death. Or those who are very old may be viewed as almost dead. Many have argued that the warehousing of the elderly in sub-standard U.S. nursing homes constitutes a form of social death. In a series of pioneering ethnographic studies of hospital-based death

in the U.S.—in the immediately "pre-bioethics" period—Glaser and Strauss conceive of the isolation of the dying as a form of social death (1965; 1968).

Arguably the most important example of social death in contemporary biomedicine is the notion of "brain death." A body maintained in a modern intensive care unit, pink, with heart beating and lungs inflating and deflating, appears to most observers as a living being. Yet a diagnosis of brain death results in that person's abrupt transition to a socially recognized state of death, and transforms the corpse into a container to house organs awaiting harvesting for another donor. A detailed analysis of the historical development of the concept of brain death, as well as a chronicle of contemporary brain death debates is found in Margaret Lock's 2002 *Twice Dead.* Lock uses a classic anthropological technique called the comparative method to reveal how culture shapes seemingly technical scientific and medical practices. The state of brain death appears to follow the straightforward application of a set of technical criteria about the functioning of the human brain. Lock tells the story of Japanese resistance to organ transplants that require the use of a brain dead patient. By contrasting Japan and the U.S., she reveals how the category of social death can only be understood in cultural context. In Japan, the core site or physical location of personhood is associated with the heart, not the brain. However, Lock makes it clear that the story is not simply about "traditional beliefs," rather many features of contemporary Japanese society—including distrust of the medical profession—play a role in widespread resistance to organ harvesting from brain dead donors.

New Rituals of Dying

For most in the wealthy, developed world the idea that death is an evil to be prevented at all cost, including the use of aggressive therapies like the totally implantable artificial heart, is commonplace. Buoyed by past successes, the arc of medical practice has extended to the moment of death, which increasingly is seen as a process to be stopped whenever possible. As new technologies became available, seeing a patient in cardiac arrest necessitated an action. Resuscitation, in reality attempts at resuscitation, became routinized and normalized at the moment of death (Timmermans). By the late 1960s dying within the sphere of biomedicine became defined as a problem in need of a solution.

The outcome of the many commissions, legal cases, and academic discussions described by Jonsen in the *Birth of Bioethics* (1998) is a set of novel, autonomy-based practices that seek to enhance the self-determination of the dying, and protect patients from the abuses of overzealous physicians "programmed" by their instrumental training to over treat, prolonging the dying process. These practices incude:

1. formal implementation of advance care planning (and execution of advance directives), institutionalized by law following the passage of the American "Patient Self-Determination Act" in 1991;
2. explicit discussion and decision making about the use of cardiopulmonary resuscitation, or DNR orders;
3. open discussion of diagnosis/prognosis and shared decision making about foregoing or withdrawing curative interventions; and
4. transition to "palliative care" or, in some cases, hospice.

Of course this ideal narrative is rarely followed. All of these practices required a commitment to open and full disclosure of information about death and detailed discussions about how one wishes to die, and assumed that the patient himself—and a gendered pronoun is used purposefully—was in full control of his destiny and fate. The model is gendered male by the focus on individual agency and control, as opposed to the inevitable interdependence of a dying person with her social environment.

What Differences Make a Difference?

Thus far, only broad cultural responses to death have been considered. With increased border crossing and south/north migrations throughout the world, how should we view and define difference in bioethics? Turning to contemporary biomedicine, considerable research documents the relevance of ethnic or cultural and religious differences in the experience of death and dying and in clinical approaches to end-of-life care. However, health researchers and clinicians generally do a poor job of making clear analytic distinctions among the key elements of difference, in answering the question, "What differences make a difference?" When we talk about *cultural* difference, do we mean a patient or family's voluntarily adopted and expressed *ethnic identity,* their nation of origin if recent immigrants, their *race* as assigned by a government enforcing discriminatory laws such as segregation or apartheid, or their adoption of specific health-related practices such as diet or use of medicinal herbs? In healthcare research there is considerable confusion in terminology, particularly with regard to the use of the term "race."

The lack of consistency in the use of terminology for concepts of race, ethnicity, ancestry, and culture is manifest in the wide variance in terms used to describe individual and group identities. Terms such as white, Caucasian, Anglo, and European are routinely used interchangeably to refer to

certain groups, whereas black, colored, Negro, and African-American are used to refer to comparison groups. Also, white-black comparisons are straightforward in contrast to the confused use of terms such as Hispanic and Asian. Both of these labels, one based on linguistic criteria and the other on continental origin, lump together many populations of people reflecting enormous variability in factors related to health and medical care. The terms we use gloss over enormous diversity.

Debates in the biomedical literature focus on the appropriate use of terms such as race, ethnicity, and culture. Asking how race is relevant to bioethics, death, and end-of-life care is relevant, but caution is needed whenever the category of race is invoked. Much is "at stake" in how these categories of difference are utilized when conducting research or in designing programs to improve the care of patients, by way of enhancing the *cultural competence* of healthcare providers who must aid patients and families in decision making at the end of life. In particular, approaches to conceptualizing disease etiology or health outcomes may have moral significance if one naïvely assumes that culture predicts behavior in a precise way or that something essential or *inherent* in a certain population leads to poor health outcomes or barriers to healthcare access (Gunaratnam).

In the case of black-white differences in infant mortality or homicide rates, for example, how one thinks about causation, and the relative contribution of genes, environment, and social structure, may determine the type of intervention recommended. Meaningful genetic and biological differences do not always map clearly onto social categories of human difference, whether defined as race, ethnicity, or culture. American patients who self-identify as African American generally seek more aggressive care and are underrepresented in hospice services. If we talk about *racial* differences about preferences for palliative care services, what exactly do we mean? In the United States efforts to tease apart the independent contributions of *race* and socioeconomic status (SES) when analyzing healthcare outcomes may be daunting.

Although the dimensions of difference most relevant to end-of-life care are likely to be social or cultural, biological or genetic variation may also be germane. For example, the field of pharmacogenomics tracks individual and group differences in drug metabolizing enzymes to predict response to medications such as chemotherapy or pain medicines. Although classic understandings of human "races" do not parallel actual genetic variation at the molecular level, there may be frequency differences among socially defined populations relevant to pharmacogenomics. It has been known for decades that there is ethnic or cultural variation in the expression of pain or painful symptoms (Zbrowski; Garro); the degree of variation in the actual experience of pain—possibly modulated through the action of pain medicines—remains unexplored.

Immigration status is another key category of cultural difference. Recent immigrants provide challenges to the healthcare system, particularly in end-of-life care. In much of the world, the American ideal of open disclosure of information about diagnosis and prognosis is not the norm (Gordon and Paci; Die Trill and Kovalick). In fact, patients and families may experience the directness about diagnosis characteristic of U.S. healthcare as needlessly and aggressively brutal, violating norms espousing "protection" of the ill. Although children may be seen as more in need of protection than adults, much pediatric palliative care literature recommends openness, appropriate to an ill child's age, as preferable to concealment. U.S. bioethics procedures governing end-of-life care may seem unfathomable to those newly in this country, but it is perhaps the assumptions of bioethics that are culturally bound. As Die Trill and Kovalick note, "Those who argue that children always should be told the truth about having cancer must recognize that the truth is susceptible to many interpretations" (p. 203). Whether the dying person is a child or an adult, family members who object to sharing the full differential diagnosis with an ill child may be accused of being "in denial" about the severity of the patient's illness, their concerns "psychologized" rather than understood. Lastly, the experience of those immigrants who are refugees from political violence or war adds another dimension. The effects of multiple losses on family members—including the death of other children and adults in the family, one's country, one's entire history—are difficult to predict but clearly shape a family's response to the serious illness and threatened loss. Responses may appear to be overly stoic or overly emotional.

When considering societies with histories of deep racial divisions, it is especially important to separate analytically the concepts of culture, ethnicity, and race from the effects of social and economic status. Historically underserved populations may have special barriers to end-of-life care that have little to do with difficulties in communication and are not related to their identification with a certain set of ethnic traditions. Culturally specific values and beliefs often exist, but may not be of signal importance. In a ground-breaking study, an American physician documented the lack of availability of narcotic analgesics in minority communities such as Harlem (a low income, historically African American and Hispanic neighborhood in New York City); pharmacies simply did not carry the opiates that are "state-of-the-art" drugs for pain control (Morrison, Wallenstein, and Natale et al.). The American "drug wars," including the recent battles about the abuse of time-release opiates like oxycontin, are

often fought in poor neighborhoods with limited access to legitimate employment. Patients from minority backgrounds may not receive adequate pain control if drugs are not prescribed because of fears of theft or abuse. When members of the healthcare team are hesitant to prescribe narcotics it may be a legitimate concern based on factual information about a particular family's drug history, or it may be the exercise of racial stereotyping. The end result is the same: patients may be denied needed pain relief.

The experience of people with sickle cell disease, whose pain is often undertreated because of concerns about drug abuse, is another example of stereotyping. Culture thus contributes to inadequate symptom management, but indirectly, through the actions of healthcare providers, not the essential cultural characteristics of a population. Research in a Los Angeles emergency department documented that Hispanic patients with injuries identical to whites were given less analgesic medication (Todd, Samaroo, and Hoffman). Do patients in such situations have different cultural values about analgesia? Can they exercise full autonomy when faced with decisions about foregoing or withdrawing life prolonging therapies? Surely not, without the assurance of adequate analgesia and palliative care.

Karla Holloway's *Passed On: African American Mourning Stories* (2002) vividly reveals how the unique history of Blacks in the U.S.—including the legacy of slavery, Jim Crow policies, and violent death, such as lynching—shape the experience of death for patients receiving care in hospitals that were segregated two generations ago. Clearly *difference* is relevant to bioethics; assuming that end-of-life procedures and practices have universal applicability is at best naïve and at worst harmful. In addition to the varieties of cultural and social class differences described here, other domains of difference that intersect with culture, such as gender, sexual orientation, disability, and religious background, must also be considered within bioethics (Parens).

Culture Matters: Bioethics, End-of-Life Care and Decision Making

In its report detailing needed changes in care of the dying, the Institute of Medicine has recommended attention to cultural diversity as a national policy objective (Field and Cassel). There is a growing literature based on empirical studies documenting the cultural dimensions of end-of-life care for patients and families. (For reviews see Kagawa-Singer and Blackhall; Koenig and Davies; Crawley, Marshall, and Koenig). Based on this literature, it is possible to identify the key domains of clinical significance in caring for patients from diverse ethnocultural backgrounds who are unlikely to survive.

In general, the cultural challenges of end-of-life care can be divided into two fundamental categories: those that do, and those that do not, violate the healthcare team's foundational cultural values, norms that may also be enforced by legal requirements in some societies. In the first category are cultural values or practices that call into question the biomedical goal of combating disease and extending life at all costs. A family who refused to allow a potentially curative limb amputation for a female child with osteosarcoma because of beliefs about the need to preserve bodily integrity, and a daughter's marriageability, would immediately create consternation for healthcare team members. By contrast, another family who wished to engage a spiritual healer to pray for a successful outcome to the same potentially life-saving surgery would *not* create a cultural crisis, since the family's goals could easily and effortlessly be incorporated into the clinicians' care plan.

Generally, issues such as care of the body after death do not provide a fundamental challenge to biomedical values and beliefs; thus customs prescribing particular approaches to post-death care are relatively easy to implement unless they violate laws governing disposal of the body. However, even in post-death care there may be situations that lead to cultural conflict, such as requests for autopsy or organ donation in situations where the wholeness of the body is highly valued. And the domain of grief counseling and bereavement care may or may not elicit conflict. For medical specialists focused on cure, less is "at stake" once a patient has died and can no longer be saved, but conflicts may still emerge over differing definitions of acceptable grieving practices.

Family Roles and Responsibilities in Shared Decision Making

Within the current conventions of bioethical decision making about end-of-life care for a competent adult patient, the decisions are left up to the individual; theoretically the family or broader community is not critical to the patient's choices. Autonomy is the primary value at play. In the case of children or the severely mentally incapacited, where family members become surrogate decision makers, the situation is much more complex. A growing body of research documents how autonomy-focused bioethics practices may not adequately meet the needs of patients from diverse backgrounds. The value of respect for individual autonomy is not universal. Patients may express confusion and ambivalence when asked to participate in advance care planning about death (Frank, Blackhall, and Michel).

Disagreements about the goals of care, although rare, are emotionally difficult for all. In many cross-cultural

situations, the Western view that individual patients will (and should) make decisions about care may be too narrow. In some societies a social unit beyond the nuclear family may also have considerable decision-making authority. Elders in an extended family or clan group may expect to be involved, and patients may desire this. Integrating extended family or kin groups into care in a Western hospital, hospice, or nursing home is hard but may be desirable. Gender may play a role as well. In traditional male-dominated societies, mothers may never have experienced the level of decision-making authority automatically granted to both parents in the United States. This may be a source of tension. Similarly, the evolving practice in pediatrics of requesting "assent" to care by older children, especially girls, may create tensions within the family.

A further dynamic may result from the ideal "shared decision-making" model. Tilden and colleagues have documented stress among family members involved in decisions to withhold treatment. The impact of family involvement in decisions to terminate treatment has not been studied extensively. Inexperienced clinicians or trainees may present decisions about limiting painful or aggressive procedures, sometimes an opening to a transition to palliative or hospice care, in an insensitive way, making it appear that the family decision makers must give "permission" for futile care to be withheld. Although the family's involvment in making decisions on behalf of their loved one is expected, few individuals, regardless of their cultural background, are able to do this easily. In fact, the resistance to giving up hope and explicitly limiting therapies found among families from diverse backgrounds may be appropriate. Models of care that do not require that curative therapies be abandoned in order to obtain excellent palliative services may ultimately lessen this problem. Patients or family members should never be told that care will be withheld; rather the focus should be on meeting the needs of the patient and family.

Varied Understandings of the Role of Health Professionals or Healers

Just as the appropriate role of parents or family members caring for a seriously ill person may vary, the families' expectation of the role played by health professionals may differ. In some societies, healers are expected to make a diagnosis almost magically, perhaps by feeling the pulse without asking any questions. Healers may exert considerable power and authority; they may expect and receive deferential behavior. Patients and families schooled in these traditions may be confused by the shared decision-making ideals of Western practice. They may lose confidence in physicians who do not appear to know unequivocally the correct course of action but instead ask for the patient's views.

In many societies the roles of healer and religious specialist intersect. "Each religious tradition has its own images and ideals of the doctor, in which the individual engaged in healing is defined as enacting some of the highest ideals of the tradition itself" (Barnes, Plotnikoff, Fox, and Pendleton). The healer's role at the end of life may be particularly meaningful, or it may be proscribed to take on the care of those not expected to survive, as in the Hippocratic tradition.

Families who have been denied access to healthcare providers may also question the trustworthiness of the "establishment" health system, worried that those in power do not have their best interest at heart. The disparities in morbidity and mortality across U.S. populations suggest that often African-American patients receive less intensive care. The irony is that research on end-of-life decision making in adults reveals that minority patients may actually desire more aggressive care near the end of life (Caralis, Davis, Wright, and Marcial; Tulsky, Cassileth, and Bennett).

Communication Barriers: The Need for Translation

Negotiation about the appropriateness of clinical services for patients nearing the end-of-life is a complex task when healthcare professionals, patients, and family members share fundamental goals and assumptions. By no means has a successful "formula" for such communication been established. When cultural barriers exist, particularly those created by language, the goal of open and effective communication is exceptionally difficult. Language translators may be available only intermittently, and are often poorly trained. In 2002, two hospitals in Brooklyn, New York, that routinely serve large numbers of Spanish-speaking patients were sued for failure to provide translation services, examples of a number of such legal actions dating back several decades.

The task of language translation in the arena of ethical decision making and end-of-life care is particularly complex. How does one translate a discussion about a "do not resuscitate" decision to a family with no previous experience of cardiopulmonary resuscitation (CPR), and no prior knowledge of the American bioethics tradition of requiring permission not to offer CPR, even to a patient who is actively dying an "expected" death, or may be frail because of extreme old age? What if the language characters representing resuscitation are interchangeable with those suggesting the religious concept of resurrection? Although it sounds

odd from the perspective of Western, scientific understandings of death, who would not elect to have themselves or their dying loved one brought back to life if offered the choice in those words? How might medical interventions at the moment of death be understood among practitioners of Buddhism who believe that rituals spoken during the dying process guide the "soul" through dangerous spiritual territory and ultimately determine where and how a person will be reborn? How do you negotiate with a family about the location of death—home versus hospital—against a cultural background where speaking of an individual's death is thought to bring it about or where certain illnesses cannot be named? The use of family members as interpreters, which may be unavoidable, may make discussions such as these even more problematic. Family members may see their primary role as protecting others in the family from harm and thus "shield" them from information viewed as harmful. Such shielding is counter to bioethics norms of open disclosure.

Furthermore, models of professional translation, such as those employed in courtrooms where relationships are fundamentally adversarial rather than collaborative, assume that language interpreters should function as neutral "machines." Healthcare providers need to be aware that translation services such as those available by phone from AT&T may be based on legal models of interpretation. This stance ignores the interpreter's potential value in providing information about the family's cultural background, as well as providing language interpretation. When interpreters are engaged as full partners in providing care, they may aid in negotiations about difficult end-of-life dilemmas (Kaufert, Putsch, and Lavallee). When included as part of the healthcare team—for example, in programs where native speakers of commonly encountered languages are employed as bilingual medical assistants—interpreters can also serve the useful function of explaining the culture of biomedicine, and the seemingly peculiar assumptions of bioethics, to families.

Integration of Alternative and Complementary Medicine into Palliative Care

Patients and their families may be subject to strong pressures to utilize "ethnomedical" practices and procedures believed to be efficacious. Recent immigrants may utilize products obtained abroad or from Mexico and Central America. Practices vary widely, including acupuncture for pain, cupping or coining, dietary prohibitions based on "hot-cold" belief systems, Chinese herbal products, Ayurvedic patent medicines, and full-blown rituals including chanting and the sacrifice of animals. A skilled practitioner creates an open environment in which the patient, family, and perhaps a ritual specialist from the community may openly discuss the appropriate blending of biomedically sanctioned medicines and procedures with ethnomedical products. Although some patent medicines and food supplements are known to be harmful and may actually contain potent pharmaceuticals, the healthcare team is unlikely to obtain a full accounting of all treatments used for a particular dying patient unless a nonjudgmental attitude is maintained. This may be a challenge when a healthcare provider must compromise his or her own "ideal" care.

The need to integrate alternative and complementary medicine into palliative care is not limited to patients from particular ethnocultural communities. Research documents that a large percentage of Americans have utilized "alternative" medicine in the recent past (Eisenberg, Davis, Ettner et al.), with prayer being the most widely utilized practice (82 percent of Americans believe in the healing power of personal prayer) (Barnes, Plotnikoff, Fox, and Pendleton).

The Meaning of Pain and Suffering

End-of-life care has as a primary goal the relief of pain and suffering. Cultural difference is relevant to pain management in multiple ways. The effectiveness of symptom management may be lessened by economic barriers to medicines or special treatments. Cross-cultural research with adult patients has documented differences in the way people experience and express pain (Garro). What is considered acceptable way to express painful symptoms? Is stoicism rewarded? Are there gender differences in outward discussion of painful symptoms? Spirituality may have an impact on the meaning of suffering and hence on the management of symptoms. A study of infants and children with a rare genetic disease (recombinant 8 syndrome) in long-time Spanish-speaking residents of the American Southwest revealed the complexity of suffering. The experience of affected children in these devout Catholic families was thought to mirror Christ's suffering, providing meaning to an otherwise unexplainable tragedy (Blake).

Defining the Boundary of Life and Death

Biomedical definitions of death, including the concept of brain death, appear to be clear cut. However, when examined closely considerable ambiguity remains. Even among biomedical professionals one frequently hears confusion in language when speaking, say, about an organ donor who is technically brain dead, but may appear to be as "alive" as adjacent patients in an ICU. Linguistically, these brain-dead

bodies experience a second "death" once organs are retrieved for transplantation and ventilatory support is removed (Lock). It is thus not surprising that patients and families can also become quite confused about states resembling death, including brain death, the persistent vegetative state, or coma (Kaufman).

Disputes arise when a patient meets the biomedical criteria for "brain death," but the family refuses to allow withdrawal of "life" support. In a masterful essay, Joseph Fins describes two clinical negotiations about withdrawing life support from children defined as brain dead (1998). In one case, the hospital team engages the family's orthodox rabbi and other religious authorities in a complex series of negotiations, respecting throughout the family's view that the patient is not truly dead and that only God can declare death. A more contentious case involves an African-American family who maintains a stance of mistrust toward the healthcare establishment in spite of every effort on the part of the clinical team. The family's past experience shaped its understanding of the team's intentions in spite of great effort to gain their trust. Disputes such as these are the "hard" cases, revealing cultural clashes that cannot be ameliorated simply by motivated clinicians, sensitivity, or excellent communication skills, although clearly those things may keep conflict to a minimum or may keep small cultural disputes from erupting into major pitched battles.

Work has focused on care of the body after death, particularly the question of autopsy, since in some societies the body is considered inviolable after death; its contents sacred and necessary for the individual's appropriate survival into the afterlife. These cultural practices were most fully-developed in Egyptian dynasties, where funeral practices and preparation for life after death—including mummification and building of elaborate tombs—consumed the society's symbolic attention and material resources. The acceptability of autopsy, or other uses of the body following death, is deeply sensitive to cultural and religious prohibitions. Knowledge about the acceptability of autopsy, or requests for organ donation in the case of acute trauma, cannot usually be guessed by "reading" a family's background.

Furthermore, different ethnocultural groups may have varied understandings of the nature, meaning, and importance of cognitive impairment in a patient. In a society where social relationships are a core value, esteemed more highly than individual achievement, disabilities that affect intellectual functioning but do not interfere with the ill person's role in the family may be more readily "accepted." By contrast, in some societies severely handicapped people may experience a form of social death, isolated from the broader community.

Acceptance of Hospice Philosophy

Utilization of hospice care programs is not identical across racialized U.S. populations. African Americans utilize hospice services at a lower rate than do European Americans. Home death is often considered an ideal within the hospice philosophy. A *good death* is often characterized as one that takes place at home, surrounded by family and/or friends, with pain and symptoms under control, spiritual needs identified and met, and following appropriate good-byes. Traditionally, this ideal good death required giving up curative interventions. At the moment in U.S. history, the 1970s, when hospice care became a viable alternative, aggressive end-of-life interventions were commonplace, and efforts to secure patient participation in decision making were not yet fully realized. Thus, the home became a refuge from the ravages of hospital death. Even though the strict implementation of a six-month prognosis requirement for hospice is changing, it remains difficult to predict the terminal or near-terminal phase of common illnesses, particularly cardiac, pulmonary, and metabolic conditions, in contrast with cancer. Acknowledging that death is near may be particularly difficult. Home death may not be valued in ethnocultural groups where it is considered inappropriate, dangerous, or polluting to be around the dead. Among traditional Navajo, the dying were removed from the Hogan dwelling through a special door to a separate shed-like room to avoid the catastrophe of a death occurring in the Hogan, which would then have to be destroyed. Burial practices were organized to make certain that ghosts could not find their way back to the Hogan, and family members did not touch the dead body. This task was relegated to outsiders. These issues remain salient for those practicing in the Indian Health Service. In some Chinese immigrant communities a death at home may affect the value of a particular property on resale.

Culture, Grief, and Mourning

Bioethics practices generally focus on decision making prior to death. Clinical interventions to aid the bereaved—increasingly seen as a critical component of services provided to patients and families—must take into account cultural differences. It is critical to acknowledge that Western ways of grieving and disposing of the body are not universally accepted as the *right* way. It is also likely that our theories of grief and mourning, including definitions of *normal,* are inappropriately based on Western behavioral norms. For example, a standard way in the West of dealing with grief is to talk-about one's experience, one's relationship with the deceased, one's feelings. But in some cultures, talking may

disrupt hard-earned efforts to feel what is appropriate, and to disrupt those efforts may jeopardize one's health. In some cultures, talk is acceptable, but one must never mention the name of the deceased person. In other cultures, talk is acceptable as long as it doesn't focus on oneself. Even in the West, however, not everyone is open to talking. It is important not to label those who do not openly express their emotions as *pathological.* In fact, the concept of pathological grief is primarily a Western construction. A mother in the slums of Cairo, Egypt, locked for seven years in the depths of a deep depression over the death of a child is not behaving pathologically by the standards of her community (Wikan). There is enormous variation in what is considered appropriate behavior following death. The ideal among traditional Navajo is to express no emotion, while in tribal societies a death may be met with wild outpourings of grief, including self-mutilation (Barley). In contrast to clinical notions of pathological grief, in some Mediterranean societies widowhood was considered a permanent state of mourning, and mourning clothes were worn for years, if not decades. In a compelling book titled *Consuming Grief,* Conklin describes how native Amazonians assuage their grief by consuming the body of their dead kin (2001). A number of anthologies provide examples of the range of cross-cultural variation in post-death management (Counts and Counts; Metcalf and Huntington; Irish, Lundquist, and Jenkins Nelsen; Parkes, Laungani, and Pittu; Rosenblatt, Walsh, and Jackson).

The Need for Clinical Compromise: A Challenge for Bioethics

Respecting cultural difference may offer a profound challenge to healthcare practitioners' most fundamental values. In perhaps the best "text" explaining the cultural dynamics underlying the treatment of a critically ill patient, Anne Fadiman, in *The Sprit Catches You and You Fall Down* (1997), offers a detailed account of how the physicians caring for a young Hmong child with life-threatening, difficult-to-control epilepsy ultimately fail her because of their desire to offer her "state-of-the-art" care identical to that offered to any of their other patients. Through her detailed ethnographic account, Fadiman reveals how in this case the physician's quest for the "perfect" treatment was the proverbial "enemy of the good." The parents of the child, Lia Lee, were refugees from the American war in Southeast Asia, illiterate in their own language, with ideas about the cause of epilepsy and its appropriate treatment that were completely at odds with the views of the Western healthcare team. They were not, however, the only participants in the exchange shaped by cultural background and context. Fadiman's work documents the culture of biomedicine, explaining with great clarity how the physician's uncompromising dedication to perfection kept them from negotiating a treatment regimen acceptable to all.

Often in cross-cultural settings it is imperative to learn to compromise one's own clinical goals in order to meet the patient "halfway." Fadiman's book recounts the profound miscommunication between the pediatricians and family physicians involved in Lia's care, the Lee family, and the broader Hmong community. When her parents are unable to carry out a complex regimen of anti-epilepsy drugs, the child is turned over to the state's child protective services agency, provoking a profound and deepening spiral of tragedies. In the end, the physicians wish they had compromised their goals and prescribed a more simple medication schedule. Ironically, the parents' observation that the medicines were making Lia sick proved true in that one of the antiepileptic drugs contributed to an episode of profound sepsis that resulted in Lia's persistent vegetative state. A number of American medical schools assign this book as a required text in cultural sensitivity training. Its brilliance lies in revealing both sides of a complex equation: a Hmong enclave transported to semi-rural California and a group of elite, Western-trained physicians and healthcare practitioners caught up in a drama they cannot understand, not because the Lee family's cultural practices are so esoteric but because they fail to recognize how their own cultural assumptions and deeply held values limit their ability to help the ill child.

The Culture of Biomedicine and Biomedical Death Reflect Features of U.S. Society

National efforts to improve end-of-life care often include the notion that *cultural change* or promotion of *cultural readiness* is essential for reform efforts to be successful (Moskowitz and Nelson). Yet, what this cultural change would look like and what barriers to such change exist are rarely itemized. National public awareness campaigns such as "Last Acts" have used a variety of strategies to change the *culture of dying* in America, including working with the media. For example, one strategy has been to sponsor scriptwriting conferences to encourage widely viewed television programs, such as "ER," to include realistic stories about patients near the end of life. In fact, one episode focused on end-stage cystic fibrosis. Narratives created for television might convey the idea that a comfortable, pain-free death is possible and should be *demanded* by patients and families as an essential feature of a comprehensive healthcare system. The stories might convey the important lesson that physicians and other caregivers may forgo their most aggressive efforts at cure without abandoning patients.

Unfortunately, these efforts at promoting cultural change ignore a fundamental and problematic social fact—a profound cultural resistance to foregoing high technology interventions and giving up hope for recovery. narratives of hope and recovery compete with stories of patients abandoning efforts at cure after a valiant struggle with disease.

Research by Koenig and her team revealed that patients from minority backgrounds, in particular recent immigrants, seemed to lack a sense of the narrative structure of end-of-life care that English-speaking, middle-class European-American families understood more readily. In particular, the idea that patients and families would make an explicit choice to abandon curative therapy, followed by the "limiting" of aggressive interventions like intensive care and cardiopulmonary resuscitation, did not seem to be a story patients understood. Recent Chinese immigrant patients could not answer questions that presupposed a transition from curative to palliative goals; it was simply beyond their experience (Hern, Koenig, Moore, and Marshall). In their worldview, doctors do not *stop* treating patients. Efforts to change the culture through engagements with the media—encouraging op-ed pieces in newspapers, scriptwriting workshops, and so forth—may educate potential patients about existing approaches in palliative and hospice care.

One cultural barrier is particularly difficult to surmount. Before physicians can recommend palliative care and before patients and families agree to it, in our current system one must first accept the possibility that death is imminent or at least that one's likely survival is seriously limited. Eventually, current reform efforts to introduce palliative care early in a trajectory of disease or illness may decrease the need for patients or families to embrace their own death in order to make a clear transition between curative and palliative modalities of treatment. But it is unlikely that the tension caused by the need to balance conflicting goals will ever dissipate totally.

Even if one embraces the narrative of limiting aggressive treatment and adopting comfort care, including attention to spiritual and interpersonal goals, as a good idea "in principle" for those facing death, there still exists the radically difficult and jarring transition itself, the need to imagine you or your family member as now taking center stage in a particular EOL narrative. It is no longer theoretical but real. The resistance to seeing oneself (or a loved one) in this role is considerable and may prove insurmountable for many. A set of powerful cultural narratives operates to feed this resistance and encourage its perpetuation. Consider, as one example, the heroic narratives of successful research and triumphant cure that are much more often portrayed by the media than stories of failed therapy and excellent end-of-life care (Koenig). The content of public relations materials produced by medical centers and ads published by drug companies conveys powerful cultural metaphors that are directly counter to the mundane realities of palliative care, often focused on managing symptoms such as constipation. Hospital ads suggest that it is vital to "keep shopping" and eventually you will find the program offering the experimental or innovative therapy that will lead to cure. The heroic search for cure is celebrated in media accounts such as the film *Lorenzo's Oil* or news accounts of a family seeking gene therapy to cure their child's severe, life-limiting genetic illness (Canavan disease). A full analysis of the culture of dying in the United States must acknowledge these powerful counter images.

It is important to bear in mind that such stories and advertisements are features of a particular political economy of healthcare. Unlike providing palliative care, which does not generate an economic surplus for hospitals, administering chemotherapy generates profits even when the likelihood of its success is low or nonexistant. One recent study documents that curative chemotherapy is often given very close to the end of life, when its use may be futile (Emanuel et al.). This is not to suggest that individual physicians are primarily motivated by financial gain when they prescribe chemotherapy that they know has little chance of success. The full picture is a much more complex mix of faith in research, trust in therapeutic rituals as opposed to inaction, genuine prognostic uncertainty, and unwillingness to acknowledge the likely poor outcome of patients one knows well. But it is critical to acknowledge that the economic structure of U.S. healthcare for children creates few barriers for the use of advanced life-prolonging therapies such as chemotherapy or days in an intensive care unit, at least for those with insurance or access to government-funded programs. The most intensive services often generate the highest profits. By contrast, hospice and palliative care programs are often supported by philanthropy; providing excellent palliative care is at best revenue neutral and more often a money loser for medical centers. Thus, the political economy of healthcare supports what Daniel Callahan has called "technological brinkmanship," or the aggressive use of technology until the last possible moment, often leading to its overuse. Culture shapes the realities of care at many levels.

Conclusion: Bioethics, Culture, and Globalization

The experiences of death are culturally constructed within particular social and historical moments. An anthropological account of death takes into account the network of human relationships within which behaviors and practices associated with death and mourning are situated. A cultural

analysis of the rituals and symbols evoked by death and dying also suggest the powerful role of social and economic conditions that necessarily define and constrain death experiences, including the treatment of bodies, burial practices, and reactions to grief. Viewed from a cultural perspective, death practices provide an important foundation for understanding the meaning of human suffering in response to loss.

Cultural analysis using ethnographic methods provides unique insights into the nature of bioethics practices that have become the new rituals of dying. These insights will be of increasing use in the context of a globalized biomedicine, which moves bioethics practices into multiple settings, often quite different from the social and historical context that shaped their development. When implemented in societies characterized by an increasing degree of cultural diversity, the limitations of these practices, and their cultural roots and sources, are revealed. Cultural analysis—particularly studies that highlight the response of ethnically different others to bioethics practices—is incomplete if not augmented by attention to the political economy of healthcare. Cultural variability does not *determine* ones views about death. Rather, we are all shaped by culture, and in turn contribute to dynamic change.

There is a naïve hope that cultural competency training will lead effortlessly to improved outcomes. It may under some circumstances, but significant cultural difference inevitably brings with it true conflicts that may not be resolved, even with ideal, open communication and mutual respect. In some situations, the distance between families and the healthcare team may be too profound to overcome in spite of considerable efforts by all. Anne Fadiman recounts a physician involved in the care of Lia Lee, who lamented that even if it had been possible to send the Lee family to medical school with an interpreter, the difference in world views separating a refugee Hmong family from mainstream Western pediatrics would remain insurmountable.

How one thinks about culture matters. A serious flaw in current cultural competency training in biomedical settings is a simplistic and unsophisticated account of culture itself. It is almost as if there is a belief that culture codes for—and predicts—behavior in the same way that DNA codes for a certain protein. Reductionist approaches to education in cultural difference will inevitably fail because, at best, they teach a few general clues that must be verified through interaction with a family and, at worst, they model an unsophisticated approach to culture that leads to simple stereotyping, thus doing more harm than good. Educational techniques and programs that emphasize an interpretive approach to understanding cultural difference are more likely to be successful.

If one accepts that analyzing the nature of ethical practice, and ultimately improving end-of-life care, is a fundamental goal of bioethics, then bioethics scholars must take account of culture in their work. Culture must be engaged at many levels, not just through a focus of *the other.* Ethnic and cultural difference in response to bioethics practices—the new end-of-life rituals—must be respected in a sophisticated manner, free of harmful stereotyping. But we must not stop there. Those working in bioethics must engage in a critical analysis of the culture of biomedical science and practice. And finally, they must be active students of the cultural assumptions underlying bioethics itself, interrogating the foundations of the field.

II. EASTERN THOUGHT

Unlike other species, humans can reflect on death. One response to the mystery and fear humans associate with death is to create systems of religious meaning that give purpose to life in the face of death. A corollary of the fact that people can reflect on death is their realization that it is possible for them intentionally to end life. Religion constrains this possibility in the interest of human survival; only a few exceptions to the taboo against killing humans are allowed. Animals, by contrast, cannot decide to kill themselves and seldom kill members of their own species.

Concepts of death in Asian religions include two basic types: natural—for example, death by disease and old age; and unnatural—for example, death by an accident, by the intention of another person (homicide), or by one's own intention. The latter, here called self-willed death, may be subdivided into three types: (1) suicide (self-willed death out of depression or passion, an irrational and private act); (2) heroic (self-willed death by warriors, and sometimes their wives, to avoid being killed or captured by an enemy, and therefore shamed; or to follow a leader in death because of loyalty); and (3) religious (self-willed death as a rational and public act sanctioned by a religion; for example, in cases of terminal illness or debilitating old age, or as a means to achieve heaven or enlightenment).

Hinduism

THE CONCEPT OF NATURAL DEATH. In no small measure, Vedic (Brahmanical) religion (1500–600 B.C.E.), its sequel now called Hinduism, and other Indian religions (Jainism and Buddhism) inherited views of death from the Indo-Europeans who came to India, probably from eastern Anatolia. Because life expectancy in the prehistoric world was about thirty years, on account of disease, natural calamities, and warfare, people turned to religion for help, performing rituals for health, physical security, longevity, or immortality.

A proto-Indo-European myth about death involved a primordial sacrifice in which Manu (literally Man), the first priest, sacrificed Yemo, his twin and the first king, to create the cosmos, including the realm of the dead. Located to the south, symbolizing warmth, the realm of the dead was described as a paradise where cold, suffering, labor, injustice, evil, darkness, aging, sickness, and death were unknown (Lincoln). According to one Indian version found in the *Rgveda* (10.13.4)—the earliest and most authoritative Hindu scripture—Manu sacrificed King Yama, who showed the path to where the forebears of old had gone: The *Rgveda* considered this place either the southern world or the highest region—a paradise with light, beauty, and joy. (In

later texts, Yama was demoted to preside over a hell; the fetters that once bound him as the sacrificial victim for creation were now used by him to fetter sinners.) In another early Indian version, the Puruṣasūkta (*Ṛgveda,* 10.90), Man, the sacrificial victim, was bound, killed, and dismembered. His mind became the moon; his eye, the sun; his mouth, the fire; his breath, the wind; his feet, the earth. Henceforth, each sacrifice repeated the cosmogonic one, with animals representing the human victims of earlier Indo-European myths or rituals, to ensure the continued existence of the cosmos. A symbolic reenactment of the cosmogonic sacrifice occurred in the funeral ritual; according to *Ṛgveda* 10.16, different parts of a dead person went to various parts of the universe.

The Vedas prescribed a life of one hundred years, indicating a desire for longevity and natural death. For those who died a natural death, the funeral ritual (*śrāddha*) would be performed; this would provide them the status of ancestor, ensuring rebirth as a human or existence as a god (hence creating a double buffer against death as annihilation).

Drawing on their pastoral practice of seasonal migration, the Indo-Europeans referred to the dead as traveling along a pathway. In India, the Vedas also referred to the paths of the dead. The straight and easy one ascended to a luminous paradise where the gods lived; the tortuous and difficult one descended to a dark netherworld. By performing sacrifices and funerals, people gained access to the former (*Ṛgveda,* 10.2.3). The most common Indo-European image of the dead following a path involved crossing a river or ocean by means of a ferry guided by a ferryman, the personification of old age, to paradise (Lincoln). During their migrations into India, the Indo-Europeans conquered settlements at fords (*tīrtha*) to cross rivers. A popular Vedic myth alludes to this: The warrior god Indra killed the native serpent demon Vṛtra, thus creating a passage from drought to water, barrenness to prosperity, death to survival, danger to security, darkness to light, and chaos to order (Young, 1980). Hence the Vedic notion of figuratively crossing over dangers to arrive happily on the other shore, to make a way through experience or suffering, and to penetrate the real or the true.

Some of these ideas prefigured a new worldview that led to a dramatic transformation of Vedic religion and the birth of two new religions (Jainism and Buddhism) around the sixth century B.C.E. This period witnessed a great increase in life expectancy. Seeing the miseries of frailty and old age, however, led many people to increasing anxiety over the end of life (Tilak). This gave rise to reflections on old age, the meaning and purpose of life, and ways to move beyond death. The path no longer led to another realm *within* the cosmos; it now crossed the cosmos (symbolized as the ocean of *saṁsāra,* characterized by the cycles of time, rebirth, finitude, suffering, and ignorance) to liberation.

One of the Vedic texts that elaborated on the ritual, the *Śatapatha Brāhmaṇa,* said the Vedic sacrifice was a boat; the priests, oars; and the patron, a passenger who would reach heaven if no error were made in performing the ritual (4.5.10). Sacrifice also became a way of overcoming death by moving beyond *saṁsāra,* the cycles of death and rebirth (2.3.3.7). A personification of death demanded what would happen to him. He was told by the other gods that he had dominion over the body but not over immortality, which would occur without him. In other words, the god of death controlled the process and time of dying, but he could not influence those who attained enlightenment because they were beyond the cycles of death and rebirth (10.4.3.1–9).

In the *Upaniṣads* (philosophical speculations said to reveal the supreme truth of the Vedas but, from a historical perspective, beginning the transformation of Vedic religion to Hinduism), this extracosmic liberation (*mokṣa*) was characterized by the realization of eternal consciousness, called Brahman. This could be achieved during life; at death the body would disappear forever. Or it could be achieved by a postmortem passage to a supreme heaven where there would be eternal life with a supreme God. Some Upaniṣadic texts spoke of sacrifice leading to the path of the forefathers (*pitṛyāna*) and thus to rebirth (indicating a demotion of the status of Vedic rituals), whereas others spoke of self-knowledge leading to the path of the gods (*devayāna*). Still others spoke of a passage to liberation made possible by religious discipline (*sādhana*) and the guidance of a teacher (guru) leading to supreme knowledge. This notion was expressed as a boat guided by a pilot, ferrying the individual across to the other shore. In *Kauśītaki Upanisad* 1.4, for example, the deceased proceeded to the river Vijará (literally, "apart from old age", shaking off their good and bad deeds. Their good deeds were transferred to relatives for a better rebirth; their bad ones, to other people. Beyond deeds and dualities, the deceased approached the god Brahmá. Although the human body represented bondage, it also provided the only opportunity for liberation (an argument that was probably necessary to inspire humans to pursue a path to liberation in this life, because they might be reborn as plants or animals).

Closely associated with this development was the law of karma, according to which actions (karma) determined destiny. People were reborn higher or lower in the scale of beings (from high-caste people down to plants), depending on the quantity of good (*puṇya*) or bad (*pāpa*) karma they had accumulated. With an excess of good karma, they had a temporary vacation in a paradise; with an excess of bad karma, they descended to a hellish realm. But with an

extraordinary religious effort (based on knowledge or devotion), they could negate the law of karma by removing the bondage of action and the perpetual cycles of rebirth. Despite the highly individualistic nature of this karma doctrine (people reap what they sow), some versions allowed the transfer of merit from an extraordinary person, or divine grace from a deity, in order to redirect destiny and ultimately achieve liberation.

After the sixth century B.C.E., the idea of crossing over, signified in the term *tīrtha,* became associated with various bodies of water; these were sacred places where people could cross over to a better rebirth, a vacation in a cosmic paradise (*svarga*), or liberation beyond the cosmos (*mokṣa*). To facilitate crossing over, they followed a religious path characterized by action (*karmayoga*), knowledge (*jñānayoga*), and devotion (*bhaktiyoga*); different schools order the three in different ways.

Even today, most Hindus want to die on the banks of the Ganges—believed to be the river of heaven, the nectar of immortality, a goddess, a mother, or even a physician, since this allows them to cross over to liberation. From all parts of India, the dying come to Banaras to live on its banks. They spend their final days in a hospice where spiritual help but no medicine is provided. Hearing the names of the gods chanted continually, they eat sacred *tulsī* leaves and drink Ganges water, focusing their thoughts exclusively on God. Śiva, Lord of Death, whispers the ferryboat mantra into their ears. After they die, their corpses are taken to the cremation ground, given a final bath in the Ganges, decked with garlands of flowers, and honored as a guest or deity. Then the last sacrifice (*antyeṣṭi*) is performed. The eldest son circumambulates the corpse counterclockwise (reversal symbolizing death) and lights the pyre. Relatives are silent, for wailing is inauspicious or even painful for the dead. Finally, the eldest son turns his back to the pyre, throws water over his shoulders to douse the embers, and leaves the pyre without looking back. For the next eleven days, during the performance of the *śrāddha* rituals, ideally at Banaras or another holy place, rice balls are offered to the dead; on the twelfth day, the departed soul reaches its destination (Eck). It is said that when people die in Banaras, their souls attain liberation—though the idea that transitional souls (*preta*) are transformed into ancestors (*pitr*) is also maintained, as are a host of other ideas about destiny.

If dying by the Ganges is impossible, dying at some other *tīrtha* in India may be a substitute, for the Ganges is said to be there, too, just as all rivers are said to be in the Ganges. And if even that is impossible, simply thinking about the Ganges at the moment of death may influence destiny. Casting the bones that remain after cremation into a *tīrtha* is also effective. Ascetics are buried, however, because they have given up their śrauta fires (the locus of the Vedic rituals) and their sacrificial implements (Kane). Hindus perform the annual sraddha ceremonies for the dead (offering rice balls to three generations of male ancestors, pitṛs) at the Ganges or any other *tīrtha,* since this will either sustain the ancestors until rebirth as humans or allow them a long vacation as gods (*viśvadeva*) in heaven. In short, the Hindu tradition offers a number of safeguards against annihilation at death: rebirth, a visit to another realm, liberation. Individuals can influence destiny or others can help them by the transfer of merit. Gods, through their grace, also may influence an individual's destiny. There is always hope. The sting is taken out of death, for it is said that even mosquitoes are liberated in Banaras (Eck).

THE CONCEPT OF SELF-WILLED DEATH IN HINDUISM. According to the traditional law books, funeral rituals were not to be performed for those who died in unnatural ways. This may have been used as a deterrent against suicide; the Hindu tradition disapproved of suicide, which was defined as killing oneself because of depression, passion, or uncontrollable circumstance. But unnatural death was not always viewed negatively; death by violence (war, murder, or accident) was viewed as powerful, leading to heaven or deification. The type of unnatural death that has relevance for bioethics is the self-willed death, which is given religious sanction. During the late classical and medieval periods, Hinduism came to accept a rational decision either (1) to kill oneself as a way to destroy bad karma, create good karma, and thus attain heaven or liberation; or (2) if liberated in life, to remove the body. Such self-willed death (*iṣṭamṛtyu*), took many forms. People could walk without food or drink until they dropped dead (*mahāprasthāna*); bury themselves alive and meditate (*samādhimāraṇa*); abstain from food and wait in a seated posture for the approach of death (*prāyopaveśaṇa*); or jump into fire, over a cliff, into sacred water, or under the wheels of a temple cart. The terminally ill and the extremely old who were no longer able to perform their religious duties and rituals sometimes killed themselves by one of these methods. Such self-willed death was religiously permitted. *Sati* (a woman's self-immolation on the funeral pyre of her husband) was a variant of self-willed death that produced a surplus of merit that ensured heaven for both spouses. Despite efforts to prevent abuse, it appears that there was some, for by the tenth century, with the Kalivarjya Prohibitions, all forms of killing oneself—*except sati*—were prohibited (in theory though not in practice).

Some families continued to endorse *sati* because the alternative was lifelong support for widows or, as in Bengal, a share in the inheritance. After additional criticism by both Muslims and Christians in the following centuries, this

practice virtually ended. The Indian Penal Code in 1860 made suicide and abetting suicide crimes; judges interpreted suicide as any form of self-willed death and used that interpretation to stop *sati* as well as other practices of self-willed death (Young, 1989). There have been isolated incidents since then, including the widely publicized case of Roop Kanwar in 1987. Almost 160 years after *sati* was declared culpable homicide, Roop Kanwar, an eighteen-year-old Rajasthani woman, performed *sati.* The government alleged that she was forced onto the pyre and pinned down with heavy firewood. This caused the Indian parliament to pass another law in December 1987 to check the practice. According to the new law, the death penalty is imposed for those who help carry out the ritual of *sati*; the woman who tries to perform *sati* may be sentenced to six months in jail; those who glorify *sati* may be given prison sentences up to seven years; and the government is empowered to dismantle memorials and temples related to *sati.* Accordingly, her brother-in-law, who lit the pyre, was charged with murder and twenty-two others received lesser charges.

IMPLICATIONS OF HINDU VIEWS OF DEATH FOR BIOETHICS. According to the *Caraka Saṁhitā* (a classical text on medicine with religious legitimation written about the first century B.C.E.), physicians were not to treat incurable diseases (a policy to establish the benefits of the fledgling science of medicine and to protect the physician's reputation as a healer). This refusal could provide traditional religious legitimation for modern withdrawal of treatment by physicians in cases of terminal disease.

Physicians also were not to reveal the possibility of impending death, unless there was a specific request, so that negative thoughts would not be imposed on the patient that might create bad karma and hasten death. Rather, the process of death should be peaceful and auspicious, because it was the prelude to rebirth or final liberation. The implication of this view for modern medicine is that pain relief provided by a physician might make the dying process peaceful and therefore auspicious in Hindu terms; however, the refusal to inform the patient about terminal illness unless directly asked would be against the modern concept of mandatory truth-telling by the physician and the patient's right to know the prognosis. But another view also existed in traditional Indian religions: a person's last thought influences destiny. In this case, the individual should know of impending death and should not allow anything to cloud the mind. The implication of this view for modern medicine is that pain relief should be given only to the extent that the person remains alert.

Finally, the long tradition of self-willed death, especially fasting to death, in cases of terminal illness or debilitating old age, can be used to give religious legitimation for refusal or withdrawal of treatment in modern India, for it accords with the voluntary and public nature of living wills requesting refusal or withdrawal of treatment and nutrition. Whether it will be used to invoke precedent for active euthanasia depends on the assessment of assistance and whether there had been a slippery slope in the practice of self-willed death. As for the first issue, the Hindu tradition was quite careful to insist on the voluntary nature of self-willed death, though once there was a public declaration and the person could not be discouraged from his or her decision, assistance was allowed, at least in the case of *sati.* For instance, priests were allowed to hold a woman down during her self-immolation if they had been convinced that the decision for *sati* had been her own. As for the second issue, the types of self-willed death and possibly their numbers increased over the centuries; since there was criticism of the practice internal to the religion by the tenth century, there was probably the perception of a slippery slope.

Jainism

THE CONCEPT OF NATURAL DEATH. Jainism is an Indian religion that developed about the sixth century B.C.E. The Jains speak of the twenty-four *tīrthaṅkaras,* such as their founder Mahāvīra, who are the makers of the path or causeway to liberation, enabling people to cross over *saṁsāra.* The Jain view of death is related to its view of liberation: Because karmas (actions) cause bondage in the cycles of existence (reincarnation), they should be eliminated by fasting and meditation leading to the realization of liberation, the radical autonomy of pure consciousness (*kaivalya*).

THE JAIN CONCEPT OF SELF-WILLED DEATH. According to tradition, Mahāvīra fasted to death. Henceforth, the ideal form of death for Jain monastics was a "final fast" to death known by different names—*bhaktapratyākhyāna, inginī, prāyopagamana, samādhi, pañcapada, sallekhanā, ārādhanā*—depending on variants in the practice such as whether there is the assistance of others, whether one dies meditating or chanting, whether the body is to be eliminated by emasculation after initiation, or whether death occurs after the attainment of wisdom (Settar, 1990). Jainism was the first Indian religion to legitimate self-willed death. Initially, the fast to death was to be done only by monastics late in life but before debilitating old age or terminal illness, so that they would be in full control of the meditative and fasting process. Some centuries later, however, the practice was extended to the Jain laity as a legitimate form of death in

times of public crisis (natural calamities and military defeat) or personal crisis (debilitating old age and terminal illness).

IMPLICATIONS OF JAIN VIEWS OF DEATH FOR BIOETHICS. Although self-willed death is illegal in India, Jains are arguing for the decriminalization of suicide so that they can restore the traditional practice of fasting to death. They argue that this practice legitimates refusal or withdrawal of nutrition and life-support systems in modern medical contexts for the terminally ill. They also argue that prolongation of the dying process is immoral, because it increases suffering or depletes the resources of the family or community; thus the fast to death is a way to "permit oneself the honour of dying without undue prolongation of the process" (Bilimoria). But since the fast to death was also practiced traditionally in nonmedical contexts, it was not always a way to avoid the prolongation of dying; on the contrary, it was a way of hastening death by the cultural act of fasting when the body was not about to die of natural causes. Although the fast to death was generally understood to be voluntary and planned (and in a category distinct from both homicide and suicide), there were several exceptions. According to some, severely handicapped newborns were allowed to die (*bālamarana*) when permission was given by parents or a preceptor. In the *Bhāva Pāhuḍa Ṭīku, bālamarana* is classified as: "The death of the ignoramus, or a foolish process of meeting death … *Bāla* means childish, undeveloped, or yet-to-be-developed, premature and silly" (Settar, 1990, p. 15). It includes the death of infants and those who have an infantile knowledge—who are ignorant, who do not understand the moral codes, or who have a wrong notion of the faith and kill themselves by fire, smoke, poison, water, rope, suffocation, or jumping. While the original classification indicated simply a subdivision of natural death that would lead to rebirth, it seems that at some point in the tradition or perhaps in the modern period, the classification *bāla-marana* has been reinterpreted. Accordingly, Bilimoria (reporting on statements made by Jain informants) observes that

> in principle there appeared to be no reason why a child afflicted with or suffering from the kinds of conditions described earlier should not be given the terminal fast (*sallekhanā*). Parental permission would be required where there is contact, failing which a preceptor (for instance in an ashram) may be in a position to make a pronouncement. Consent of the recipient is not necessary (hence, a case of *nonvoluntary* terminal fast). One who has fallen in a state of unconsciousness, again, can be given the fast … even if the person had made no requests while she was conscious, though parents or kin would be consulted. It seemed evident that 'consent,' either of the individual or a proxy, or of the parent, does not seem to be a necessary condition for commending [a] final fast. This would seem to constitute a case of *involuntary sallekhanā*.… When … asked whether it would be acceptable to inject lethal poison to bring on the impending death, the response was that under extreme conditions where the pain and suffering is unendurable and not abating.… (p. 347)

It is argued by Jains that the history of fasting to death demonstrates that self-willed death need not lead to other forms of self-willed or other-willed death. While it is true that in the past there were a number of safeguards (permission of the head of the monastery, a formal public vow, established ascetic discipline, evidence of courage and will rather than cowardice) and the history of fasting to death was without any extreme abuse in India, there was still a change in the number of groups involved (from monastics to lay people) indicating extension or popularization of the practice. Moreover, the fact that Jainism was the first Indian religion to legitimate a form of self-willed death means that it set an example, which may have inspired legitimation of self-willed death without such careful safeguards by other Indian religions (Young, 1989). In other words, its indirect contribution to a slippery slope in Indian religions cannot be ruled out despite Jain disclaimers. When the Indian penal code made suicide illegal, fasting to death was included. Despite the fact that any form of self-willed death is still illegal in India, there are between six and ten reported Jain fasts to death annually (Bilimoria).

Buddhism

THE CONCEPT OF NATURAL DEATH. The imagery of crossing the ocean or river of *saṁsāra* to the other shore of enlightenment is used by Buddhists as well as Hindus. Theravāda (one of the main branches of Buddhism, which purportedly continues the early tradition and is still found in Sri Lanka, Burma, Thailand, Cambodia, and Vietnam) metaphorically considers the Buddha's teaching (*dhamma*) a boat and the individual its pilot. For instance, in Burma, a coin called "ferry fare" is placed in the mouth of a dead person (Spiro).

The Buddha thought often about the nature of death. According to Aśvaghosa's version of his life, the *Buddhacarita,* the future Buddha was surrounded by royal luxury as a youth, sealed off from the real world in a palace. When he finally ventured into the world, he was overwhelmed by his first sight of a sick person, an old person, and a dead person. These shocking revelations about dimensions of human existence beyond anything he had known so troubled him that he left his life of ease to become an ascetic and search for

meaning. Later, on the verge of enlightenment, he recalled his own previous lives, meditated on the cycles of rebirth common to all creatures, and came to understand that all beings are propelled into repeated lives by ignorance and desire. The Buddha spent his life teaching others how to blow out (*nibbāna*) the flame of ignorance and desire by realizing that all beings are composite and impermanent (subject to suffering, decay, and death). In the final analysis, there was no "person" who died; there was only the process of dying. As narrated in the *Mahāparinibbāna Sutta,* written down about the first century B.C.E., the Buddha attained final release from his body (*parinibbāna*) at the age of eighty. After falling ill, he chose the time and place of his departure: Telling those present that all composite things must pass away and advising them to strive diligently for liberation, he meditated with complete equanimity and took his last breath.

Despite the Buddha's emphasis on liberation, subsequent generations of monks and nuns took precautions in case they were to be reborn. The *Mulāsarvāstivāda-vinaya* (a text composed at the end of the seventh century) describes the monastic funeral: A gong was sounded; the body was taken to the cremation ground and honored; verses on impermanence were recited; merit from this act was transferred to the deceased, suggesting extra insurance in case the monastic was to be reborn; ownership of property was transferred; and cremation was performed. Finally, Buddhist sacred monuments (*stūpa* or *caitya*) were worshipped by the living, who then took a sacred bath (Schopen). Laypeople tried to attain a better rebirth by practicing morality, accumulating merit, reflecting on the nature of suffering, and disengaging from activities during old age. They were helped by merit transferred to them through the religious activities of families and friends, especially during the dying process, the funeral, and subsequent ancestral rituals.

As in Hinduism, the moment of death was important, because the final thought influenced rebirth. Even today, according to the popular religion of Burma, relatives chant Buddhist texts or have monks chant the *paritta,* canonical verses for protection against danger, to calm those who are dying; good thoughts thus arise and lead them either to a better rebirth or to a heavenly reward (Spiro). In popular forms of Theravāda Buddhism, ideas of the soul often replace the doctrine of no soul (*anatta*). The soul, or ghost, lurks around the house for some days after death and must be ritually fed, placated, and induced to leave the world of the living. Death rituals, ideally involving food and gifts for the monks, not only eliminate the danger posed by a ghost but also allow for the transfer of merit to the dead person, as do rituals performed by relatives on the anniversaries of the death.

Mahāyāna (the other main branch of Buddhism, which originated in India but eventually became popular in Tibet, China, Korea, and Japan) also conceives of the teaching as a boat, but views the pilot as a *bodhisattva,* a salvific figure who refuses enlightenment until all sentient creatures are saved, graciously steering the boat across to the other shore. Nevertheless, Mahayana maintains that ultimately there is no boat, no pilot, and no shore, since all is nothingness (*śunyatā*).

In Tibet, monastics meditated on death and simulated the process of dying to attain enlightenment; they also protected themselves against a bad rebirth by certain funerary rituals. Laypeople focused mainly on rebirth and sought help to ensure a good destiny. A spiritual teacher performed the ritual *gzhan po wa,* by which a disciple went to a paradise. Or the *Tibetan Book of the Dead,* which describes the journey from the moment of death through an intermediate state to rebirth, was read to the deceased over a number of days. Each of the three stages, or *bardos,* offered an experience of past karma along with a vision of both peaceful and wrathful divine figures. These provided more opportunities to attain enlightenment (Buddhahood) or a better rebirth, even though each succeeding one was more difficult than the last. Only by recognizing that the deities were ultimately illusory, for all was emptiness (*śunyatā*), would one attain liberation. These beliefs and practices are still found in Tibetan communities.

In China, Mahayana views of death were reinterpreted in several ways: (1) The notion of heaven was modeled on both Daoist ideas of paradise and its images of Confucian kingdoms complete with palaces, courts, and bureaucracy; the notion of hell was based on Daoist hells and Confucian prisons. (2) Some Chinese argued that the existence of a soul was implied in the theory of reincarnation, in the storehouse of consciousness, or in the Buddhahood of all living creatures. (3) Transferring merit from monastics or relatives became extremely popular. Buddhist monks instituted the annual All Souls festival based on the story of Maudgalyāyana (Mu-lien), who rescued his mother from the lowest hell, as told in the *Ullambana Sūtra* of Central Asian origin (Smith). Food, clothing, and other gifts were offered to rescue seven generations of ancestors from their sufferings in various hells, and the story was reenacted at Chinese funerals (Berling). (4) Pure Land Buddhism, which became particularly popular in China, promoted, in some versions, an otherworldly paradise attained through faith in Amida (a savior whose grace allows people to be reborn in a paradise called the Land of Bliss until they reach *nirvāṇa*) and calling out his name at the moment of death. According to Pure Land philosophers, this paradise was not real, however, but a

product of the mind. (5) Ch'an claimed that the Buddha nature was in all sentient beings, truth was near at hand, and Earth was the Lotus Land; enlightenment was the realization that nothing existed beyond the realm of *saṁsāra.* Consequently, death meant reabsorption into nature.

Just as Chinese Buddhism had absorbed Daoist ideas of death and native Confucian ancestor worship, so Japanese Buddhism assimilated, in turn, native Shintō views of death and ancestor worship. According to ancient Shintō, death was a curse; the corpse, polluting; and the spirit of the deceased, frightening. Buddhism contributed rituals to purify the spirits of the dead and transform them into gods: Spirits were deified thirty-three years after death and henceforth worshipped with the Shintō *kami* (entities with a spiritual function that inspire awe). In the seventh century, Empress Saimei ordered that the *Ullambana Sūtra* be taught in all the temples of the capital and that offerings be made on behalf of the spirits of the dead. The Japanese version of the All Souls festival, called Bon, dates from this time. The association of Buddhism with ancestor worship was reinforced in the anti-Christian edicts of the seventeenth century, which insisted on the formal affiliation of every Japanese household with a Buddhist temple and its death rituals (Smith).

Modern Japanese Buddhism has been primarily associated with death: In addition to funerals, there are seventh-day, monthly, hundredth-day, seventh-month, and annual rituals (Smith). Besides these, the collectivity of the spirits of the household dead is given daily offerings and honored at festival times. The Japanese hold conflicting opinions about where the spirits live: (1) Spirits may live peacefully in ancestor tablets on the altar in the home. (2) As depicted in Nō plays, those who suffered tragedy during life or died violently haunt their graves or former homes. (3) Spirits may have a continued existence as buddhas. Curiously, the dead are referred to as buddhas (*hotoke*). The Japanese misunderstood the term *nibbāna,* "to blow out" (in Japanese, *nehan*). Whereas in Indian Buddhism it expressed the metaphorical idea of blowing out the flames of desire in life and thereby achieving enlightenment, in Japanese Buddhism it was understood literally: People attained continued existence as buddhas when life was "blown out," a euphemism for death (Smith); this may have inspired self-willed death. (4) By chanting Amida's mantra (according to Hōnen) or having faith in him (according to Shinran), spirits enter paradise. (5) Spirits go to mountains such as Osore or Morinoyama with its Sōtō Zen and Jōdo-shin shrines. Many of these beliefs and rituals are dying out. The breakdown of the extended family due to mobility and urbanization has contributed to the lessening of interest in ancestor worship. Now, memory and prayers are for the immediate ancestors; tablets and altars, therefore, are becoming smaller (Smith).

BUDDHIST VIEWS OF SELF-WILLED DEATH. Despite his discussion of the body as the locus of suffering, the Buddha did not endorse self-willed death for everyone. He himself lived out his natural life span. An incident is recorded in the *Pārājika* (a text of the Pāli Canon, the scripture of Theravāda Buddhism) about how, when some monks became depressed in their meditation on the impurity of their bodies, a sham monk encouraged them—up to sixty in one day—to take their lives or be killed by him so that they could cross *samsāra* immediately. When he heard about this, the Buddha changed the form of meditation to a breathing exercise and declared that intentionally encouraging or assisting another person to die would lead to expulsion from the monastery. The Buddha also condemned, on the basis of nonviolence (*ahimsā*), any monk who told people to do away with their wretched lives. It is possible that the Buddha, known as the "good physician," allowed one exception to this general principle: From the accounts of the cases of Vakkali, Godhika, Channa, Assaji, Anāthapiṇḍika, and Dīghāvu, it seems that if people were experiencing unbearable pain in dying, they could kill themselves. There is some controversy over such an interpretation, however, for good palliative care had been offered and there were serious attempts to dissuade people from taking their lives. Moreover, neither the Buddha nor the monks gave explicit permission for these monastics and laypeople to take their lives, although the account implies that the act was condoned, perhaps because there were no options aside from physical force to restrain them.

According to an observation of I-Ching, a Chinese pilgrim who traveled to India (671–695), the practice of self-willed death was not popular among the Buddhists in India. Several centuries later, however, its popularity may have grown. In China, some Buddhist monks chose the time, place, and manner of death to bring its uncertainty under their control. It is possible that a story in the *Saddharmapuṇḍarīka* about how the *bodhisattva* Bhaisajyarāja, who was so dissatisfied with his worship that he set himself on fire, may have inspired the Chinese practice. But the fact that Chinese monks fasted to death in a yogic posture in underground pits (as in the Indian *samādhimāraṇa*), and after death their bodies were smoked, wrapped, lacquered, and installed in temples as objects of great veneration (Welch), suggests a different Indian Buddhist influence. This may have been combined with Daoist techniques to achieve immortality. Finally, it has been argued that self-willed death was popularized in China by a misunderstanding of Pure Land Buddhism, which suggested that people

should kill themselves to reach the Pure Land more quickly. Shan-Tao's disciple, for example, jumped out of a tree to reach the Pure Land (Kato).

Some sects of Japanese Pure Land continued this idea. Kūya (903–972) and Ippen (1239–1289), both charismatic leaders among the masses, killed themselves by drowning in order to reach the Pure Land. Before his death Ippen instigated Nyudo to drown while meditating on Amida (a story illustrated on many scrolls). Ippen's death prompted six disciples to drown in sympathy. These examples were further popularized by a tradition of drowning to reach the Pure Land; ordinary people who lost their nerve would be hauled ashore by a rope attached around their waist (Becker). Devotees were told to "Delight in dying" and "Hasten your death" (Kato).

These Pure Land practices inspired more secular forms of self-willed death. There are over forty-five terms in Japanese to describe the various forms of self-willed death; for example, the tradition of parents killing first their children and then themselves to avoid further suffering; the tradition of abandoning old women in distant mountains; and the tradition of *joshi* or love-killing, also known as *oshinjuo* or *aitai-shi* (a death pact between two people, such as lovers who want to attain a happier realm) (Kato). Such practices (which also included death by fasting or fire), collectively called *shashinojo,* came under scrutiny by subsequent Pure Land leaders who argued that such acts of self-willed death were a denial of Amida's grace.

Some views held by Zen leaders may have been misinterpreted, inspiring self-willed death; Dogen, for example, says to throw away your "body-mind." Zen inspired the samurai warriors and helped them cultivate a stoicism to face death. In medieval Japan, *harakiri* or *seppuku* was practiced by warriors to expiate crimes, apologize for errors, escape disgrace, redeem friends, or express devotion to their master by following him in death. These forms of warrior self-willed death are similar to the forms of heroic death by warriors in India. Sometimes *seppuku* was assisted by a relative or friend. By the Tokugawa period (1603–1867), it involved an elaborate ceremony and, for the famous, burial in a Buddhist tomb.

The popularity of self-willed death in Japan may have been derived in part from ancient Shintō views of death. The lack of a definitive boundary between life and death led to a feeling of intimacy with death and a desire to take refuge in holistic being, understood as *kami* (nature). This Shintō idea was combined with the concept of the Dao (the transcendent and immanent reality of the universe, represented by vacuity or emptiness because of its being formless and imperceptible) or the concept of the Buddha as nothingness (*śunyatā*), pure consciousness, or nature. It was also combined with the Buddhist idea of life as suffering and transience, which could be escaped by attaining the Pure Land (Kato).

The Buddhist practice of self-willed death has acquired political significance in the modern period. Known as "falling down like cherry blossoms" or "dying with a smile" (Kato), this way of dying belonging to *bushido,* the way of the warriors, contributed to the psychology of the Japanese kamikaze pilots of World War II. In Vietnam, the monk Thich Quang Duc's selfimmolation in Saigon (1963) focused world attention on the plight of the Vietnamese under Ngo Dinh Diem's oppressive regime.

IMPLICATIONS OF BUDDHIST VIEWS OF DEATH FOR BIOETHICS. Assessments of the importance of Buddhist views of death for bioethics vary considerably, depending on whether Theravāda or Mahāyāna is the focus and what the commentator thinks about issues such as withdrawal of treatment and euthanasia. Pinit Ratanakul (1988) observes, for instance, that in Thailand the Buddhist principle of the sanctity of life is maintained and self-willed death is not condoned as a rule, even in cases of pain and suffering. Two reasons are given: (1) suffering is a way for bad karma to come to fruition rather than be transferred to the next life; and (2) a person who assists suicide or performs euthanasia will be affected by such an act, since it involves repugnance toward suffering and his or her own desire to eliminate that which arouses a disagreeable sensation. But one exception is allowed: self-willed death when incurably ill, in order to attain enlightenment. These comments suggest that Thailand has maintained a reluctance to endorse self-willed death, in line with its Theravāda tradition, but continues to acknowledge the precedent established by the cases of the terminally ill Vakkali, Godhika, Channa, and others reported in the Palī Canon.

Current Japanese views show a greater acceptance of euthanasia, which is to be predicted, given the history of self-willed death in Japanese Buddhism. It is striking that the modern word for euthanasia is *anraku-shi* (literally, "ease—pleasure—death"), also a name for the Pure Land, though now some Japanese prefer the term *songen-shi* (death with dignity). Carl B. Becker, a Western scholar who has discussed this topic with Japanese people, argues that the Buddha accepted or condoned "many" cases of suicide but gives only three examples. He also argues that Buddhists view death as a transition, not an end; therefore, it is the state of mind at the moment of death that is important, not whether the body lives or dies. Those who are not fruitful members of society should be able to die, according to his assessment of Japanese views. Once consciousness (which he

takes as brain activity) has permanently dissociated itself from the body, there is no reason to maintain the body, "for the body deprived of its *skandhas* [the constituents of human existence] is not a person" (Becker, p. 554). In short, all that matters is clarity of mind at the moment of death. We must be careful in using Becker's analysis of the data. In point of fact, the Buddha was very reluctant to condone self-willed death if indeed he did so; it was only a few people who possibly killed themselves with the Buddha's blessing, because they were suffering from terminal illness and because they desired enlightenment. The other examples were simply threats. Becker also ignores the fact that the Buddha called the mere encouragement for others to perform self-willed death—or to provide the means—a deplorable act that would lead to expulsion from the monastery. One traditional commentator on the Parajita includes poison in the list of means. Because Buddhist monks were often physicians in ancient India, it is noteworthy that they were told not to perform abortions nor provide the means or even information to facilitate it; moreover, they must not help a family to kill a physically dependent member. This amounts to a strong position against physician-assisted suicide.

Shigeru Kato is much more cautious in his assessment of the Japanese practice of self-willed death and current Japanese interest in self-willed death, but for different reasons. After noting that some prominent Japanese jurists are advocating the legalization of euthanasia, he reflects on Japan's reputation of being "a kingdom of suicides" and relates the fact that it has the largest number of suicides among all Buddhist countries to its tendency to beautify suicide or absolve it of a sense of wrong. Kato argues that "Human beings have no right to manipulate arbitrarily and selfishly their 'own' lives, which are transiently borrowed and must be returned soon to the holistic Being" (p. 71). He opines that "We can never dismiss this religious holism as an outdated superstition; we must keep it as a brake against the drive toward euthanasia" (pp. 78–79). He also looks to the formation of a better hospice organization in Japan in the 1980s as a way of resolving the "euthanasia problem" through the practice of withdrawal of treatment combined with dialogue and religious and aesthetic care. In the final analysis, however, he is willing to entertain active euthanasia as the right to die "with dignity" and to consider the merits of each case.

Confucianism and Daoism

CONCEPTS OF NATURAL DEATH. Confucian concepts of death are closely associated with ancestor worship, which was practiced as early as the first historical dynasty, the Shang (ca. 1500–1045/1046 B.C.E.). Judging from the written record provided by inscriptions of oracles written on bones, the dead were consulted by means of divination, as if they were living. Everything needed for the next life was put in the tombs of the kings and nobles. Originally servants, entertainers, and others were buried with them. Later, pottery figures were substituted. (In modern times, paper effigies of servants are used.) The cult of the ancestors must also have been practiced by commoners, because it was considered an ancient and widespread practice by Confucius in the sixth century B.C.E.

The ancestor cult was based on rituals, or *li.* It assumed the continuity of life after death, communication between the living and the dead, the legitimacy of a social hierarchy, and a virtual deification of the ancestors. In his *Analects,* Confucius upheld the ancient practices, refusing to shorten the period of mourning (XVII.21). Nevertheless, he taught that the spirits should be kept at a distance, so as not to preoccupy the living (VII.20; XI.11). He also thought that mourning rituals should be moderate; they should express grief rather than fear (III.3). Four centuries later, details of the mourning rituals were described in the ritual text *Yi Li.* Now elaborate, they were to last for three years. During the first year, the eldest son (as chief mourner) had to wear sackcloth, live in a hut outside the home, wail periodically, and eat very little food. Over the next two years, the restrictions were gradually lifted. Even after life returned to normal, though, he reported family business to the ancestors. In Confucianism, as in other patrilineal traditions, the performance of funerary and ancestral rites by the eldest son has contributed to a preference for sons. As a result, female infanticide has sometimes been practiced unofficially.

The Chinese developed two other perspectives on death: a return to nature and physical immortality. The Daoist philosopher Chuang Tzu (365–290 B.C.E.) wrote that life and death were two aspects of the same reality, mere differences of form. Death was a natural and welcomed release from life, and was to be neither feared nor desired. Because individuals were reabsorbed into nature, both birth and death were as natural as the progression of the four seasons. Other Daoists were interested in alchemy, macrobiotic diets, exercises, fasting, and meditation. Besides desiring health, youth, and longevity, they wanted immortality. They had several views of the latter: the physical body would rise to heaven; the "real body," not the physical one in the tomb, would rise; the physical body would go to the Isles of the Blessed, said to be off the northeast coast of China; or the self would emerge from the body at death, like the butterfly from its cocoon, to wander freely about the universe or go to the realm of the immortals.

In Taiwan, the Chinese still practice ancestor worship. They believe that people are related to common ancestors and to each other by an elaborate kinship system in which status is symbolized by the length of time spent mourning and authority is passed through the eldest son. They also believe in two souls: the *hun,* living in a tablet at the shrine, and the *p'o,* living in the grave. Both souls may influence the living. Kin meet periodically in the ancestral temple for sacrifices to the *hun*; the latter are offered wine, food, rice, and first fruits in exchange for health, longevity, prosperity, offspring, virtue, and a peaceful death. They are also remembered by preserving extensive genealogical records and documents written by the deceased. Families visit graves to communicate with or pay respect to the *p'o* and thus ensure the *p'o*'s goodwill toward the living.

The Taiwanese euphemistically call death "longevity"; after fifty, a person begins to prepare for death by making "longevity clothes" in the Han style of the second century B.C.E., a coffin, and if possible, a tomb. At the time of death, the eldest son of the deceased person eats "longevity noodles" and puts on the "longevity clothes" inside out. Then he puts these garments on the corpse, whose personal name henceforth may not be spoken. Other family members don sackcloth, leave their hair uncombed, and wail periodically (Thompson). The *hun* is first given a temporary resting place in a paper sword, placed in front of the corpse to receive prayers. After processions to and from the grave, this sword is transferred to a home shrine where the son and relatives offer it food. Finally it is burned, and the spirit is thus transferred to a permanent tablet in the shrine. To keep the *p'o,* the body's orifices are plugged. The body is then rubbed with an elixir, placed in a coffin, and buried. Sometimes it is placed in a strong, watertight tomb to prevent decay. Coffins and graves are positioned according to exact rules for magical protection. If mistreated, the *p'o* causes trouble and threatens to become a ghost (*kuei*). Ritual specialists are then asked to inspect the grave, coffin, or bones to see why the p'o is unhappy (Berling). Daoist and Buddhist priests participate in the rituals of families who can afford them. For instance, priests hold services for seven weeks, during which they chant and pray for the soul to pass quickly through purgatory. Clearly, the Taiwanese try to ensure every advantage for the soul by incorporating practices from many religions.

In Taiwan, death remains associated with the ancestor cult. In the People's Republic of China, by contrast, there have been attempts to reform and even destroy ancestor worship. Communists have argued that traditional funeral rites and customs are remnants of the feudal economy and social structure; those lower in the clan hierarchy are exploited, and women, who cannot attend banquets in the ancestral temple, are excluded. Mourning clothes, moreover, waste cotton; wooden coffins waste timber; graves and tombs waste land; lavish funerals put families into debt; and beliefs in the afterlife instill superstition. Consequently, Communists have recommended the following: simple memorial services for the cadre, factory, village, or cooperative; the replacement of mourning clothes by arm bands; and the introduction of cremation (MacInnis).

CHINESE CONCEPTS OF SELF-WILLED DEATH. Some of these concepts have already been discussed in the section on Buddhism. But it is important to point out that there were practices of self-willed death in the warrior circles of China as well. In fact, it was the obligation, not only the privilege of warriors to practice self-willed death under certain circumstances. This tradition, which had once been found among the elite, became common among the lower classes when warriors began to be recruited from them in the late Chou Dynasty. Later, members of the Mohist school of philosophy, which had links with the lower-class warriors, maintained a tradition of absolute loyalty to their leader. In one incident, eighty-three disciples followed their leader in death (Fung Yu-lan, p. 83).

IMPLICATIONS OF CHINESE VIEWS OF SELF-WILLED DEATH FOR BIOETHICS. According to a report by Shi Da Pu (1991), euthanasia in China, once a taboo topic, has been discussed since the 1980s in the magazine *Medicine and Philosophy.* After the controversial case of the active euthanasia of a patient named Xia in 1986, which led to a court case being filed by her two daughters against their brother, who had authorized it, the topic was hotly debated in the media. It was also debated by the Chinese Dialectical Institute and Beijing Medical Ethics Academy, which concluded that active euthanasia was permissible for patients with no hope of cure. When the widow of former premier Zhou En-lai wrote that euthanasia was a "proper point of dialectical materialism" in need of discussion, there followed even more public debate. Some argued that it represented the height of civilization because it was a pure act of freedom; others, that it was "the result of the infection in the area of medicine from sick Western customs and morality … sharply against our socialist ethical values" (Shi Da Pu, p. 133). In 1988, a survey of 400 people (health professionals and nonprofessionals) showed that 80 percent were in favor of euthanasia. Both withdrawal of treatment and active euthanasia are being quietly practiced; though they are illegal, no one has been charged. Shi Da Pu concludes that most experts in China think that euthanasia should be regarded as part of the agenda of modernization, that the country should develop appropriate legislation to legalize it, and that the

press should be enlisted to spread the dialectical materialist teaching about it.

Conclusion

Four major views of natural death emerge when Asian religions are compared: (1) the cosmic, (2) the existential, (3) the familial, and (4) the natural. Hinduism has focused on the cosmic dimension of death, though it has also included the familial in connection with ancestor worship and the existential because of its long interaction with Buddhism. Buddhist views of death are existential in philosophical texts and some monastic circles; cosmic in the popular religion of both Theravāda and Mahāyāna countries; and familial (in countries with traditions of ancestor worship). Chinese religions emphasize the familial aspect of death, though cosmic dimensions are derived from Buddhism and popular Daoism, along with natural ones from philosophical Daoism.

Some of the Asian religions legitimated self-willed death (and sometimes assistance) in certain circumstances—such as a way to attain heaven or enlightenment, or a way to cope with a crisis such as terminal disease or extreme old age—as an exception to natural death. Although there were attempts to distinguish such self-willed death and assistance from suicide and homicide, respectively, some of the religions decided that the practice had created problems over time.

Each religion has a tendency to assimilate many, often contradictory, views, as if these provide extra antidotes against death. When views are too this-worldly—for example, the desire to eliminate suffering or mundane problems—or too otherworldly—for example, promises of easy heaven or liberation by self-willed death—premature death may occur. People, it seems, need to balance respect for the body and transcendence of it in order to live with health and purpose, thereby doing justice to their full humanity.

III. WESTERN PHILOSOPHICAL THOUGHT

For both humankind generally and each living person individually, the recognition of the universality and inevitability of death is but the beginning of the problem of death. Indeed, recognizing death as the individual and collective fate of human beings, and of all living creatures, creates the problem of death: Why does it happen? What does it mean? Is death final? Is death a good thing or a bad thing? At least as often these questions emerge for us in their mirror image, still provoked by death: What is the meaning of life, its purpose? Can life be meaningful if it ends in death? What purposes could outlast the inevitability of my death?

Philosophers have struggled with a human fear of death. Recognizing the inevitability of death is very different from supposing death is final. At a very general level, philosophical reflections on death divide those who deny the finality of death and suppose there is ongoing, usually individual, self-consciousness after death, and those who regard bodily death as final, as the destruction of consciousness, but who offer consolation meant to assuage fear of the inevitability of personal extinction. A very few philosophers have found death to be inevitable, final, and horrible. What binds all together in a recognizably *Western* tradition are the analytically and argumentatively philosophical approaches each group takes and the exclusively human-centered character of their views.

Probably the single most persistent theme in Western philosophical reflection on death is the view that death is not the annihilation of the self but its transformation into another form of existence. The conviction that individual human beings survive death, perhaps eternally, has been very differently grounded and elaborated in the history of philosophy, but in some form has persisted and frequently dominated through antiquity, the long era of Christian

theologizing, modernity, and into contemporary *postmodern* thinking. Considerably less attended to is the attempt to reconcile human beings to death's finality, to death as the end of individual human experiencing beyond which there exists no consciousness.

The Pre-Socratic Philosophers

The tension in Western philosophy between regarding death as transformation and thinking of death as final appears at the very outset of what is conventionally regarded as the beginning of Western philosophy, in the fragmentary remains of writing that have survived from thinkers in the early Greek colonies of Asia Minor, especially the Ionians. Anaximander (ca. 610–547 B.C.E.) and Heraclitus (ca. 533–475 B.C.E.) in particular were singularly impressed with the transitoriness of all things, as captured in the best-known corruption of a Heraclitean fragment, "One cannot step into the same river twice" (Kirk and Raven, fr. 217). The attempt to reconcile opposites—such as life and death—and to perceive the underlying unity, even harmony, in all of reality was preeminent for the pre-Socratics.

The very earliest surviving pre-Socratic fragment, from a book attributed to Anaximander, contains a passage that allows one to see both of the subsequent views about death—death as final and death as transitory—that have dominated Western thinking:

> And the source of coming-to-be for existing things is that into which destruction, too, happens, "according to necessity; for they pay penalty and retribution to each other for their injustice according to the assessment of Time." (Kirk and Raven, fr.112)

Jacques Choron, to whom all subsequent accounts of death in Western philosophy are indebted, reads this passage as evidence of how impressed Anaximander was with the terrible fact that things perish, but also as expressing the hope "that somewhere and somehow death shall have no dominion" (p. 35). Further, there is the suggestion that despite appearances, death is not annihilation: In the everlasting boundlessness (*aperion*), individual death is not meaningless, perhaps not even final.

In what is now southern Italy, Pythagoras (ca. 572–497 B.C.E.) struggled with these same realities, teaching that the soul suffered from embodiment, longed for release and reunion with the divine, possibly at death experienced transmigration into possibly other life forms, and could be purified in part through the process of rebirth. For the purification needed to overcome death and to be evermore united with the divine, it was most important to live a philosophical life, especially one that paid considerable attention to the contemplation of mathematical truth. This very abstract, highly intellectual element in Pythagoreanism distinguished it from the Orphic cults and Dionysian predecessors that so influenced it, and gave Pythagoreanism considerable appeal for Plato.

Continuity and change, constancy through flux, permanence and impermanence, death, extinction, and recurrence are the enduring concerns of pre-Socratic philosopher/scientists. If, as mathematician and philosopher Alfred North Whitehead (1861–1947) has suggested, the whole of Western philosophy is but a series of footnotes to Plato, it might equally be said that the history of Western philosophy on death is but a series of footnotes to Plato's predecessors.

Socrates, Plato, and Aristotle

What we know of Socrates's (ca. 470–399 B.C.E.) view of death is largely detached from a theoretical context replete with ontological and metaphysical doctrines. His views seem to be rooted in the immediacy of his experience and circumstances, at a time when he is first anticipating, then under, a death sentence. It is the example Socrates sets, more than the words that Plato (or Xenophon) reports him to have said, that have influenced generations of students.

Early in *Apology* (29Aff.), Socrates is tentative in his assertions about death, saying only that "To be afraid of death is only another form of thinking that one is wise when one is not; it is to think that one knows what one does not know." Later, having been sentenced to death, Socrates ventures that death is either dreamless sleep from which, it seems, we do not awaken (annihilation) or transport to a place where we might ever after commune with those who precede us in death. The first is not fearsome; the second is to be joyfully celebrated (41B–42A). Socrates's deepest and most influential conviction, however, may have been that "Nothing can harm a good man, either in life or after death" (41D).

Socrates's courage and equanimity in the face of a manifestly unjust death sentence is universally admired. But exactly why he was so compliant with injustice at the end of his life is a continuing mystery (Momeyer, 1982).

Less mysterious is how Socrates could go from the cautious and skeptical views on death expressed in *Apology* to the far more metaphysically burdened opinions of *Phaedo.* The accepted explanation here is that in *Phaedo,* written later than *Apology* and *Crito,* Socrates has been transformed into a spokesperson for Plato (ca. 428–348 B.C.E.). As such, *Phaedo* is best read as the most complete case that Plato makes for his views on the immortality of the soul, with only

the final death scene bearing any likely resemblance to Socrates's actual words.

Plato's view of death is inseparable from his doctrine of the soul, his identification of the soul with personhood, and ultimately the theory of Forms. Curiously, Plato's arguments are directed more to establishing the immortality of the soul than to the logically prior task of showing that the soul is the person. Whether the soul is identical to the person is a matter of continuing controversy in bioethical debates over the definition of death and criteria for personhood.

In *Phaedo,* Plato reminds readers that knowledge is recollection and shows that the soul must have existed before birth and embodiment in order for us to know most of what we do know during life. While this does not show that the soul survives death, it is suggestive in that it implies the soul's independence from the body. Other arguments attempt to show that the soul is *simple,* that is, not composed of parts and hence not subject to dissolution; that the soul resembles immortal gods in ruling the body; and that since the essence of the soul is life, it cannot admit of its negation or opposite any more than fire can be cold. Similarly, Plato holds that since the soul is capable of apprehending the eternal and immutable Forms or Ideas, it must be of a similar nature, eternal and divine.

It is not clear how seriously Plato intends most of these arguments to be taken, nor how seriously he himself takes them. But at least two central Platonic views are relevant and seriously maintained. The first is the reality of ideas, a domain of pure, unchanging essences the apprehension of which, however imperfect, is as close to real knowledge as living human beings can get. Second, Plato's suspicion of the body—construed by much later followers to be outright disdain—and his longing to be free of its burdens are consistent throughout his work. In Plato's judgment, intellectual pursuits are the most noble, but these are consistently and constantly hindered by bodily appetites and bodily limitations of sensory experience. Hence the true philosopher aspires to death, we are assured in *Phaedo,* and lives to die, in the expectation that only the soul's liberation from embodiment will make possible the fullest attainment of knowledge.

Plato's premier student began his own philosophizing in *Eudemos,* espousing Platonic views on the immortality of the soul and how individual selves survive death. Soon, however, Aristotle (384–322 B.C.E.) departed substantially from his mentor, and in *De anima* sees the soul as almost entirely physical, the entelechy of the body. More than being physically inseparable from the body, Aristotle argues, the soul is logically inseparable, as vision is logically inseparable from the seeing eye. The closest Aristotle will allow us to come to immortality is in the same fashion other creatures experience it, in successive generations of progeny. (Aristotle, 1941).

Aristotle does allow for the possibility that part of the soul survives death, the part that distinguishes us from other animals: reason, our divine element. But Aristotle's writings on these matters are fraught with ambiguity, and it is not clear that he thinks there is any survival of individual personalities.

In any case, the strongest imperative for Aristotle is to live a life of reason, an important part of which requires one to overcome a natural fear of death through courage and virtue. It seems to be Aristotle's considered judgment that individual selves do not survive death, and no benign deity watches over us; yet life is still meaningful so long as we are awed by the beauty and order of nature, and meet life's misfortunes with courage and perseverance.

Aristotle's death in 322 B.C.E. brought an appropriate close to the Hellenic period of philosophizing and provided some of the central themes in reflections on death for the Hellenistic schools that followed. Chief among these were Epicureanism and Stoicism.

Hellenistic Schools: Epicureanism and Stoicism

Where death had been a distinctly secondary concern for Socratic thinking, it soon became a primary one for Hellenistic philosophers. For Epicurus, Lucretius, and Zeno, then Seneca, Epictetus, and Marcus Aurelius, discovering how to live life and confront death were the central tasks of philosophy.

Although Epicureans and Stoics differed on what they most valued in life, they equally valued attaining equanimity in the face of imminent death. Epicureans in particular saw no reason to fear death, believing that at death the soul, composed of the finest atoms, simply dissipated, so that there was nothing left to have experiences. Epicurus argued that one need not fear an unpleasant afterlife, for there was no afterlife; nor need one fear death as annihilation, for as soon as it occurred, one no longer existed to suffer anything. Epicurus's view is well captured in his memorable letter to Menoecus, in which he asserts:

> Death … is nothing to us, since so long as we exist, death is not with us; but when death comes, then we do not exist. It does not then concern either the living or the dead, since for the former it is not, and the latter are no more. (Epicurus, 1926, p. 85)

Epicurus may well be on strong ground in urging us to regard death as final and afterlife as nonexistent, for this

claim at least is supportable by overwhelming empirical evidence: People die, and they do not return. His second assurance, however—that the living need not fear death because once it occurs, they no longer exist to experience it—is far more problematic.

Epicurus's argument seems to be the following: Only that which is experienced can be evil and fearful. But death is a condition in which nothing is experienced, for the subject of experience no longer exists. Hence, it is unreasonable to fear death.

The problematic assumption here is that only that which is experienced is harmful. Deception, betrayal, and ridicule behind one's back are all capable of doing great harm, though one may never be aware of them, know of the damage they do, or be able to mind the harm. Consequently, it is legitimate to argue, contrary to Epicurus, that death is a harm (even though not experienced) precisely because it is the irrevocable loss of opportunity, of the continued good of life. Death is the deprivation of life, and were one not dead, possibilities for satisfying experiences could be realized (cf. Nagel).

The Stoics pursued a rather different strategy than the Epicureans in attempting to accommodate people to their mortality. Though we have only the most minimal fragments from the early Stoics—Zeno of Citium (ca. 336–264 B.C.E.), Cleanthes of Assos (ca. 331–232 B.C.E.), and Chrysippus of Soli (ca. 280–206 B.C.E.)—it is clear that they were much influenced by Heraclitus and emphasized discoveries in logic and cosmology. In ethics, they were early natural-law theorists, urging the unity of physical and moral universes and the duty to live a life as orderly as the cosmos, always striving for *autarkeia* (autonomy) of the virtuous person. Socrates, especially during his trial and execution, was a model and inspiration for Stoics of all eras.

Most closely identified with Stoicism are the later Stoics of the first two centuries of the Christian era in imperial Rome. The most prominent of these were Seneca (ca. 4 B.C.E.–65 C.E.), Epictetus (ca. 50–130 C.E.), and Marcus Aurelius (121–180 C.E.). What bound these philosophers together was their commitment to virtue, understood as willing behavior in accord with reason (or nature) and unresisting resignation before what was uncontrollable.

The art of mastering the fear of death is not easily learned. Stoics recommend emulating great men [sic], virtuously living the life of a philosopher, and always remembering that living well is by far the most important thing. Reminders of the futility of fearing or resisting death are also prevalent in their writings. For all of its inevitability, death need not be our imposed fate before which impassibility is required. No philosopher more than Seneca recommended so enthusiastically and vigorously, nor practiced so decisively, taking control of death by choosing it in the form of suicide. In a remarkable letter he says the following:

> For mere living is not a good, but living well. Accordingly, the wise man will live as long as he ought, not as long as he can.… soon as there are many events in his life that give him trouble and disturb his peace of mind, he sets himself free.… It is not a question of dying earlier or later, but of dying well or ill. And dying well means escape from the danger of living ill.… Just as I shall select my ship as I am about to go on a voyage … so shall I choose my death when I am about to depart from life.… Every man ought to make his life acceptable to others besides himself, but his death to himself alone. The best form of death is one we like. (Seneca, 1970, Letter No. 70)

Seneca was not, in practice, so casual about self-killing as some of the above implies. Still, when Nero accused him of conspiring against the state, and ordered him to take his own life, Seneca is reported to have paused only long enough to remind his followers of the philosophical precepts they had striven to live by before slashing his wrists and bleeding to death.

The Long Transition to a Modern View of Death

In tracing our theme through Western philosophy—whether death is final or whether some notion of afterlife is envisioned—there is very little more to say about this between the time of Stoicism's greatest influence and the onset of a secular, scientific modern renaissance. For over 1,200 years Christian religious views held sway, and philosophy, dominated by theology, had little of substance and still less that was novel to say about death. Enormously important philosophical work was done during this long era, but little of it had much new to contribute to Western philosophical thought on death.

Western philosophical thought on death did not take a turn back to the secular until Francis Bacon (1561–1626) promoted an increasingly scientific methodology and worldview, and René Descartes (1596–1650) reordered the philosophical agenda. Both reflect on death with the aim of excising the fear of death (which in the late Middle Ages, overwhelmed by both plague and superstition, reached new heights). Bacon, however, does so by emphasizing the continuity of dying with living, such that once we learn to live fearlessly, we will be assured of dying fearlessly. Descartes chooses to assuage fears of death by the now more traditional route of arguing for the immortality of the soul.

And as is well known, Descartes's argument to this end relies upon a radical division of persons into different substances, body and soul, mysteriously and problematically united, which sets the stage for much subsequent philosophizing.

Most of modern philosophy pursues Cartesian themes, and the variety of responses is considerable. Rationalist philosophers have generally sought to salvage hopes of surviving death. (Benedict Spinoza [1632–1677] is a notable exception.) But the philosophers of the eighteenth century, and the empiricists they often looked to, came to regard doctrines of the immortality of the soul as *priestly lies.* French writer Voltaire (1694–1778), through Candide's misadventures in "The Best of All Possible Worlds," savagely ridicules Gottfried Wilhelm Leibniz's (1646–1716) faith in universal harmony, and other philosophers look back to the Epicureans and Stoics for inspiration on how to face the prospects of death as annihilation.

But it was David Hume (1711–1776) who most systematically and rigorously called into question doctrines of the soul's immortality. His attack is two-pronged: First he argues against the notion of substance, specifically the self as a substance, and second, he directs a series of arguments against the notion that some part of a person survives death. In his essay "On the Immortality of the Soul" (1777), Hume characterizes *substance* as a "wholly confused and imperfect notion," an "aggregate of particular qualities inhering in an unknown something" (p. 591). As for the self as a substance, he states in *A Treatise of Human Nature* (1739):

> There is no impression constant and invariable. Pain and pleasure, grief and joy, passions and sensations, succeed each other, and never all exist at the same time. It cannot therefore be from any of these impressions, or from any other, that the idea of self is derived; and consequently there is no such idea. (1978, bk. I, pt. 4, sec. 6)

Hume claims to be "insensible of *myself,*" for the self is "nothing but a bundle or collection of different perceptions which succeed each other with an inconceivable rapidity, and are in a perpetual flux and movement." All that binds perceptions together is memory and constancy, but it is futile to ask what it is that "has" memory or experiences constancy of conjoined perceptions (1978, bk. I, pt. 4, sec. 6).

Hume's more vigorous critique of immortality is reserved for benighted attempts to settle questions of fact by a priori metaphysical speculation, which is what is done by all doctrines of *immaterial substance* and all attempts to identify personhood with an immaterial *soul* substance that is individuated and survives the demise of the body. Placing his faith in the conviction that all natural processes have some point (if not purpose), Hume notes the universal fear of death and remarks that "Nature does nothing in vain, she would never give us a horror against an *impossible* event" (p. 598).

The only admissible arguments on such a question of fact as whether human beings survive death are those from experience, and these, Hume asserts, are "strong for the mortality of the soul." What possible argument could prove a "state of existence which no one ever saw and which in no way resembles any that ever was seen?" Body and mind grow together, age together, ail together, and, from all experience conveys to us, perish together. (p. 598).

Moral arguments that turn on a just Deity's desire to punish the wicked and reward the good fare no better than metaphysical ones when attempting to prove immortality. It would be a "barbarous deceit," "an injustice in nature," Hume asserts, to restrict "all our knowledge to the present life if there be another scene still waiting us of infinitely greater consequence." Still worse, it would be monstrous for a loving God to base a judgment of how each of us will spend eternity upon the all too finite experience of one human lifetime. (p. 593)

Notwithstanding that it was Immanuel Kant's (1724–1804) reading of Hume that woke him up from a comfortable immersion in conventional dogmas. Kant advanced his own version of a moral argument for the immortality of the human soul. Kant agrees with Hume that no argument from nature (i.e., experience) can demonstrate the immortality of a human soul, and he even concedes that *pure reason* is not up to the task. Nonetheless, Kant is firmly convinced that a compelling metaphysical/moral argument will do the job.

Kant apparently never doubted his belief in human immortality, and his argument to show the soul's immortality is both elegant in its simplicity and rich in the number of fundamental Kantian tenets that it incorporates or presupposes. Kant asserts in the *Critique of Practical Reason* (1788) that the most basic requirement of the moral law is the attainment of perfection. Such an achievement is not possible in a finite life, however. But the moral law can command only what it is possible for moral agents to do. Hence the necessity of an immortal soul so that moral agents will have the opportunity to do what they ought to do.

One of the more interesting features of Kant's *proof* is that it breaks with the long tradition that sees afterlife as occurring in paradise. In Kant's moral universe, there must still be pain and suffering in the hereafter, for these are inseparable features of the moral life. Further, doubt, uncertainty, and struggle for constant improvement must accompany our disembodied journey through eternity. The moral law would appear to be nearly as powerful as God.

The soundness of Kant's argument turns on the truth of at least the following Kantian doctrines: Objective reality must conform to the essential structure of the human mind; moral certainty is as sure a route to knowledge as the logical demonstrations of reason; moral perfection is required of all who would live a moral life; human beings exist, simultaneously, in two worlds, one phenomenal, the other noumenal. If any of these dogmas fail—and all have been extensively criticized—Kant's argument for the immortality of the human soul fails as well. Any number of philosophers after Kant, less enamored of metaphysical arguments, have turned his argument around and observed that if perfection is not possible in a human life span, the moral law cannot require perfection of human beings. Far from showing human immortality, Kant's insight into morality shows the limits of what a reasonable morality can demand of mortal creatures.

Toward Postmodernism

Variations on religious, usually Christian, views of death and immortality continued in the writings of eighteenth- and nineteenth-century philosophers, including most notably the idealism of Georg W. F. Hegel (1770–1831) and the atheistic pessimism of Arthur Schopenhauer (1788–1860). Not until a real break with modern thought occurred did genuinely novel views about the significance of death and the possibility of immortality arise. In the thought of Friedrich Nietzsche (1844–1900) many now find both the culmination of ancient and modern approaches to death and the transition to a postmodern worldview. And it is certainly true that in Nietzsche's various writings, one can find many different historically grounded and historically transcendent approaches to the problem of death.

While still a student, Nietzsche read Schopenhauer's *The World as Will and Idea*(1819). Profoundly moved and deeply disturbed, he sought escape from Schopenhauer's pessimism and atheism, and saw the task of philosophy as overcoming the former while taking responsibility for the latter (*Ecce Homo,* 1888). Physical pain and mental suffering were lifelong companions; staring into the abyss of despair and coping with the guilt of killing God, Nietzsche tried a number of different strategies for finding life worth continuing.

Through classical studies and art, Nietzsche supposed, one might escape the profound misery of existence (*The Birth of Tragedy,* 1872). The consolations of *beautiful dreams* soon faded, however, and Nietzsche turned to a detached, critical search for knowledge, and the "*interesting* illusion of science replaces the *beautiful* illusion of art" (Choron, p. 201).

Objective knowledge, or its semblance, proved unsatisfying as well, and Nietzsche then began to develop the idea of the *superman* as the disciplined Dionysian man capable of living a pain-filled life with full creativity. Truth is painful and, to all but the superman, unbearable. Above all, one must love fate (*amor fati*), which becomes possible with the Eternal Recurrence of the Same:

> Everything goes, everything returns; eternally rolls the wheel of existence. Everything dies, everything blossoms forth again; eternally runs the year of existence … All things return eternally and we ourselves have already been numberless times, and all things with us. (*Also Sprach Zarathustra,* 1891 quoted by Choron, p. 202)

At least Heraclitus's voice seems to recur here.

How such a view of the one life we have and the one death we experience, albeit endlessly repeated, solves the problem of death is not clear. Sometimes Nietzsche suggests that recognizing the Eternal Recurrence of the Same should lead us to passionately embrace and affirm life, to live with as much conviction and determination as we can muster, for life might otherwise be all the more miserable for its endless repetition. But Nietzsche, who attempted suicide three times, must have been terrified at the prospect of such recurrence. It is the ultimate test of the superman to love fate while recognizing precisely what fate has in store.

Contemporary Philosophy

The problem of death has not often been seen by contemporary philosophers as a choice between devising consolations for our finitude and demonstrations of our eternalness. For many, perhaps most philosophers early in the twenty-first century, the death of God is more than a century past, the grieving finished more than half a century ago. The problem of death, understood as the struggle to make life meaningful in an increasingly secular age plagued by the temptations of nihilism, continues. The little that philosophers in the present time have had to say about death—outside of chiefly moral concerns centering on choosing death—has tended to suppose death is final, not, in any form, to be survived.

German philosopher Martin Heidegger (1889–1976), once a student of Edmund Husserl (1859–1938), took as his project the application of phenomenological method to the fundamental question of metaphysics, the study of *Being-as-such.* To this philosophically most contentious enterprise in the twentieth century, Heidegger brought a particular concern for death. Since Heidegger is addressing the issue of why there is something rather than nothing, it is not nonexistence of Being that concerns him, but rather how individual beings—most particularly, individual self-conscious human beings (*Dasein*)—can possibly come to not exist.

Heidegger uses language in highly idiosyncratic ways, so when he talks about possibility and non-possibility and impossibility it is best to leave our conventional (and philosophical) understandings of these terms behind and attend to Heidegger's peculiar uses.

Understanding our own being at a deep level requires the attainment of wholeness and authenticity, which enables life to be lived with integrity and clear thinking. Nothing is more central to this quest than an appreciation of temporality and possibility, which provides insight into Being in general and Dasein in particular.

Dasein aspires to wholeness, but has future possibilities open to it only so long as it exists and can freely choose. But so long as Dasein exists and can make free choices, it cannot be whole. Death appears to us an end of Dasein and of possibility, but is it the attainment of wholeness? How can non-existence constitute completion?

Heidegger's resolution of these paradoxes involves an analysis of the unique way in which Dasein has possibilities and of how these are limited. Dasein's possibilities are ever limited by *the possibility of the impossibility of existing,* which in Heidegger's discourse is a synonym for death. Yet Heidegger maintains that his view of death leaves open the question of afterlife.

Death creates for Dasein its *ownmost possibility,* one that invites a uniquely free choice in response to mortality from each individual. The certainty of death is the ultimate realization of each Dasein, experienced alone and not shared by another. Attaining authenticity requires *Vorlaufen,* literally a *running forwards,* metaphorically, an ever self-conscious anticipation of death—a *being towards death*—that will free one from life's trivia and focus on using freedom to create an authentic self.

Jean Paul Sartre (1905–1980) in philosophy, and Carl Gustav Jung (1875–1961) in psychoanalytic theory, were both influenced by Heidegger's thinking. Jung developed Heidegger's notion of being towards death as a central focus of his psychoanalytic theory, and Sartre, along with French writers Simone de Beauvoir (1908–1986) and Albert Camus (1913–1960) articulated some of the most distinctive things to say about the problem of death in the twentieth century. Building on Nietzsche's alienation from convention, despair at the death of God, and attraction to nihilism, and struggling with revelations of the distinctly human capacity for genocide revealed during the Holocaust and the era of nuclear weaponry, existentialists have sought ways to affirm against all odds the meaningfulness of individual human existence. A good deal of the spirit of this distinctive approach to death is captured in de Beauvoir's unsettling judgment on the very difficult dying of her mother:

> There is no such thing as a natural death: nothing that happens to a man is ever natural, since his presence calls the world into question. All men must die: but for every man his death is an accident and, even if he knows it and consents to it, an unjustifiable violation. (p. 123)

Far from providing assurances of immortality or consolations designed to meet death with equanimity, existentialists recommend a rebellious, often angry response to the *cosmic injustice* that human beings die. Rebellion against or resistance toward death, however, is not recommended as a strategy for overcoming death; no illusions are allowed as to the inevitability and finality of death. Rather, for Camus especially, such resistance is recommended as an affirmation of one's decency, caring about life, and personal integrity. Nowhere is this better illustrated than in Camus's novel *The Plague,* an extended allegory about any number of evils, not the least of which is death itself. Dr. Bernard Rieux and his closest friend, Jean Tarrou, struggle mightily against the ravages of the plague in the seaside town of Oran in Algeria. In time, however, Tarrou succumbs to the plague, and Rieux reflects on what it means:

> Tarrou had lost the match, as he put it. But what had he, Rieux, won? No more than the experience of having known plague and remembering it, of having known friendship and remembering it, of knowing affection and being destined one day to remember it. So all a man could win in the conflict between plague and life was knowledge and memories. But Tarrou, perhaps, would have called that winning the match. (Camus, p. 262)

Afterword

Most Western philosophical views on death have been singularly human-centered, driven by the assumption of human uniqueness. Even atheistic existentialists, for whom God is displaced altogether from the universe, seem lost with no center, and substitute human beings and a kind of humanism as their moral center.

We have only just begun to explore the post-Darwinian implications of regarding human beings as a natural kind—as creatures like other creatures known to us, evolved from simpler life forms without conscious direction. The moral implications of such a change in worldview are getting considerable attention from philosophers at present—in reflections on ecology and the moral status of nonhuman animals, in more sympathetic treatments of rational suicide and euthanasia, in greater openness about the difficulties of dying—but the larger ontological and metaphysical consequences are infrequently addressed. If there is to be any

substantial breakthrough in our philosophical thinking about death, it might well come only with the displacement of human self-centeredness, with seeing human beings as one among many natural kinds on a solitary planet in an ordinary solar system that is on the fringes of one of many billions of galaxies in an apparently infinitely expanding universe. Such a potentially revitalized naturalism need not imply that life is meaningless for solitary, mortal human beings, nor does it guarantee significant life, but it might suggest that our plight is not unique, not unshared by others, and not, finally, to be resolved (or dissolved) by exclusive self-centered speciesist concerns.

But maybe not. Even such a revitalized naturalism might prove to be but one more variation on one side of the recurrent debate between those who seek a satisfactory means to reconcile each of us to the finality of death, and those who, on the other hand, seek to sustain the hope that life does not end with death and that individual consciousness continues beyond the grave.

IV. WESTERN RELIGIOUS THOUGHT

Death in Biblical Thought

There is no "biblical view of death" as such. This lack of a single scriptural understanding of death is hardly surprising, given the fact that the Bible is sacred scripture for three world religions and that its contents were written and compiled over a period of a thousand years or more. But the history of literary and religious development embedded within the Bible itself does allow for a kind of "archaeology" of death in biblical thought. Though admittedly vastly oversimplified, the following narrative of the Bible's evolving views on death can be traced backward through their random branchings and read forward toward their studied convergences.

Put in its simplest terms, an ancient desert god named Yahweh came to be regarded not only as the national god of a holy nation, but ultimately as the one and only God of the universe. These momentous shifts in the biblical understanding of God were paralleled by remarkable changes in biblical views of death, beginning with the denial and concluding with the affirmation of individual postmortem existence.

THE HEBREW BIBLE. Hebrew religion emerged out of the tribal polytheisms of ancient Mesopotamia. The protagonists of Yahwism only gradually succeeded in establishing their deity as the national god of the various Semitic tribes that were finally welded together, during the latter half of the second millennium B.C.E., into the people known as the Israelites. A key weapon in their struggle to establish Yahweh's supremacy was the suppression of prevailing beliefs and practices dealing with death. In two very different responses to death, Mesopotamian culture had preserved primitive notions of life after death as a continuation of the life before death. On the one hand, mortuary cults affirmed a significant afterlife for the powerful and privileged who commanded the worship and fealty of the living. On the other hand, postmortem existence was limited to an awful underworld where the departed dead were shrouded in darkness and subsisted on clay. In either case, the realm of the dead was under the control of the gods of the underworld. For that reason, the champions of Yahwism denounced the polytheistic beliefs and practices of both the mortuary cults and the "house of dust."

Against the mortuary cults, the Yahwists presented a view of human nature and destiny that undercut all ancestor worship and necromancy. In the Yahwist creation myth, the protohuman couple was created from the soil and destined to return to the soil (Gen. 3:19). Human beings are material bodies animated by a life force (*nephesh* or *ruach*) residing in the breath or the blood. Death comes when the life force leaves the body and returns to Yahweh. Thus, a common fate awaits all persons upon death—master and slave, rich and poor, good and bad—all descend beneath the earth to the place of the dead called She'ol, where they continue a shadowy existence, but only for a brief period of time. This land of the dead was variously described as an awful pit shrouded in darkness or a walled city covered with dust. Although reminiscent of the Mesopotamian underworld, the Yahwist notion of She'ol excluded any divine ruler of the infernal regions. Neither a god of the underworld nor Yahweh himself was involved with the denizens of She'ol. Yahweh reigned supreme over the community of the living, meting out collective rewards and punishments only in the present life. In other words, mortality was accepted as a fact of life. Premature and violent deaths were feared as great evils and regarded as punishments for sin. As such, the untimely or agonizing death remained under the control of Yahweh (Isa. 45:7). But death at the end of a long and happy life was accepted, if not welcomed (Gen. 25:8; Job 5:26). What mattered were those things which survived the mortal individual: a good reputation (Prov. 10:7), male offspring (Isa. 56:3–5), the promised land (Gen. 48:21), and the God of Israel (Ps. 90).

Precisely this emphasis on present existence contributed to the eventual transformation of Yahwism. The naive assumption that Yahweh rewards the pious with prosperity and a long life while punishing the wicked with misfortune and a brief life was obviously contradicted by communal and individual experience. Especially the disasters that befell Israel between the eighth and the sixth centuries B.C.E. raised radical doubts about Yahweh's justice and omnipotence, because the entire social and religious order of Israel was disrupted and eventually destroyed.

This massive destruction evinced two distinctive responses. On the one hand, most of the great prophets of Israel responded to these dire circumstances by reaffirming collective retribution and promising collective restoration (Isa. 11:10–16; Ezek. 36:16–36). Some prophets moved beyond communal responsibility and punishment (Jer. 21:3), but their new emphasis on the individual only heightened the tension between divine power and justice in the face of innocent suffering (Job 10:2–9). On the other hand, an apocalyptic school of thought slowly emerged that anticipated a miraculous deliverance of the faithful living and dead at the end of time. Envisioned in this apocalyptic outlook was the final defeat of death itself, which had increasingly been personified as a destructive evil force. Thus, by the end of the second century B.C.E., two sharply contrasting views of death dominated the Hebraic worldview. The older notion that death marked the end of life remained the traditional view among those who came to be known as the Sadducees. The newer view that affirmed postmortem divine judgment and human resurrection flourished among such sectarian movements as the Pharisees and the Essenes. For these sectarians, the powers of death would eventually be overcome by the power of God.

THE INTERTESTAMENTAL LITERATURE. This sectarian transformation of the Hebraic view of death during the so-called intertestamental period was immense (ca. 200 B.C.E. to 50 C.E.). A number of disparate ideas were combined into a dramatically new eschatology. The Book of Daniel marked a watershed in Hebrew religious thought by promising Yahweh's final intervention in history to rescue his people from their enemies and to resurrect past generations from the dead to participate in this ultimate restoration. To be sure, this final restoration was limited to the nation of Israel. But, under the impact of speculative thought and foreign influences concerning life after death, the prospect of a final resurrection and judgment for all humankind appeared in the later apocalyptic literature, much of which is contained in the Apocrypha. In this apocalyptic literature, human consciousness and the life force were fused into an entity (*psyche* or *pneuma*) which, unlike the earlier conceptions of *nephesh* or

ruach, survived the cessation of bodily functions in some spiritual fashion. She'ol was reconceived as a holding place for the dead until their ultimate fate was decided at a final judgment. More significantly, She'ol was divided into compartments reflecting the moral character of the dead, wherein rewards and punishments were already meted out in anticipation of the catastrophic end of the existing world order (Enoch 22:9–14). Thus, death held no terror for the righteous. In fact, death through martyrdom was seen as a seal of divine favor (2 Macc. 6:30–31) and even premature death from serious illness freed the righteous from further suffering (Wisd. of Sol. 4:11). Death was only a threat and curse to the wicked. Reminiscent of the older Yahwist traditions, the apocalyptic emphasis remained largely on the collective aspects of human destiny, for it is the nations that are arraigned for the final judgment (2 Ezd. 7:32–38). The postmortem survival of the individual became an affirmation of faith within certain Jewish circles only following the shattering of the Jewish state in 70 C.E.

THE NEW TESTAMENT. Primitive Christianity emerged out of Jewish apocalyptic expectations of the catastrophic end of the existing world order and the final judgment of the living and the dead. These apocalyptic expectations had been joined in the popular imagination with the older prophetic Messianic traditions in which a divinely appointed and endowed figure would crush the enemies and restore the glories of Israel. So far as the New Testament Gospels allow for historical reconstruction, the message of Jesus centered in the nearness of the Day of the Lord, when the chosen people of Yahweh would be vindicated before the nations of the world. Jesus called his compatriots to prepare themselves for the Coming Judgment through repentance and obedience to the written and oral Law of God. But, unlike the earlier nationalistic preoccupations of Jewish apocalypticism, this newer eschatology emphasized the eternal destiny of individuals in accordance with their moral achievements (Matt. 25:40–46). After his death and resurrection, the followers of Jesus identified him as the promised Messiah who would restore the righteous and judge the wicked. This same "Christianized" apocalyptic tradition informs the Revelation to John, which so profoundly influenced later Christian views of human death and destiny. Here the "end of the world" was described in elaborate detail as a cataclysmic establishment of the millennial reign of Christ and the saints on earth, after which the righteous are rewarded with eternal life and the wicked are punished with eternal death. Thus, the earliest Christian view of life after death was heavily influenced by, but not identical with, Jewish apocalypticism. Jesus was heralded by his early followers as their resurrected Lord who would shortly return in supernatural power and glory to preside over the Final Judgment of the living and the dead.

A somewhat different interpretation of the message and mission of Jesus was offered by Paul in his outreach to a Gentile audience. Paul regarded the death of Christ as a divinely planned event to rescue humankind from enslavement to the demonic powers of evil and death that ruled the world. Although influenced by apocalyptic thought, Paul's interpretation of a divine Savior's death and resurrection involved an eschatology very different from the apocalyptic scheme of things. No longer was obedience to the Twofold Law the basis on which the living and the dead would be judged; instead, faith in the crucified and risen Lord became the crucial factor. The ritual of baptism, which reenacted the death, burial, and resurrection of Christ, initiated believers into immortal life while still living in their material bodies. The baptized Christian, having become a new creation *in Christo,* had already passed from death to life. Thus, the imminent return of Christ and the end of the world held no fear for baptized believers, for their final judgment and destiny had already been settled.

With the Roman overthrow of the Jewish state in 70 C.E., the Mother Church of Jerusalem disappeared and eventually Pauline Christianity became the normative interpretation of Christ. Elements of the earlier apocalyptic eschatology were carried over into this form of faith. Christianity became a salvation religion centered in a Savior God who would shortly return to bring the existing world to a catastrophic end and to judge those who had oppressed the faithful. But the continuing delay of the second coming of Christ forced the Church to rethink its notions of eschatological fulfillment. The Church could no longer think of itself as an eschatological community awaiting the imminent return of their Lord. Rather, the Church developed a hierarchical structure and a sacramental system to shepherd believers through the perils and pitfalls of life from birth to death. Accordingly, Christ was reconceived as the heavenly mediator between God and humankind. Despite these doctrinal and ecclesiological developments, the apocalyptic vision of the catastrophic end of the world was retained, raising anew all sorts of problems about the status of the dead before the final day of resurrection and judgment. Over time, these problems were resolved in ever more vivid and complicated schemes of postmortem paradisal bliss for the saints and purgatorial torment for the sinners until the day of Final Judgment (Luke 16:19–26).

ETHICAL IMPLICATIONS. As noted above, the Bible is a diverse literature containing a variety of religious perspectives on death. Religious affirmation of the triumph of life over death is a common theme running through the whole

of scripture, but how, where, and when this victory is won differs dramatically among biblical perspectives. For that reason, the Bible offers no consensus of direct guidelines on death and dying. Nevertheless some application of the biblical tradition to modern "end of life" ethical issues can be ventured.

1. Biblical views of death are greatly influenced by the wider cultural milieu. As human conditions and needs changed, so did prevailing religious beliefs and practices concerning death. Thus, the Bible itself seems to allow for changing definitions and responses to death in the light of new social conditions, scientific knowledge, and religious insights.

2. The biblical tradition's intimate connection between body and spirit is not only a mandate for medical care as treatment of the whole person but also grounds for regarding human life as more than biological functioning. While the Bible does not authoritatively establish when death occurs, it defines death as the separation of the spirit from the body. Thereby, the Bible provides indirect warrants for withholding or withdrawing extraordinary means of life support when the vital bond between body and spirit has been dissolved or destroyed.

3. The biblical tradition never accords absolute power or independent status to death. Death, whether viewed as a natural event or an evil force, is always subordinated to the power and purposes of God. While the Bible speaks of sin as both a cause and a consequence of death, even the death of the sinner remains under divine control and serves the divine will. God's sovereignty over death serves as a caution against simplistic religious warrants for directly or indirectly terminating the lives of the suffering.

4. Biblical support can be found both for death as a natural part of life and death as an evil power opposed to life. Those who regard death as an "enemy" that must be battled at all costs will find more support for their view in the New Testament. Those who see death as a "friend" that can be welcomed at the end of life will feel more kinship with the Hebrew Bible. But both Jewish and Christian scriptures regard untimely and violent deaths as evils to be avoided and enemies to be combatted by all legitimate means that do not compromise religious or moral duties. Of course, death by coercive martyrdom can be affirmed as a seal of great faith, and even premature death from debilitating illness can be welcomed by the believer as a deliverance from great suffering.

5. Taken as a whole, the Bible does not unambiguously affirm individual life after death. But where postmortem existence is affirmed in the Bible, the grounds are theological rather than anthropological. The individual's survival beyond death is a divine possibility rather than a human certainty. Immortal life is a "supernatural" endowment rather than a "natural" attribute. In other words, a belief in life after death is neither a given of human nature nor a constant of human culture. Thus, the idea of life after death cannot become an explicit warrant for public policies or ethical decisions regarding "end of life" issues in a pluralistic society.

Death in Systematic Religious Thought

The classical doctrines and rituals of Judaism and Christianity are no less complicated and diverse than their biblical backgrounds. Neither the Judaic nor the Christian tradition is monolithic. Both faiths have been developed over extended periods of time in response to changing historical circumstances and cultural influences. But these theological complexities can be simplified for purposes of comparing and contrasting their respective views of death. Just as there are elements of continuity and mutuality within the Hebrew Bible and the New Testament, so are there broad similarities between Judaism and Christianity in their traditional beliefs and practices regarding death.

POSTBIBLICAL JEWISH BELIEFS AND PRACTICES. A long and slow transformation took place from the completion of the Hebrew Bible (ca. 200 B.C.E.) to the completion of the Talmud (ca. 500 C.E.), during which time biblical Hebraism emerged as rabbinic Judaism. The Talmud brought together eight hundred years of rabbinic commentary on scripture that was broadly categorized as *halakhah* (law) and *haggadah* (story), the former describing the obligations, the latter explaining the meaning of God's covenant with Israel. This massive compendium of rabbinic thought explicated the scripture's "moralization" of life and death in vast and vivid detail. For example, heaven (*Gan Eden*) and hell (*Gehinnom*) were each divided into five separate chambers, reflecting different levels of eternal rewards for the righteous and punishments for the wicked. Similarly, the rabbis described 903 forms of death. The hardest way of dying is by asthma and the easiest, which is reserved for the righteous, is "like drawing a hair from milk." Death following five days of illness was considered ordinary. Death after four days or less indicated increasing degrees of divine reprimand. Those who died before fifty were "cut off," sixty years was "ripe age," and above seventy was "old age." Despite all this moralizing about death, comparatively few rabbis held that death as such was the wages of sin. Against those who taught that Adam's sin brought death into the world, the majority of rabbis taught that Adam's mortality was given with his creation. Death was an integral part of the good world that God created in the beginning. Thus, sin hastens death but does not cause it in the first place.

In other words, only the timing and manner of death are affected by moral conditions. Acts of benevolence and confessions of sins can delay the hour of death as surely as sins of impurity and injustice can speed it. But there is no avoiding death once the angel of death receives the order from God. Given God's permission to destroy, the angel of death makes no distinction between good and bad, but wields the sword against royalty and commoner, old and young, pious and pagan, animal and human alike. While both the wicked and the righteous must die, their deaths are as different as their lives. The wicked perish to pay for their sins while the righteous die to be freed from their sins. Death is a punishment for the sins of the wicked but an atonement for the sins of the righteous. Put another way, the righteous are still alive even though dead, while the wicked are already dead though still alive.

When death occurs, the soul leaves the body with a silent cry that echoes from one end of the world to the other. The soul's departure from the body is marked by the absence of breathing, heartbeat, and pulse. The slightest sign of movement is an indication that death has not yet occurred. Where the soul goes was a matter of considerable dispute among the rabbis. Some taught that the soul sleeps until the resurrection of the dead and the final judgment. Others believed that the soul passes into an interim state of consciousness and activity. But they all agreed that the body that remains must be treated with dignity and given a proper burial. Desecration of the body, such as mutilation or burial with missing body parts, is forbidden, and burial must be before nightfall if possible. Interment must be in the ground to fulfill the biblical mandate ("Dust you are and to dust you shall return") and to complete the atoning process ("May my death be an atonement for all my sins"). A speedy and simple burial also accorded with widespread popular beliefs that the soul is free to complete its journey to the other world only when the body has decomposed.

These beliefs about death were reflected in a number of customs and rituals surrounding the dying and mourning process. A dying person (*goses*) was given special consideration by loved ones who gave support and comfort during the last hours. The dying person was never to be left alone. Last wishes and spiritual advice were to be faithfully observed. When nearing the end, the dying were encouraged to make a confession such as the following: "I acknowledge unto Thee, O Lord my God, and God of my fathers, that both my cure and my death are in Thy hands. May it be Thy will to send me a perfect healing. Yet if my death be fully determined by Thee, I will in love accept it at Thy hand. O, may my death be an atonement for all my sins, iniquities, and transgressions of which I have been guilty against Thee." This confession was followed with the traditional Jewish affirmation of faith: "Hear, O Israel: The Lord is our God, the Lord is One" (Deut. 6:4).

When death had occurred, the eyes and mouth were closed by the eldest son or nearest relative. The arms were extended alongside the body, which was placed on the floor with the feet toward the door and covered by a sheet. A lighted candle was placed close to the head. Mirrors were turned to the wall or covered. Water in the death room was poured out, reflecting the ancient legend that the angel of death washes its bloody sword in nearby water. The windows of the death chamber were opened to allow the spirits to enter and depart. The dead body was never left alone, whether on weekdays or the Sabbath, until the funeral. Thus, the entire deathbed drama was structured to allow the dying to face the future realistically, yet within a reassuring framework of family and faith.

The theological and literary diversity of the talmudic period yielded two very different developments of the Jewish tradition during the Middle Ages (ca. 1100–1600). A mystical school emerged whose teachings concerning death and the afterlife went far beyond rabbinical Judaism. An emphasis on divine immanence and human transcendence lay at the heart of the *Kabbalah,* the most commonly used term for the esoteric teachings of medieval Judaism. Human life is the journey of the soul from God and back to God. During the interim period of life on earth and in the body, the soul must attain the "knowledge of the mysteries of the faith," which will purify and prepare it for its return to God. Since this esoteric knowledge is seldom learned in a single life, the soul transmigrates from one embodiment to another until all sins are purged and all duties fulfilled. In this mystical scheme of things, death is simply a threshold marking the passage from one life to another in the soul's ascent to God.

By contrast, a scholastic approach emerged, which codified talmudic beliefs and practices concerning death and dying. The greatest halakist of medieval Judaism was Rabbi Joseph Caro. His sixteenth-century work, *Shulhan Arukh,* became the authoritative code of Jewish law by synthesizing and reconciling the three giants of medieval *halakhah*—Isaac Alfasia, Moses Maimonides, and Asher B. Jehiel. Unlike Maimonides, who reinterpreted traditional Jewish teachings in Aristotelian terms, Caro did not subject Jewish law to speculative criticism. Rather, he brought order out of chaos by investigating each stage of development of every single law, finally arriving at a decisive interpretation and application of that law. His work has remained the indispensable guide to the development and interpretation of Jewish laws and customs for two millennia. Included in *Shulhan Arukh* are the detailed halakic rites and duties surrounding

death, burial, and mourning observed throughout Orthodox Jewry to this day.

In the modern period, a variety of reform movements have modified many traditional Jewish beliefs and practices concerning death. Orthodox Jews have for the most part remained loyal to rabbinic eschatology, with its emphasis on the final resurrection, but they diverge on whether the resurrection awaits all humankind, the righteous of every age, or only the Jewish people. These otherworldly notions of Messianic redemption and divine judgment have largely faded into the background for Conservative Jewish thinkers. They interpret the Messianic Hope historically in terms of the restoration of the nation of Israel, and spiritually in terms of the immortality of the soul. References to the resurrection of the dead in Jewish rituals of death, burial, and mourning are retained, but the language of resurrection is assimilated to teachings about the immortality of the soul.

Reform Judaism has gone even further in rejecting doctrines of bodily resurrection and the Messianic Age. The "Pittsburgh Platform" of Reformed Judaism (1885) excluded all bodily notions of heaven and hell as abodes for everlasting punishment and reward. Indeed, some liberal Jewish thinkers have rejected the idea of individual immortality entirely, though they affirm the lasting value of each human life within the everlasting life of God. These reformulations of Jewish belief have also produced liberalizations in the areas of Jewish death, burial, and mourning rites. Curiously enough, this turn away from the otherworld and afterlife has fueled a profound concern for the salvation of humankind in the full reality of their historical existence. Thus, many Reformed Jews have returned full cycle to the essentially "humanistic" outlook of the great prophets of ancient Israel.

POSTBIBLICAL CHRISTIAN BELIEFS AND PRACTICES. The traditional Christian understanding of death developed largely in response to two challenges facing the Church at the close of the first century. Internally, the delay of the second coming of Christ forced Christian thinkers to deal with the state of the soul between death and resurrection. For the most part, primitive Christians believed that the dead slept until the Last Day, at which time they would be resurrected from the grave to receive their everlasting rewards or punishments. But, as this period of time lengthened, questions about the interim between individual death and universal judgment became ever more pressing. Externally, the pervasive view of death in Hellenistic religion and philosophy called for some theological response. The Greeks believed that the immortal soul is released from its bodily entrapment by death. This understanding of death was so widespread that some Christian assimilation of the soul's immortality and the body's inferiority was inevitable. Taken together over time, the delay of the return of Christ and the appropriation of Greek ideas of immortality fostered an elaborate system of Christian beliefs and practices concerning the active life of the soul during the period between one's death and the general resurrection at the end of the age. In time, this new eschatology displaced the apocalyptic vision of the Last Days, which vision survived for the most part in millenarian or chiliastic sects, who looked forward to the return of Christ and the establishment of the Kingdom of God on earth.

The church fathers adopted many of the categories of Greek philosophy but retained most of the substance of Pauline Christianity. They affirmed the immortality of the soul but rejected the ultimate separability of soul and body, along with all Hellenistic notions of reincarnation and immediate judgment. The soul is the vivifying principle and as such is incomplete without a body. Indeed, had Adam and Eve not sinned, humankind never would have experienced death. But all must suffer the separation of soul and body in death as punishment for their sins. Their souls, however, cannot perish because they are immortal. Therefore, these souls must eventually be reunited with "the dust of bodies long dead" (Augustine) in order to receive their final inheritance of everlasting salvation or eternal damnation. Surprisingly, there was little speculation among the church fathers about this interim between individual death and general resurrection. Since the soul is immaterial during this period, the dead could experience no sense of place or time, no awareness of comfort or pain, until the resurrection.

Given its finality, death thus became a decisive moment in the soul's destiny. The hour of death sealed the fate of the saved and damned alike. Those who died with their sins forgiven were destined for heaven's bliss. Those who died "while yet in their sins" were condemned to hell's agony. This emphasis on penance in relation to God's mercy and judgment fueled the more elaborate view of heaven, hell, and purgatory that characterized medieval Christianity. The materials for that view were already available in the earlier periods, but an adequate conceptual framework was lacking. The notion of a fire that cleanses the righteous and consumes the wicked at the final resurrection belonged to the earliest biblical traditions. Pushing this purgation of sins back from the final judgment into the interim period after death was encouraged by pietistic and penitential practices. Prayers to the saints and masses for the dead whose sins require expiation implied an active existence for souls following death and suggested a postmortem purgation of sins. But these implications were not fully worked out until the High Middle Ages (1200–1500).

Drawing on Aristotelian philosophy, Thomas Aquinas worked out an eschatology that combined an active spiritual afterlife with the traditional biblical notions of a general resurrection and last judgment. While the soul actualizes the body as its matter, it contains within itself to a degree all the perfections of physical and spiritual existence. Thus, the infliction of punishment or the bestowal of reward on the soul begins immediately after its separation from the body. But neither ultimate happiness nor ultimate misery is possible for a disembodied soul and, therefore, both must await the reunion of soul and body at the resurrection. Moreover, the soul that is ultimately rewarded must be entirely purified, either during or after this life. In other words, the existence of purgatory was a logical correlate of the immortal soul and the sacrament of penance, which requires contrition and satisfaction for all sins committed after baptism.

This thirteenth-century theological synthesis ineluctably shifted the emphasis to the individual's judgment at death rather than the universal judgment of humankind at the final resurrection of the dead. The Church's official view retained the two judgments, but in popular belief and practice they were in effect merged into one. People simply went to heaven, hell, or purgatory at the moment of death. Accordingly, the hour of death became overloaded with urgency. Dying in a state of grace meant eternal salvation, in a state of sin, eternal damnation, while dying with unconfessed sin required purgatorial cleansing. Thus, dying became more important than living. This focus on death was most obvious in the medieval *Ars moriendi* art of dying manuals that gave step-by-step advice to the dying and to the persons attending the dying to ensure a "good death." Of greater significance was the increasing importance of the sacrament of extreme unction, which was administered to the dying for all sins of sight, hearing, smell, speech, touch, and action. For those believers who died ill-prepared, there were masses for the dead and indulgences for the remission of sin for those in purgatory. In other words, a whole arsenal of beliefs and practices were mobilized against the terror of dying outside the state of grace.

What was developed in the thirteenth century as gifts of divine grace became in the fourteenth and fifteenth century marks of human folly. Or so the Protestant reformers claimed. Abuses surrounding the sacraments and indulgences for the dying were rife in the late medieval Church. These abuses were a precipitating cause of the sixteenth-century reform movements that swept both church and society. In point of fact, neither Luther nor Calvin broke with the fundamental worldview of medieval Christianity. Both challenged current beliefs and practices from within the medieval tradition. Thus, with regard to eschatology, the reformers retained the concept of the soul's immortality and eternal destiny. But they both undercut the entire penitential system with a different understanding of divine mercy and justice. The blood of Christ is the sole satisfaction for the sins of believers. Thus, medieval notions of a purgatorial state and a treasury of merits fell to the ground because these practices compromised the sole ground of salvation in Christ through faith. What remained for the reformers was an affirmation of the imperishable soul, which immediately enters its eternal reward or punishment upon separation from the body in death. The older idea of a general resurrection and judgment at the End of the Age was retained, but this last state of the soul only ratifies and perfects the fate of the saved and the damned at death.

In the modern world, mainline Catholic theologians have for the most part remained faithful to the position of Thomas Aquinas. The lurid images and frantic piety surrounding death and the afterlife in the Middle Ages have long since been rejected by educated Catholics. But the devout Catholic can still face the enemy of death armed with the traditional sacramental graces and doctrinal truths of life everlasting. To be sure, some contemporary Catholic theologians interpret these traditional beliefs and practices in symbolic rather than literal terms. For them, the experience of death is viewed as pilgrimage in faith rather than punishment for sin. Death is seen as "the law of human growth," whereby each stage of growth requires a tearing away from previous environments, which have become like so many prisons. In death, one's own body, like the mother's body at birth, is abandoned so that personal growth may continue. Alternatively, death allows the soul to enter into a new all-embracing unity. At death the soul is freed from the limitation of being related to one particular human body and becomes related to the whole universe. The pouring out of the self at death leads to a pan-cosmic level of personal and communal existence. But for the most part, contemporary Roman Catholics simply "look forward to the resurrection of the dead and the life of the world to come," in the words of the Nicene Creed.

Modern Protestant theologians have been even more innovative than their Catholic counterparts. To be sure, mainline Protestants have followed the guidelines laid down by the Reformers. They have combined an emphasis on postmortem rewards and punishments for the soul at death with some notion or another of a Final Consummation of the Age. But a growing freedom from ecclesiastical authority and biblical literalism allowed for a wide range of Protestant theological innovations. These new theologies were usually developed in response to the challenges of modern science and in partnership with one or another modern philosophy.

Beginning in the eighteenth century, the Christian faith was interpreted within such diverse philosophical frameworks as rationalism, romanticism, empiricism, existentialism, and process thought. Not surprisingly, each philosophical theology has dealt with the problem of death and the afterlife in its own distinctive way. These liberal theological experiments share certain convictions about life after death. They reject apocalyptic schemes of history and literalistic views of the afterlife. They empty the afterlife of all ideas of eternal torment, preferring instead to speak of either the total annihilation or eventual salvation of the wicked. But their concrete notions of eternal life run the gamut from the soul's immaterial existence in heaven to the self's authentic existence while on earth. Despite these wide-ranging theological reflections on death, most present-day Protestants hold to the idea of death as the soul's passage to its immortal destiny, either in eternal communion with or eternal separation from God and the people of God.

ETHICAL IMPLICATIONS. The long histories of Judaism and Christianity reveal disagreements within as well as differences between these religious traditions. And yet there are striking parallels between the ways they deal with death over the centuries. Of course, both traditions come out of the same Hebraic background and confront the same broad cultural challenges. But of greater importance is the fact that both traditions are preoccupied with the issue of theodicy. There must be some ultimate justification of the brute fact that the righteous suffer and die along with the wicked. The stubbornly moral character of the Judaic and Christian traditions militates against either indiscriminate immortality or universal annihilation. Thus, for all their differences, Judaism and Christianity are bound together by their efforts to reconcile ethics and eschatology. Not surprisingly, Judaism and Christianity respond in similar ways to a number of "end of life" ethical issues.

1. For the most part, Judaism and Christianity traditionally define death as the moment the spirit leaves the body. The accepted signs of the spirit's departure are the absence of breathing, heartbeat, and pulse. But there is nothing in these theological traditions that directly rules out more precise empirical signs of death, such as a flat brain wave. Most Christian theologians, and many Jewish thinkers, have accepted a brain-oriented definition of death, but some, especially within Orthodox Judaism, oppose such a definition, focusing instead on breathing as the definitive indicator of life. Some contemporary theologians are openly embracing higher-brain oriented definitions of death as modern equivalents of the departure of the spirit from the body.

2. Regardless of the etiology of death, the Jewish and Christian traditions regard death as an evil to be endured rather than a good to be embraced. Though death is inevitable, it is an event to be held at bay by every possible and honorable means that is not excessively burdensome or morally ambiguous. Therefore, most traditional Jews and Christians are categorically opposed to suicide and active euthanasia, or "mercy killing." Since martyrdom is not considered suicide, choosing death over life in service to one's faith or for the sake of others is allowable if it cannot be avoided in an honorable way.

3. Although all must die, not all deaths are the same in the Jewish and Christian traditions. Clearly, there are better and worse ways of dying. The best of deaths is the death of a person at peace with God who is "full of years," relatively free of pain, and surrounded by loved ones. The worst of deaths is to die "before your time," in rebellion against God, and alienated from family and friends. Recognition of these different ways of dying lends at least indirect religious sanctions to modern-day concerns about the "good death." There are no clear-cut religious obligations to prolong the dying process by extraordinarily burdensome means of life support. Indeed, the moral permissibility of withholding or withdrawing heroic means of life support from the terminally ill enjoys wide support among contemporary Jews and Christians alike, even though some Jewish scholars, particularly among the Orthodox, prefer to provide support, whenever possible, until the patient is moribund.

4. For both Jews and Christians, death is a reality that cannot be ignored or wished away. Whether death comes slowly or suddenly, the worst time to deal with death is after it happens. Believers should be prepared to deal with the heartache and havoc it brings before illness or tragedy strikes. We are ready to live only when we are prepared to die. While such preparation need not require the cultivated preoccupation with death of the medieval *Ars moriendi*, it should include a recognition of human mortality and an acceptance of human limits. In principle, such preparation might include the execution of advanced directives regarding terminal care.

5. Although the soul is infinitely more valuable than the body, the bodies of the dead deserve to be treated with care and love. For traditional Jews, such respect for the human body ordinarily excludes mutilation of the body, although sanctions against autopsies and dissection may yield to the superior value of protecting life or punishing crime. Some contemporary Jewish thinkers extend this overriding obligation to preserve life to the justification of organ harvesting for transplantation. Despite centuries of theological opposition, traditional Christians have reconciled themselves to the

legitimacy of anatomical dissection and organ harvesting in the interests of science and medicine, perhaps reflecting the Christian view that the resurrected body is a new creation of God. But more liberal Jews and Christians are untroubled by any of these postmortem procedures, provided they do not disgrace the corpse or disturb the family.

6. Both the Jewish and Christian emphasis on death is, in reality, the obverse of an even greater emphasis on life. At best, death serves as a motive for a creative and responsible life. At worst, death looms as a menace to a courageous and generous life. Either way, death lends an urgency to life that would be utterly lacking without it. Death enhances rather than cheapens the value of life.

7. For both Jews and Christians, there is hope that death does not have the final word in human experience. For many, death is a corridor that leads to a life free of sorrow, suffering, and separation. For others, death is powerless to cut off the faithful from the life of the community and the life of God. On either reckoning, death is incorporated as a meaningful stage in the life cycle. Both the Jewish and Christian traditions, strengthened by centuries of suffering and surviving, provide a variety of ways of affirming life in the face of death.

V. DEATH IN THE WESTERN WORLD

This entry, by the late Talcott Parsons, is reprinted from the first edition. It is followed immediately by a Postscript, prepared by Victor Lidz for the purposes of updating the original entry.

That the death of every known human individual has been one of the central facts of life so long as there has been any human awareness of the human condition does not mean that, being so well known, it is not problematical. On the contrary, like history, it has needed to be redefined and newly analyzed, virtually with every generation. However, as has also been the case with history, with the advancement of knowledge later reinterpretations may have some advantages over earlier ones.

Some conceptualization, beyond common sense, of a human individual or "person" is necessary in order to understand the set of problems presented by death. Therefore, a few comments on this topic are in order before proceeding to a reflection on some of the more salient features of death as it has been understood in the Western world.

The Person and the Problematic of Death

The human individual has often been viewed in the Western world as a synthesized combination of a living organism and a "personality system" (an older terminology made the person a combination of "body" and "mind" or "soul"). It is in fact no more mystical to conceive of a personality analytically distinct from an organism than it is to conceive of a "culture" distinct from the human populations of organisms who are its bearers. The primary criterion of personality, as distinct from organism, is an organization in terms of symbols and their meaningful relations to each other and to persons.

Human individuals, in their organic aspect, come into being through a process of bisexual reproduction. They then go through a more or less well-defined "life course" and eventually die. That human individuals die as organisms is indisputable. If any biological proposition can be regarded as firmly established, it is that the mortality of individual organisms of a sexually reproducing species is completely normal. The death of individuals has a positive survival value for the species.

As Sigmund Freud said, organic death, while a many-faceted thing, is in one principal aspect the "return to the inorganic state." At this level the human organism is "made up" of inorganic materials but is organized in quite special ways. When that organization breaks down—and there is evidence that this is inevitable by reason of the aging process—the constituent elements are no longer part of the living organism but come to be assimilated to the inorganic environment. Still, even within such a perspective on the human individual as an organism, life goes on. The human individual does not stand alone but is part of an intergenerational chain of indefinite durability, the species. The individual organism dies, but if he or she reproduces, the line continues into future generations.

But the problematic of human death arises from the fact that the human individual is not only an organism but also a user of symbols who learns symbolic meanings, communicates with others and with himself or herself through them as media, and regulates his or her behavior, thought, and feelings in symbolic terms. The individual is an "actor" or a "personality." The human actor clearly is not born in the same sense in which an organism is. The personality or actor comes into being through a gradual and complicated process sometimes termed "socialization."

Furthermore, there is a parallel—in my judgment, something more than a mere analogy—between the continuity of the actor and that of the organism. Just as there is an intergenerational continuity on the organic side, so is there an intergenerational continuity on the personality or action side of the human individual. An individual personality is generated in symbiosis with a growing individual organism and, for all we know, dies with that organism. But the individual personality is embedded in transindividual action systems, both social and cultural. Thus the sociocultural matrix in which the individual personality is embedded is in an important sense the counterpart of the population-species matrix in which the individual organism is embedded. The individual personality dies, but the society and cultural system, of which in life he or she was a part, goes on.

But what happens when the personality dies? Is the death of a personality to be simply assimilated to the organic paradigm? It would seem that the answer is yes, for just as no personality in the human sense can be conceived as such to develop independently of a living organism, so no human personality can be conceived as such to survive the death of the same organism. Nevertheless, the personality or actor certainly influences what happens in the organism—as suicide and all sorts of psychic factors in illnesses and deaths bear witness. Thus, although most positivists and materialists would affirm that the death of the personality must be viewed strictly according to the organic paradigm, this answer to the problem of human death has not been accepted by the majority in most human societies and cultures. From such primitive peoples as the Australian aborigines to the most sophisticated of the world religions, beliefs in the existence of an individual "soul" have persisted, conceivably with a capacity both to antedate and to survive the individual organism or body. The persistence of that belief and the factors giving rise to it provide the framework for the problematic of death in the Western world.

Christian Orientations toward Death

Because the dominant religious influence in this history of the Western world has been that of Christianity, it is appropriate to outline the main Christian patterns of orientation toward death.

There is no doubt of the predominance of a duality of levels in the Christian paradigm of the human condition, the levels of the spiritual and the material, the eternal and the temporal. On the one hand, there is the material-temporal world, of which one religious symbol is the "dust" to which humankind is said to return at death. On the other hand, there is the spiritual world of "eternal life," which is the location of things divine, not human. The human person stands at the meeting of the two worlds, for he or she is, like the animals, made of "dust," but is also, unlike the animals, made in the image of God. This biblical notion of humanity, when linked to Greek philosophical thought, gave rise to the idea in Catholic Christianity that the divine image was centered in the human soul, which was conceived as in some sense an emanation from the spiritual world of eternal life. Thus arose the notion of the "immortal soul," which could survive the death of the organism, to be rejoined to a resurrected body. The hope of the resurrection, rooted in the Easter faith of the Christian community, was from the beginning a part of the Christian faith and provided another dimension behind the teaching on the immortality of the soul.

The Christian understanding of death as an event in which "life is changed, not taken away," in the words of the traditional requiem hymn, *Dies irae,* can be interpreted in

terms of Marcel Mauss's paradigm of the gift and its reciprocation (Parsons, Fox, and Lidz). Seen in this way, the life of the individual is a gift from God, and like other gifts it creates expectations of reciprocation. Living "in the faith" is part of the reciprocation, but, more important to us, dying in the faith completes the cycle. The language of giving also permeates the transcendental level of symbolism in the Christian context. Thus, Mary, like any other woman, *gave* birth to Jesus, God also *gave* his only begotten Son for the redemption of humankind. Finally, Jesus, in the Crucifixion and thus the Eucharist, gave his blood for the same purpose. By the doctrine of reciprocation humankind assumes, it may be said, three principal obligations: to accept the human condition as ordained by the Divine Will, to live in the faith, and to die in the faith (with the hope of resurrection). If these conditions are fulfilled, "salvation," life eternal with God, will come about.

This basically was the paradigm of death in Catholic Christianity. Although the Reformation did collapse some elements in the Catholic paradigm of dualism between the eternal and the temporal, it did not fundamentally alter the meaning of death in societies shaped by the Christian faith. Still, the collapse of the Catholic paradigm did put great pressures on the received doctrine of salvation. The promise of a personal afterlife in heaven, especially if this were conceived to be eternal—which must be taken to mean altogether outside the framework of time—became increasingly difficult to accept. The doctrine of eternal punishment in some kind of hell has proved even more difficult to uphold.

The primary consequence of this collapsing was not, as it has often been interpreted, so much the secularization of the religious component of society as it was the sacralization of secular society, making it the forum for the religious life—notably, though by no means exclusively, through work in a "calling" (as Max Weber held).

Though John Calvin, in his doctrine of predestination, attempted to remove salvation from human control, his doctrine could not survive the cooling of the effervescence of the Reformation. Thus, all later versions of Protestantism accepted some version of the bearing of the individual's moral or attitudinal (faith) merit on salvation. Such control as there was, however, was no longer vested in an ecclesiastical organization but was left to the individual, thus immensely increasing religious and moral responsibility.

The concept of a higher level of reality, a supernatural world in which human persons survived after death, did not give way but became more and more difficult to visualize by simple extrapolation from this-worldly experience; the same problem occurred with the meaning of death as an event in which one gave life back to its Giver and in return was initiated into a new and eternal life. In addition to the changes in conceptualization set in motion by the Reformation, the rise of modern science, which by the eighteenth century had produced a philosophy of scientific materialism, posed an additional challenge to the Christian paradigm of death, manifesting itself primarily in a monism of the physical world. There was at that time little scientific analysis of the world of action, and there was accordingly a tendency to regard the physical universe as unchanging and hence eternal. Death, then, was simply the return to the inorganic state, which implied a complete negation of the conception of eternal life, since the physical, inorganic world was by definition the antithesis of life in any sense.

Contemporary Scientific Orientations

The subsequent development of science has modified, or at least brought into question, the monistic and materialistic paradigm generated by the early enthusiasm for a purely positivistic approach. For one thing, beginning in the nineteenth century and continuing into the twentieth, the sciences of organic life have matured, thanks largely to placing the conception of evolutionary change at the very center of biological thought. This resulted in the view, which has been already noted, that death is biologically normal for individual members of evolving species.

A second and more recent development has been the maturing of the sciences of action. Although these have historical roots in the humanistic tradition, they have only recently been differentiated from the humanistic trunk to become generalizing sciences, integrating within themselves the same conception of evolutionary change that has become the hallmark of the sciences of life.

The development of the action sciences has given rise, as already noted, to a viable conception of the human person as analytically distinct from the organism. At the same time these sciences, by inserting the person into an evolutionary sociocultural matrix analogous to the physico-organic species matrix within which the individual organism is embedded, have been able to create an intellectual framework within which the death of the personality can be understood to be as normal as the death of the organism.

Finally, the concept of evolutionary change has been extended from the life sciences (concerned with the organism) and the action sciences (concerned with the person-actor) to include the whole of empirical reality. And at the same time we have been made aware—principally by the ways in which Einstein's theory of relativity modified the previous assumptions of the absolute empirical "givenness"

of physical nature in the Newtonian tradition—of the relative character of our human understanding of the human condition.

Thus there is now a serious questioning of absolutes, both in our search for absolutely universal laws of physical nature and in our quest for metaphysical absolutes in the philosophical wake of Christian theology.

The Kantian Impact and the Limits of Understanding

The developments in a contemporary scientific understanding of the human condition are both congruent with, and in part anticipated and influenced by, Immanuel Kant, whose work during the late eighteenth century was the decisive turning point away from both physical and metaphysical absolutism. Kant basically accepted the reality of the physical universe, as it is humanly known, but at the same time he relativized our knowledge of it to the categories of the understanding, which were not grounded in our direct experience of physical reality but in something transcending this. At the same time Kant equally relativized our conceptions of transcendental reality, whose existence he by no means denied, to something closer to the human condition. Indeed, it may be suggested that Kant substituted procedural conceptions of the absolute, whether physical or metaphysical, for substantive propositions.

While relativizing our knowledge both of the physical world, including the individual human organism, and of the metaphysical world, with its certitude about the immortality of the soul, Kant nonetheless insisted on a transcendental component in human understanding and explicitly included belief in personal immortality in the sense of eternal life.

With respect to the bearing of Kant's thought and its influence through subsequent culture on the problem of the meaning of death, I have already noted that he prepared the way, procedurally, for the development of the action sciences and their ability to account intellectually for the personality or actor experienced as one aspect of the human individual without the need to infer, of necessity, the existence of a spiritual soul existentially and not merely analytically distinct from the living organism. The action sciences, in a very real sense, attempt to provide a coherent account of human subjectivity, much as Kant attempted to do in his *Critique of Judgment,* without collapsing the difference of levels between the physical and what may be called the telic realm.

The framework provided by Kant's thought is indeed congenial to the scientific perspective on the normality of the death of a person, conceived as an actor whose coming into existence is in symbiosis with a growing individual organism and whose individual personality, while continuing into a new generation in the same sociocultural system, can be understood to die in symbiosis with the same organism. Nonetheless, if Kant was right in refusing to collapse the boundaries of the human condition into the one vis-à-vis the physical world, the meaning of human individual death can no more be exhausted by that of the involvement of the human individual in a sociocultural system of more comprehensive temporal duration than can the meaning of our sensory experience of empirical reality be exhausted by the impressions emanating from that external world, or even the theoretical ordering of those impressions.

If Kant's fundamental position is accepted, then his skepticism about absolutes must apply to both sides of the fundamental dichotomy. Modern biology certainly must be classed as knowledge of the empirical world in his sense, and the same is true of our scientific knowledge of human action. In his famous terminology, there is no demonstrable knowledge of the thing in itself in any scientific field.

In empirical terms organic death is completely normal. We have, and according to Kant we presumably can have, no knowledge of the survival of any organic entity after death, except through the processes of organic reproduction that enable the genetic heritage to survive. Kant, however, would equally deny that such survival can be excluded on empirical grounds. This has an obvious bearing on the Christian doctrine of the resurrection of the body. If that is meant in a literal biological sense (though this is by no means universally the way in which Christians understand it), then the inference is clearly that it can never be proved, but it can still be speculated about and can be a matter of faith, even though it cannot be the object of either philosophical or scientific demonstration.

The same seems to hold for the personality-action component of the human individual. Empirically, the action sciences can account for its coming-to-be and its demise without postulating its survival. But they cannot exclude the possibility of such survival. Thus the eternal life of the individual soul, although metaphysically unknowable, can, like resurrected bodies, be speculated about and believed in as a matter of faith.

Thus, included in the victims of Kant's skepticism or relativization is belief in the cognitive necessity of belief in the survival of human individuality after death as well as belief in the cognitive necessity of belief in the nonsurvival of human individuality after death. Kant's relativization of our knowledge, both empirical and metaphysical, both closed and opened doors. It did, of course, undermine the traditional specificities of received beliefs; but at the same time,

and for the very same reason, it opened the door, by contrast to scientific materialism, not merely to one alternative to received Christian belief but to a multiplicity of them.

This leaves us with the position that the problem of the meaning of death in the Western tradition has, from a position of relative closure defined by the Christian syndrome, been "opened up" in its recent phase. There is above all a new freedom for individuals and sociocultural movements to try their hands at innovative definitions and conceptions. At the same time, the viability of their innovations is subject to the constraints of the human condition, both empirical and transcendental, noted by Kant.

The grounding of this door-opening process lies in Kant's conception of freedom as the central feature of what he called "practical reason." In essence, the human will, as he called it, can no more be bound by a set of metaphysical dogmas than a person's active intellect can be bound by alleged inherent necessities of the empirical, relevant *Ding an sich.* This doctrine of freedom, among other things, opens the door to Western receptivity to other, notably Oriental, religious traditions. Thus, Buddhist tradition, on the whole by contrast with Christian, stresses not individuality except for this terrestrial life but, rather, the desirability of absorption, after death, into an impersonal, eternal matrix (as opposed to a personal eternal life). The recent vogue of Oriental religion in Western circles suggests that this possibility has become meaningful in the West.

The problem of the meaning of death in the West is now in what must appear to many to be a strangely unsatisfactory state. It seems to come down to the proposition that the meaning of death is that, in the human condition, it cannot have any "apodictically certain" meaning without abridgment of the essential human freedom of thought, experience, and imagination. Within limits, its meaning, as it is thought about, experienced for the case of others, and anticipated for oneself, must be autonomously interpreted. But this is not pure negativism or nihilism, because such openness is not the same as declaring death, and of course with it individual life, to be meaningless.

Conclusion

So far as Western society is concerned, I think the tolerability of this relatively open definition of the situation is associated with the activistic strain in our values, the attitude that human life is a challenging undertaking that in some respects may be treated as an adventure—by contrast with a view that treats human life as a matter of passively enduring an externally imposed fate. Even though Western religion has sometimes stressed humanity's extreme dependency on God, and indeed the sinfulness of asserting independence, on the whole the activistic strain has been dominant. If this is the case, it seems that humans can face their deaths and those of others in the spirit that whatever this unknown future may portend, they can enter upon it with good courage.

Insofar as it is accessible to cognitive understanding at all, the problem of the meaning of death for individual human beings must be approached in the framework of the human condition as a whole. It must include both the relevant scientific understanding and understanding at philosophical levels, and must attempt to synthesize them. Finally it must, as clearly as possible, recognize and take account of the limits of both our scientific and our philosophical understanding.

We have contended that the development of modern science has so changed the picture as to require revision of many of the received features of Christian tradition, both Catholic and Protestant. This emergence of science took place in three great stages marked by the synthesis of physical science in the seventeenth century, that of biological science in the nineteenth, and that of the action sciences in the nineteenth to twentieth.

The most important generalizations seem to be the following. First, the human individual constitutes a unique symbiotic synthesis of two main components, a living organism and a living personality. Second, both components seem to be inherently limited in duration of life, and we have no knowledge that indicates their symbiosis can be in any radical sense dissociated. Third, the individualized entity is embedded in, and derives in some sense from, a transgenerational matrix that, seen in relation to individual mortality, has indefinite but not infinite durability.

From this point of view, death, or the limited temporal duration of the individual life course, must be regarded as one of the facts of life that is as inexorable as the need to eat and breathe in order to live. In this sense, death is completely normal, to the point that its denial must be regarded as pathological. Moreover, this normality includes the consideration that, from an evolutionary point of view, which we have contended is basic to all modern science, death must be regarded as having high survival value, organically at least to the species, actionwise to the future of the sociocultural system. These scientific considerations are not trivial, or conventional, or culture-bound but are fundamental.

There is a parallel set of considerations on the philosophical side. For purposes of elucidating this aspect of the problem complex, I have used Kant's framework as presented in his three critiques. On the one hand, this orientation is critical in that it challenges the contention that absolute knowledge is demonstrable in any of the three aspects of human condition. Thus, any conception like that

of the ontological essence of nature, the idea of God, or the notion of the eternal life of the human soul is categorized as *Ding an sich,* which in principle is not demonstrable by rational cognitive procedures.

At the same time, Kant insisted, and I follow him here, on the cognitive necessity of assuming a transcendental component, a set of categories in each of the three realms, that is not reducible to the status of humanly available inputs from either the empirical or the absolute telic references of the human condition. We have interpreted this to mean that human orientation must be relativized to the human condition, not treated as dogmatically fixed in the nature of things.

The consequence of this relativization that we have particularly emphasized is that it creates a new openness for orientations, which humans are free to exploit by speculation and to commit themselves in faith, but with reference to which they cannot claim what Kant called apodictic certainty.

If the account provided in the preceding sections is a correct appraisal of the situation in the Western world today, it is not surprising that there is a great deal of bafflement, anxiety, and downright confusion in contemporary attitudes and opinions in this area. Any consensus about the meaning of death in the Western world today seems far off, although the attitude reflected in this entry would seem to be the one most firmly established at philosophical levels and the level of rather abstract scientific theory.

A very brief discussion of three empirical points may help to mitigate the impression of extreme abstractness. First, though scientific evidence has established the fact of the inevitability of death with increasing clarity, this does not mean that the experience of death by human populations may not change with changing circumstances. Thus, we may distinguish between inevitable death and "adventitious" death, that is, deaths that are premature relative to the full lifespan, and in principle preventable by human action (Parsons and Lidz). Since about 1840, this latter category of deaths has decreased enormously. The proportion of persons in modern populations over sixty-five has thus increased greatly, as has the expectancy of life at birth. This clearly means that a greatly increased proportion of modern humans approximate to living out a full life course, rather than dying prematurely. Individuals living to "a ripe old age" will have experienced an inevitably larger number of deaths of persons who were important to them. These will be in decreasing number the deaths of persons younger than themselves, notably their own children, and increasingly deaths of their parents and whole ranges of persons of an older generation, such as teachers, senior occupational associates, and many public figures. Quite clearly these demographic changes will have a strong effect on the balance of experience and expectations, of the deaths of significant others, and of anticipation of one's own death.

Second, one of the centrally important aspects of a process of change in orientation of the sort described should be the appearance of signs of the differentiation of attitudes and conceptions with regard to the meaning of the life cycle. There has already been such a process of differentiation, apparently not yet completed, with respect to both ends of the life cycle (Parsons, Fox, and Lidz). With respect to the beginning, of course, this centers on the controversy over the legitimacy of abortion and the beginning of life. And concomitant with this controversy has been an attempt at redefinition of death. So far the most important movement has been to draw a line within the organic sector between what has been called brain death, where irreversible changes have taken place, destroying the functioning of the central nervous system, and what has been called metabolic death, where, above all, the functions of heartbeat and respiration have ceased. The problem has been highlighted by the capacity of artificial measures to keep a person alive for long periods after the irreversible cessation of brain function. The main point of interest here is the connection of brain function with the personality level of individuality. An organism that continues to live at only the metabolic level may be said to be dead as an actor or person.

Third, and finally, a few remarks about the significance for our problem of Freud's most mature theoretical statement need to be made. It was printed in the monograph published in English under the title *The Problem of Anxiety.* In this, his last major theoretical work, Freud rather drastically revised his previous views about the nature of anxiety. He focused on the expectation of the loss of an "object." For Freud the relevant meaning of the term "object" was a human individual standing in an emotionally significant relation to the person of reference. To the growing child, of course, the parents became "lost objects" in the nature of the process of growing up, in that their significance for the growing child was inevitably "lost" at later ages. The ultimate loss of a concrete human person as object—of cathexis, Freud said—is the death of that person. To have "grown away" from one's parents is one thing, but to experience their actual deaths is another. Freud's account of the impact on him of the death of his father is a particularly relevant case in point.

Equally clearly, an individual's own death, in anticipation, can be subsumed under the category of object loss, particularly in view of Freud's theory of narcissism, by which he meant the individual's cathexis of his or her own self as a love object. Anxiety, however, is not the actual experience of object loss, nor is it, according to Freud, the fear of it. It is an anticipatory orientation in which the actor's own emotional

security is particularly involved. It is a field of rather free play of fantasy as to what might be the consequences of an anticipated or merely possible event.

Given the hypothesis that, in our scientifically oriented civilization, there is widespread acceptance of death—meant as the antithesis of its denial—there is no reason why this should lead to a cessation or even substantial diminution of anxiety about death, both that of others and one's own. Indeed, in certain circumstances the levels of anxiety may be expected to increase rather than the reverse. The frequent assertions that our society is characterized by pervasive denial of death may often be interpreted as calling attention to pervasive anxieties about death, which is not the same thing. There can be no doubt that in most cases death is, in experience and in anticipation, a traumatic event. Fantasies, in such circumstances, are often characterized by strains of unrealism, but the prevalence of such phenomena does not constitute a distortion of the basic cultural framework within which we moderns orient ourselves to the meaning of death.

Indeed, the preceding illustrations serve to enhance the importance of clarification, at the theoretical and philosophical levels, to which the bulk of this entry has been devoted. This is essential if an intelligible approach is to be made to the understanding of such problems as shifts in attitudes toward various age groups in modern society, particularly the older groups, and the relatively sudden eruption of dissatisfaction with the traditional modes of conceptualizing the beginning and the termination of a human life, and with allegations about the pervasive denial of death, which is often interpreted as a kind of failure of "intestinal fortitude." However important the recent movements for increasing expression of emotional interests and the like, ours remains a culture to which its cognitive framework is of paramount significance.

POSTSCRIPT

Talcott Parsons's entry "Death in the Western World" addresses the changing and conflicting orientations toward death in contemporary culture. Parsons sought to connect these orientations to broad cultural frameworks that have shaped Western civilization over hundreds of years. His effort was an extension of his previous writings on American orientations toward death and on more general patterns of Western civilization (Parsons and Lidz; Parsons; Parsons, Fox, and Lidz).

In the 1960s and 1970s, a number of authors argued that Americans "deny" death in a defensive manner (Mitford; Becker). They cited particular funeral and mourning customs as evidence, especially the preparing of remains to appear lifelike and peaceful for ritual viewing and the expectation that formal mourning need divert the family of a deceased person from other social obligations for only a brief time. Parsons, however, perceived that if there were a generalized denial of death, it would conflict with the pragmatic realism rooted in American culture since Puritan times.

Instrumental Activism

Parsons drew on German sociologist Max Weber's (1864–1920) characterization of the Puritan religious ethic as an "inner-worldly asceticism" that sought to engage the harsher realities of life to transform them into elements of the "kingdom of God on earth" (Weber, 1930). While agreeing with Weber's analysis, he preferred the term *instrumental activism* to characterize the basic values and worldview of American society. This term underscored that American civilization had secularized the Puritan emphasis on mastery over the given conditions of life and made it the ethical basis for a wide range of worldly social institutions. Thus, secular variants of the mastery ethic now guide the formation of institutions in science and technology, formally rational law and bureaucracy, the market system and entrepreneurship, and motives of personal self-discipline and improvement (Parsons). Highlighting consistency with this basic cultural theme, Parsons found not "denial" of death but mastery over its disrupting effects on personal and social life.

While death is inevitable, its social impact is meliorable. Parsons explored two respects in which this is true (Parsons and Lidz; Parsons, Fox, and Lidz). First, medical and public health technologies have reduced premature death and now typically enable members of society to use "God-given" talents to advance their vocations in good health over long lives. The demographic changes of the late nineteenth and twentieth centuries, and related efficiencies in the use of human talents, thus flowed from an effort to master death. Second, when individuals die, the resulting experiences of social loss can be controlled. Measures ranging from life insurance to retirement planning in business to estate planning in personal affairs to psychotherapy for grief and loss reduce harms ensuing from death (Zelizer, 1983). Similarly, American mourning customs emphasize austerely supporting the bereaved in overcoming grief and guilt, so they are able to return to their routine social obligations without long delay.

Parsons recognized that, despite sharing the values of "instrumental activism," Americans disagree over many matters related to death. Abortion, capital punishment, licensing of firearms, euthanasia, medical care for the terminally ill, and organ transplantation, for example, were matters of public controversy when Parsons wrote and remain so today. "Death in the Western World" attempts to explain why this particular domain of contemporary culture has been chronically ridden with controversy. Parsons sought an answer in the rationalism of the Enlightenment, focusing on its synthesis in the philosophy of Immanuel Kant (1724–1804).

Secular Rationalism

Kant epitomized the Enlightenment's elevation of Reason as a force of human betterment and a method of transforming culture (Cassirer). Ever since the Enlightenment, Reason has provided a principle for critique of traditional culture, social institutions, and customary practices. Over time, critique of the traditional has gradually given way to the articulation of new principles of legitimacy. Since the eighteenth century,

the appeal to Reason has given rise to a secular moral culture as the primary ground of legitimation for the major institutional frameworks of modern society—for the institutional complexes that Weber characterized as having "rational-legal" legitimation (Weber, 1968; Lidz, 1979a, 1979b). Parsons epitomized this long and complex process of cultural change by focusing on Kant's writings and their long-term impact on the creation of new intellectual disciplines and moral-political ideologies.

In Parsons's view, Kant's critique of Newtonian physics became a model for assessing the intellectual legitimacy of new disciplines. It led to the opening of the domain of methodically developed and evaluated knowledge to new forms. Thus, from Kant's time to ours, there has been continuous growth in specialized scientific and scholarly disciplines. Kant's critiques of the human faculties of judgment and practical reason proved no less important, as they legitimated the voice of moral Reason and, as Parsons emphasized, undercut all claims to ultimate moral certainty. Ever since, Western civilization has been engulfed in ever-renewed moral and ideological controversies on almost every topic of social import. As Parsons expected, orientations toward death, given their irreducible significance to humanity, have been caught up in a range of the controversies.

Varying Worldviews

Across the Western world, one observes considerable variation in the adoption of principles of instrumental activism and secular rationalism. Parsons concentrated on a predominant American pattern, but one that many parts of Western civilization, including important groups in American society, have adopted only with qualifications. Catholic societies have generally shown more attachment to tradition, to historical continuity, and to sustaining community structures, and thus less activism in transforming traditional institutions and less individualism. Lutheran societies have given more emphasis to the inner moral cultivation of the individual and less to mastery of the outer world. Fundamentalist Protestantism has been less accepting of secular rationalism and has tended to maintain the emphasis of the Reformation on immediate mastery of morally problematic situations. Anglo-American versions of Enlightenment rationalism have been profoundly individualistic, while French rationalism has been more collectivistic, and German rationalism more focused on transcendental frames of judgment (Mead). In an article published in 2002, Hans Joas criticized Parsons's treatment of the gift of life as a basis of religious ethics in Western Christianity for having overlooked the continuing variation in worldviews. One may add that the variation in outlooks contributes importantly to contemporary controversies, sustaining the disagreements and adding to the anxiety over difficulties in resolving them.

Parsons's emphasis on Enlightenment rationalism as a foundation of modern intellectual disciplines and public moral discourse helps one to understand the nature of contemporary bioethics. Research on the history of bioethics shows that the field has emerged in the mold of an academic specialty that, although interdisciplinary, is dominated by philosophers (Messikomer, Fox, and Swazey). Philosophers trained in the field of ethics have successfully asserted the centrality of their expertise for resolving bioethical issues. Although the relevance of issues of life, death, illness, suffering, incapacity, and worry would seem to create a large role for theologians and religious philosophers in the field of bioethics, they have in fact been marginalized by the prestige of academic philosophy (Messikomer, Fox, and Swazey). Moreover, given the extent to which key innovations in biomedicine have been concentrated in the United States and that the issues created by such innovations have been suffused with the problematics of American moral discourse, the individualism and positivism of Anglo-American philosophy has predominated in bioethics internationally. This process has been further supported by the strategic role that American governmental regulations have assumed in the international structures of biomedical research, in particular regarding clinical trials for new medications and medical devices.

Recent Evolution of Cultural Conflicts

Although Parsons expected death-related matters to remain controversial, he could not foresee the recent evolution of cultural conflicts. The intense social criticism of funeral and mourning customs has subsided, though practices have changed little. How "life" and "living being" should be defined before birth and at the approach of death remain effervescent issues. Public debates over abortion not only have persisted but have grown in intensity, bitterness, and political importance. Issues of end-of-life care and the use of extreme measures to maintain life continue to figure in public discussion, often in connection with legal cases. Procedures once viewed as extreme, such as kidney, liver, and heart transplants, have become routine at many medical centers, but discussion continues around such issues as who should be treated—for example, whether persons with alcohol dependence should receive new livers or smokers new lungs, or whether HIV-positive patients qualify for organ transplants. The public attends with ever greater interest to advances in medicine, with new findings and procedures

featured routinely on television and in newspapers. Coverage of heroic lifesaving procedures in particular resonates deeply in American moral culture, dramatizing shared beliefs in the unique value of each life. Themes of self-improvement pervade reports on the health food, antismoking, physical exercise, environmental, and even animal-rights movements.

Despite impressive institutions to master death, contemporary civilization remains acutely insecure over life (Fox and Swazey). The mass media's increasing attention to medicine, and especially to life-threatening conditions, has left the public less secure about health and more readily made anxious over environmental threats and even endemic conditions. The intensity of public fears over apparent "hot spots" of breast cancer in particular communities, over risks of anthrax infection following "terroristic" mailings of a small number of letters containing anthrax spores in the autumn of 2001, and over small risks of West Nile virus in the summer of 2002 are instances. In the context of anxiety over health, matters of personal habit and lifestyle, including diet, exercise, work schedules, and even sexual practices, are adjusted by many whenever new knowledge suggests possible effects on well-being or longevity. Parsons would have viewed such changes in personal habits as efforts to extend mastery over the conditions of life, including death.

In attending patients with highly cultivated medical insecurities, physicians have a limited fund of trust to draw upon, a situation that promotes the practice of "defensive medicine." When the lives of patients are genuinely at risk, pressures build to use the most advanced technologies and extreme measures to show that everything possible is being attempted. This is sometimes the case even when the chances of success are small and when the quality of the lives that may be extended will be quite limited. These tendencies persist while the public also worries over the rising aggregate costs of medical care and health insurance.

In the context of post-Enlightenment secular beliefs about human rights, Western societies have generally established a right of citizens to receive medical care. Different institutions have been established to secure this right, including government single-payer, publicly subsidized private, employer-paid, and combined health insurance systems. The United States stands out among Western nations for not having established universal healthcare or health insurance, although Medicare for the elderly and Medicaid for the poor cover many economically vulnerable citizens.

From the mid-1990s, U.S. national policy has engaged the issue of further democratization of access to medical care. The public has become aware that large sectors of the population lack medical insurance and, hence, access to healthcare independent of personal ability to pay for it. Although the desirability of providing better care to citizens of modest means and the poor is generally accepted, proposals about how to manage the costs while protecting the freedom of doctor–patient relationships are controversial. Proposals that appear to restrict the freedom of relationships between patients and practitioners, whether rights of patients to select their practitioners or the rights of practitioners to treat patients as they believe correct, are widely opposed. Moreover, new plans for cost containment have not directly confronted public sentiments favoring use of "heroic measures" and experimental procedures regardless of cost—sentiments that become especially forceful when physicians and family members face a patient's impending death. Eventual policy remains uncertain, but a system of national health insurance would extend "instrumental activism" in medicine by offering more secure protection from illness, suffering, and death for less affluent citizens.

Shaken Optimism about Modern Medicine

Parsons believed, along with many scientists in the 1960s and 1970s, that modern medicine verged on conquering all major infectious diseases, at least for societies with effective systems of sanitation and public health. The appearance in the 1980s of the human immunodeficiency virus (HIV) and acquired immunodeficiency syndrome (AIDS) has shaken such optimism. It has now become clear that humankind faces a major pandemic that, despite modern science and technology, will take scores of millions of lives globally (WHO). Twenty years of research has failed to produce an effective vaccine. New antiretroviral medications are extending the life and health of many patients with HIV/AIDS, but not all patients are helped, and how long the others will benefit remains unclear (IAPAC). In the meantime, many patients do not receive the new treatments because they have not been diagnosed, are not willing to face the consequences of an HIV/AIDS diagnosis, lack access to care or means of paying for treatment, or do not trust medical institutions to help them (Klitzman).

The costs of the new medications for HIV/AIDS are prohibitively high for most of the populations in non-Western nations, and an active controversy in the early 2000s concerned ways of making them available at reduced cost in African, Asian, and Latin American societies. Until there is an effective vaccine or a less expensive cure, prevention programs must play a prominent role in overall HIV/AIDS policy. In the United States, prevention programming still faces challenges in communicating effectively with sectors of the population most seriously at risk, in part because of political constraints on frank communication

with adolescents and young adults regarding sexual practices and condom use and on laws affecting availability of sterile injection paraphernalia.

Western nations have had the public health resources to stabilize rates of HIV infections at low or moderate levels. According to World Health Organization (WHO) data from 2002, Thailand and Uganda had managed to reduce formerly high rates of infection. In a number of nations in sub-Saharan Africa, however, the continued rapid spread of HIV, as of 2003 affecting more than 28.5 million people, in some countries over 30 percent of adults in their reproductive years, is radically changing demographic structures and life-cycle patterns. In Parsons's terms, a major feature of the epidemic is that it afflicts mainly youths, young adults, and people in early middle age. People who become diseased and die are losing their most productive years. Their deaths represent unfulfilled lives, with future achievements, relationships, and experiences all lost. The economic impact on whole regions and nations is becoming immense, as is the burden of caring for children whose parents have died. WHO reported in 2002 that India, China, Burma, Indonesia, and perhaps Russia also had rapidly growing epidemics and were at risk of experiencing similar effects on regional if not national bases.

In Western societies, where HIV infection is concentrated in homosexual men, injection drug users, and, increasingly, women sex partners of injection drug users and of men who have sex with men (CDC), its transmission has often involved stigmatized behavior. HIV, with the ugly image of a wasting, disfiguring, and dementing disease, has added vastly to the burdens of prior stigmas. Many people with HIV disease have experienced intense feelings of guilt, shame, and self-blame as an added dimension of their suffering (Klitzman). Moreover, many have experienced great loss. In social circles where HIV has become common, many individuals still in early adulthood have lost many friends and associates, an otherwise rare experience in modern societies, given the generally thorough control of death before old age. Many are burdened by the "survivors' guilt" typical of people who live through disasters that have claimed the lives of many others (Erikson). They often find that any attempt at a spirited resumption of everyday activities is complicated by feelings that their futures are hopeless or meaningless without the individuals who have been lost. People not infected but aware of being at risk of infection may feel that they will inevitably become diseased—even that they are already "dead," although still walking around. Efforts to change personal conduct in order to avoid exposure to HIV may be complicated by beliefs that it is impossible to stay well or that it would be better to accompany friends in heroic suffering and death (Weitz). In some Western communities and in African and Asian nations, lassitude engendered by the HIV epidemic, through social loss, fear of death, and guilt, is causing immense social dislocation and will likely cause more in the future.

Conclusion

Parsons's entry highlighted the distinctive pattern of Western institutions relating to death. In comparative perspective, Parsons argued, the modern West has uniquely endeavored to "master" death. Such mastery has involved a range of institutions, including scientific medicine and public health services designed to protect life; insurance, retirement, and estate planning to manage the practical consequences of deaths; and mourning customs that emphasize recovery of survivors' abilities to perform ordinary social roles soon after the death of family members, friends, and associates. Some elements of these institutions remain closely tied to the "instrumental activism" of Western cultural values, while other elements, such as the techniques of scientific medicine or the actuarial tables and formulas of the insurance industry, have transcultural validity now that they have been developed. A matter for future investigation concerns the ways in which these universal elements will be institutionalized in sociocultural settings where they may be disconnected from Western value orientations. Scientific medicine is now practiced almost the world over, but in some non-Western societies it is generally reserved for patients from elite status groups, combined with traditional healing in ways that create different doctor and patient roles, or may be linked to personal relationships of political patronage (Kleinman; Scheper-Hughes). In these settings, the bioethical cultures that emerge in the future may prove to be very different from Western frameworks of the past several decades, not least because they will rest on different value orientations toward life and death. Comparative study of bioethical cultures may become a powerful way of building on, correcting, and refining the analysis developed by Parsons in his writings on Western orientations toward death.

VI. PROFESSIONAL EDUCATION

Palliative care represents a new health professional discipline in the United States focused on the care of seriously ill and dying patients, although not necessarily just for patients at the end of their lives. There is widespread agreement that all facets of the end-of-life experience have been neglected in health professional education, including, but not limited to, pain and symptom management, communication skills, ethics, personal awareness and hospice care. Educational initiatives have emerged, especially within medicine and nursing, to address these deficiencies. This discussion will focus primarily on physician education within palliative care, although the discussion is directly applicable to other health professions.

Requirements for End-of-Life Physician Education in the United States

Until recently, few medical schools offered comprehensive training in end-of-life care. The training that existed was largely elective, in lecture format, and with limited patient contact. Although some U.S. medical schools developed dedicated palliative care courses or comprehensive curricula, this was the exception until very recently. The Liaison Committee on Medical Education (LCME), the accrediting authority for United States medical schools, mandated in 2000 that all medical schools provide instruction in end of life care, which may improve the situation.

Graduate physician education requirements for end-of-life training are also highly variable. Since 1997 the oversight educational committees for Geriatrics, Family Medicine, Internal Medicine, Neurology, General Surgery and Hematology/Oncology have added requirements for end-of-life

training. In the realm of testing, the National Board of Medical Examiners started work in 1999 to review, re-write and expand end-of-life content on test questions administered to all medical students and interns.

Although there is no national requirement for physicians already in practice to attend continuing education courses in end-of-life care, the American Medical Association (AMA) has encouraged all its member physicians to participate in *Education for Physicians on End-of-life Care* (EPEC), a comprehensive training program. In addition, starting in 2000, the state of California began requiring that all applicants for a medical license successfully complete a medical curriculum that provides instruction in pain management and end-of-life care. As with the LCME requirement for medical schools, the exact criteria to determine what constitutes end of life instruction have not been defined.

Curriculum Guides for End-of-Life Physician Education

Several groups have worked to define the components of a comprehensive end-of-life and palliative care curriculum. Curriculum guidelines have been developed for Canadian medical schools and separate guidelines exist for medical student training in Great Britain and Ireland. Palliative care teaching objectives for U.S. physicians were first published in 1994. In 1997, a national consensus conference on U.S. undergraduate and graduate education was held, outlining curriculum features and opportunities for education across different educational venues (e.g. ambulatory care, inpatient care). Although each venue presented somewhat different aspects of end-of-life care education, there is broad similarity on the major educational domains (see Table 1). Finally, a consensus document was developed by participants from eleven U.S. medical schools working on an end of life curriculum project. This document outlines goals and objectives for medical student education along with a discussion of potential student assessment measures and curriculum implementation strategies.

The American Academy of Hospice and Palliative Medicine (AAHPM) developed a curriculum designed for medical educators and practicing physicians. This curriculum includes twenty-two modules, each containing a listing of learning objectives and core content for key domains in symptom control, communication, hospice care, and ethics. The AAHPM curriculum was originally designed for physicians working as hospice medical directors, but can easily be adapted for other levels of physician education. The EPEC project, designed for physicians in practice, contains a comprehensive palliative care curriculum including pain and symptom control, communication skills, ethics, and legal aspects of care. The most recent curriculum for medical oncologists and oncology trainees, developed in 2001 by the American Society of Clinical Oncology, includes twenty-nine modules covering symptom control, communication skills, and related aspects of palliative care. Curriculum standards for palliative care fellowships have been proposed by the American Board of Hospice and Palliative Medicine and the AAHPM. An extensive listing of peer-reviewed educational tools, curriculum guides, reference articles, and palliative care links are available at the End-of-Life Education Resource Center.

TABLE 1

Domains and Locations for Palliative Care Physician Education

Educational Domains

- Pain assessment and treatment
- Non-pain symptom assessment and treatment
- Ethical principles and legal aspects of end-of-life care
- Communication skills; Personal reflection
- Psychosocial Aspects of Death and Dying:
  - Death as a life-cycle event
  - Psychological aspects of care for patient/family
  - Cultural and spiritual aspects of end-of-life care
  - Suffering/Hope
  - Patient/family counseling skills
- Working as part of an interdisciplinary team

Care Locations

- Hospital
- Hospice/ Palliative Care Consultation Service or Inpatient Unit
- Outpatient Clinic
- Home
- Residential Hospice
- Long-term care facility

SOURCE: Author.

In parallel to physician education, the nursing profession has been working to develop curriculum guidelines and materials for nursing education. Palliative care education content has been reviewed in nursing textbooks and two educational products have been developed for nursing education, *ELNEC* (end-of-life nursing education consortium) and *TNEEL* (the toolkit for nursing excellence at end-of-life transitions) (Ferrell et al.). In addition, a national consortium of nursing groups has come together to plan for institutional changes in nursing education and practice surrounding palliative care (Palliative Care).

Planning an End of Life Education Program

The first step in the design of any educational intervention is to conduct a needs assessment, to understand the gap between what is being taught and evaluated and the ideal. A

variety of multidimensional palliative care needs assessments have been reported for different populations of learners.

Once the needs assessment has defined important domains for focused education, specific learning objectives can be developed. Objectives communicate to the learner what is expected of the educational encounter and form the basis for evaluating the impact of training. Learning objectives are broadly defined as those directed at attitudes, knowledge or skills. Given the pervasive and often negative attitudes, which shape caring for the dying, it is advisable to include a mixture of attitude, knowledge, and skill objectives in all training experiences. Thus, it is also desirable to include a mixture of teaching methods in each educational exercise. Addressing attitudes tends to be the most challenging feature of end-of-life education. It is a truism of medical education that attitudes can not be taught. Rather, a shift in attitudes requires the learner to feel safe and respected enough to give up one attitude (e.g. I am afraid to use opioids for fear of causing addiction) for another (e.g. opioids rarely lead to addiction, they are safe and improve quality of life). Providing information to address knowledge objectives can be done via lectures, self-study guides, journal articles, videotapes and audiotapes. Teaching directed at skill objectives requires the learner to practice and demonstrate a defined skill such as patient counseling, calculating equianalgesic doses or pronouncing death.

As with teaching methods, different assessment methods work best when appropriately matched to the learning objective. Attitudes are best assessed through personal interactions, directed questioning and surveys. Knowledge can be assessed via oral or written examinations and skills through direct observation, feedback from patients, or written problem solving (e.g. calculating opioid equianalgesic doses).

Awareness of adult learning principles is essential when developing an end-of-life educational encounter. These include keeping the experience *learner-centered,* with relevant information keyed to the learners *need to know,* and understanding that adult learners make choices about their participation (e.g. they leave the room if the information is not relevant to their needs).

Educational Issues for Specific End-of-Life Domains

PAIN EDUCATION. Pain must be controlled before physicians can assist patients with the myriad of physical, psychological, and spiritual problems at end-of-life. Yet, physicians frequently fail to apply accepted standards of care for acute or chronic pain management. Moreover, it is clear that despite a multitude of clinical guidelines, position papers, workshops, lectures, grand rounds, journal articles, and book chapters written about pain management, clinical practice is still far from ideal.

The primary reason that conventional education formats fail to translate into a change in clinical practice is that physicians harbor a host of attitudes about pain and pain management that inhibit the appropriate application of knowledge and skills. These attitudes fall into two broad categories. First are physician attitudes about pain that reflect societal views about the meaning of pain and pain treatment. Second are the fears and myths about opioid analgesics. These include fears of addiction, respiratory depression, and regulatory scrutiny, along with the secondary consequences of these fears—malpractice claims, professional sanctions, loss of practice privileges, and personal guilt about potential culpability for causing death.

In addition to attitudes, deficits in pain knowledge and skills are widespread. These include how to conduct a pain assessment, clinical pharmacology of analgesic medications, use of non-drug treatments, and skills in patient education and counseling. Educational techniques and results from various pain education programs have been reported; key findings from these include the following principles: pain education must include attention to attitudinal issues along with knowledge and skills; pain education must be longitudinal across all years of medical training; and pain education must be coupled to other elements of institutional change, such as quality monitoring, team building with non-physicians, development of routine assessment, and documentation and analgesic standards development.

ETHICS, LAW AND COMMUNICATION SKILLS EDUCATION. There is considerable content overlap between ethics and communication skills. For example, to effectively care for patients, trainees need to understand both the ethical and legal framework of advance directives *and* the communication skills necessary to discuss these with patients. Similarly, trainees need to understand the ethical and legal background to make decisions about treatment withdrawal *and* to acquire the skills to discuss these issues with patients and families.

There is a rich literature on educational methods and outcomes in ethics and communication skills education. Although ethics is generally considered a preclinical course in medical school, it is advisable that training in ethics be incorporated throughout medical school, residency, and fellowship training. As the level of professional responsibility increases with each year of training, such responsibility imposes demands on the trainee to make increasingly complex and ethically challenging decisions. Such decisions

often strain the trainee's personal understanding of professionalism and altruism and thus merit dedicated time for self-reflection and mentoring. Although both ethics and communication skill training require attention to attitudes and knowledge deficits, communication skill training requires special and dedicated attention to the acquisition and demonstration of specific skills. Notably, trainees must be able to demonstrate their ability to give bad news and discuss treatment goals, treatment withdrawal, and issues surrounding hospice and palliative care empathetically and professionally.

CLINICAL TRAINING EXPERIENCES. Hospital-based palliative care teams are a valuable venue for clinical education in end-of-life care. Trainees, both physicians and nurses, can learn how to work within a multidisciplinary group and experience a collaborative process with the educational focus enlarged to include the physical, psychological, social, and spiritual dimensions of care. Since 1992 many medical schools and residency programs have established successful clinical experiences in hospice and palliative care at acute care hospitals, hospice residence facilities, and at home.

PERSONAL AWARENESS TRAINING. Very few health professionals have had formal training in how to deal with the emotions that arise when caring for patients with progressive fatal illness. Undergraduate course, residency, and fellowship directors have a number of options that can help trainees gain the needed personal awareness including support groups, family of origin group discussions, meaningful experiences discussion, personal awareness groups, literature in medicine discussion groups, and psychosocial morbidity and mortality conferences.

Future Directions

One important avenue to improve of end of life care is through health professional education. Much progress has been made since the early 1990s in defining curriculum content and establishing standards for education for medical students and primary care residencies. The most recent development in end of life education is the focus on training existing academic faculty and fellows in palliative care. Faculty development is needed if the established goals and standards in undergraduate and graduate palliative care education are to be met. Several courses have been developed in the United States, with the explicit goal of training academic faculty to become role models for end-of-life education. Fellowship training in palliative care is needed to prepare medical trainees for community or academic careers focused on care of the seriously ill and dying. In 2003 there are approximately twenty-five fellowship programs in the United States.

DEATH, DEFINITION AND DETERMINATION OF

• • •

I. CRITERIA FOR DEATH

Before the middle of the twentieth century there was no major dispute about the criteria for death. In the nineteenth century several isolated cases of premature burial from around the world raised some alarm, and safeguards (e.g., coffins equipped with alarms) were established to minimize the possibility of that practice. However, concern about the accuracy of diagnosing death largely abated by the turn of the twentieth century.

Beginning with the advent of more effective artificial respirators in the 1940s, major technological breakthroughs in modern medicine raised serious questions about the traditional ways of diagnosing death. Before the widespread use of respirators, defibrillators, intensive-care units, and cardiopulmonary resuscitation failures of cardiac, respiratory, and neurological functions were closely linked. When one system failed, the other two inevitably failed as well. However, respirators and other advanced life-support systems can sustain cardiac, respiratory, and other autonomic functions for prolonged periods even after neurological functions have ceased.

Terminology

With the advent of those new technologies neurological specialists became aware of certain new neurological syndromes, to which an array of confusing and inconsistent terms were applied.

Several landmark medical events stand out in the early days of the new neurologic syndromes. In 1959 the French first described the syndrome of brain death (*coma dépassé*) (Mollaret and Coulon), in 1968 a special committee of the Harvard Medical School formulated specific neurological criteria to diagnose brain death ("Definition of Irreversible Coma"), and in 1972 Bryan Jennett of Scotland and Fred Plum of the United States first used the term *persistent vegetative state,* or PVS (Jennett and Plum).

A variety of terms have been used to describe the medical syndrome of brain death: *cerebral death, coma dépassé,* and *irreversible coma.* Terms used as imprecise equivalents for the persistent vegetative state have included *apallic state, neocortical death, irreversible coma,* and *permanent unconsciousness* It also became necessary to distinguish the new neurological syndromes from common and well-accepted neurological conditions such as coma and dementia. Many newer terms, for example, *persistent vegetative state,* were used solely to describe the clinical condition. Others, such as the *apallic state* and *neocortical death,* were used in an attempt to correlate the loss of neurological functions with the underlying pathological changes in the brain.

As of 1994 there were two different legal/philosophical positions about what it means to be dead in terms of brain functions. Proponents of the whole-brain-oriented position consider a person dead if there is an irreversible loss of all the functions of the entire brain (brain death). Under the other position, which is not law in any jurisdiction in 2003, a person will be pronounced dead when there is an irreversible loss of higher brain functions (permanent unconsciousness).

Dilemmas surrounding these new syndromes, such as when it is appropriate to stop treatment and when death has occurred, have raised fundamental questions about the meaning of medical concepts such as consciousness, awareness, self-awareness, voluntary interactions with the environment, purposeful movement, pain, and psychological and physical suffering.

Neurological specialists are achieving a much greater understanding of these syndromes and their similarities and differences and are reaching a degree of consensus on terminology. However, they have not reached universal

agreement on several major issues related primarily to the persistent vegetative state. A historical example illustrates how difficult it can be to reach consensus on terminology. The Harvard Committee ("Definition of Irreversible Coma,") equated irreversible coma with brain death, as did many neurological specialists in the 1970s. Others, equally knowledgeable and experienced, equated irreversible coma with the persistent vegetative state. Still others used the term in a much broader fashion to denote any form of permanent unconsciousness. Because this term has gathered so many different and contradictory meanings, the only reasonable alternative for neurological specialists was to drop it entirely.

Traditional Criteria

With all the controversy surrounding neurological criteria for death, the traditional criteria related to heartbeat and breathing have remained largely unchanged and undisputed except in the University of Pittsburgh Medical Center's program in which organs are taken from certain patients as soon as possible after expected cardiopulmonary death (Lynn). No major legal or ethical concerns have been raised about the traditional criteria for death. Medical organizations around the world have not felt it necessary to establish specific clinical criteria for the diagnosis of death that are based on the irreversible loss of cardiac and respiratory functions. The medical consultants to the President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research recommended that the clinical examination disclose at least the absence of consciousness, heartbeat, and respiratory effort and that irreversibility be established by persistent loss of these functions for an appropriate period of observation and trial of therapy ("Guidelines for the Determination of Death"). However, these consultants recommended no specific length of time for this period of observation.

Brain Death

The neurological syndrome of brain death has been accepted by the medical profession as a distinct clinical entity that experienced clinicians can diagnose with an extremely high degree of certainty and usually can distinguish easily from other neurological syndromes. Brain death is defined as the irreversible cessation of all the functions of the entire brain, including the brainstem. If the brain can be viewed simplistically as consisting of two parts—the cerebral hemispheres (higher centers) and the brainstem (lower centers)—brain death is defined as the destruction of the entire brain, both the cerebral hemispheres and the brainstem. In contrast, in the permanent vegetative state the cerebral hemispheres are damaged extensively and permanently but the brainstem is relatively intact (Cranford, 1988).

An understanding of the pathological sequence of events that leads to brain death is essential if one is to appreciate fully why brain death is a unique syndrome and why it can be differentiated readily from other neurological syndromes with a high degree of certainty. Although a variety of insults can cause the brain to die, head trauma, cardiorespiratory failure, and intracerebral hemorrhage are the most common causes. Regardless of the underlying cause, the pathological sequence is essentially the same in almost all cases. The acute massive insult to the brain causes brain swelling (cerebral edema). Because the brain is contained in an enclosed cavity, brain swelling gives rise to a massive increase in intracranial pressure. In brain death the increased intracranial pressure becomes so great that it exceeds the systolic blood pressure, thus causing a loss of blood flow to both the cerebral hemispheres and the brainstem. Whatever the primary cause of brain death, this end result of loss of blood flow results in the destruction of the entire brain. This sequence of events usually occurs within a matter of hours after the primary event, and so brain death can be diagnosed within a short period of time with an extraordinarily high degree of certainty.

The loss of both cerebral hemisphere and brainstem functions is usually clearly evident to an experienced clinician from the clinical bedside examination. The patient is in a coma, the deepest possible coma, a sleeplike state associated with a loss of all brainstem functions, such as pupillary reaction to light; gag, swallowing, and cough reflexes; eye movements in response to passive head turning (the oculocephalic response) and in response to cold caloric stimulation (oculovestibular response); and spontaneous respiratory efforts.

However, whereas respirations are completely dependent on the functioning of the brainstem, cardiac function can continue independent of brain destruction because the heart has an independent mechanism for spontaneously firing (semiautonomous functioning). With modern life-support systems continued cardiac and blood pressure functions can persist for hours, days, or even longer. Extremely rare cases of continued cardiovascular functions for over a year in the presence of the loss of all brain functions have been reported. The first cases of prolonged somatic survival in brain death usually occurred in the context of brain-dead pregnant women who were maintained on life-support systems for several months so that a viable fetus could be delivered (Wijdicks). However, the most extraordinary case of prolonged somatic survival of a patient with well-documented brain death involved a young adult age twenty-two who for eighteen years has been without

any brain functions (Shewmon, 1998; Cranford, 1998; Shewmon, 2000).

In the 1970s and 1980s numerous medical organizations in the United States and around the world developed specific medical criteria for the diagnosis of brain death (Bernat). In the United States major criteria were published by Harvard University, the University of Minnesota, the National Institutes of Health, Cornell University, and the President's Commission. Major international criteria emerged from Sweden, Japan, the United Kingdom, and Canada. All those standards essentially agreed on three clinical findings: coma, apnea (loss of spontaneous respirations), and absence of brainstem reflexes.

The critical issue distinguishing these international criteria was not the clinical findings but how best to establish irreversibility. The United Kingdom, deemphasizing the use of laboratory studies such as electroencephalography, focused on the basic diagnosis as clinical and asserted that the best way to establish irreversibility was to preclude any reversible processes before making a final determination of brain death (Conference of Royal Colleges). Reversible processes that could mimic brain death include a variety of sedative medications and hypothermia (low body temperature, below 32.2° Centigrade). The British also recommended a period of observation of at least twelve hours. In contrast, the Swedish criteria focused less on the period of observation and more on the need for definitive laboratory studies to document a loss of blood flow to the brain, such as intracranial angiography.

In the United States the earlier standards emphasized the use of electroencephalography to establish electrocerebral silence (a loss of all electrical activity of the brain); more recent standards focused on establishing a loss of intracranial circulation by means of radioisotope angiography. The 1981 report of the medical consultants to the President's Commission, which became the definitive medical standard in the United States, recommended a period of observation of at least six hours combined with a confirmatory study, such as tests measuring intracranial circulation ("Guidelines for the Determination of Death"). If no confirmatory laboratory studies were performed, an observation period of at least twelve hours was suggested, assuming that all reversible causes of loss of brain functions had been excluded. In cases of damage to the brain caused by the lack of blood or oxygen (hypoxic-ischemic encephalopathy) the consultants recommended an observation period of at least twenty-four hours if confirmatory studies were not performed.

The diagnosis of brain death in newborns, infants, and children is often more difficult than is the diagnosis in adults. A major reason for this difficulty is that the usual pathological sequence of events in adults that leads to increased intracranial pressure and loss of all blood flow to the brain does not apply to newborns and infants because the cranial cavity in those patients has not yet closed completely. Thus, the mechanism for brain death in newborns and infants may be different from what it is in older children and adults.

To address this question a task force for the determination of brain death in children representing several neurological and pediatric specialty organizations in the United States developed specific diagnostic criteria for the younger age groups (Task Force for the Determination of Brain Death in Children). That task force stated that it would be extremely difficult to establish brain death in newborns less than seven days old. It recommended that in infants seven days to two months of age there should be two separate clinical examinations and two electroencephalograms separated by at least forty-eight hours; for infants two months to one year of age, two clinical examinations and two electroencephalograms separated by at least twenty-four hours; and for children over one year of age, criteria similar to those established for adults.

Beginning in the early 1990s, the University of Pittsburgh and a few other large transplants centers developed protocols for removing organs from patients whose hearts had stopped beating but who were not brain-dead (non-heartbeating organ donors, or NHBOD) (DeVita et al.). In cases of brain death and organ donation the patient is first pronounced dead after the medical diagnosis of brain death has been established, including a period of time to establish irreversibility. The patient then is transferred to the operating room for organ removal while life-support systems are continued. After the transplantable organs are removed, life-support systems are discontinued, but the cessation of heartbeat at this time has no clinical or legal significance. In cases of non-heartbeating organ donors, patients who are terminally ill or have sustained severe irreversible brain damage and are ventilator-dependent are transferred to the operating room, where the respirator is removed, with the resultant loss of heartbeat, usually within minutes. After two minutes of pulselessness, apnea, and unresponsiveness the patient is pronounced dead on the basis of cardiorespiratory criteria. Organ removal then occurs as expeditiously as possible before the organs incur ischemic damage from lack of perfusion. The entire process is carried out in the most humane and caring way possible, including full disclosure to the appropriate surrogate decision makers and the obtaining of their consent (Ethics Committee, American College of Critical Care Medicine). The success and limitations of this

controversial procedure have been reported by some of the pioneering transplant centers.

Permanent Unconsciousness

The syndromes of permanent unconsciousness include two major types. The first is a permanent coma: an eyes-closed, sleeplike form of unarousable unconsciousness. The second is the permanent vegetative state: an eyes-open, wakeful form of unconsciousness (U.S. President's Commission for the Study of Ethical Problems). This entry takes no position on the ethical and legal issues involved in choosing between the whole-brain and higher-brain formulations of death but describes the neurological syndromes of permanent unconsciousness that would be considered the medical basis for the higher-brain formulation of death.

A permanent coma is an uncommon neurological syndrome because most patients with damage sufficient to cause brainstem impairment resulting in permanent coma die soon either naturally or because a decision is made to discontinue treatment as a result of the poor prognosis. Cases of prolonged (more than a few weeks) permanent coma do occur but are extremely uncommon.

The vegetative state has three major classes, depending on the temporal profile of the onset and the progression of the brain damage. The first form is the acute vegetative state. This occurs when the onset of brain damage is sudden and severe, such as with head trauma (traumatic vegetative state) or loss of blood flow to the brain caused by sudden cardiorespiratory insufficiencies (hypoxic-ischemic vegetative state). The second form is the degenerative, or metabolic, vegetative state, in which the brain damage begins gradually and progresses slowly over a period of months to years. In adults the most common form of the degenerative vegetative state is the final stage of Alzheimer's disease, whereas in children it is the final stage of a variety of degenerative and metabolic diseases of childhood. The third form is the congenital vegetative state secondary to a variety of severe congenital malformations of the brain that are present at birth, such as anencephaly.

The vegetative state is considered persistent when it is present longer than one month in the acute form and permanent when the condition becomes irreversible. The exact prevalence is unknown, but it is estimated that in the United States there are approximately 10,000 to 25,000 adults and 4,000 to 10,000 children in a vegetative state (Multi-Society Task Force on PVS). When it becomes permanent, this syndrome is the major neurological condition that is the prototype for the higher-brain formulation of death.

Vegetative State

The vegetative state is characterized by the loss of all higher brain functions, with relative sparing of brainstem functions. Because brainstem functions are still present, the arousal mechanisms contained in the brainstem are relatively intact and the patient therefore is not in a coma. The patient has sleep/wake cycles but at no time manifests any signs of consciousness, awareness, voluntary interaction with the environment, or purposeful movements. Thus, the patient can be awake but is always unaware: a mindless wakefulness.

Unlike brain death, in which the pathology and sequence of changes are relatively uniform regardless of the primary cause of the brain damage, the pathological changes in the vegetative state vary substantially with the cause of the unconsciousness. Although there are a variety of causes, the two most common causes of the acute form are head trauma and hypoxic-ischemic encephalopathy. In head trauma the major damage is due to shearing injuries to the subcortical white matter (the fiber tracts that connect the cell bodies of the cerebral cortex with the rest of the brain) of the cerebral hemispheres. With hypoxic-ischemic encephalopathy the primary damage is to the neurons in the cerebral cortex. These different patterns of brain damage are important for several reasons, among them the fact that the chances for recovery of neurological functions and the time necessary to establish irreversibility vary with the underlying cause.

For patients, both adults and children, in a hypoxic-ischemic vegetative state that lasts longer than three months the prognosis for recovery is uniformly dismal. The vast majority who recover and do well after a hypoxic-ischemic insult to the brain are those who have regained consciousness in the first three months. Among adults in a traumatic vegetative state the majority who do well usually will have regained consciousness within six months of the injury. The prognosis for the recovery of children in a traumatic vegetative state is slightly more favorable than that for adults (Council on Scientific Affairs and Council on Ethical and Judicial Affairs). However, in both children and adults a period of observation of at least twelve months may be appropriate before permanency is established (Multi-Society Task Force on PVS).

Although specific medical criteria for brain death have been established by numerous organizations around the world, no comparable criteria have been established for the diagnosis of the vegetative state. It is unlikely that any criteria as specific as those for brain death will be formulated in the near future because the diagnosis of the vegetative state is not nearly as precise and definitive. The determination of irreversibility in brain death usually takes hours and

does not vary according to etiology, whereas it may take months to establish irreversibility in patients who are in the permanent vegetative state, and the time necessary to establish this irreversibility varies substantially with cause and age (Institute of Medical Ethics Working Party on the Ethics of Prolonging Life and Assisting Death).

Because all vegetative state patients are unconscious, they are unable to experience suffering of any kind, psychological or physical. These patients normally manifest periods of eyes opening and closing with accompanying sleep/wake cycles. They also may demonstrate a variety of facial expressions and eye movements that originate from the lower centers of the brain and do not indicate consciousness. They may appear at times to smile and grimace, but observation over prolonged periods reveals no evidence either of voluntary interaction with the environment or of self-awareness (Executive Board, American Academy of Neurology). Neuroimaging studies such as computerized axial tomography (CAT) and magnetic resonance imaging (MRI) may be helpful in establishing the severity and irreversibility of the brain damage. After several months in a vegetative state the brain begins to show progressive shrinkage (atrophy), primarily of the cerebral hemispheres. The loss of consciousness and the inability to experience suffering, which are established on the basis of clinical observations, have been supported by measuring the metabolism of glucose and oxygen at the level of the cerebral cortex by means of positron emission tomography (PET) scanning. These studies have shown a 50 to 60 percent decrease in cerebral cortical metabolism, a level consistent with unconsciousness and deep anesthesia (Levy et al.).

Long-term survival of vegetative state patients at all ages is reduced drastically compared with the normal population. Life expectancy in adult patients is generally about two to five years; the vast majority do not live longer than ten years. In elderly patients the prognosis for survival is even worse; many do not survive for more than a few months. Infants and children may survive longer than adults do, but probably not significantly longer. Some studies have shown the average life expectancy to be four years for infants up to two months of age and about seven years for children seven to eighteen years old (Ashwal et al.).

Cases of prolonged survival—longer than twenty years—have been reported but are rare. One patient, Elaine Esposito from Tarpon Springs, Florida, lived for 37 years and 111 days without regaining consciousness, from age six to age forty-three. Another patient, Rita Greene, a surgical nurse from Wheeling, West Virginia, who survived for 47 years, 100 days from age twenty-four to age seventy-one, is probably the longest survivor in a permanent vegetative state ("Woman Lived Since '51 in Comalike State"). Considering the total estimated number of patients in a persistent vegetative state and the small number of well-documented cases of survival beyond fifteen years, the probability of an individual patient having such a prolonged survival is extremely low, probably less than 1 in 15,000 to 1 in 75,000 (Multi-Society Task Force on PVS).

It is more difficult to make the diagnosis of the vegetative state in newborns and infants. Generally, the diagnosis cannot be made below the age of three months except in the case of the condition of anencephaly. Anencephaly is the congenital malformation form of the permanent vegetative state (Stumpf et al.). This extensive and severe congenital malformation of the brain can be diagnosed with an extraordinarily high degree of certainty. At birth it is readily apparent by visual observation alone that the child has only rudimentary cerebral hemispheres and no skull except in the rear of the head. These children have variable degrees of brainstem functions but usually not enough functions to sustain life for any length of time. The vast majority are dead within two months, and most die within a few weeks.

The Locked-In Syndrome and the Minimally Conscious State

Brain death and the vegetative state should be contrasted with two other contemporary neurological syndromes of severe brain damage: the locked-in syndrome and the minimally conscious state. The locked-in syndrome, first named by Fred Plum and Jerome Posner in 1966, is characterized by a severe paralysis of the entire body, including the extremities and facial muscles, but with normal or nearly normal consciousness. This often results from a severe stroke to the brainstem that spares the cerebral hemispheres (in one sense the reverse of the vegetative state), and these patients often appear to be unconscious; however, a careful history and neurological examination uncover a high degree of cognitive functioning. Some physicians use this term to denote patients with any degree (e.g., mild to moderate) of disparity between paralysis and cognitive functioning. However, this term, when used properly, means a profound disparity between paralysis (severe) and consciousness (normal or nearly normal).

Unlike brain death, the vegetative state, and the locked-in syndrome, all of which are fairly well characterized and accepted by the medical profession, the term *minimally conscious state* is of relatively recent vintage, and its acceptance and potential usefulness as a distinct neurological syndrome are far from settled. Formally called the minimally responsive state, the minimally conscious state is defined as a condition of "severely altered consciousness in which minimal but definite behavioral evidence of self or environmental

awareness is demonstrated," in other words, a condition of severely to profoundly impaired cognitive functioning (Giacino et al.). This diagnosis is made by the demonstration on a reproducible or sustained basis of one or more of the following behaviors: following simple commands, gestural or verbal yes/no responses, intelligible verbalization, and purposeful behavior such as appropriate smiling or crying, pursuit eye movement, and sustained visual fixation. Even though the difference between being vegetative and thus completely unconscious and being "minimally" conscious may seem to be a subtle distinction and even though some have argued that being minimally conscious is a medical fate worse than being vegetative, the courts in recent landmark decisions and many healthcare professionals have treated these syndromes radically differently from a medical, ethical, and legal standpoint (Rich).

Conclusion

The criteria for diagnosing cardiorespiratory death and brain death have been well established and accepted by the medical profession. Even though there are differences in how physicians may apply these criteria in individual cases and even though the standards may vary somewhat in different countries, there are no major disputes about the medical diagnosis itself.

The syndromes of permanent unconsciousness, in contrast, are much more variable than are those of brain death. The three major forms of the vegetative state—acute, degenerative, and congenital—are substantially different in terms of causes, type of brain damage, and length of time necessary to establish irreversibility. Thus, the criteria for a higher-brain formulation of death are far more complex and uncertain than are those for the whole-brain formulation of death.

II. LEGAL ISSUES IN PRONOUNCING DEATH

The following is a revision and update of the first-edition entry "Death, Definition and Determination of, II. Legal Aspects of Pronouncing Death" by the same author.

The capability of biomedicine to sustain vital human functions artificially has created problems not only for medical practitioners but for the public and its legal institutions as well. In some cases, determining that people have died is no longer the relatively simple matter of ascertaining that their heart and lungs have stopped functioning. Mechanical respirators, electronic pacemakers, and drugs that stimulate functioning and affect blood pressure can create the appearance of circulation and respiration in what is otherwise a corpse. The general public first recognized the need to update public policy concerning when and how death could be declared when Christiaan Barnard performed the first human-to-human heart transplant in Cape Town, South Africa, on December 3, 1967. Beyond amazement at the technical feat, many people were astonished that a heart taken from a woman who had been declared dead conferred life on a man whose own heart had been removed.

Cardiac transplantation provides the most dramatic illustration of the need for clear standards to classify the outcomes of intensive medical support (e.g., respirators). But only a handful of the moribund, unconscious patients maintained through intensive support long after they formerly would have ceased living become organ donors (U.S. President's Commission). Sometimes such medical intervention is ended because it has succeeded in enabling the patient to recover; more often, it is terminated because the patient's bodily systems have collapsed so totally that circulation and respiration cannot be maintained. But for a significant number of patients, artificial support can be continued indefinitely with no prospect that consciousness will ever return. For some of this latter group of patients—especially those who can eventually be weaned from the respirator and require only nutrition and hydration by tube—the question arises whether to withdraw treatment and allow death to occur. But for others who have suffered great brain damage, the need arises to recognize that death has occurred and that further attempts to keep the patient alive are therefore no longer appropriate even before the point (usually within several weeks) when physiological processes in the body can usually no longer be maintained.

Beginning in the 1960s, the response of the medical profession was to develop new criteria, such as those articulated in 1968 by an ad hoc committee at Harvard Medical School. Experts in the United States tend to rely on certain clinical signs of the absence of any activity in the entire brain (Ad Hoc Committee); British neurologists focus on the loss of functioning in the brain stem, while doctors in certain European countries search for conditions for brain function, such as intracranial blood circulation (Van Till). Despite differences in technique, the medical profession arrived at a consensus that the total and irreversible absence of brain function is equivalent to the traditional cardiorespiratory indicators of death (Medical Consultants).

The story of the law's response to these new medical criteria can be divided into three parts. The first, largely played out in the late 1960s and the 1970s, concerned an issue of process—how ought society respond to the divergence between new medical precepts and practices, on the one hand, and the common understanding of the lay public of rules embodied in custom and law, on the other? (Anglo-American common law, for example, had traditionally defined death as the total cessation of all vital functions.) The

second phase, from the 1970s through the 1980s, centered on the specific changes being made in the law. In the third period, which is still continuing, commentators (principally philosophers and a few physicians) have raised questions about the appropriateness of the legal standards that have been adopted and called for various changes in those standards.

Phase One: Framing Definitions

A MEDICAL MATTER? A number of routes were advanced for arriving at what was often termed a new definition of death that would encompass the neurological understanding of the phenomenon of death that emerged in the 1960s and has since been further refined. (The common shorthand phrase "definition of death" is misleading since "definition" suggests an explanation of a fact whereas the task at hand is specifying the significance of particular facts for the process of determining whether, and when, a person has died.) Early commentators proposed that the task should be left to physicians, because the subject is technical and because the law might set the definition prematurely, leading to conflicts with developments that will inevitably occur in medical techniques (Kennedy). Yet the belief that defining death is wholly a medical matter misapprehends the undertaking. At issue is not a biological understanding of the inherent nature of cells or organ systems but a social formulation of humanhood. It is largely through its declaration of the points at which life begins and ends that a society determines who is a full human being, with the resulting rights and responsibilities.

Since physicians have no special competence on the philosophical issue of the nature of human beings and no special authority to arrogate the choice among definitions to themselves, their role is properly one of elucidating the significance of various vital signs. By the 1970s, it became apparent that a new definition should be forthcoming, not simply to accommodate biomedical practitioners' wishes but as a result of perceived social need and of evidence that tests for brain function were as reliable as the traditional heart-lung tests.

JUDICIAL DECISIONS? If not physicians, then who should frame the definition? One answer was, "Let the courts decide." In the United States and other common-law countries, law is to be found not only on the statute books but in the rules enunciated by judges as they resolve disputes in individual civil and criminal cases. Facing a factual situation that does not fit comfortably within the existing legal rules, a court may choose to formulate a new rule in order to more accurately reflect current scientific understanding and social viewpoints.

Nonetheless, problems of principle and practicality emerged in placing primary reliance on the courts for a redefinition of death. Like the medical profession, the judiciary may be too narrowly based for the task. While the judiciary is an organ of the state with recognized authority in public matters, it still has no means for actively involving the public in its decision-making processes. Judge-made law has been most successful in factual settings embedded in well-defined social and economic practices, with the guidance of past decisions and commentary. Courts operate within a limited compass—the facts and contentions of a particular case—and with limited expertise; they have neither the staff nor the authority to investigate or to conduct hearings in order to explore such issues as public opinion or the scientific merits of competing "definitions." Consequently, a judge's decision may be merely a rubber-stamping of the opinions expressed by the medical experts who appeared in court. Moreover, testimony in an adversary proceeding is usually restricted to the "two sides" of a particular issue and may not fairly represent the spectrum of opinion held by authorities in the field.

Furthermore, in the U.S. cases in which parties first argued for a redefinition, the courts were unwilling to disturb the existing legal definition. Such deference to precedent is understandable, because people need to be able to rely on predictable legal rules in managing their affairs. As late as 1968, a California appellate tribunal, in a case involving an inheritorship issue, declined to redefine death in terms of brain functioning despite the admittedly anachronistic nature of an exclusively heart-lung definition (Cate and Capron).

The unfortunate consequences for physicians and patients of the unsettled state of the common-law definition of death in the 1970s is illustrated by several cases. In the first, *Tucker v. Lower,* which came to trial in Virginia in 1972, the brother of a man whose heart was taken in an early transplant operation sued the physicians, alleging that the operation was begun before the donor had died. The evidence showed that the donor's pulse, blood pressure, respiration, and other vital signs were normal but that he had been declared dead when the physicians decided these signs resulted solely from medical efforts and not from his own functioning, since his brain functions had ceased. At the start of the trial, the judge indicated that he would adhere to the traditional definition of death, but when charging the jury, he permitted them to find that death had occurred when the brain ceased functioning irreversibly. Although a verdict was returned for the defendants, the law was not clarified since the court did not explain its action.

The other two cases arose in California in 1974, when two transplant operations were performed using hearts

removed from the victims of alleged crimes. The defendant in each case, charged with homicide, attempted to interpose the action of the surgeons in removing the victim's still-beating heart as a complete defense to the charge. One trial judge accepted this argument as being compelled by the existing definition of death, but his ruling was reversed on appeal, and both defendants were eventually convicted. This graphic illustration of legal confusion and uncertainty led California to join several other jurisdictions in the United States, Canada, and Australia that, beginning in 1970, followed a third route to redefining death, the adoption of a statutory definition.

STATUTORY STANDARDS? The legislative process allows a wider range of information to enter into the framing of standards for determining death, as well as offering an avenue for participation of the public. That is important because basic and perhaps controversial choices among alternative definitions must be made. Because they provide prospective guidance, statutory standards have the additional advantage of dispelling public and professional doubt, thereby reducing both the fear and the likelihood of cases against physicians for malpractice or homicide.

Not all countries have adopted legislation. In Great Britain, for example, the standards for determining death reside not in a statute but in medically promulgated codes of practice, which have been indirectly accepted in several judicial decisions (Kennedy and Grubb). Yet in the United States and among most commentators internationally, the first period in policymaking on a new definition of death produced wide agreement that an official response was necessary in light of the changes wrought by medical science, and that this response ought to be statutory.

Phase Two: The Contours of a Statute

By 1979 four model statutes had been proposed in the United States; in addition to those from the American Bar Association (ABA), the American Medical Association (AMA), and the National Conference of Commissioners of Uniform State Laws (NCCUSL), the most widely adopted was the Capron-Kass proposal, which grew out of the work of a research group at the Hastings Center (U.S. President's Commission, 1981). Ironically, the major barrier to legislation became the very multiplicity of proposals; though they were consistent in their aims, their sponsors tended to lobby for their own bills, which in turn produced apprehension among legislators over the possible importance of the bills' verbal differences. Accordingly, the President's Commission worked with the three major sponsors—the ABA, the AMA, and the NCCUSL—to draft a single model bill that could be proposed for adoption in all jurisdictions. The resulting statute—the Uniform Determination of Death Act (UDDA)—was proposed in 1981 and is law in more than half of U.S. jurisdictions, while virtually all the rest have some other, essentially similar statute. In four states the law derives from a decision by the highest court recognizing cessation of all functions of the brain as one means of determining death (Cate and Capron).

The UDDA provides that an individual who has sustained either (1) irreversible cessation of circulatory and respiratory functions, or (2) irreversible cessation of all functions of the entire brain, including the brain stem, is dead. A determination of death must be made in accordance with accepted medical standards. This statute is guided by several principles. First, the phenomenon of interest to physicians, legislators, and the public alike is a human being's death, not the "death" of his or her cells, tissues, or organs. Indeed, one problem with the term "brain death" is that it wrongly suggests that an organ can die; organisms die, but organs cease functioning. Second, a statute on death will resolve the problem of whether to continue artificial support in only some of the cases of comatose patients. Additional guidance has been developed by courts and legislatures as well as by professional bodies concerning the cessation of treatment in patients who are alive by brain or heart-lung criteria, but for whom further treatment is considered (by the patients or by others) to be pointless or degrading. This question of "when to allow to die?" is distinct from "when to declare dead?"

Third, the merits of a legislative definition are judged by whether its purposes are properly defined and how well the legislation meets those purposes. In addition to its cultural and religious importance, a definition of death is needed to resolve a number of legal issues (besides deciding whether to terminate medical care or transplant organs) such as homicide, damages for the wrongful death of a person, property and wealth transmission, insurance, taxes, and marital status. While some commentators have argued that a single definition is inappropriate because different policy objectives might exist in different contexts, it has been generally agreed that a single definition of death is capable of being applied in a wide variety of contexts, as indeed was the traditional heart-lung definition. Having a single definition to be used for many purposes does not preclude relying on other events besides death as a trigger for some decisions. Most jurisdictions make provision, for example, for the distribution of property and the termination of marriage after a person has been absent without explanation for a period of years, even though a person "presumed dead"

under such a law could not be treated as a corpse were he or she actually still alive (Capron).

Fourth, although dying is a process (since not all parts of the body cease functioning equally and synchronously), a line can and must be drawn between those who are alive and those who are dead (Kass). The ability of modern biomedicine to extend the functioning of various organ systems may have made knowing which side of the line a patient is on more problematic, but it has not erased the line. The line drawn by the UDDA is an arbitrary one in the sense that it results from human choice among a number of possibilities, but not in the sense of having no acceptable, articulated rationale.

Fifth, legislated standards must be uniform for all persons. It is, to say the least, unseemly for a person's wealth or potential social utility as an organ donor to affect the way in which the moment of his or her death is determined. One jurisdiction, in an attempt to accommodate religious and cultural diversity, has departed from the general objective of uniformity in the standards for determining death. In 1991, New Jersey adopted a statute that allows people whose religious beliefs would be violated by the use of whole-brain criteria to have their deaths declared solely on the traditional cardiorespiratory basis (New Jersey Commission).

Sixth, the UDDA was framed on the premise that it is often beneficial for the law to move incrementally, particularly when matters of basic cultural and ethical values are implicated. Thus, the statute provides a modern restatement of the traditional understanding of death that ties together the accepted cardiopulmonary standard with a new brain-based standard that measures the same phenomenon.

Finally, in making law in a highly technological area, care is needed that the definition be at once sufficiently precise to determine behavior in the manner desired by the public and yet not so specific that it is tied to the details of contemporary technology. The UDDA achieves this flexible precision by confining itself to the general standards by which death is to be determined. It leaves to the developing judgment of biomedical practitioners the establishment and application of appropriate criteria and specific tests for determining that the standards have been met. To provide a contemporary statement of "accepted medical standards," the U.S. President's Commission assembled a group of leading neurologists, neurosurgeons, pediatricians, anesthesiologists, and other authorities on determination of death (Medical Consultants). Their guidelines, which provide the basis for the clinical methodology used in most American institutions, have since been supplemented by special guidance regarding children (Task Force).

Phase Three: The Continuing Points of Debate

As a practical matter, the law nearly everywhere (most recently including Japan) (Akabayashi) recognizes that death may be diagnosed based upon the determination that the brain as a whole has ceased functioning. In the United States, this consensus is embodied in the UDDA, which has therefore become the focus of criticism from certain people—principally some philosophers, but also physicians and lawyers—who are not comfortable with this consensus. Their objections can be summarized in three challenges to the UDDA.

WHOLE-BRAIN VERSUS HIGHER-BRAIN DEATH. The strongest position against the UDDA is mounted by those who would substitute for its "whole brain" standard a "higher brain" standard. Many philosophers have argued that certain features of consciousness (or at least the potential for consciousness) are essential to being a person as distinct from merely a human being (Veatch; Zaner). The absence of consciousness and cognition—as occurs, for example, in patients in the permanent vegetative state (PVS)—thus results in the loss of personhood. A related argument rests on the ontological proposition that the meaning of being a person—that is, a particular individual—is to have a personal identity, which depends on continuity of personal history as well as on self-awareness. The permanent loss of consciousness destroys such identity and hence means the death of that person, even if the body persists.

Consideration of the implications of these theories for determination of death takes several forms. On a conceptual level, the specific characteristics deemed by philosophers to be essential for personhood have varied widely from John Locke's focus on self-awareness to Immanuel Kant's requirement of a capacity for rational moral agency (Lizza). Thus, while certain definitions would exclude only those who lack any capacity for self-knowledge, such as PVS (persistent vegetative state) patients, other conceptions would encompass senile or severely retarded patients who cannot synthesize experience or act on moral principles.

On a practical level, trying to base a definition of death on cessation of higher-brain functions creates at least two problems. The first is the absence of agreed-upon clinical tests for cessation of these functions. Although certain clinical conditions such as PVS that involve the loss of neocortical functioning when brainstem functions persist can be determined sufficiently reliably for prognostic purposes (such as when deciding that further treatment is no longer in the best interests of a dying patient), the greater complexity and uncertainty that remain prevent testing with

the same degree of accuracy as with the whole-brain standards. The practical problems increase enormously if the higher-brain definition is grounded on loss of personhood or personal identity, because loss of such a characteristic is not associated with particular neurologic structures.

More fundamentally, patients who are found to have lost (or never to have had) personhood because they lack higher-brain functions, or because they no longer have the same personal identity, will still be breathing spontaneously if they do not also meet whole-brain standards such as those of the UDDA. While such entities may no longer be "persons," they are still living bodies as "living" is generally understood and commonly used. "Death can be applied directly only to biological organisms and not to persons" (Culver and Gert, p. 183). To regard a human being who lacks only cerebral functions as dead would lead either to burying spontaneously respiring bodies or to having first to take affirmative steps, such as those used in active euthanasia, to end breathing, circulation, and the like. Neither of these would comport with the practices or beliefs of most people despite widespread agreement that such bodies, especially those that have permanently lost consciousness, lack distinctive human characteristics and need not be sustained through further medical interventions. Perhaps for this reason, in proposing a statute that would base death on cessation of cerebral functions, Robert Veatch condones allowing persons, while still competent, or their next of kin to opt out of having their death determined on the higher-brain standard. No state has adopted a "conscience clause" of this type, and the New Jersey statute mentioned above does not endorse the higher-brain standard (Olick).

The major legal evaluation of the higher-brain standard has arisen in the context of infant organ transplantation because of several highly publicized attempts in the 1980s to transplant organs from anencephalic infants (babies born without a neocortex and with the tops of their skulls open, exposing the underlying tissue). In 1987–1988, Loma Linda Medical Center in California mounted a protocol (a formal plan for conducting research) to obtain more organs, particularly hearts, from this source. The protocol took two forms. At first, the anencephalic infants were placed on respirators shortly after birth; but such infants did not lose functions and die within the two-week period the physicians had set, based on historical experience that virtually all anencephalics expire within two weeks of birth. In the second phase of the protocol, the physicians delayed the use of life support until the infants had begun experiencing apnea (cessation of breathing). Yet by the time death could be diagnosed neurologically in these infants, the damage to other organs besides the brain was so great as to render the organs useless. No organs were transplanted under the Loma Linda protocol.

Proposals to modify either the determination of death or the organ-transplant statutes to permit the use of organs from anencephalic infants before they meet the general criteria for death have not been approved by any legislature, nor was the Florida Supreme Court persuaded to change the law in the only appellate case regarding anencephalic organ donation. In that case, the parents of a child prenatally diagnosed with anencephaly requested that she be regarded as dead from the moment of birth so that her organs could be donated without waiting for breathing and heartbeat to cease. The Florida statute limits brain-based determinations of death to patients on artificial support. Turning to the common law, the court held that it established the cardiopulmonary standard, and the court then declined to create a judicial standard of death for anencephalics in the absence of a "public necessity" for doing so or any medical consensus that such a step would be good public policy (T.A.C.P.).

Although the Loma Linda protocol for using anencephalic infants as organ sources attempted to comply with the general consensus on death determination, it also proved that the "slippery slope" is not merely a hypothetical possibility. While the program was ongoing and receiving a great deal of media attention, the neonatologist who ran the pediatric intensive-care unit where potential donors were cared for reported receiving offers from well-meaning physicians of infants with hydrocephalus, intraventricular hemorrhage, and severe congenital anomalies. These physicians found it difficult to accept Loma Linda's rejection of such infants, whom the referring physicians saw as comparable on relevant grounds to the anencephalic infants who had been accepted. Beyond the risk of error in diagnosing anencephaly, it is hard to draw a line at this one condition, since the salient criteria—absence of higher-brain function and limited life expectancy—apply to other persons as well. The criterion that really moves many people—namely, the gross physical deformity of anencephalic infants' skulls—is without moral significance. Thus, a decision to accept anencephaly as a basis for declaring death would imply acceptance of some perhaps undefined higher-brain standard for diagnosing any and all patients.

CHANGING CLINICAL CRITERIA. Some medical commentators have suggested that society should rethink brain death because studies of bodies determined to be dead on neurological grounds have shown results that fail to accord with the standard of "irreversible loss of all functions of the entire brain" (Truog and Fackler). Specifically, some of these

patients still have hypothalamic-endocrine function, cerebral electrical activity, or responsiveness to the environment.

Although the technical aspects of these various findings differ, similar reasoning can be applied to assessing their meaning for the concept of brain death. For each, one must ask first, are such findings observed among patients diagnosed through cardiopulmonary as well as neurological means of diagnosing death? Second, are such findings inconsistent with the irreversible loss of integrative functioning of the organism? Finally, do such findings relate to functions that when lost do not return and are not replaceable?

If some patients diagnosed dead on heart-lung grounds also have hypothalamic-endocrine function, cerebral electrical activity, or environmental responses, then the presence of these findings in neurologically diagnosed patients would not be cause for concern that the clinical criteria for the latter groups are inaccurate, and no redefinition would be needed.

Plainly, in many dead bodies some activity (as opposed to full functions) remains temporarily within parts of the brain. The question then becomes whether the secretion of a particular hormone (such as arginine vasopressin, which stimulates the contraction of capillaries and arterioles) is so physiologically integrative that it must be irreversibly absent for death to be declared. Depending upon the answer, it might be appropriate to add to the tests performed in diagnosing death measurements of arginine vasopressin or other tests and procedures that have meaning and significance consistent with existing criteria.

Such a modest updating of the clinical criteria is all that is required by Truog and Fackler's data and is preferable to the alternative they favor, modifying the conceptual standards to permanent loss of the capacity for consciousness while leaving the existing criteria for the time being. Not only does this change fail to respond to their data that testing can evoke electrical activity in the brain stem, despite the absence of such activity in the neocortex (called electrocerebral silence); it also has all the problems of lack of general acceptability that attach to any standard that would result in declaring patients with spontaneous breathing and heartbeat dead because they are comatose (i.e., deeply unconscious).

THE MEANING OF IRREVERSIBILITY. The final challenge to the UDDA is less an attempt to refute its theory than it is a contradiction of the standards established by the statute and accompanying medical guidelines. Under a protocol developed at the University of Pittsburgh in 1992, patients who are dependent on life-support technology for continued vital functions and who desire to be organ donors are wheeled into the operating room and the life support disconnected, leading to cardiac arrest. After two minutes of asystole (lack of heartbeat), death is declared based upon the "irreversible cessation of circulatory and respiratory functions," at which point blood flow is artificially restored to the organs which are to be removed for transplantation (Youngner et al., 1993). Yet the failure to attempt to restore circulatory and respiratory functions in these patients shows that death had not occurred according to the existing criteria. The requirement of "irreversible cessation" must mean more than simply the physician "chose not to reverse." If no attempt is made to restore circulation and respiration before organs are removed it is not appropriate to make a diagnosis of death—merely a prognosis that death will occur if available means of resuscitation continue not to be used.

The reason for alternative standards for determining death is not because there are two kinds of death. On the contrary, there is one phenomenon that can be viewed through two windows, and the requirement of irreversibility ensures that what is seen is virtually the same thing through both. To replace "irreversible cessation of circulatory and respiratory functions" with "choose not to reverse" contradicts the underlying premise, because in the absence of the irreversibility there is no reason to suppose that brain functions have also permanently ceased.

A different, and more potent, challenge to the irreversibility requirement is posed by the prospect inherent in current research on human stem cells that some time in the future it may be possible to restore brain functions whose loss is at present beyond repair. Should such treatments become a clinical reality, the present standards for determining death will need to be reconsidered because the occurrence of death will in all cases turn on the decision whether or not to attempt repair.

Conclusion

The movement toward a modern legal formulation of the bases for pronouncing death has not been completed, and it is not clear that a complete consensus is possible (Younger, Arnold, and Shapiro, 1999). In some societies, that task may be left to the medical profession, since the problems faced in medical practice provide the impetus for change. Tradition as well as sound policy suggests, however, that the ground rules for decisions about individual patients should be established by public authorities. Whether the new legal definition of death emerges from the resolution of court cases or from the legislative process, it will be greatly influenced by opinion from the medical community. Recognition that the standards for determining death are matters of social and not merely professional concern only serves to

underline the education of the public on this subject as an important ethical obligation of the profession.

III. PHILOSOPHICAL AND THEOLOGICAL PERSPECTIVES

The bioethics debate concerning the definition and criteria of human death emerged during the rise of organ transplantation in the 1960s, prompted by the advent of functional mechanical replacements for the heart, lungs, and brain stem, and by the ability to diagnose the pervasive brain destruction that is termed *brain death.* Previously, there had been no need to explore the conceptual or definitional basis of the established practice of declaring death or to consider additional criteria for determining death, since the irreversible cessation of either heart or lung function quickly led to the permanent loss of any other functioning considered a sign of life. New technologies and advances in resuscitation changed all this by permitting the dissociated functioning of the heart, lungs, and brain. In particular, society experienced the phenomenon of a mechanically sustained patient whose whole brain was said to be in a state of irreversible coma. And there were an increasing number of *vegetative* patients sustained by feeding tubes, whose bodies had been resuscitated to the status of spontaneously functioning organisms, but whose higher brains had permanently lost the capacity for consciousness. Such phenomena as these pressed a decision as to whether the irreversible loss of whole or higher-brain functioning should be considered the death of the individual, despite the continuation of respiration and heartbeat. With mounting pressure to increase the number of viable organs for transplant within the unquestioned constraint of the Dead Donor Rule which requires that the organ donor be dead before organ removal, the debate concerning whole-brain death arose.

The Beginnings of the Debate

The debate opened in 1968, when the Ad Hoc Committee of the Harvard Medical School to Examine the Definition of Brain Death (Harvard Committee) recommended an *updating* of the criteria for determining that a patient has died. The Harvard Committee put forth a set of clinical tests it claimed was sufficient to determine the death of the entire brain. It then recommended that whole-brain death be considered direct and sufficient evidence of the death of the patient. Thus arose the suggestion, which has become entrenched practice in the United States, that a binary standard be used for determining death: that in addition to the traditional heart and lung criteria still applicable in the vast majority of cases, a whole-brain death criterion be used to determine death for respirator-dependent, permanently unconscious patients.

This was the modest beginning of the so-called *definition-of-death* debate. Rather than having resolved over the last thirty-five years, this debate has evolved and intensified due to fascinating and complex constellations of philosophical, clinical, and policy disagreements. To best appreciate these disagreements, one must understand the definitional debate as one that has three logically distinct, yet interdependent levels: (1) the conceptual or definitional level; (2) the criteriological level; and (3) the medical diagnostic level. Let us look at each of the three levels in turn.

THE THREE LEVELS OF THE DEBATE. ***Level One: The conceptual or definitional level.*** At level one, the question is, What is human death? While some people think basic definitions such as this one are somehow written on the face of reality for our discernment, defining death is in fact a normative activity that draws on deeply held philosophical, religious, or cultural beliefs and values. The definition or concept of death reflects a human choice to count a particular loss as death. The level two and level three activities of deciding which physiological functions underlie that loss (i.e., choosing a criterion for determining death), and of specifying the medical tests for determining that the criterion is fulfilled, are medical/scientific activities. The conceptual question can be answered in a general, yet uninformative way by saying that human death is the irreversible loss of that which is essentially significant to the nature of the human being. No one will take issue with this definition, but it does not go far enough. There is still a need to decide what is essentially significant to the nature of the human being.

People differ radically in their views on the distinctive nature of the human being and its essentially significant characteristic(s). Because their fundamentally different perspectives on human nature flow from deeply rooted beliefs and values, the difficult policy question arises concerning the extent to which a principle of toleration should guide medical practice to honor the alternative definitions of human death that exist.

The discussion later in this section will show that the human being can be thought of as a wholly material or physical entity, as a physical/mental amalgam, or as an essentially spiritual (though temporarily embodied) being. The way the human is thought of will influence the view of

what is essentially significant to the nature of the human being, and ground one's view about the functional loss that should be counted as human death. A metaphysical decision concerning the kind of being the human is, is the ultimate grounding for the normative choice of criteria for determining that an individual human being has died. There could be no more interesting or important a philosophical problem, then, than the problem of deciding: What is human death? Why? And, there could be no more interesting an ethical/policy problem than that of deciding whether and how to tolerate and enable a diversity of answers to these questions.

Level Two: The criteriological level. Based on the resolution of the ontological and normative questions at the conceptual level, a criterion for determining that an individual has died, reflecting the physiological function(s) considered necessary for life and sufficient for death, is specified. That is, the essentially significant human characteristic(s) delineated at the conceptual level is (are) located in (a) functional system(s) of the human organism. The traditional criteria center on heart and lung function, suggesting that the essentially significant characteristics are respiration and circulation. The whole-brain-death criterion is said by its proponents to focus on the integrated functioning of the organism as a whole. The higher-brain-death criterion centers on the irreversible absence of a capacity for consciousness.

Level Three: The diagnostic level. At this level are the medical diagnostic tests to determine that the functional failure identified as the criterion of death has in fact occurred. These tests are used by medical professionals to determine whether the criterion is met, and thus that death should be declared. As technological development proceeds, diagnostic sophistication increases. The Harvard Committee believed that the death of the entire brain could be clinically diagnosed using the tests it identified in its report, and recommended that the whole-brain-death criterion be used to determine death in cases of respirator dependency. However, it provided no conceptual argument (i.e., no answer to the level one question, What is human death?) to support the criterion and practice it recommended.

These three levels—conceptual, criteriological, and diagnostic—provide a crucial intellectual grid for following the complex definition-of-death debate since 1968. The debate encompasses all three levels. In any reading and reflection associated with this complex debate, it is essential to remember what level of the debate one is on, and what sort of expertise is required on the part of those party to the debate at that level. Further, any analysis and critical assessment of suggested criteria for determining death require that one attend to the important interconnections among tests, criteria, and concepts. Criteria without tests are useless in practice; criteria without concepts lack justification. It is the philosophical task of constructing an adequate concept or definition of human death that becomes central to a justified medical practice of declaring death. As Scot philosopher and historian David Hume (1711–1776) said centuries ago, "Concepts without percepts are blind." At the beginning of the twenty-first century, a criterion for determining death without a philosophical analysis of what constitutes death is equally blind. All in all, there ought to be coherence among concept, criterion, and clinical tests. At least this is the way one would normally wish to operate. Among other things, the definition-of-death debate can be expressed as a debate among alternative formulations of death: the traditional cardio-pulmonary, whole-brain and higher-brain formulations.

The Traditional Cardio-Pulmonary Formulation

Initially, many objected to the whole-brain formulation because they saw it to be a change in our fundamental understanding of the human being, and a dramatic change from the essentially cardiac-centered concept and criterion for determining death (the traditional cardio-pulmonary criteria, which required the final stoppage of the heart). Several have called for a return to the use of the traditional criteria, consistent with an understanding of death as the irreversible loss of the integrative functioning of the organism as a whole. The claim has been that whether mechanically or spontaneously sustained, a beating heart signifies the ongoing integrated functioning of the organism as a whole, whether or not the patient is *brain-dead.* On this view, death has not occurred until the heart and lungs have irreversibly ceased to function. Some religious traditions adhere steadfastly to this concept of death, and consider the brain-death criterion an unacceptable basis on which to declare death.

The Whole-Brain-Death Formulation: Concept and Criterion

When the Harvard Committee recommended that a whole-brain-death criterion be used to determine death in respirator-dependent patients, thus creating an exception to the use of the traditional cardio-pulmonary criteria for a specific category of patients, controversy arose over whether the adoption of this criterion constituted a departure from the concept of death implicit in the use of the traditional cardio-pulmonary criteria for the determination of death.

Some saw the use of the brain-death criterion to be a blatantly utilitarian maneuver to increase the availability of transplantable organs. Some opposed it because it was inconsistent with their view of the human self and/or failed

to protect and respect dying patients. While others agreed that the neurological focus represented an alternative understanding of the self, they saw the move to be eminently logical: What argument could one have with the notion that someone whose whole brain is dead, is dead? Others continued to affirm that life was essentially a heart-centered reality rather than a brain-centered reality: They saw the shift to a neurological focus on the human to be a discounting of the relevance of the spontaneous beating of the heart and the mechanically sustained functioning of the lungs. So, representatives of some cultures and faith traditions opposed the shift to the brain-death criterion, suggesting that it was a radically unacceptable way of understanding and determining the death of a human being.

The Harvard Committee report was a clinical recommendation, not a philosophical argument. It made recommendations at levels two and three (the criteriological and the diagnostic), and prompted but did not answer a number of level one definitional questions. What is death, such that either the traditional criteria or the whole-brain-death criterion may be used to determine its occurrence? Do the traditional criteria and the brain-death criterion presuppose the same definition of death? If not, should human death be *redefined* in response to technological change? It gave rise to a philosophical debate that is ongoing on the question, What is so essentially significant to the nature of a human being that its irreversible loss should be considered human death?

The literature has been replete with answers to this question, including the irreversible loss of the flow of vital fluids, the irreversible departure of the soul from the body, the irreversible loss of the capacity for bodily integration, the irreversible cessation of integrative unity (i.e., of the anti-entropic mutual interaction of all of the body's cells and tissues), the irreversible loss of the integrated functioning of the organism as a whole, and the irreversible loss of the capacity for consciousness or social interaction. Without such an account of what is essentially significant, the criterion used as a basis for determining death lacks an explicit foundation. However, the plurality of thoughtful answers to this fundamental conceptual question raises the issues of whether a consensus view can be fashioned, whether to tolerate diverse understandings of human death, and of how to assure societal stability concerning the determination of death.

While the Harvard Committee provided no philosophical defense of its position, adherents of the whole-brain formulation have continued to argue over the years that the traditional criteria and the whole-brain-death criterion share a common concept of death—the irreversible loss of the capacity for integrated functioning of the organism as a whole. Not everyone has agreed with this position, however. Some resist the adoption of the brain-death criterion for this reason, considering the shift to a new understanding of human death to be philosophically unjustifiable. However, others have welcomed the change: Reflecting on the contingency of the definition of death under circumstances of technological change, some have argued in favor of redefining death even further. In their view, the philosophical concept of death said to underlie the whole-brain-death criterion inadequately reflects the essentially significant characteristic of human existence: existence as an embodied consciousness. A more adequate concept of human death, they contend, would center on the permanent cessation of consciousness (requiring a higher-brain-death criterion), not on the permanent cessation of the integrated functioning of the organism. Advocates of the higher-brain formulation of death oppose the whole-brain formulation on the ground that the latter unjustifiably defers to the characteristics biological organisms have in common and ignores the relevance of the distinctively human characteristics associated with life as a person.

If the whole-brain formulation is essentially an organismically-based concept, and the higher-brain formulation is essentially a person-based concept, the controversy between whole- and higher-brain formulations suggests that in order to answer the question, What is human death? another layer of philosophical reflection is required. The central normative question concerning what is essentially significant to the nature of the human being requires a prior account of the nature of the human being. In philosophical terms, such an account of the nature of a being is referred to as an ontological account. One's view of the nature of the human being is informed by philosophical, theological and/or cultural perspectives on the nature of human existence, its essentially significant characteristics, and the nature of its boundary events. In the case of the human, there appear to be two logically distinct choices concerning the nature of the human being: one either sees it as one organism among others, for which meanings-in-common of life and death should be sought; or one sees the human being as distinctive among organisms for the purpose of characterizing its life and death, in ways we signify by the term *person.* In short we need to make and defend a decision concerning the way we look at the human—as organism or as person—for the purpose of determining what constitutes human death.

The Whole-Brain Formulation: Public Policy

In 1981 the whole-brain-death formulation originally advanced by the Harvard Committee was articulated in a major U.S. policy document. The President's Commission

for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research published its report, *Defining Death: A Report on the Medical, Legal, and Ethical Issues in the Determination of Death.* In this document, it provided a model law called the Uniform Determination of Death Act, to encourage the uniform adoption in each of the United States of the traditional criteria and the brain-death criterion as alternative approaches to declaring death. The supporting framework they offered for this recommendation was this: The concept of human death is the irreversible cessation of the integrated functioning of the organism as a whole. This, they claimed, is a function of the activity of the entire brain, not just a portion of the brain, and its occurrence can be measured, depending on the patient's circumstances, either by the traditional criteria or the brain-death criterion.

Questioning the Whole-Brain Formulation

The whole-brain formulation has been attacked at the conceptual level, and on the ground that the answers at each level collectively provide an incoherent account of concept, criterion and clinical tests for determining death. The President's Commission's concept or definition of death has been objected to by those who favor one centered on the essential features of a personal life, as well as by those who favor a circulatory concept and consider that only the irreversible cessation of circulation adequately signals death.

In addition, since 1981, clinical findings have confirmed that what has come to be called whole-brain death is not in fact synonymous with the death of the brain in all of its parts. There are instances of isolated continued functioning in the brain-dead brain. Those wishing to support the established consensus around the use of the brain-death criterion argue that such *residual functioning* in the brain-dead brain is insignificant to the determination of death. Specifically, then, they refuse to allow that these kinds of residual brain functioning have significance: (i) persistent cortical functioning as evidenced by electroencephalograph (EEG) activity, and in rare cases a sleep/wake pattern; (ii) ongoing brainstem functioning as evidenced by auditory or visual evoked potential recording; and (iii) preserved antidiuretic neurohormonal functioning. Such instances of residual functioning suggest that brain death, as customarily diagnosed, does not include the hypothalamus and the posterior pituitary. Most importantly, the third instance of residual functioning just cited actually plays an *integrative* role in the life of the organism as a whole. Hence, one of the residual functions fulfills the concept of life implicit in the definition of death underlying the whole-brain formulation.

So, the clinical tests used to establish the death of the entire brain have been shown to reflect a pervasive but nonetheless *partial* death of the brain only, opening wide the question, If brain death is to remain a reasonable basis upon which to declare death, which brain functions are so essentially significant that their irreversible loss should be counted as brain death? Why?

Both philosophically and clinically speaking, then, many feel that a rethinking of the U.S. societal adherence to the brain-death criterion is warranted. It rests on a contested understanding of what human death is, raising the issue of whether the brain-death criterion should be used to declare someone dead who holds philosophical/theological/cultural objections to it. It lacks coherence among its levels because (1) the brain-death criterion does not correlate with the irreversible loss of the integrated functioning of the organism as a whole; and (2) because the clinical tests for brain death fail to reflect the death of the entire brain. No important societally established practice can be imagined to be so highly problematic as this one.

The supporters of the whole-brain formulation have nonetheless stood their ground, claiming that the instances of residual cellular and subcellular activities occurring in the brain are irrelevant to the determination of the life/death status of the patient. In their view, the brain-death criterion should continue to be used, despite that it really reflects a pervasive albeit partial brain death.

The basic challenge to the whole-brain formulation has been that its defenders need to provide criteria for distinguishing between brain activity that is relevant and irrelevant for the purpose of determining death. Some have argued that the only bright line that could be drawn in this regard is between the brain functions essential for consciousness and those that are not; others have argued that the brain should be abandoned entirely as a locus for establishing that a human being has died. In point of fact then, advocates of the whole-brain formulation have embraced a partial-brain-death criterion but have failed to provide a non-question-begging, principled basis for it.

Another aspect of the whole-brain formulation that has been challenged concerns its reliance on the non-spontaneous function of the lungs to support the claim that the irreversible cessation of the integrated functioning of the organism as a whole has occurred. They claim that the integrated functioning continues, and that the manner of its support is irrelevant. Their point is that as long as the respirator is functioning, it seems something of a word game to say that the organism is not functioning as an integrated whole.

While in brain death the brain stem is no longer playing its linking role in the triangle of function along with lungs and heart, the respirator is standing in for the brain stem, just as it might if there were partial brain destruction in the

area of the brain stem. If the patient were conscious, but just as dependent on the respirator in order to continue functioning as an organism, there would be no inclination to pronounce the patient dead. Hence, it would seem that even the brain-dead patient is exhibiting integrated organismic functioning until the respirator is turned off, the lungs stop, and the heart eventually stops beating. The phenomenon of a mechanically-sustained brain-dead pregnant woman producing a healthy newborn certainly seems to bear out their insight: Whatever the sort of organismic disintegration possessed in such a case, it seems most unfitting to call it death. Integrated organismic functioning is present in brain death, so if brain death *should be* considered the death of the human being, it is not because brain death signals the irreversible loss of the integrated functioning of the organism as a whole.

As this last point makes clear, the real reason so many people are inclined to agree that the brain-dead patient is dead has much more to do with the fact that the brain-dead patient is permanently unconscious than with the facts of brain stem destruction and respirator dependency. It is this loss of the self, the loss of consciousness and thus of embodiment as a self, that is for many of us a good reason to consider the brain-dead patient dead. This suggests that the concept of human death underlying people's willingness to adopt the brain-death criterion may have more to do with the loss of the capacity for embodied consciousness than with the loss of the capacity for integrated organismic functioning.

The Higher-Brain Formulation

Consistent with this insight, some contributors to the definition-of-death debate propose a higher-brain-death criterion for the determination of death, contending that this criterion presupposes a different and preferable view of what is essentially significant to the nature of the human being. They hold that consciousness, sometimes characterized as a capacity for social interaction, is the *sine qua non* of human existence, and that the criterion used to determine death should reflect this loss. In their view, requiring that the brain-death criterion be used when the patient is permanently unconscious is biologically reductionistic. That is, the brain-death criterion attaches primary significance to the functional connection of the brainstem, lungs and heart, and not the conscious capacity that that functioning supports. Unless the concept of human death reflects what is essentially significant to the nature of the human being as a person—conscious awareness—it fails to provide a community with an effective moral divide between the living and the dead.

Questioning the Higher-Brain Formulation

Critics of the higher-brain formulation object that the emphasis on consciousness and person-centered functions of the human being places us on a *slippery slope* that will eventually lead to a broadening of the definition of death to include those who are severely demented or only marginally or intermittently conscious. They argue further that the adoption of a higher-brain basis for determining death would require us to bury spontaneously respiring (and heart beating) *cadavers*.

These arguments have little to recommend them. First there is a bright and empirically demonstrable line between those who are in a permanent vegetative state (recall the cases of Karen Quinlan, Paul Brophy, Nancy Cruzan, and others) and those who retain the capacity for higher-brain functioning. The slippery slope worry that we would begin to declare conscious patients dead is unfounded. By contrast the slippery slope objection is telling in relation to the whole-brain-death criterion, which does not in fact measure the death of the brain in its entirety. Whole-brain-death adherents have failed to provide criteria for identifying some brain functions as residual and insignificant, so the opportunity for the unprincipled enlargement of the residual functioning category is ever present.

Finally, for aesthetic reasons as well as reasons of respect, society does not permit certain forms of treatment of the dead. There is no reason to think that a consciousness-based concept of death would lead to the abandonment of long-held understandings of the dignified and appropriate treatment of the body of the deceased person. One would not bury a spontaneously breathing body any more than one would bury a brain-dead body still attached to a respirator. A higher-brain advocate might argue that stopping residual heart and lung function would be as morally appropriate in the case of a permanently unconscious patient as the discontinuation of the ventilator is in the case of a brain-dead patient.

Questioning the Irreversibility of Death

Still laboring under the power of the Dead Donor Rule and a concern to increase the supply of transplantable organs, a 1990s effort to update the clinical tests associated with the cardiac-centered traditional criteria occurred. Several transplant centers began the practice, in the case of a dying patient who had consented in advance to be an organ donor and to forego both life-sustaining treatment and resuscitative efforts, of declaring death two minutes after the patient's last heartbeat, as the measure of the patient's irreversible loss of cardiopulmonary function. This approach to assessing the irreversible loss of cardiopulmonary function challenged

people to accept a particular and unprecedented definition of *irreversibility* in relation to declaring patients dead. Both common understanding and the Uniform Determination of Death Act were understood to require irreversibility of functional loss in the stronger sense that the functional loss could in no way be recovered or restored.

If death is declared two minutes after the loss of cardiopulmonary function, when, conceivably, the heart could resume functioning on its own (auto-resuscitation) or resuscitation could successfully restart the heart, in what sense is the loss of function irreversible? It appears that irreversibility is only a function of a morally valid decision on the part of a patient or perhaps a surrogate to forego resuscitation. Is this change in the association of death with the irreversible loss of function ethically acceptable?

The interest in declaring death as close to the cessation of cardiopulmonary function as possible arises from the need to remove organs before warm ischemia destroys their viability for transplantation. But what sense of the concept of irreversibility should be required to assess a loss of critical function sufficient to ground a declaration of death? In the weak moral sense indicated above, two minutes after the last heartbeat when resuscitation has been refused? In the relatively stronger sense that auto-resuscitation of the heart has become physiologically impossible? Or in the strongest sense, that the heart cannot be restarted by any means?

While many hold the religious belief that the self survives the death of the body, the commonly held view is that the death of the body is a finished, non-reversible condition. The Uniform Determination of Death Act requires that the cessation of brain function be irreversible in the sense that all function throughout the entire brain is permanently absent, or it requires that cardiopulmonary function has ceased in the sense that the patient can never again exhibit respiration or heartbeat. Clearly, then, because it entails a novel understanding of the conceptual connections between death and irreversibility, the variation in the application of the cardiopulmonary criterion adopted by many transplant centers after 1992 requires philosophical justification.

In addition this new strategy for determining death raises interesting issues about the overall consistency of alternative approaches to determining death. It has always been the case that a patient declared brain-dead could not be declared dead using the traditional criteria, since the respirator was maintaining lung and heart functions. Those functions were effectively ruled out as signs of life. Yet after only two minutes of cardiac cessation, the patient is arguably not yet brain-dead, raising a question: Is the non-heart beating donor (NHBD) whose heart has stopped for two minutes but whose brain retains some functional capacity *really* dead? In order to be declared dead, should a patient be required to fulfill at least one but not necessarily all extant criteria and their associated clinical tests for the determination of death? Which way of being determined dead is more morally appropriate when surgery to procure organs is to be undertaken?

In sum, the definition-of-death debate goes on. The deep and disturbing irony in this debate surrounds the disagreement among ethicists as to whether the public should be informed about the degree of dissension on the conceptual, clinical, and policy issues central to the debate. Despite the rather stable practice in the United States of using the brain-death criterion to determine death, the definition-of-death debate is at loggerheads. The situation is such that, some have argued, parties to the debate should share none of this dissension with the public lest they disturb the acceptance of the brain-death criterion and the improved access to transplantable organs it allows over the traditional criteria for determining death. Others argue that every question in this debate, including the question of the kind of irreversibility that should ground the determination of deaths, is still an open question, and that the public should be informed and polled for its views. Yet others have suggested that one of the prime movers in the definitional debate, the Dead Donor Rule, should be rethought, and the practices of declaring death, discontinuing life-sustaining treatment, and removing organs for transplantation should be decided independently of one another.

Public Policy for a Diverse Society

The public policy issue in the definition-of-death debate arises because there are diverse, deeply held understandings concerning the nature of the human and human death. Because these views derive from fundamental philosophical, religious, or cultural perspectives, should people have any say in the concept and criteria for determining death that might be applied to them? If, for example, a person is aware that being declared dead under the brain-death criterion contradicts his or her religiously-based understanding of death, should that person be allowed to conscientiously object to the use of this criterion? Some argue that toleration in such matters is imperative because of the extraordinary damage done to persons by ignoring and disrespecting their foundational understandings. They claim that individuals should be allowed to use a conscience clause to express their wishes. Others claim that diversity on such a fundamental matter as the determination of when someone has died can only lead to social and legal instability. The next section explores the diverse philosophical perspectives that might be

taken on human death. On this basis, the reader must decide on the importance and practicality of a conscience clause for those who disagree with the concept and criteria for determining death that have become established U.S. policy.

Philosophical and Theological Perspectives: Preliminaries

Human groups engage in different behaviors upon the death of one of their members. They do so because they have different understandings of the nature of the individual self and, consequently, of the death of the self. Yet every human society needs a way of determining when one of its members has died, when the quantum change in the self that both requires and justifies *death behaviors* has occurred, when the preparation of the bodily remainder of the individual for removal from the sphere of communal interaction both may and must begin.

This need for a line of demarcation between life and death suggests that for societal purposes, the death of an individual must be a determinable event. There has been debate, however, about whether death is an event or a process. Those engaged in this debate have appealed to the biological phenomena associated with the shutting down of a living organism. Some of them have argued that death is a discrete biological event; others, that it is a biological process. In fact, neither biological claim settles the philosophical question of whether death is an event or a process. Different communities decide whether to view the biological phenomena associated with death as an event or a process. For societal/cultural reasons, it is essential that some terminus be recognized.

Death is a biological process that poses a decisional dilemma because, arguably, the biological shutdown of the organism is not *complete* until putrefaction has occurred. Human communities have a need to decide when, in the course of the process of biological shutdown, the individual should be declared dead; they must decide which functions are so essentially significant to human life that their permanent cessation is death. For a variety of reasons, death has come to be associated with the permanent cessation of functions considered to be vital to the organism rather than with the end of all biological functioning in the organism. These vital functions play a pervasive and obvious role in the functioning of the organism as a whole, and so their use as lines of demarcation is reasonable. With their cessation, the most valued features of human life cease forever, and it is reasonable to regard that as the event of a person's death. Advances in medical technology, permitting the mechanical maintenance of cardiac and respiratory functions in the absence of consciousness, force us to evaluate the functions we have always associated with life, and to choose which of them are essentially significant to human life or so valuable to us that their permanent loss constitutes death. The ancient and (until the late-twentieth century) reasonable assumption has been that death is an irreversible condition, so it should not be declared until the essentially significant functions have irreversibly ceased.

In pretechnological cultures, humans undoubtedly drew on the functional commonalities between other animal species and themselves to decide that the flow of blood and breathing were essentially significant functions. When either of these functions stopped, no other *important* functions continued, and predictable changes to the body ensued. Since it was beyond human power to alter this course of events, the permanent cessation of heart and lung functioning became the criterion used to determine that someone had died.

This choice has clearly stood the test of time. Often referred to as the traditional cardio-pulmonary criteria, there is certainly no reason to impugn this choice for a society lacking the technological life-support interventions characteristic of modern medicine. But it is important to see that even in a pretechnological culture, the choice of the traditional cardiopulmonary criteria was a choice, an imposition of values on biological data. It was a choice based on a decision concerning significant function, that is, a decision concerning what is so essentially significant to the nature of the human being that its irreversible cessation constitutes human death. Such a decision is informed by fundamental beliefs and values that are philosophical/theological/cultural in nature.

If a technologically advanced culture is to update its criteria for declaring death, it must reach to the level that informs such a decision. Deciding the normative issue concerning the essentially significant characteristic of a human being is impossible without an ontological account of the nature of the human being. The assumptions and beliefs we hold on these matters form the combined philosophical/theological/cultural basis upon which we dissect the biological data and eventually bisect them into *life* and *death.*

Such assumptions and beliefs constitute the most fundamental understandings and function as the often unseen frame through which people view, assess, and manipulate reality. As a rule, this frame is inculcated through the broad range of processes that a social group uses to shape its members. The frame itself consists of assumptions and beliefs that are used to organize and interpret experience. They are deeply yet pragmatically held beliefs that may be adjusted, adapted, discarded, or transformed when they

cause individual or social confusion, cease to be useful, or no longer make sense. Arguably, changes in the capacity to resuscitate and support the human body in the absence of consciousness have brought that society to such a point of non-sense. To respond fully to this crisis, people must consider the various philosophical and theological perspectives in their culture that inform thinking about human nature and death.

Representative Philosophical and Theological Perspectives

Death is the word we use to signify the end of life as we know it. As stated above, individuals and groups hold different understandings of the existence and the death of the self. These understandings are the background for the *nuts and bolts* medical decision that a person has died, when death should be declared, and what ought/ought not be done to and with the physical remains of the person who has died.

As individuals and as cultural groups, humans differ in their most basic assumptions and beliefs about human death. For some the death of the body marks the absolute end of the self; for others it is a transition to another form of existence for the continuously existing self. This transition may be to continued life in either a material or an immaterial form. Despite these differences, every human community needs a way of determining when one of its members has died, a necessary and sufficient condition for considering the body as the remainder of the individual that can now be treated in ways that would have been inappropriate or immoral before, and for preparing the body for removal from the communal setting. Different philosophical and theological perspectives on the nature of death, the individual self, and the death of the self will yield different choices of criteria for the determination of death, just as these differing perspectives yield very different death practices or death behaviors. To see why this is the case, various philosophical and theological views of death and the self must be reviewed.

In the Hebrew tradition of the Old Testament, death is considered a punishment for the sin of disobedience. It is an absolute punishment. This tradition does not hold a concept of an afterlife following the punishment of death. But it would be misleading to say that this tradition has no conception of immortality, since the communal setting of the individual's experience and life remains the arena of that person's identity and impact, even after the death of the body. Although the conscious life of the person ceases, the person lives on in the collective life, unless he or she lived badly. Thus, immortality is the community's conscious and unconscious memory of the person.

Another view, originating in Platonic philosophy and found in Christian and Orthodox Judaic thought, and in Islam and Hinduism, holds that death is not the cessation of conscious life. The conscious self, often referred to as the soul, survives in a new form, possibly in a new realm. The experience of the self after the death of the body depends on the moral quality of the person's life. The body is the soul's temporary housing, and the soul's journey is toward the good, or God, or existence as pure rational spirit without bodily distractions. Thus, death is the disconnection of the spiritual element of the self (mind, soul, spirit) from the physical or bodily aspect of the self.

Traditions believing in eternal life differ in their view of the soul and its relationship to the body. This has implications for the criteria that might be used to determine death, as well as for the appropriate treatment of the body after death. The soul is viewed by some as separate and capable of migrating or moving into different bodies as it journeys toward eternal life. The Christian tradition, by contrast, posits the self as an eternally existing entity created by God. The death of the body is just that—the person continues, with body transformed, either punished in hell for living badly or rewarded in heaven for having faith and living righteously. These diverse views have a common belief: Everyone survives death in some way. This may influence the understanding of what constitutes the death of the body as well as of what ought/ought not to be done to the body of the person who has died. For some traditions, certain bodily functions are indicative of life, whether or not those functions are mechanically supported, and damage to the body is damage to the self.

In contrast to these theological conceptions of death and the self, three philosophical perspectives, secular in that they hold materialist views of the self, figure in Western thought: the Epicurean, the Stoic, and the existential. A materialist view of the self considers the human to be an entirely physical or material entity, with no soul or immaterial aspect. The Epicurean view of the self holds that humans are fully material beings without souls. The goal of life is to live it well as it is and not to fear death since death is the end of experience, not something one experiences. Therefore, there is no eternal life for souls; the body dies and disintegrates back into the material nature from which it sprang. The death of the body marks the end of consciousness, and thus the death of the self. A materialist holding a view such as this could conclude that the cessation of consciousness itself should be considered death, whether or not the body continues to function in an integrated manner.

The Stoic view acknowledges death as the absolute end of the conscious self but directs persons to have courage about its inevitability and to resign to it creatively. This

creative resignation is achieved by focusing on the inevitability of death in such a way that one treats every moment of life as a creative opportunity. The necessity of death becomes the active inspiration for the way one lives. Like the Epicurean view, the Stoic conception ties the self to the body; the end of the self to the death of the body. But it is the consciousness supported by the body that is the creative self.

In contrast existential thought believes that the absoluteness of death renders human life absurd and meaningless. The other materialist views of the self saw death as the occasion for meaning in life, not the denial that life has meaning. Rather than infusing meaning into life and inspiring a commitment to striving, existentialism holds that death demonstrates the absurdity of human striving. While individuals may pursue subjective goals and try to realize subjective values during their lives, there are no objective values in relation to which to orient one's striving, and so all striving is ultimately absurd. Since death is the end of the self, there is nothing to prepare for beyond the terms of physical existence and the consciousness it supports.

Without critiquing these theological and philosophical perspectives on death and the self, an inquiry into their diversity is relevant to a discussion of the debate in bioethics about the criteria for determining that a human being has died. The earlier demonstration that the criteria rest on a decision of functional significance, and that a decision of functional significance is philosophically/theologically informed, coupled with this demonstration of philosophical/theological diversity on the fundamental concepts of self and the death of the self, together show that criteria are acceptable only if they are seen to be consistent with an accepted philosophical/theological frame, and that what is acceptable in one frame may be unacceptable in another.

Further, while it might be the case that virtually every tradition has agreed on the appropriateness of the traditional heart and lung criteria for declaring death, they may do so for vastly different reasons deriving from their specific understanding of death and the self. There may be ways of reconciling virtually every ontological view to the use of the traditional criteria but not to the use of consciousness-centered criteria like the higher brain-death criterion, or even the brain-death criterion (which appears, to a tradition like Orthodox Judaism, to deny that the still-functioning body is indicative of life, even when the entire brain is dead).

Philosophical and theological commitments relate centrally to society's death practices, including conclusions concerning the acceptability of traditional, and whole-brain, and higher-brain formulations of death. How philosophically and theologically sophisticated has the bioethics debate on the definition of death been, over the years?

The Persistence of the Debate

Why do arguments concerning the definition and criteria of death persist? The debate has been intractable since 1968. One important reason is that the concepts of self and death that inform the various positions in the debate are based on fundamental beliefs and values that suggest that they will remain irreconcilably different. While it is true that persons holding different philosophical/theological/cultural premises may assent to the use of the same criteria for determining death, they may well do so for very different reasons. Because of this, it is reasonable to seek and adopt a broadly acceptable societal standard for the determination of death.

For example, the several materialist views of the self that were examined earlier suggest a consciousness-centered concept of self and death that further recommends a higher-brain formulation of death. But equally, the prevailing Judeo-Christian understandings of the self and death—that of death as the dissociation of consciousness from the body, the end of embodied consciousness—are also compatible with a higher-brain formulation of death.

Some traditions, like Orthodox Judaism, and certain Japanese and Native American perspectives, resist the use of the brain-death criterion because they understand death to be a complete stoppage of the vital functions of the body. The self is not departed until such stoppage has occurred. Such groups will be uncomfortable with the use of the brain-death criterion because it permits the determination of death while vital functions continue. This kind of philosophical/theological difference in perspective on the human self, intimately linked to a person's religious and cultural identity, raises serious questions about how a pluralistic culture should deal with deeply held differences in designing a policy for the determination of death.

Given that there are a finite number of possible perspectives on the human person and on human death, and given the rootedness of these perspectives in conscientiously held philosophical and religious views and cultural identities, public policy on the determination of death in a complex and diverse culture could well manage to service conscience through the addition of a conscience clause in a determination-of-death statute. Similar to and perhaps in conjunction with a living will, a person could execute a conscience-clause exclusion to the statute's implicit concept of death. For instance, an Orthodox Jew could direct that death be determined using the traditional criteria alone, and also indicate personal preferences concerning the use of life-sustaining treatment such as ventilator support in the situation of brain death.

The fact that a conscience clause would permit some to reject the use of the brain-death criterion need not hinder

the law from specifying punishable harms against others on the basis of considerations additional to whether death was caused. The exotic life-sustaining technologies now available have already generated arguments concerning whether the person who causes someone to be brain-dead or the person who turns off the ventilator on that brain-dead patient causes the patient's death.

Life-sustaining technologies as well as the alternative concepts of death underscore the need for more precise legal classifications of punishable harms to persons. Such a classification should recognize permanent loss of consciousness as a harm punishable to the same extent as permanent stoppage of the heart and lungs.

The self can be thought of in a variety of ways: as an entirely material entity, as an essentially mental entity, and as a combined physical/mental duality. In contemporary language, the human being may be thought of as a physical organism, as an embodied consciousness (which we often call person), or as an amalgam of the two. As one examines the definition-of-death debate, one sees that fundamentally different ontological perspectives on the human have been taken.

Once such an ontological perspective on the human being has been chosen, a further decision as to what is essentially significant to the nature of the human being can be made. When a conclusion is reached as to which function is essentially significant to the human being, the potential exists for settling on the criterion (or criteria) for determining death. To the extent that these two steps of philosophical analysis support attention to the brain as the locus of the relevant human functions, views may divide on whether a whole-brain or a higher-brain formulation of death is adopted.

A complex entity that manifests its aliveness in a variety of ways has the potential to engender dispute about the ontological perspective that should be taken toward it, as well as about what is essentially significant to it. Hence, there may be no agreement on the definition of death that should be applied. Instead, the greatest achievement may be to articulate a policy on the determination of death that honors a plurality of philosophical/theological perspectives.

DEATH PENALTY

• • •

Fewer and fewer crimes are punishable by death even in countries where execution is legal, and crimes that are widely considered to be extremely serious, such as murder, often lead to prison sentences rather than capital punishment. In 1991, offenses under the laws of over ninety countries carried a penalty of death. In eighty-five, execution was illegal or had ceased to be imposed. These included virtually all of the nations of western Europe, as well as Canada, Australia, Hungary, and Czechoslovakia. In the United States, in addition to military and federal jurisdictions, thirty-six states impose the death penalty. Not all of these states do so regularly, however; and in those where capital punishment has become routine, it is sometimes a relatively new development. From 1967 to 1977 there were no executions in the United States; between 1977 and 1992, there were 190, and over 2,500 people in 34 states were on death row. In a few countries in which the death penalty was still used in the 1980s—Brazil, Argentina, and Nepal—it had been reintroduced (in Brazil and Argentina by military governments) after a long period of abolition.

The reintroduction of capital punishment after centuries of decline has once again raised the question of the morality of execution. No code of law now prescribes death for the theft of fruit or salad, as Draco's code did in ancient Athens; and boiling to death is no longer a recognized punishment for murder by poisoning, as it was in England under the Tudors and Stuarts. Can a principle that explains why these developments are good also explain why it is good that some codes of law no longer prescribe death as punishment for murder? Or can a principle that condemns the death penalty for some crimes also support its imposition for others? These are live questions, for one of the arguments commonly presented against the death penalty turns on the suggestion that retaining it or reintroducing it is a case of being morally behind the times. According to this argument, standards of humane punishment have now risen to a point where killing a human being—even one who is guilty of a terrible crime—can only be understood as cruel, and therefore immoral. Such an argument is sometimes used to counter another that is perhaps even more familiar: that the death penalty is justified because of its power to deter people from violent crime. The argument from deterrence will be examined later.

The Argument from Cruelty

The language of this argument is sometimes taken from the Eighth Amendment of the U.S. Constitution ("Excessive bail shall not be required, nor excessive fines imposed, nor cruel and unusual punishments inflicted"); or from human-rights declarations that outlaw "cruel, inhuman or degrading" treatment or punishment. Thus, a brochure titled *When the State Kills,* issued by the British Section of Amnesty International (1990), contains the following passage under the heading "Cruel, Inhuman and Degrading": "International law states that torture or cruel, inhuman or degrading punishments can never be justified. The cruelty of the death penalty is self-evident."

Certain methods of execution are quite plausibly said to be so painful that any application of them must be cruel. Amnesty International cites the case of a Nigerian military governor who in July 1986 ordered successive volleys of bullets to be fired at convicted armed robbers. The shots would first be aimed at the ankles, to produce painful wounds, and only gradually would the firing squad shoot to kill. Other methods, believed by some authorities to be painless, can undoubtedly cause suffering when clumsily applied. According to eyewitness reports, the first death sentence carried out by use of the electric chair in the United States; in August 1890, was very painful. But these ill effects may not be typical. Certainly the electric chair was not introduced because it was thought to be painful; on the contrary, along with other methods of execution, such as the guillotine, it was thought to spare the convicted person suffering.

Execution by lethal injection is the latest in a series of supposedly humane methods of execution to be introduced. It is now being used in a number of states in the United States. Is this technique cruel? Perhaps not, if severe pain is the test of cruelty. Deliberate poisoning is normally cruel, and Amnesty International classifies the use of lethal injection as deliberate poisoning. But is it clear that poisoning in the form of lethal injection is always cruel? What if the injection is self-administered in a suicide or given at the request of someone who is dying in intense pain? If poisoning is always cruel, then it must be so in these cases. On the other hand, if it is not cruel in these cases, then it is not necessarily cruel in the case of execution. It is true that execution is usually not in line with the wishes of the convicted person, as it is when poison is administered to

someone at his or her request. But that by itself cannot make execution cruel, unless virtually all punishment is cruel: Virtually all punishment is inflicted on people against their wishes. If it is not pain and not the unwillingness of the criminal to undergo it that makes lethal injection cruel, then what does? If nothing does—if lethal injection is sometimes painless and not cruel in other respects—then there may be principles that consistently explain why it is good for murderers, for example, to be punished with death (severe crimes deserve severe punishments); why it was bad for murderers to be put to death in the past by boiling (torture is wrong); and why it is not necessarily bad for murderers to be put to death today by lethal injection.

Arguments from Finality and Arbitrariness

Arguments against the death penalty sometimes emphasize its finality. There are several versions of the argument from finality, some religious, some secular. One religious version has to do with the way the death penalty removes all possibility of repentance or a saving change of heart on the part of the offender (Carpenter). Capital punishment writes off the offender in a way that, for example, imprisonment combined with education or religious instruction does not. It arguably refuses the offender the sort of love that Christianity enjoins, and it presumes to judge once and for all—a prerogative that may belong to God alone.

Secular arguments from finality are almost always combined with considerations about the fallibility of judicial institutions and doubt whether people who are accused of crimes are fully responsible agents. In some views, society contributes to the wrongdoing of criminals (Carpenter), so that they are not fully responsible and should not be punished. This argument shows sympathy for those who are accused of wrongdoing, but because it does not take wrongdoers as full-fledged agents it may not show them as much respect as apparently harsher arguments do. As for fallible judicial institutions, certain factors—such as prejudice against some accused people, and poor legal representation—can produce wrong or arbitrary verdicts and sentences; even conscientious judges and juries can be mistaken. When errors occur and the punishment is not death, something can be done to compensate the victims of miscarriages of justice. The compensation may never make up entirely for what is lost, but at least a partial restitution is possible; but where what is lost is the accused person's life, on the other hand, the possibility of compensation is ruled out. This argument is particularly forceful where evidence exists that certain groups (black males in the United States, Tibetans in China) are disproportionately represented among those receiving harsh sentences, including the death sentence (Amnesty International, 1991; Wolfgang and Reidel). In these cases, the possibility of an error with disastrous consequences starts to grow into something like a probability. What is more, the evidence of certain groups being disproportionately represented suggests that the law is not being applied justly. This adds to the argument that the death penalty should not be applied, for it suggests that people are fallible, the background conditions for the existence of justice are not being met, and consequently that some miscarriages of justice result from factors other than honest error.

Arguments from Side Effects

EFFECTS ON PROFESSIONALS. Executions are carried out by officials who are not always hardened to their task, and at times they rely on the services of medical people, who have sworn to preserve life. The burdens of those who officiate and serve in these ways; the suffering of those who are close to the convicted person; and the ill effects on society at large of public hangings, gassings, or electrocutions are sometimes thought to constitute an argument against capital punishment over and above the argument from cruelty to the offender.

The side effects on medical personnel have recently been brought into prominence in the United States by the use of lethal injection. The method involves intravenous injection of a lethal dose of barbiturate as well as a second drug, such as tubocurarine or succinylcholine, that produces paralysis and prevents breathing, leading to death by asphyxiation. Doctors have sometimes had to check that the veins of the convicted person were suitable for the needle used and, where death took longer than expected, to attend and give direction during the process of execution. In Oklahoma, which was the first state to adopt lethal injection as a method of execution, the medical director of the Department of Corrections is required to order the drugs to be injected; the physician in attendance during the execution itself has to inspect the intravenous line to the prisoner's arm and also pronounce him dead.

Of course, doctors have been in attendance at executions carried out by other methods, and some of the moral objections to their involvement are applicable no matter which method is used. What is different about intravenous injection, in the opinion of some writers (e.g., Curran and Cassells), is that it involves the direct application of biomedical knowledge for the taking of life. This practice is often said to be in violation of the Hippocratic Oath (Committee on Bioethical Issues of the Medical Society of the State of

New York); and many national and international medical associations oppose the involvement of doctors in the death penalty. The fear that nurses might assist at executions led the American Nurses Association in 1983 to declare it a "breach of the nursing code of ethical conduct to participate either directly or indirectly in legally authorized execution."

The conflict between providing medical services to further an execution and abiding by the Hippocratic Oath makes the moral problem facing doctors particularly sharp, but other professionals may face difficulties as well. Judges and lawyers may be caught up unwillingly or reluctantly in prosecutions that will lead to the imposition of the death sentence. They, too, have a reason for withdrawing their services if they are sincerely opposed to capital punishment; but if all the professionals with qualms acted upon them, the legal process, and the protections it extends to those accused of capital crimes, might be compromised as well (Bonnie). This argument probably understates the differences between legal and medical professionals: the latter recognize a duty of healing and of relieving pain; the former are committed to upholding the law and seeing that justice is done, which does not necessarily conflict with participation in a regime of execution.

EFFECTS ON PERSONS CLOSE TO THE CONDEMNED AND ON SOCIETY. In addition to the effects of the death penalty on involved professionals, the effects on persons close to condemned prisoners are sometimes cited in utilitarian arguments against the death penalty (Glover). These effects are undoubtedly unpleasant, but it is unclear whether they are to be traced to the existence of capital punishment or to the commission of the crimes classified as capital. As for the effects on society at large, they are harder to assess. Samuel Romilly, who campaigned successfully for a reduction in the very large number of capital offenses recognized in English law at the beginning of the 1800s, maintained that "cruel punishments have an inevitable tendency to produce cruelty in people." In fact, Romilly's success in law reform owed something to the benevolence of juries, who had consistently, and often against evidence, found accused people innocent of capital offenses as minor as shoplifting. Whoever was made cruel by the existence of cruel punishments, it was not ordinary English jurors. Judges avoided imposing the death penalty for minor crimes by transporting criminals to the colonies.

Deterrence

The death penalty has often been introduced to act as a strong deterrent against serious crime, and the deterrence argument is commonly used to justify reintroduction. In a British parliamentary debate on the reintroduction of capital punishment in May 1982, one legislator said, "The death penalty will act as a deterrent. A would-be murderer will think twice before taking a life if he knows that he may well forfeit his own in so doing" (Sorell, pp. 32–33). He went on to argue that the absence of the death penalty had been associated with a rise in the number of ordinary murders, and an increase in the rate of murder of police officers. But the evidence for its having the power to discourage, or for its having a greater such power than imprisonment, is inconclusive (Hood). Indeed, deterrence generally seems to depend on potential offenders expecting to be caught rather than on their judging the punishment for an offense to be severe (Walker). In the case of murder, the deterrent effect is particularly doubtful: Murder is often committed in a moment of high passion or by those who are mentally disturbed (Sorell). Either way, the serious consequences of the act are unlikely to register so as to make the agent hesitate. An American review of statistical studies concludes that the deterrent effect of capital punishment is definitely not a settled matter, and that the statistical methods necessary for reaching firm conclusions have yet to be devised (Klein et al.).

Incapacitation

A purpose of punishment that is more convincingly served by the death penalty is the incapacitation of offenders. The death penalty undoubtedly does incapacitate, but this is just another aspect of its finality, which has already been seen to be morally objectionable from some points of view. Again, for incapacitation to be a compelling general ground for the imposition of the death penalty—that is, a ground that justifies the imposition of the penalty in more than the occasional case—there has to be strong evidence that people who have the opportunity to repeat capital crimes frequently do so. Although killers sometimes kill again, it is not clear that they are *likely* to reoffend. Finally, life imprisonment without parole may be sufficiently incapacitating to make the death penalty unnecessary.

Retribution

Another argument in favor of the death penalty is based on the value of retribution. Here the idea is that the evil of a crime can be counterbalanced or canceled out by an appropriate punishment, and that in the case of the most serious crime, death can be the appropriate punishment because it is deserved. Appropriateness should be understood against the

background of the thought that penal justice requires what Immanuel Kant called an "equality of crime and punishment." His examples show that he meant an act of punishment not identical to the crime but proportionate to its severity; Kant held that death was uniquely appropriate to the crime of murder. John Stuart Mill, in a famous speech in favor of capital punishment delivered in the British House of Commons in 1868, argued that only those guilty of aggravated murder—defined as brutal murder in the absence of all excusing conditions—deserved to be executed. Mill called the punishment "appropriate" to the crime and argued that it had a deterrent effect. He meant "appropriate" in view of the severity of the crime.

Retribution should not be confused with revenge. It is generally considered revenge, not retribution, when there is love or sympathy for the one who has suffered an injury; retribution requires a response even to injuries of people no one cares about. Its impersonality makes the injuries of the friendless have as much weight as the injuries of the popular. Again, revenge is still revenge when the retaliation is utterly out of proportion to the original injury, but the retributivist *lex talionis*—an eye for an eye—limits what can be done in return.

One question raised by the retributivist defense of capital punishment is how a punishment can counterbalance or cancel out an evil act. Retributivists sometimes refer in this connection to the ideal case in which the offender willingly undergoes a punishment as a sign of remorse and of wishing to be restored to a community from which he or she has been excluded due to a criminal act (Duff). In that case the punishment is supposed to counterbalance the crime. But it is unnecessary for retributivism to be committed to the idea that a punishment cancels out an offense. One can appeal instead, as Kant did, to a punishment's fitting an offense—being proportional in quality to the quality of the offense—and one can justify the imposition of punishment by reference to the following three considerations: (1) laws have to promise punishment if people who are not wholly rational and who are subject to strong impulses and temptations are to obey the laws, and promises must be kept; (2) offenders who are convicted of breaking laws in a just society can be understood to have been party to a social contract designed to protect people's freedom; and (3) threats of punishment in a just society are intended to prevent encroachments on freedom.

This is not a justification of capital punishment, until one specifies a crime that capital punishment uncontroversially fits. Murder is not always the right choice, since such factors as provocation, the numbers of people who die, and the quality of the intention can make some murders much more serious than others; while crimes other than murder—crimes in which, despite the criminal's best efforts, the victim survives—can be as bad as or worse than those in which death occurs. Aggravated murder is, as Mill maintained, a more plausible candidate for capital crime than is plain murder. But execution even for aggravated murder has something to be said against it: the danger of executing the innocent in error, and the suspicion—which goes to the heart of retributivism—that it is bad for pain or unpleasantness to be visited even on wrongdoers.

DEEP BRAIN STIMULATION

• • •

Electrical stimulation of the brain is an important therapy for refractory neurological disorders such as drug resistant Parkinson's disease and severe tremor and has become an area of active clinical research in both neurology and psychiatry. Using a technique called *deep brain stimulation* (DBS), small electrical leads are placed into the brain using stereotactic localization. A special head frame is attached to the skull under local anesthesia, and electrodes are implanted using internal brain targets located with reference to anatomical landmarks determined by brain imaging techniques such as computed tomography (CT) or magnetic resonance imaging (MRI). This technique allows for the precise targeting of specific brain sites or nuclei. Insertion of electrodes can be done without damage to adjacent tissue. These electrodes are connected by a wire to a pacemaker implanted in the chest that generates electrical stimulation. Stimulation parameters can be modified by manipulation of the pacemaker.

Unlike ablative surgery that results in irreversible damage of brain tissue from the intentional destruction of targeted areas, the effects of DBS are reversible. The stimulator can be turned off, and the electrodes can generally be removed without any significant aftereffects. DBS differs from other methods that employ electrical stimulation of the central nervous system. Electroconvulsive therapy (ECT), primarily used to treat severe depression, stimulates the brain using electrodes placed on the scalp. Transcranial magnetic stimulation induces electrical currents in the brain using external magnetic coils. Electrical stimulation in the neck of the vagus nerve has been demonstrated to reduce epileptic seizures. Cortical stimulation of the brain is also employed as a treatment for chronic pain disorders (Greenberg).

Electrical stimulation of the brain is also used as a diagnostic tool in the treatment of epilepsy and as a means to localize specific brain areas in order to avoid injury

during surgical procedures. Electrical stimulation has also been applied within the peripheral nervous system for neuroprosthethic applications such as reconstituting motor function in a paralyzed limb.

Historical Considerations

The modern history of electrical stimulation of the brain dates to the nineteenth century During this period the French surgeon and anthropologist Paul Broca (1824–1880) correlated speech with an area in the left hemisphere that is known as Broca's area, and the English neurologist John Hughlings Jackson hypothesized that electrical activity in the cortex could result in seizures. In tandem with these efforts to correlate cerebral structure and function, early neurophysiologists engaged in animal experimentation using electrical stimulation In 1870 the German neurologists Eduard Hitzig and Gustav Fritsch demonstrated motor activity in a dog following stimulation (Thomas and Young). In 1873 the Scottish neurologist David Ferrier induced contralateral seizures in a dog after unilateral hemispheric stimulation.

The first known electrical stimulation of the human brain was conducted by the American neurosurgeon Roberts Bartholow in Cincinnati, Ohio, in 1874 on a terminally ill woman with locally invasive basal cell carcinoma that had eroded her skull and left her brain exposed. Bartholow demonstrated that the dura mater covering the brain was insensate, that motor activity on one side of the body could be induced by stimulation of the opposite hemisphere, and that electrical stimulation of the brain could induce localized seizures and transient loss of consciousness when the amount of current was increased. The patient subsequently died from recurrent seizure activity. Contemporaries harshly criticized Bartholow on ethical grounds because of the fatal complications of the intervention, the uncertain nature of the patient's "consent," and the suffering that she experienced (Morgan).

Early electrical stimulation of the brain was used as a method of mapping cerebral cortical function, matching the site of stimulation of the brain's surface with the patient's response during operations under local anesthesia. Pioneering work was done by two American neurosurgeons: Harvey Cushing in the early twentieth century and Wilder Penfield, who later in the century used electrical stimulation in his study of epilepsy and the mapping of cognitive function. An important advance was the development in 1947 of stereotactic surgery, which enabled brain targets to be precisely located in three dimensions. With this technique, electrodes could now be inserted in the brain without the completion of a full craniotomy in which the entire skull needs to be opened (Gildenberg, 1990).

Robert G. Heath first described electrical stimulation for the control of chronic pain in his 1954 book, *Studies in Schizophrenia.* In the 1960s and 70s investigators demonstrated that deep stimulation of selected targets within the brain was demonstrated to relieve pain In 1985, the Swiss neurosurgeon, Jean Siegfried noted that stimulation of the thalamus for pain control could improve tremor in a patient with Parkinson's disease (Gildenberg, 1998).

The Psychosurgery Debate

Research involving electrical stimulation of the brain was closely linked to the broader debate over psychosurgery in the 1960s and 1970s (Fins, 2003). Commentators from that era worried about the use of electrical stimulation of the brain as a means of behavior control to address social problems such as crime and civic unrest. These concerns were prompted, in part, by the work of José M. R. Delgado who advanced the idea of "psychocivilizing society" using a brain implant that could be operated by remote control. Delgado came to international attention in 1965 when he stopped a charging bull in a bullring using a "stimoceiver" he had developed. Speculation was enhanced by popular novels such as Michael Crichton's *The Terminal Man* whose main character underwent electrical stimulation of the brain to treat violent behavior.

The National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, authorized by the National Research Act of 1974, was specifically ordered by the U.S. Congress to issue a report on psychosurgery (*National Research Act of 1974. U.S. Statutes at Large*). The National Commission, which issued its report in 1977, included electrical stimulation of the brain under its definition of psychosurgery, noting that "psychosurgery includes the implantation of electrodes, destruction or direct stimulation of the brain by any means" when its primary purpose was to "control, change, or affect any behavioral or emotional disturbance" (National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research). The National Commission's definition of psychosurgery excluded brain surgery for the treatment of somatic disorders such as Parkinson's disease or epilepsy or for pain management.

Of the National Commission, the Behavioral Control Research Group of the Hastings Institute (Blatte), and the American Psychiatric Association's Task Force on Psychosurgery (Donnelly), none found reliable evidence that psychosurgery had been used for social control, for

political purposes, or as an instrument for racist repression as had been alleged. Contrary to expectations of the day, the National Commission did not recommend that psychosurgical procedures be banned. Instead, it found sufficient evidence of efficacy of some psychosurgical procedures to endorse continued experimentation as long as strict regulatory guidelines and limitations were in place.

Although allegations of mind control were never substantiated, contemporary media reports about modern deep brain stimulation often allude to these earlier fears This misuse of historical analogy has the potential to distort current policy regarding the regulation of this novel technology (Fins, 2002).

Clinical Applications in Neuromodulation

The modern era of neuromodulation began in 1987 when the French neurosurgeon Alim Benabid noted improvements of parkinsonian tremor following stimulation of the thalamus (Speelman and Bosch). While engaged in mapping with electrodes prior to ablative surgery for Parkinson's disease, Benabid discovered that electrical stimulation of specific targets could modulate motor symptoms and tremor—a technique that came to be known as neuromodulation. These observations inspired him to develop the modern deep brain stimulator in use today (Fins and Schachter).

Deep brain stimulation is viewed as the standard of care for the treatment of refractory Parkinson's disease and is no longer investigational. In 1997 the U.S. Food and Drug Administration (FDA) approved use of the deep brain stimulator for refractory Parkinson's disease and essential tremor (Blank). DBS has been found effective in prospective, double-blind studies in patients with advanced Parkinson's disease (Deep-Brain Stimulation, 2001; Kumar et al.).

Complications can be related to the procedure, device, or stimulation, and they include hemorrhage, infection, seizures, and hardware-related complications. Such complications can necessitate revision or removal of the device at a rate per electrode year of 8.4 percent (Oh et al.). In one large series of patients, there were no fatalities or permanent severe neurological complications, although 6 percent of patients had some persistent neurological complication (Beric et al.).

In addition to being used to treat Parkinson's disease, neuromodulation using DBS has been used to treat chronic pain and manage epilepsy (Kopell and Rezai). Cortical mapping continues, with more electronic sophistication. Such mapping is being used to guide neurosurgical procedures; to prevent injuries to critical areas, such as those associated with speech or movement, during operations on the brain; and to precisely locate areas of the brain involved with epilepsy, occasionally by provoking seizures through stimulation (Feindel).

Investigational Applications

Research in deep brain stimulation is blurring the disciplinary boundaries between neurology and psychiatry. French investigators have discovered that DBS caused transient acute depression in a patient with Parkinson's disease whose motor function had improved markedly through DBS intervention (Bejjani et al.). Investigators are conducting clinical trials for the use of DBS for severe psychiatric illnesses such as obsessive–compulsive disorder using techniques pioneered in the treatment of movement disorders (Roth et al.; Rapoport and Inoff-Germain). Nicholas D. Schiff and colleagues have proposed the use of DBS for the modulation of consciousness after severe traumatic brain injury (Schiff, Plum, and Rezai).

Ethical Considerations

Deep brain stimulation raises special concerns because neuromodulation techniques deal with the direct stimulation of the brain. No other organ is so closely involved with concepts of mind or self, self-determination and consent.

POTENTIAL ALTERATION OF THE SELF. Interventions involving brain structure or function may result in alterations in cognition, memory, or emotions that may have a bearing on personhood. The potential of DBS to alter brain function may lead some to argue categorically against these interventions. This position would fail to appreciate that psychoactive drugs and cognitive rehabilitation alter brain states and that DBS can be used to restore brain functions that had themselves been altered by injury or disease.

The use of DBS as a potential agent of cognitive rehabilitation raises the question of whether helping a patient regain self-awareness is always an ethical good (Fins, 2000). Partial recovery of cognitive function could theoretically lead to greater awareness of impairment and increased suffering. These perceptions, which may also accompany improvement from more conventional rehabilitation, might be reversed with cessation of stimulation or be treated with antidepressant therapy.

THERAPEUTIC VERSUS INVESTIGATIONAL USE. Given the rapid development of this field, it is important to determine whether the application of deep brain stimulation

to a particular disease is therapeutic or investigational. Historically, a treatment has moved from investigational use to therapeutic use when it is shown to relieve the symptoms it is intended to relieve with an acceptable degree of risk and when a significant proportion of physicians, especially those working in the field, are convinced that the intended outcome will appear without adverse long- or short-term effects that outweigh the benefits. This delineation between research and therapy has implications for the informed-consent process and the ability of surrogates to provide consent for DBS when a patient or subject lacks decision-making capacity. In the early twenty-first century DBS is recognized as therapeutic for the management of chronic pain, Parkinson's disease, and other movement disorders. It remains investigational for other indications.

Today, the use of a device such as the deep brain stimulator goes through several investigational stages before it is accepted as therapeutic. Formal mechanisms are in place to codify this transition. The FDA uses the investigational device exemption process to regulate devices that pose significant risk, such as the deep brain stimulator (Pritchard, Abel, and Karanian). FDA procedures, which supplement institutional review board (IRB) oversight of clinical trials, are designed to establish the safety and efficacy of devices and are required by law.

Once a device has been approved for use in humans, a clinical trial can proceed to assess the safety and efficacy of the device for a particular indication. Use of a device is deemed therapeutic when its safety and efficacy have been demonstrated in prospective trials, the most rigorous being ones that are double-blinded and randomized (a double-blinded study is one in which during the course of the study neither the subjects nor the conductors of the study know which subjects are in the active therapy or placebo group). Blinded studies can be conducted in the evaluation of DBS. Once the electrodes have been implanted, patients can be blinded to whether they are receiving stimulation, and their responses can be evaluated. Such methodological rigor is essential in the assessment of DBS because of the potential for a powerful placebo effect. The placebo effect has been shown to improve motor performance of patients with Parkinson's disease who were led to believe that they were being stimulated (Pollo et al.).

Demarcating the therapeutic use of DBS from the investigational may be difficult. For example, the use of an approved device does not, in itself, mean that an intervention is therapeutic. In these cases, the intent of the physician or clinical investigator may be important. Many would assert that if the physician's *intent* is to produce effects generally beneficial to the patient that have previously been demonstrated in similar cases, the intervention can be considered therapeutic. But when the investigator intends to use an approved device to increase knowledge of safety or efficacy for an approved indication or use the device at a new anatomical site or for a new indication, such interventions should be considered to be investigational and undergo review by an IRB.

Because investigational uses of DBS require more regulatory oversight, clinicians might be biased to classify borderline uses of DBS as therapeutic When it is unclear whether the use of DBS is therapeutic or investigational, clinicians should seek the guidance of their local IRB to mitigate this potential conflict of interest.

INFORMED CONSENT. The delineation of DBS as either therapeutic or investigational is also critical given ethical norms that govern informed consent. Given the ongoing investigational nature of many DBS procedures, potential candidates for stimulation need to be informed of whether the proposed procedure is therapeutic or experimental. Physicians who obtain consent from patients for therapeutic procedures should explain the risks, benefits, and alternatives so that the patient, or a surrogate authorized to consent for medical treatment, can provide consent.

Clinicians should seek to maintain the patient's voluntariness and ability to make an informed and reasonable decision about treatment with DBS. Those obtaining consent should appreciate that the chronic nature of the illness and desperation may lead a patient to consent to any treatment that promises symptomatic relief.

When individuals are approached for enrollment in an IRB-approved clinical trial, it is especially important to state the investigational nature of the intervention. Investigators should be careful to avoid the suggestion of a "therapeutic misconception" that falsely equates a clinical trial with safe and effective therapy (Applebaum et al.).

DBS RESEARCH IN THE DECISIONALLY INCAPACITATED. Individuals with severe psychiatric illness or head trauma, who may become candidates for enrollment in DBS clinical trials, may lack decision-making capacity. When these individuals are unable to engage in the informed-consent process, they are considered a vulnerable population and in need of special protections. While surrogates are generally allowed to consent to therapeutic procedures, their authority is more constrained when permission is sought for enrollment in a clinical trial unless they have been authorized through an advance directive for prospective research.

The National Bioethics Advisory Commission (NBAC), in its 1998 report, *Research Involving Persons with Mental*

Disorders That May Affect Decisionmaking Capacity, proposed guidelines to regulate the conduct of research on individuals who are unable to provide consent. While the NBAC recommendations were never enacted into law, they do point to the ethical complexity of neuromodulation research in several cases: when subjects lack decision-making capacity, when the research has yet to demonstrate the prospect of direct medical benefit, and when the research poses more than minimal risk.

BALANCING THE PROTECTION OF HUMAN SUBJECTS WITH ACCESS TO RESEARCH. When considering the balance between the protection of human subjects and access to neuromodulation research, it is important to ask whether current ethical norms deprive decisionally incapacitated individuals of interventions that have the potential to promote self-determination by restoring cognitive function (Fins, 2000). While the ethical principles of respect for persons, beneficence, and justice require that decisionally incapacitated subjects are protected from harm, these principles can also be invoked to affirm a fiduciary obligation to promote well-designed and potentially valuable research for this historically underserved population (Fins and Miller; Fins and Schiff). This justice claim becomes especially compelling as developments in neuromodulation demonstrate growing clinical potential (Fins, 2003).

DEMENTIA

• • •

The syndrome of dementia is an irreversible decline in cognitive abilities that causes significant dysfunction. Like most syndromes, dementia can be caused by a number of diseases. In the nineteenth century, for example, a main cause of dementia was syphilis. As a result of dramatic increases in average human life expectancy, dementia is caused primarily by a number of neurological diseases associated with old age. Dementia is distinguished from *pseudo-dementia* because the latter is reversible—for example, depression, extreme stress, and infection can cause dementia but with treatment a return to a former cognitive state is likely (Oizilbash et al.). Dementia is also distinguished from *normal age-related memory loss,* which effects most people by about age seventy in the form of some slowing of cognitive skills and a deterioration in various aspects of memory. But *senior moments* of forgetfulness do not constitute dementia, which is a precipitous and disease-related decline resulting in remarkable disability. Since 1997, a degree of cognitive impairment that is greater than normal age-related decline but not yet diagnosable as dementia has been labeled *mild cognitive impairment* (MCI), with about one-third of those in this category *converting* to dementia each year. These cognitive conditions from normal age-related forgetfulness to dementia form a continuum. Specialized clinics that were once called Alzheimer's Centers are increasingly changing their name to Memory Disorders Centers in order to begin to treat patients at various points along the continuum prior to the onset of dementia.

Although dementia can have many causes, the primary cause of dementia in our aging societies is Alzheimer disease (AD). Approximately 60 percent of dementia in the American elderly and worldwide in industrialized nations is secondary to AD (U.S. General Accounting Office). This discussion will focus on so-called *Alzheimer's dementia* in order to illustrate ethical issues that pertain to all progressive dementias. One epidemiological study in the United States estimated that 47 percent of persons eighty-five years and older (the *old-old*) had probable AD, although this is a widely considered inflated (Evans et al). Epidemiologists differ in their estimates of late-life AD prevalence, but most studies agree roughly on the following: about 1 percent to 2 percent of older adults at age sixty have probable AD, and this percentage doubles every five years so that 3 percent are affected at age sixty-five, 6 percent at age seventy, 12 percent at age seventy-five, and 24 percent by age eighty. While some argue that those who live into their nineties without being affected by AD will usually never be affected by it, this is still speculative. According to a Swiss study, 10 percent of non-demented persons between the ages of eighty-five and eighty-eight become demented each year (Aevarsson). There are very few people in their late forties and early fifties who are diagnosed with AD. Without delaying or preventive interventions, the number of people with AD, in the United States alone, will increase to 14.3 million by 2050 (Evans et

al). These numbers represent a new problem of major proportions and immense financial consequences for medicine, families, and society (Binstock et al).

There is a second very rare form of AD which is early onset that is clearly familial. About 3 percent of AD cases are caused by rare autosomal dominant (or causative) single gene mutations, of which three are clearly defined. In these cases of *familial* AD, symptoms usually occur in the early forties or mid- to late-thirties, and death occurs within five years of diagnosis, in contrast to the more typical seven to eight years for ordinary late-onset disease (Post and Whitehouse).

Various stage theories of disease progression have been developed. However, in clinical practice, professionals speak roughly of three stages. In *mild stage dementia,* the newly diagnosed patient has significant cognitive losses resulting in disorientation and dysfunction, and often displays affective flatness and possibly depression. In *moderate stage dementia,* the patient forgets that he or she forgets, thereby gaining relief from insight into losses. Some patients will at this point adjust well emotionally to a life lived largely in the pure present, although some long-term memories are still in place. The recognition of loved ones is usually still possible. However, as many as one-third of patients in the moderate stage will struggle with emotional and behavior problems, including agitation, combativeness, paranoia, hallucinations, wandering, and depression. A small percentage becomes sexually disinhibited. The *advanced stage of dementia* includes a loss of all or nearly all ability to communicate by speech, inability to recognize loved ones in most cases, loss of ambulation without assistance, incontinence of bowel and/or bladder, and some weight loss due to swallowing difficulties. The advanced stage is generally considered terminal, with death occurring on average within two years. AD, however, is heterogeneous in its manifestations, and defies simplistic staging. For example, while most people with advanced AD will have no obvious ability to recognize loved ones, this is not always the case. In late December 2000, for example, the daughter of a man recently deceased sent an e-mail note to the AD networks around the world:

> Hello Dear Friends: As many of you know, my father has been suffering from Alzheimer's disease for the past 4.5. years. It has been a long and often very hard road for him, for my mom, and for me too. However, as of 7 p.m. last night, my father no longer has to struggle with the disease that robbed him of every part of his being, except one. He never once stopped recognizing my mom and never, ever stopped reaching out to her and wanting to give her a kiss. No matter how many parts of his personality were lost, no matter how many hospital visits full of needles and catheters, no matter how many diapers, he always retained his kind, gentle sweetness and his European manners as a gentleman. In the end, things went very quickly for him. He simply closed his eyes and closed his mouth, indicating no more food or water.

The gentleman described above was in the advanced and therefore terminal stage of AD. Yet he retained the ability to recognize loved ones.

The Fundamental Moral Question: Do People with Dementia *Count*?

Despite the seriousness of dementia and the responsibilities it creates for caregivers, it is ethically important that the person with dementia not be judged by *hypercognitive* values (Post, 1995, 2000a). The self is not cognition alone, but is rather a complex entity with emotional and relational aspects that should be deemed morally significant and worthy of affirmation (Sabat). A bias against the deeply forgetful is especially pronounced in *personhood* theories of moral status in which persons are defined by the presence of a set of cognitive abilities (Kitwood). After discussion of the disparities in bioethical thinking about what constitutes a person, Stanley Rudman concludes, "It is clear that the emphasis on rationality easily leads to diminished concern for certain human beings such as infants, … and the senile, groups of people who have, under the influence of both Christian and humanistic considerations, been given special considerations" (Rudman, p. 47). Often, the personhood theorists couple their exclusionary rationalistic views with utilitarian ethical theories that are deeply incoherent with regard to life and death. As Rudman summarizes the concern, rationality is too severe a ground for moral standing, "allowing if not requiring the deaths of many individuals who may, in fact, continue to enjoy simple pleasures despite their lack of rationality …" (Rudman, p. 57). Of course, in the real world of families, love, and care, personhood theories have no practical significance.

The philosophical tendency to diminish the moral status or considerability of people with dementia is also related to a radical differentiation between the formerly intact or *then* self and the currently demented or *now* self. The reality is that until the very advanced and even terminal stage of AD, the person with dementia will usually have sporadically articulated memories of deeply meaningful events and relationships ensconced in long-term memory. It is wrong to bifurcate the self into then and now, as if continuities are not at least occasionally striking (Kitwood, Sabat). This is why it is essential that professional caregivers

be aware of the person's life story, making up for losses by providing cues toward continuity in self-identity. Even in the advanced stage of dementia, as in the case presented at the outset of this entry, one finds varying degrees of emotional and relational expression, remnants of personality, and even meaningful nonverbal communication as in the reaching out for a hug.

The fitting moral response to people with dementia, according to western ethical thought as informed by Judaism and Christianity, is to enlarge our sense of human worth to counter an exclusionary emphasis on rationality, efficient use of time and energy, ability to control distracting impulses, thrift, economic success, self-reliance, self-control, *language advantage,* and the like. As Alasdair MacIntyre argues, too much has been made of the significance of language, for instance, obscuring the moral significance of species who lack linguistic abilities, or human beings who have lost such abilities (MacIntyre). It is possible to distinguish two fundamental views of persons with dementia. Those in the tradition of Stoic and Enlightenment rationalism have achieved much for universal human moral standing by emphasizing the spark of reason (*logos*) in us all; yet when this rationality dissipates, so does moral status. Those who take an alternative position see the Stoic heritage as an arrogant view in the sense that it makes the worth of a human being entirely dependent on rationality, and then gives too much power to the reasonable. This alternative view is generally associated with most Jewish and Christian thought, as well as that of other religious traditions in which the individual retains equal value regardless of cognitive decline. As the Protestant ethicist Reinhold Niebuhr wrote, "In Stoicism life beyond the narrow bonds of class, community, and race is affirmed because all life reveals a unifying divine principle. Since the principle is reason, the logic of Stoicism tends to include only the intelligent in the divine community. An aristocratic condescension, therefore, corrupts Stoic universalism." (p. 53). This rationalistic inclusivity lacks the deep universalism of other-regarding or unlimited love (Post, 2000a).

The perils of forgetfulness are especially evident in our culture of independence and economic productivity that so values intellect, memory, and self-control. AD is a quantifiable neurological atrophy that objectively assaults normal human functioning; on the other hand, as medical anthropologists's highlight, AD is also viewed within the context of socially constructed images of the human self and its fulfillment. A longitudinal study carried out in urban China, for example, by Charlotte Ikels, which was published in 1998, indicates that dementia does not evoke the same level of dread there as it does among Americans. Thus, the stigma associated with the mental incapacitation of dementia varies according to culture. Peter Singer, for example, is part of a *preference utilitarian* philosophical culture that happens to believe that those who do not project preferences into the future and implement them are not persons. According to Singer, those with memory impairment must then ultimately be devalued. While this devaluation is plausible for those human beings in the persistent vegetative state where the essentially human capacities—cognitive, emotional, relational, or aesthetic—no longer survive, people with dementia can experience many forms of gratification. The challenge is to work with remaining capacities. The first principle of care for persons with dementia is to reveal to them their value by providing attention and tenderness in love (Kitwood).

Enhancing Quality of Life

Emotional, relational, aesthetic, and symbolic well-being are possible to varying degrees in people with progressive dementia (Kitwood). Quality of life can be much enhanced by working with these aspects of the person. The aesthetic well-being available to people with AD is obvious to anyone who has watched art or music therapy sessions. In some cases, a person with advanced AD may still draw the same valued symbol, as though through art a sense of self is retained (Firlik).

A sense of purpose or meaning on the part of caregivers can enhance quality of life for the person with dementia. In an important study by Peter V. Rabinsand and his colleagues, thirty-two family caregivers of persons with AD and thirty caregivers of persons with cancer were compared cross-sectionally to determine whether the type of illness cared for affected the emotional state of the caregiver and to identity correlates of both undesirable and desirable emotional outcomes. While no prominent differences in negative or positive states were found between the two groups, correlates of negative and positive emotional status were identified. These include caregiver personality variables, number of social supports, and the feeling that one is supported by one's religious faith. Specifically, "emotional distress was predicted by self-reported low or absent religious faith" (Rabins et al., p. 335). Moreover, spirituality predicted positive emotional states in caregiving. Interestingly, the study suggests that it was "belief, rather than social contact, that was important" (Rabins et al., p. 332) Spirituality and religion are especially important to the quality of life of African-American caregivers, for whom it is shown to protect against depression (Picot et al.). Spirituality is also a means of coping with the diagnosis of AD for many affected individuals (Elliot).

In general, quality of life is a self-fulfilling prophesy. If those around the person with dementia see the glass as half

empty and make no efforts to relate to the person in ways that enhance his or her experience, then quality of life is minimal. Steven R. Sabat, who has produced the definitive observer study of the experience of dementia, underscores the extent to which the dignity and value of the person with dementia can be maintained through affirmation and an existential perspective.

Specific Clinical Ethical Issues

Nearly every major issue in clinical ethics pertains to AD (Post, 2000b). The Alzheimer's Disease and Related Disorders Association issued an authoritative 2001 publication on ethics issues that covers truth in diagnosis, therapeutic goals, genetic testing, research ethics, respect for autonomy, driving and dementia, end-of-life care, assisted oral feeding and tube feeding, and suicide and assisted suicide. This work borrowed considerably from focus group work that led to the Fairhill Guidelines on Ethics of the Care of People with Alzheimer's Disease (Post and Whitehouse). The Fairhill Guidelines were also the acknowledged baseline for the Alzheimer Canada's national ethics guidelines entitled "Tough Issues" (Cohen et al). The most relevant work on ethics and AD emerges in a grounded way from the affected individuals, their families, and those who serve them in loyal care.

The Association recommends truthtelling in diagnosis because this allows the affected individual, while still competent, to make plans for the future with regard to finances, healthcare, and activities. Most clinicians in the United States and Canada do disclose the probable diagnosis of AD, even though it is only about 90 percent accurate and must be verified upon autopsy. This transition has been encouraged by the emergence of new treatments (Alzheimer's Disease Association).

Genetic testing is frowned on by the Association, except in the early-onset familial cases where a single gene mutation causes the disease. AD is the object of intense genetic analysis. It is a genetically heterogeneous disorder—to date, it is associated with three determinative or causal gene mutations (i.e., someone who has the mutation will definitely get the disease) and one susceptibility or risk gene. The three causal AD genes mutations (located on chromosomes 21, 14, and 1) were discovered in the 1990s. These are autosomal-dominant genes and pertain to early-onset familial forms of AD (usually manifesting between the early 40s and mid-50s) which, according to one estimate, account for possibly fewer than 3 percent of all cases. These families are usually well aware of their unique histories. Only in these relatively few unfortunate families is genetic prediction actually possible, for those who carry the mutation clearly know that the disease is an eventuality. Many people in these families do not wish to know their genetic status, although some do get tested. Currently, there is no clearly predictive test for ordinary late-onset AD that is associated with old age. There is one well-defined susceptibility gene, an apolipoprotein E $\in 4$ allele on chromosome 19 (apoE=protein; APOE=gene), which was discovered in 1993 and found to be associated with susceptibility to late-onset AD (after fifty-five years). A single $\in 4$ gene (found in about one-third of the general population) is not predictive of AD in asymptomatic individuals—it does not come close to foretelling disease, and many people with the gene will never have AD. Among those 2 percent of people with two of the $\in 4$ genes, AD does not necessary occur either (Post et al). Such susceptibility testing can be condoned in a research setting, but is not encouraged in clinical practice because it provides no reliable predictive information upon which to base decisions, it has no medical use, and it may result in discrimination in obtaining disability or long-term care insurance (Post et al., Alzheimer's Disease Association).

The Association's 2001 statement includes the important argument that disclosing the diagnosis early in the disease process allows the person to "be involved in communicating and planning for end-of-life decisions." Diagnostic truthtelling is the necessary beginning point for an ethics of *precedent autonomy* for those who wish to implement control over their futures through advance directives such as durable power of attorney for healthcare, which allows a trusted loved one to make any and all treatment decisions once the person with dementia becomes incompetent. This can effectively be coupled with a living will or some other specific indication of the agent's material wishes with regard to end-of-life care. Unless the person knows the probable diagnosis in a timely way while still competent to file such legal instruments, the risk of burdensome medical technologies is increased. Even in the absence of such legal forms, however, many technologically advanced countries will allow next of kin to decide against efforts to extend life in severe dysfunction. This is important because many patients suffer incapacitating cognitive decline long before having a diagnostic work up; those who are diagnosed early enough to exercise their autonomy can become quickly incapacitated.

The Association does not support mandatory reporting of a probable diagnosis of AD to the Department of Motor Vehicles. There are a number of reasons for this caution, one of which is patient confidentiality. Reporting requirements might discourage some persons from coming into the clinic for early diagnosis at a time early in the course of disease when drug treatments are most clearly indicated. Eventually all people with AD must stop driving when they are a serious risk to self or others. Family members must know that if a loved one drives too long and injures others, they may even

be held financially liable and insurers may not be obliged to cover this liability. Ideally, a privilege is never limited without offering the person ways to fill in the gaps and diminish any sense of loss. An *all or nothing* approach can and should be avoided. Compromise and adjustments can be successfully implemented by those who are informed and caring, especially when the person with AD has insight into diminishing mental abilities and loss of competence. The affected person should retain a sense of freedom and self-control if possible (Alzheimer's Disease Association).

AD is on the leading edge of the debate over physician-assisted suicide (PAS) and euthanasia. The policies that emerge from this debate will have monumental significance for people with dementia, and for social attitudes toward the task of providing care when preemptive death is cheaper and easier. The Association affirms the right to dignity and life for every Alzheimer patient, and cannot condone suicide (Alzheimer's Disease Association).

The Association asserts that the refusal or withdrawal of any and all medical treatment is a moral and legal right for all competent Americans of age, and this right can be asserted by a family surrogate acting on the basis of either *substituted judgement* (what would the patient when competent have wanted) or *best interests* (what seems the most humane and least burdensome option in the present).

The Association concludes that AD *in its advanced stage should be defined as a terminal disease,* as roughly delineated by such features as the inability to recognize loves ones, to communicate by speech, to ambulate, or to maintain bowel and/or bladder control. When AD progresses to this stage, weight loss and swallowing difficulties will inevitably emerge. Death can be expected for most patients within a year or two, or even sooner, regardless of medical efforts. One useful consequence of viewing the advanced stage of AD as terminal is that family members will better appreciate the importance of palliative (pain medication) care as an alternative to medical treatments intended to extend the dying process. All efforts at life extension in this advanced stage create burdens and avoidable suffering for patients who could otherwise live out the remainder of their lives in greater comfort and peace. Cardiopulmonary resuscitation, dialysis, tube-feeding, and all other invasive technologies should be avoided. The use of antibiotics usually does not prolong survival, and comfort can be maintained without antibiotic use in patients experiencing infections. Physicians and other healthcare professionals should recommend this less burdensome and therefore more appropriate approach to family members, and to persons with dementia who are competent, ideally soon after initial diagnosis. Early discussions of a peaceful dying should occur between persons with dementia and their families, guided by information from healthcare professionals on the relative benefits of a palliative care approach (Alzheimer's Disease Association).

Avoiding hospitalization will also decrease the number of persons with advanced AD who receive tube-feeding, since many long-term care facilities send residents to hospitals for tube placement, after which they return to the facility. It should be remembered that the practice of long-term tube-feeding in persons with advanced dementia began only in the mid-1980s after the development of a new technique called percutaneous endoscopic gastrostomy (PEG). Before then, such persons were cared for through assisted oral feeding. In comparison with assisted oral feeding, however, long-term tube-feeding has no advantages, and a number of disadvantages (Alzheimer's Disease Association).

In closing this entry, attention will be directed in greater depth to three representative areas of special concern to family and professional caregivers: cognitive enhancing compounds, research risk, and tube feeding.

COGNITIVE ENHANCING COMPOUNDS. Persons with AD and their families greet the emergence of new compounds to mitigate the symptoms of dementia with great hope. These compounds, known as cholinesterase inhibitors, slightly elevate the amount of acetylcholine in the brain, slightly boosting communication between brain cells. In the earlier stages of the disease, while enough brain cells are still functional, these drugs can improve word finding, attentiveness to tasks, and recognition of others for a brief period in the range of six months to two years. Thus, some symptoms can be mitigated for a while, but these drugs have no impact on the underlying course of the disease, and neither reverse nor cure dementia. Some affected individuals, after taking any new compound whether artificial or natural, may exude a burst of renewed self-confidence in their cognitive capacities. But how much of this is due to the compound itself remains unclear. Presumably each person with AD is a part of some relational network that inevitably plays a role in the self-perception of cognitive improvement—indeed, self-perception is dependent on the perceptions of others and their need for a glimmer of hope as caregivers. Realistically, a medication may bring the self-perception of a renewed sense of mental clarity, as though *a fog has lifted,* yet none of the available cognitive enhancing compounds slow the progression of disease.

It is hard for professionals to know how to respond to the passion for the possible. Should unrealistic hopes be indulged for emotional reasons (Post, 1998, 2000b)? Should the money expended for new compounds of relatively marginal efficacy be spent on environmental and relational opportunities? Many clinicians caution both persons with AD and their family caregivers against thinking that the new

compound is a miracle cure. Many still remain somewhat skeptical of studies of cognitive testing indicating significant but always minor benefit; no such studies take into account confounding factors such as the quality of relationships, environment, and emotional well-being. Nevertheless, reports of a *fog lifting* are interesting anecdotally. Are statements of future expectations so excessive among some desperate caregivers that hope is easily exploited by pharmaceutical profiteers? Medication needs to be placed within a full program of dementia care (including emotional, relational, and environmental interventions) so as not to be excessively relied on; family members should be respected when they desire to stop medication; even when medication is desired, families need to appreciate the limits of current compounds.

It is possible as well, that the anti-dementia compounds can, in those cases where they may have some capacity to give what is always at best a modest and fleeting cognitive boost,—fleeting because the underlying cognitive decline is intractable—be double-edged swords. While some slight cognitive improvements may occur, these may come at the cost of renewed insight into the disease process on the part of the affected individual, and of relational difficulties in the context of affected individuals and their caregivers. If the kindest point in the progression of AD is when the person with dementia forgets that he or she forgets, and is therefore able to get free of *insight* and related anxiety, then a little cognitive enhancement is not obviously a good thing for quality of life and quality of lives. Is it possible, then, to speak of *detrimental benefits?*

Decisions about these compounds are ethically and financially complex because their efficacy is quite limited, the affected individual remains on the inevitable downward trajectory of irreversible progressive dementia, and there may be nonchemical interventions focusing on emotional, relational, and spiritual well-being that are both cheaper and more effective. This is not to suggest that we should all be pharmacological Calvinists rather than pharmacological hedonists, but does anyone doubt that the pharmaceuticals wield a great deal of power across the spectrum of AD support groups? In the future, as compounds emerge that can actually alter the underlying progression of AD, affected individuals and caregivers will be faced with difficult tradeoffs between length of life and quality of life (Post, 1997, 2001a).

Research Risks

The *crucial* unanswered question in AD research is this: What should be the maximal or upper limit for permissible potential risks in any AD research, regardless of whether the research is characterized as potentially therapeutic for the subject or not? A secondary unanswered question is this: Should proxy consent be permitted in higher risk research, even when there is no potential therapeutic benefit for the participant, just as it is permitted when the research is considered potentially therapeutic? Without agreement on these fundamental questions, the upcoming treatments, promising both greater benefit and greater risk, will not expeditiously reach those in most need.

The Association's 2001 statement is as follows:

> (A) For minimal risk research all individuals should be allowed to enroll, even if there is no potential benefit to the individual. In the absence of an advance directive, proxy consent is acceptable.
>
> (B) For greater than minimal risk research *and* if there is a reasonable potential for benefit to the individual, the enrollment of all individuals with Alzheimer disease is allowable based on proxy consent. The proxy's consent can be based on either a research specific advance directive *or* the proxy's judgment of the individual's best interests.
>
> (C) For greater than minimal risk research *and* if there is *no* reasonable potential for benefit to the individual only those individuals who (1) are capable of giving their own informed consent, or (2) have executed a research specific advance directive are allowed to participate. In either case, a proxy must be available to monitor the individual's involvement in the research. (*Note*: this provision means that individuals who are not capable of making their own decisions about research participation and have not executed an advance directive or do not have a proxy to monitor their participation, cannot participate in this category of research.)

The Association's statement is laudable because of its endorsement of surrogate consent in all research of potential benefit to the subject, even if there is potentially a greater than minimal risk. Surrogate consent should always be based on accurate facts about the risks and potential benefits of the clinical research or trial, rather than on understatement of risks or burdens and exaggerated claims of benefit. Participants in all research should be protected from significant pain or discomfort. It is the responsibility of all investigators and surrogates to monitor the well-being of participants.

The Association indicates that surrogates must not allow their hopes for effective therapies to overtake their critical assessment of the facts, or to diminish the significance of participant expressions of dissent. Subject dissent or other expressions of agitation should be respected, although a surrogate can attempt reasonable levels of persuasion or

assistance. People with dementia, for example, may initially refuse to have blood drawn or to take medication; once a family member helps calm the situation and explains things, they may change their minds. This kind of assistance is acceptable. Continued dissent, however, requires withdrawal of the participant from the study, even though surrogates would prefer to see the research participation continue.

At this point in time, the most important unresolved issue in dementia research is how much potential risk to those affected by AD should society allow? Research in AD is becoming increasingly physically invasive and biologically complex. Is there any maximal threshold of potential risk beyond which research should be disallowed? Furthermore, how can actual discomforts in research be properly monitored, and what degree of discomfort requires that research be halted? In general, research ethics has not addressed these issues, focusing instead on matters of subject and proxy consent.

END OF LIFE AND PEG TUBES. Gastrostomy tube feeding became common in the context of advanced dementia and in elderly patients more generally after 1981, secondary to the development of the PEG procedure. The PEG procedure was developed by Dr. Michael Gauderer and his colleagues at Rainbow Babies and Children's Hospital in Cleveland from 1979 to 1980 for use in young children with swallowing difficulties. The procedure required only local anesthesia, thus eliminating the significant surgical risk associated with general anesthesia and infection (Gauderer and Ponsky). Gauderer wrote two decades later that while PEG use has benefited countless patients, "in part because of its simplicity and low complication rate, this minimally invasive procedure also lends itself to over-utilization" (p. 879). Expressing moral concerns about the proliferation of the procedure, Gauderer indicates that as the third decade of PEG use begins to unfold, "much of our effort in the future needs to be directed toward ethical aspects …" (p. 882). PEG is being used more frequently even in those patients for whom these procedures were deemed too risky in the past.

For over a decade, researchers have underscored the burdens and risks of PEG tube-feeding in persons with advanced dementia. The mounting literature was well summarized by Finucane and his research colleagues, who found no published evidence that tube-feeding prevents aspiration pneumonia, prolongs survival, reduces risks of pressure sores or infections, improves function, or provides palliation in this population (Finucane, et al.; Gillick; Post, 2001b).

Families often perceive tube-feeding as preventing pneumonia or skin breakdown, and many assume that it extends survival. These perceptions are erroneous. The main benefit of PEG is that it makes life easier for the informal family caregiver who, for reason of competing duties or perhaps physical limitation, cannot find the time or energy to engage in assisted oral feedings. Yet PEG use is not really *easy,* because it has its technological complexities, and the recipient will usually have diarrhea. In some cases, physical restraints are used to keep a person from pulling on the several inches of tube that extend out of the abdomen. One wonders if assisted oral feeding is not easier after all. Regardless, purported technical ease and efficiency do not mean that these technologies should be applied. Should persons with advanced progressive dementia ever be provided with PEGs? In the general, assisted oral feeding and hospice are the better alternative to tube-feeding, although in practice there will be some cases in which the limited capacities of an informal family caregiver do justify tube-feeding as the ethically imperative alternative to starvation when the ability to swallow has begun to diminish. Ideally home health aides would make assisted oral feeding possible even in these cases, but this is not a priority in the healthcare system. Institutions, however, should uniformly provide assisted oral feeding as the desired alternative to tube-feeding, a measure that would profoundly obviate the overuse of this technology.

There will be many family caregivers who have no interest in PEG use and who feel that they are being loyal to their loved one's prior wishes. A physician should expect this response. A study included in-person interviews of eighty-four cognitively normal men and women aged sixty-five years and older from a variety of urban and suburban settings (including private homes, assisted-living apartments, transitional care facilities, and nursing homes). Three-fourths of the subjects would not want cardiopulmonary resuscitation, use of a respirator, or parenteral or enteral tube nutrition with the milder forms of dementia; 95 percent or more would not want any of these procedures with severe dementia (Gjerdingen et al.). These subjects were adequately informed of the burdens and benefits of such interventions.

Physicians and other healthcare professionals should recommend this less burdensome and therefore more appropriate approach to family members, and to persons with dementia who are competent, ideally soon after initial diagnosis. Early discussions of a peaceful dying should occur between persons with dementia and their families, guided by information from healthcare professionals on the relative benefits of a palliative care approach (Volicer and Hurley).

DENTISTRY

• • •

Most dentists in the United States practice as independent entrepreneurs either individually or in small groups. Nevertheless, dental care generally is not viewed as an ordinary commodity in the marketplace. Instead, the vast majority of dentists and most people in the larger community think of dentistry as a profession. That is, they consider dental care to be a component of healthcare and consider dentists to be experts in the relevant knowledge and skills, committed individually and collectively as professionals to giving priority to their patients' well-being as they practice their expertise. Consequently, when a person becomes a dentist, he or she makes a commitment to the larger community and accepts the obligations and ethical standards of the dental profession. Those obligations and standards are the subject matter of the subdiscipline called dental ethics.

Ethical Dilemmas

Because dentists rarely make life-or-death decisions, some people are unaware that the professional obligations of dentists require careful study. Important human values are at stake in dental care: relieving and preventing intense pain as well as less intense pain and discomfort; preserving and restoring patients' oral function, on which both nutrition and speech depend; preserving and restoring patients' physical appearance; and preserving and restoring patients' control over their bodies. These matters are important, and as a result dentists who are committed to responding to them in accordance with ethical standards often face complex questions.

Ethical dilemmas such as the following are faced regularly by almost every dentist:

1. When examining a new patient, a dentist finds evidence of poor earlier dental work. What should the dentist say to the patient? Should the dentist contact the previous dentist to discuss the matter? Should the dentist contact the local dental society?
2. May a dentist ethically advertise that his or her practice will produce "happy smiles" as well as quality dental care, or is such advertising false or significantly misleading?
3. May a dentist tell a patient that the patient's teeth are unattractive with a view to recommending aesthetic treatment when the patient has not asked for an opinion and has indicated no displeasure with his or her appearance?
4. May a dentist ethically decline to treat a patient with a highly infectious disease? What obligations does the dentist have regarding the information that this patient is a carrier of infection?
5. How should a dentist deal with an adult patient who cannot participate fully in making decisions about about care? Do treatment considerations depend on the reason for that inability? What should a dentist do when the guardian of a minor or an incompetent adult patient refuses to approve the best kind of therapy?
6. What may a dentist do to obtain cooperative behavior from a young or developmentally disabled patient who needs dental care but is uncontrollable in the chair?
7. What obligations does a dentist have and to whom when that dentist learns that another dentist is substance-dependent in a manner that probably affects the care he or she is providing?

Issues and Themes in Dental Ethics

The specific requirements of a dentist's ethical commitments in any aspect of professional practice depend on the specific facts and circumstances of the situation. However, the principal categories of dentists' professional obligations can be surveyed under nine headings:

1. Who are dentistry's chief clients?
2. What is the ideal relationship between a dentist and a patient?
3. What are the central values of dental practice?
4. What are the norms of competence for dental practice?
5. What sacrifices is a dentist professionally committed to, and in what respects do obligations to the patient take priority over other morally relevant considerations?
6. What is the ideal relationship between dentists and coprofessionals?
7. What is the ideal relationship between dentists, both individually and collectively, and the larger community?

8. What should members of the dental profession do to make access to the profession's services available to all those who need them?
9. What are members of the dental profession obligated to do to preserve the integrity of their commitment to its professional values and educate others about them?

THE CHIEF CLIENT. For every profession there is a person or set of persons whose well-being the profession and its members are committed to serving. The patient in the dental chair is the most obvious chief client of a dentist, but dentists also have professional obligations to the patients in the waiting room and all their patients of record, to patients who present with emergency needs, and arguably to the entire larger community, especially in matters of public health. The relative weight of a dentist's obligations to each of these entities when those obligations come into conflict ordinarily is considered to favor the patient in the chair over the others, but comparative judgments of the respective degrees of need also must be made.

THE IDEAL RELATIONSHIP BETWEEN PROFESSIONAL AND PATIENT. What is the proper relationship between the dentist and the patient in the chair as they make judgments and choices about the patient's care? There are a number of different ways of conceiving this ideal relationship when it involves the dentist and a fully competent adult: with the dentist alone making the judgment that determines action, with the judgment resting with the patient alone, and with the judgment shared by both parties.

Since the late 1960s the accepted norm of dental practice in the United States has shifted toward the third type of relationship: shared judgment and shared choice regarding treatment. The legal doctrine of informed consent identifies a minimum standard of shared decision making for dentists and their patients, but it is important to ask whether informed consent fully expresses the ideal relationship between a dentist and a fully capable patient (Segal and Warner; Ozar, 1985; Hirsch and Gert; Ozar and Sokol, 2002).

What is the appropriate relationship between the dentist and a patient who cannot participate fully in treatment decisions? What is the dentist's proper role in this relationship? What is the role of the patient up to the limit of the patient's capacity to participate? What is the proper role of other parties?

In practice most dentists depend on choices made by the parents and guardians of such patients when they are available and when these choices do not involve significant harm to the patients' oral or general health. However, there is no clear consensus about how dentistry should proceed when these conditions are absent. The dental ethics literature has begun a careful discussion of the dentist's relationship with patients of diminished capacity or no capacity for decision making (Bogert and Creedon; Ozar and Sokol, 2002).

A HIERARCHY OF CENTRAL VALUES. Regardless of many professions' rhetoric on the subject, no profession can be expert in fostering the complete well-being of those it serves. There is instead a certain set of values that are the appropriate focus of each profession's particular expertise. These values can be called the central values of that profession. They determine and/or establish parameters for most aspects of a professional's judgments in practice. They are the criteria by which a person is judged to need professional assistance in the first place and by which that need is judged to have been met properly through the professional's intervention.

What, then, are the central values of dental practice, and if there is more than one, how are those central values ranked? One proposal is that the central values of the dental profession are, in the following order:

1. the patient's life and general health;
2. the patient's oral health, which is understood as appropriate and pain-free oral functioning;
3. the patient's autonomy—to the extent that the patient is capable of exercising it—over what happens to his or her body (including the patient's ranking of health, comfort, cost, aesthetic considerations, and other values);
4. preferred patterns of practice on the part of the dentist (including differing philosophies of dental practice);
5. aesthetic considerations from the point of view of skilled dental practice and from the point of view of patients' aesthetic values; and
6. considerations of efficiency, which may include considerations of cost, from the dentist's point of view. (Ozar and Sokol, 2002)

A particular dental intervention may achieve each of these values to a greater or lesser degree, and each value is more or less urgent for a particular patient. The ethical dentist takes the details of each situation into account and attempt to maximize dentistry's central values in accordance with their ranked priority in every encounter with every patient.

COMPETENCE. Every professional is obligated to acquire and maintain the expertise required to undertake his or her professional tasks. Every professional also is obligated to undertake only the tasks that are within his or her competence. Consequently, dentists must be constantly attentive

to whether they have sufficient competence to make each specific diagnosis and perform each particular procedure for each patient in light of the clinical circumstances, especially when this involves something nonroutine.

Of necessity the dental community, not the community at large, determines the details of standards of competence because doing this requires dental expertise. However, the larger community is justified in demanding an explanation of the reasoning involved, especially regarding the trade-offs between quality of care and access to care that the setting of such standards inevitably involves.

SACRIFICE AND THE RELATIVE PRIORITY OF THE PATIENT'S WELL-BEING. Most sociologists who study professions and most of the literature of professions speak of "commitment to service" or "commitment to the public" as one of the characteristic features of a profession. Dentistry's self-descriptions are similar in this respect, but these expressions allow many different interpretations with different implications for practice. What sorts of sacrifices, for example, are dentists professionally committed to make for the sake of their patients? What sorts of risks to life and health, financial well-being, and reputation may a dentist be obligated to face?

The related question of the proper relationship between entrepreneurship and commitment to the patient, along with the sacrifice of self-interest this can involve, has been discussed in every age of the dental profession. The consensus is that especially in emergency situations, the patient's oral health and general health require significant sacrifices of personal convenience and financial interest on the part of a dentist. Since the arrival of HIV and AIDS, even more urgent implications of the obligation to give priority to the patient, including accepting an increased risk of infection, also have become part of this discussion.

RELATIONS WITH COPROFESSIONALS. Each profession has norms, usually largely implicit and unstated, concerning the proper relationship between the members of a profession. Should a dentist relate to other dentists as competitors in the marketplace, as cobeneficiaries in the monopoly their exclusive expertise gives them in the marketplace, or in some other way? What is the ideal relationship between dentists, and how is it connected with the fact that they are members of a profession, not only entrepreneurs in the same marketplace?

How should a dentist deal with another dentist's inferior work when its consequences are discovered in the mouth of a new or emergency patient or a patient referred for specialty care? The discovering dentist could inform the patient that bad work has been done or could hide that judgment from the patient. The discovering dentist could contact the dentist whose work had a bad outcome or possibly the local dental society. What is the proper balance between obligations to patients and obligations to one's fellow dentist? As in other professions obligations to the patient ordinarily take priority in dentistry, but this principle does not supply simple or automatic answers to the complexities of such situations.

There are also situations in which members of different professions are caring for the same patients. Many dentists, for example, work very closely with dental hygienists, whose professional skills and central professional values are closely related to but significantly distinct from those of dentists. In the best relationships those differences complement each other to the benefit of the patient, but in other situations the skills of the dental hygienist may be demeaned or the dental hygienist's status as a professional may be challenged. The ethical commitments of these professions imply an obligation to develop a working relationship that is conducive to mutual respect and focused on the well-being of the patient.

RELATIONS BETWEEN DENTISTS AND THE LARGER COMMUNITY. Every profession is involved in numerous relationships with the larger community and with important subgroups in it. Both the dental profession and individual dentists must monitor the quality of dental work and practice and report and address instances of inferior work and unethical practice. They also relate to the community as dental-health educators both through direct educational efforts and by monitoring the dependability and effectiveness of dental-care products offered to the public. Dentistry's relationships with the larger community also include developing proper standards for professional advertising. Dentists play an important role in public-health efforts, preserving public oral health, and addressing serious epidemic diseases such as HIV.

ACCESS TO THE PROFESSION'S SERVICES. Individual dentists and the dental profession as a whole have responsibilities in regard to access to dental care for people with unmet dental needs. Dentists also may be obligated to be educationally and politically active when policies are being made to determine how society will distribute its healthcare resources. Also, organized dentistry has an obligation to monitor access issues and use its resources to promote access for those whose dental needs are not being met.

INTEGRITY AND EDUCATION. A dentist who made no effort to influence patients to incorporate the central values of dental practice into their lives and educate them about

how to do that would be falling short as a professional committed to these values. However, dentists influence and educate patients not only through their words and professional interventions at chairside but also by the way they live and act. Thus, there is a ninth category of questions to ask about dentists' professional obligations. What are dentists required to do and what might they be required to avoid to preserve the integrity of the values to which dentistry is committed and to educate others by living in a manner consonant with those values?

Organized Dentistry and Ethics

Ultimately, the content of a profession's obligations is the product of a dialogue between the profession and the larger community that entrusts the profession and its members with a high degree of autonomy in practice, including the power of self-regulation. In the case of dentistry this dialogue is often subtle and informal. Codes of ethics formulated by professional organizations such as the American Dental Association's *Principles of Ethics and Code of Professional Conduct* (American Dental Association, 2002) play an important role in articulating the most fundamental principles of dentistry's professional ethics within American society. However, such codes, like state dental-practice acts, can never articulate more than a small part of the content of a practicing profession's ethics. It therefore is incumbent on both individual dentists and organized groups of dentists to monitor this ongoing dialogue continuously and offer representative statements of its content as they are needed.

If the larger community had no part in this ongoing dialogue, its trust of the dental profession would make no sense. Nevertheless, the community exercises its role in the dialogue more often through passive tolerance than through active articulation. Therefore, the initiative ordinarily falls first to the members of the profession to articulate in word and action the current understanding of the profession's ethical commitments.

Although the dental profession includes every dentist who practices competently and ethically, those who speak for the profession most articulately and are heard the most widely are dentistry's professional organizations. Therefore, those organizations have a special responsibility to foster reflection on and contribute to discussion of dental ethics (Ozar and Sokol, 2002).

Some dental organizations, such as the American Dental Association (ADA), the American College of Dentists (ACD), and some specialty organizations, have contributed actively to the articulation of dentistry's professional standards. Particular issues have temporarily focused the profession's attention on dentistry's ethical commitments. This occurred when the ADA's Council on Dental Therapeutics first awarded its Seal of Approval to a commercial dentifrice (Dummett and Dummett) and when the ADA first issued a policy statement regarding dentists' obligation to treat HIV-positive patients (American Dental Association, 1991; Ozar, 1993).

Until the late 1970s most dental organizations fulfilled this responsibility chiefly through editorials and other hortatory articles in their journals and sometimes through a published code of conduct. Detailed, carefully reasoned discussions of ethical issues in which assumptions were explicit and alternative points of view were accounted for or that articulated the profession's ethics in more than broad generalities were few and far between. Even the published codes of conduct, significant as they have been as representative articulations of dentistry's professional commitments, have not exhausted the contents of dental ethics, much less effectively addressed new and specific issues as they have arisen.

Since the late 1970s, however, the level of interest in and sophisticated discussion of ethical issues within organized dentistry have increased steadily. Responding to newly significant ethical issues in a rapidly changing social climate, the ADA's Council on Ethics, Bylaws, and Judicial Affairs has regularly prepared, after considerable debate in print and other forums, a number of revisions and amendments of the ADA's *Principles of Ethics and Code of Professional Conduct* (2002). The ADA and its council also have sponsored national workshops and other educational programs on specific ethical issues facing the dental community.

The ACD sponsored several national workshops and a national grassroots educational program to train dentists in more sophisticated forms of reflection on ethical issues as well as national conferences, Ethics Summits I and II, in which representatives from every part of the oral healthcare community worked to develop common understandings of the ethical issues they face and respectful collaboration in dealing with them (American College of Dentists, 1998, 2000). Many other dental organizations have incorporated programs on dental ethics into their meetings and published scholarly and popular articles on those topics in their journals. A number of them also have made major revisions of their codes of ethics.

An organization specifically focused on dental ethics and its teaching, the Professional Ethics in Dentistry Network (PEDNET), was founded in 1982 by a group of dental school faculty members and has grown into a national organization with additional members in full-time practice as well as representatives from organized dentistry, dental hygiene, and the larger healthcare ethics community. The International Dental Ethics and Law Society (IDEALS) was

established in 1999 to facilitate dialogue on dental ethics and law around the world.

The literature of dental ethics has grown significantly. In 1988 the *Journal of the American Dental Association* initiated a regular feature on dental ethics, "Ethics at Chairside," which moved in 1991 to *General Dentistry,* the journal of the American Academy of General Dentistry, and a similar series of ethics cases and commentary has appeared in the *Texas Dental Association Journal.* A peer-reviewed series, "Issues in Dental Ethics," supervised by the editorial board of PEDNET began publication in 2000, appearing as a special feature in each quarterly issue of the *Journal of the American College of Dentists.* Also since 2000, the dental journal *Quintessence* has published a series on ethical heroes in dentistry.

Dental Education

The changing climate of dental practice from the late 1970s into the 1980s and a heightened awareness of ethical issues throughout the dental profession in that period also brought about changes in dental schools. Until that time few dental schools had formal programs in dental ethics. Inspirational lectures by respected senior faculty members or local or national heroes were the standard fare (Odom). However, with prompting from the American Dental Education Association (ADEA), then called the American Association of Dental Schools, as well as the ACD, and the ADA, many dental schools began offering formal programs in dental ethics. They identified faculty members with an interest in dental ethics who began to develop curricular materials and network with the faculty in other institutions. For example, the University of Minnesota pioneered an innovative four-year curriculum in dental ethics in the early 1980s. With the founding of PEDNET, dental-ethics educators acquired a major resource for their teaching and a locus for scholarly discussions of issues in dental ethics at the national level both at annual meetings and at biennial workshops on teaching dental ethics.

During the 1990s, several new textbooks were published (Rule and Veatch; Weinstein; Ozar and Sokol, 1994, 2002) and additional educational programs and materials were developed for use in the classroom, in the clinic, and in continuing education programs. By the beginning of the new millennium, most dental schools had multiyear curricula in dental ethics in place (Zarkowski and Graham) and significant efforts were under way to integrate dental ethics education into the innovative patient-centered and problem-based-learning curricula that are the hallmark of contemporary dental school education.

Dentistry in the Twenty-First Century

As dentistry moves into the twenty-first century the focus on ethics will have to be even greater. Two of dentistry's greatest success stories of the twentieth century will yield two of its most important ethical challenges in the twenty-first.

Dentists deeply committed to preventive healthcare for the whole community lobbied successfully during the twentieth century for the fluoridation of water supplies. As a consequence most twenty-first-century dentists' patients will need much less restorative work to remedy the effects of caries than their predecessors' patients did. In these circumstances how will dentists maintain their practices fiscally and still remain true to their fundamental ethical commitments? For many patients and dentists the answer has been an increasing interest in aesthetic dentistry. However, there is a risk here. Too strong a shift in the focus of dental care in this direction could bring about a significant change in the community's view of dentistry, seeing it much more as a taste-driven commercial enterprise and much less as an expertise-grounded, value-based health profession.

The second success story concerns the tremendous advances made in dental research in recent decades. For example, the ways in which laser technology can be used in dental practice have multiplied at least tenfold since the early 1990s. However, these new technologies frequently require extensive training as well as new forms of theoretical understanding so that dentists can employ them safely and skillfully. Because so many patients are fascinated with new technologies, dentists, often fascinated themselves, feel strong pressure to purchase and employ them. The ethical standard of employing only those therapeutic techniques in which one is expert and that truly produce a marginal benefit for the patient compared with older technologies often is strained in these circumstances, and commercial pressures on dentists, both direct fiscal issues within their practices and the pressure of skillful marketing by manufacturers, enhance the challenge for twenty-first-century dentists to choose new technologies wisely and with their patients' best oral healthcare as the goal.

Further complicating both of these issues is the extent to which managed care has had an increased impact on oral healthcare since the early 1990s. More and more frequently dentists must negotiate with patients about treatments in circumstances in which a patient's insurance will pay only for the cheapest acceptable intervention and in which the patient has been poorly informed. The dentist or dental office staff frequently is the bearer of this bad news. Dealing with such situations in a way that preserves an appropriate dentist-patient relationship is often very challenging (Ozar, 2001).

Dentistry as a profession has always taken its professional ethics seriously. However, as a field of study and as a subdiscipline within the study of moral theory and professional ethics dental ethics is still a young field. Nevertheless, as reflection on ethical issues is taken more seriously and participated in more widely by practicing dentists and dental hygienists, dental school and dental hygiene faculty and students, and the leaders of organized dentistry, the dental profession's ethical standards and their implications for daily practice will be understood more clearly and creative dialogue about the ethical practice of dentistry will be more widespread and sophisticated.

DIALYSIS, KIDNEY

• • •

Two principal therapies exist for patients who develop irreversible kidney failure and require renal replacement therapy to survive: kidney dialysis and kidney transplantation. The topic of kidney transplantation is addressed elsewhere in the Encyclopedia. This entry discusses kidney dialysis.

The two main techniques for kidney dialysis are hemodialysis and peritoneal dialysis. In hemodialysis, blood is pumped from a patient's body by a dialysis machine to a dialyzer—a filter composed of thousands of thin plastic membranes that uses diffusion to remove waste products—and then returned to the body. The time a hemodialysis treatment takes varies with the patient's size and remaining kidney function; most patients are treated for three and one-half to four and one-half hours three times a week in a dialysis unit staffed by nurses and technicians. In peritoneal dialysis, a fluid containing dextrose and electrolytes is infused into the abdominal cavity; this fluid, working by osmosis and diffusion, draws waste products from the blood into the abdominal cavity and then is drained from the abdominal cavity and discarded. Most patients on peritoneal dialysis perform four procedures at home daily about six hours apart to drain out the fluid with the accumulated wastes and instill two to two and one-half liters of fresh fluid. This technique is called continuous ambulatory peritoneal dialysis (CAPD). An automated form of peritoneal dialysis at home, called continuous cycling peritoneal dialysis (CCPD), is also available.

Both hemodialysis and peritoneal dialysis require a means to enter the body, called an access. In hemodialysis, access to the blood is obtained by removing blood through needles inserted into surgically created conduits, called fistulas or synthetic grafts, from arteries to veins. In peritoneal dialysis, access to the abdominal cavity is obtained with a plastic catheter, which is surgically implanted into the abdominal wall with the tip of the catheter positioned in the abdominal cavity.

Dialysis is a benefit to patients with severe kidney failure because it removes metabolic waste products and excess fluid, electrolytes, and minerals that build up in the blood when the kidneys are not functioning normally. Without the removal of these substances, patients become very weak, short of breath, and lethargic and eventually die. While dialysis is lifesaving for these patients and some can return to their prior level of functioning, most do not, because they do not feel well. Despite dialysis and medications, patients may experience anemia, bone pain and weakness, hypertension, heart disease, strokes, infections or clotting of the dialysis access, and bleeding. In addition to these medical problems, dialysis may impose other burdens on dialysis patients and their families, including extra costs for medications and for transportation to the dialysis center, loss of time spent in the treatments and travel to the dialysis center, and loss of control over the patient and family schedule to accommodate dialysis treatments. For these reasons, renal transplantation is considered to be the preferable form of treatment for severe kidney-failure patients who are able to undergo this major surgical procedure.

Kidney dialysis predates other life-sustaining therapies. In 1945 in the Netherlands, Willem Kolff first used hemodialysis to save the life of a woman with acute renal failure. In subsequent years, Kolff and others improved hemodialysis, but it could not be provided to patients with chronic, irreversible renal failure, or what has been called end-stage renal disease (ESRD), until 1960, when Dr. Belding Scribner of Seattle, Washington, used plastic tubes to form a shunt that could be left in an artery and vein for repeated dialysis access.

By most standards, kidney dialysis can be considered a very successful life-sustaining treatment. In the United States alone, since the inception of the Medicare-funded ESRD program in 1973, well over 1 million patients have had their lives sustained by dialysis, and at least some of them have survived for longer than twenty-five years. This program has been costly, however; in 1999, for example, the cost of keeping ESRD patients alive in the United States exceeded 17 billion dollars. Because dialysis preceded many other modern life-sustaining medical technologies, and because initially there was a scarcity of resources to pay for it, many of the ethical concerns subsequently discussed for other modern medical technologies were initially debated regarding dialysis: patient-selection criteria, rationing, access to care, the just allocation of scarce resources, the right to die (by having dialysis withheld or withdrawn), end-of-life care, and conflicts of interest (in dialysis unit ownership). This entry examines a number of these concerns in the United States ESRD program and compares them with those in other countries.

Patient-Selection Criteria and Overt Rationing

The first ethical concern to arise for physicians was how to select patients for dialysis. In the early 1960s in the United

States, 10,000 people were estimated to be dying of renal failure every year, but there were not enough dialysis machines or trained physicians and nurses to treat these patients. Furthermore, the cost of treatment for one patient for one year, $15,000, was prohibitively expensive for most patients. Dialysis centers like the Seattle Artificial Kidney Center, founded in 1962, were able to treat only a small number of patients. It was therefore necessary to restrict the number of patients selected for dialysis; in other words, criteria had to be developed for the rationing of dialysis.

The problem of selecting patients had major ramifications because the patients denied access would die. The solution of the physicians of the Seattle dialysis center was to ask the county medical society to appoint a committee of seven laypersons to make the selection decisions for them from among persons they had identified as being medically appropriate. The doctors recognized that the selection decision went beyond medicine and would entail value judgments about who should have access to dialysis and be granted the privilege of continued life. Historian David Rothman says that their decision to have laypersons engaged in life-and-death decision making was the historic event that signaled the entrance of bioethics into medicine. Bioethics scholar Albert Jonsen believes that the field of bioethics emerged in response to these events in Seattle because they caused a nationwide controversy that stimulated the reflection of scholars regarding a radically new problem at the time, the allocation of scarce lifesaving resources.

The doctors regarded children and patients over the age of forty-five as medically unsuitable, but they gave the committee members no other guidelines with which to work. At first the committee members considered choosing patients by lottery, but they rejected this idea because they believed that difficult ethical decisions *could* be made about who should live and who should die. In the first few meetings, the committee members agreed on factors they would weigh in making their decisions: age and sex of the patient, marital status and number of dependents, income, net worth, emotional stability, educational background, occupation, and future potential. They also decided to limit potential candidates to residents of the state of Washington.

As the selection process evolved, a pattern emerged of the values the committee was using to reach its decisions. They weighed very heavily a person's character and contribution to society (Alexander).

Once public, the Seattle dialysis patient-selection process was subjected to harsh criticism. The committee was castigated for using middle-class American values and social-worth criteria to make decisions (Fox and Swazey). The selection process was felt to have been unfair and to have undermined American society's view of equality and the value of human life.

In 1972, lobbying efforts by nephrologists, patients, their families, and friends culminated in the passage by the U.S. Congress of Public Law 92–603 with Section 299I. This legislation classified patients with a diagnosis of ESRD as disabled, authorized Medicare entitlement for them, and provided the financial resources to pay for their dialysis. The only requirement for this entitlement was that the patients or their spouses or (if dependent children) parents were insured or entitled to monthly benefits under Social Security. The effect of this legislation was to virtually eliminate the need to ration dialysis.

When Congress passed this legislation, its members believed that money should not be an obstacle to providing lifesaving therapy (Rettig, 1976, 1991). Although the legislation stated that patients should be screened for *appropriateness* for dialysis and transplantation, the primary concern was to make dialysis available to those who needed it. Neither Congress nor physicians thought it necessary or proper for the government to determine patient-selection criteria.

By 1978, many U.S. physicians believed that it was morally unjustified to deny dialysis treatment to any patient with ESRD (Fox and Swazey). As a consequence, patients who would not previously have been accepted as dialysis candidates were started on treatment. A decade later, the first report of the U.S. Renal Data System documented the progressively greater acceptance rate of patients onto dialysis (U.S. Renal Data System), and subsequent reports have shown that the sharp rise in the number of dialysis patients could be explained in part by the inclusion of patients who had poor prognoses, especially the elderly and those with diabetic nephropathy (Hull and Parker). By 2000, of the new patients starting dialysis 48 percent were sixty-five years of age or older and 45 percent had diabetes as the cause of their ESRD.

Observers have raised concerns about the appropriateness of treating patients with a limited life expectancy and limited quality of life (Fox; Levinsky and Rettig). Specifically, questions have been raised about the appropriateness of providing dialysis to two groups of patients: those with a limited life expectancy despite the use of dialysis and those with severe neurological disease. The first group includes patients with kidney failure and other life-threatening illnesses, such as atherosclerotic cardiovascular disease, cancer, chronic pulmonary disease, and AIDS. The second group includes patients whose neurological disease renders them unable to relate to others, such as those in a persistent

vegetative state or with severe dementia or cerebrovascular disease (Rettig and Levinsky).

The Institute of Medicine Committee for the Study of the Medicare End-Stage Renal Disease Program, which issued its report in 1991, acknowledged that the existence of the public entitlement for treatment of ESRD does not obligate physicians to treat all patients who have kidney failure with dialysis or transplantation (Levinsky and Rettig). For some kidney-failure patients, the burdens of dialysis may substantially outweigh the benefits; the provision of dialysis to these patients would violate the medical maxim: Be of benefit and do no harm. This committee recommended that guidelines be developed for identifying such patients and that the guidelines allow physicians discretion in assessing individual patients. Such guidelines might help nephrologists make decisions more uniformly, with greater ease, and in a way that promotes patient benefit and the appropriate use of dialysis resources. Subsequent studies have demonstrated that nephrologists differ on how they make decisions to start or stop dialysis for patients (Moss et al., 1993; Singer).

Access to Dialysis and the Just Allocation of Scarce Resources

The numbers of dialysis patients steadily grew each year, resulting in an ever increasing cost of the Medicare ESRD program. In the 1980s the United States experienced record-breaking budget deficits, and questions began to be raised about continued federal funding for the ESRD program. Observers wondered if the money was well spent or if more good could be done with the same resources for other patients (Moskop).

Critics of the ESRD program observed that it satisfied neither of the first principles of distributive justice: equality and utility. On neither a macro- nor a microallocation level did the ESRD program provide equality of access. On the macroallocation level, observers asked, as a matter of fairness and equality, why the federal government should provide almost total support for one group of patients with end-stage disease—those with ESRD—and deny such support to those whose failing organs happened to be hearts, lungs, or livers (Moskop; Rettig, 1991). On a microallocation level, only 93 percent of patients with ESRD have been eligible for Medicare ESRD benefits. The poor and ethnic minorities are thought to constitute most of the ineligible. The Institute of Medicine Committee for the Study of the Medicare End-Stage Renal Disease Program recommended that the U.S. Congress extend Medicare entitlement to all citizens and resident aliens with ESRD (Rettig and Levinsky).

From a utilitarian perspective, the ESRD program could not be argued to be maximizing the good for the greatest number. In the 1980s, more than 5 percent of the total Medicare budget was being spent on dialysis and transplant patients, who represented less than 0.2 percent of the active Medicare patient population. A similar disproportionate expense has continued into the twenty-first century. Furthermore, while in 2000 more than 40 million Americans were without basic health insurance, the cost to treat one ESRD patient on dialysis—of whom there were over 300,000—exceeded $50,000 per year. Despite the high cost, ESRD patient unadjusted one-year mortality approached 25 percent; for many, as Anita Dottes noted, life on dialysis was synonymous with physical incapacitation, dependency, chronic depression, and disrupted family functioning (Dottes).

Withholding and Withdrawing Dialysis

After cardiovascular diseases and infections, withdrawal from dialysis is the third most common cause of dialysis-patient death. In one large study, dialysis withdrawal accounted for 22 percent of deaths (Neu and Kjellstrand). Older patients and those with diabetes have been found to be most likely to stop dialysis. Over time, as the percentage of diabetic and older patients (those sixty-five or over) on dialysis increased, withdrawal from dialysis became more common. According to surveys of dialysis units performed in the 1990s, most dialysis units had withdrawn one or more patients from dialysis in the preceding year with the mean being three. (Moss et al., 1993).

Because of the increased frequency of decisions to withhold and withdraw dialysis in the 1980s and 1990s, the clinical practices of nephrologists in reaching these decisions with patients and families generated heightened interest. Discussions of the ethics and process of withholding or withdrawing dialysis became more frequent (Hastings Center, U.S. President's Commission). Two ethical justifications were given for withholding or withdrawing dialysis: the patient's right to refuse dialysis, which was based on the right of self-determination, and an unfavorable balance of benefits to burdens to the patient that continued life with dialysis would entail. Nephrologists and ethicists recommended that decisions to start or stop dialysis be made on a case-by-case basis, because individual patients evaluate benefits and burdens differently. They noted that such decisions should result from a process of shared decision making between the nephrologist and the patient with decision-making capacity. If the patient lacked decision-making capacity, the decisions should be made on the basis of the patient's expressed wishes (given either verbally or in a written advance directive) or, if these were unknown, the patient's best interests. They also advised that in such cases a surrogate be selected to participate with the physician in making decisions for the patient.

Questions were identified to help nephrologists evaluate a patient's request to stop dialysis. For example, why does the patient want to stop? Does the patient mean what he or she says and say what he or she means? Does the patient have decision-making capacity, or is his or her capacity altered by depression, encephalopathy, or another disorder? Are there any changes that can be made that might improve life on dialysis for the patient? How do the patient's family and close friends view his or her request? Would the patient be willing to continue on dialysis while factors responsible for the patient's request to stop are addressed?

If, after patient evaluation based on these questions, the patient still requested discontinuation of dialysis, nephrologists were counseled to honor the competent patient's request. In several studies, nine out of ten nephrologists indicated that they would stop dialysis at the request of a patient with decision-making capacity (Moss et al., 1993; Singer).

In half or more of the cases in which decisions have been made to withdraw dialysis, patients have lacked decision-making capacity. Nephrologists have expressed a willingness to stop dialysis of *irreversibly incompetent* patients who had clearly said they would not want dialysis in such a condition, but they have disagreed about stopping dialysis in patients without clear advance directives (Singer). In general, there has been a presumption in favor of continued dialysis for patients who cannot or have not expressed their wishes. The patient's right to forgo dialysis in certain situations has therefore usually been difficult to exercise.

The Patient Self-Determination Act, which applied to institutions participating in Medicare and Medicaid and which became effective December 1, 1991, was intended to educate healthcare professionals and patients about advance directives and to encourage patients to complete them. Although the ESRD program is almost entirely funded by Medicare, dialysis units were inadvertently left out of the act. Nonetheless, the completion of advance directives by dialysis patients has been specifically recommended for three reasons: (1) the elderly, who constitute roughly half of the dialysis population, are those who are most likely to withdraw or be withdrawn from dialysis; (2) dialysis patients have a significantly shortened life expectancy compared to non-renal patients; and (3) unless an advance directive to withhold cardiopulmonary resuscitation (CPR) is given, it will automatically be provided, and CPR rarely leads to extended survival in dialysis patients (Moss et al., 1992).

When patients lack decision-making capacity and have not completed advance directives, ethically complex issues may arise in the decision whether to start or stop dialysis. Many nephrologists have indicated that they would consult an ethics committee, if available, for assistance in making decisions in different cases (Moss et al., 1993). Ethics consultations are most frequently requested for decisions regarding the withholding or withdrawing of life-sustaining therapy such as dialysis.

By the end of the twentieth century, nephrologists recognized the need for a guideline on starting and stopping dialysis. Such a guideline, which would address appropriateness of patients for dialysis (patient-selection criteria), had been recommended by the Institute of Medicine Committee for the Study of the Medicare ESRD Program almost a decade earlier. In a 1997 survey of the American Society of Nephrology (ASN) and the Renal Physicians Association (RPA) leadership, the respondents gave the highest priority among twenty-four choices to the development of an evidence-based clinical practice guideline on starting and stopping dialysis. In the context of a changing patient population, the RPA and ASN leaderships believed that an evidence-based clinical practice guideline would assist patients, families, and the nephrology team in making difficult decisions about initiating, continuing, and stopping dialysis. The resultant clinical practice guideline, *Shared Decision-Making in the Appropriate Initiation of and Withdrawal from Dialysis,* was developed by a working group of physicians, nurses, social workers, patients, dialysis administrators, a bioethicist, and a health policy expert (RPA and ASN, 2000). The objectives for the guideline were to:

- Synthesize available research evidence on patients with acute renal failure and ESRD as a basis for making recommendations about withholding and withdrawing dialysis;
- Enhance understanding of the principles and processes useful for and involved in making decisions to withhold or withdraw dialysis;
- Promote ethically as well as medically sound decision-making in individual cases;
- Recommend tools that can be used to promote shared decision-making in the care of patients with acute renal failure or ESRD;
- Offer a publicly understandable and acceptable ethical framework for shared decision-making among healthcare providers, patients, and their families.

The guideline makes nine recommendations. These recommendations encourage the process of shared decision-making, the obtaining of informed consent or refusal for dialysis, estimating prognosis as part of informed dialysis decision-making, systematic approaches to conflict resolution, the use and honoring of advance directives, withholding or withdrawing dialysis for patients under certain circumstances, the use of time-limited trials to assist in reaching decisions about continuing or stopping dialysis, and the use

of palliative care for ESRD patients who decide to forgo dialysis. By defining the appropriate use of dialysis and the process to be used in making dialysis decisions, this guideline should also prove to be very useful to ethics consultants when they are called to help resolve conflicts over starting or stopping dialysis (Moss).

End-of-Life Care

In the wake of public dissatisfaction with end-of-life care and efforts to legalize physician-assisted suicide in several states, physician groups, including the RPA and ASN, recognized their ethical responsibility to improve end-of-life care for their patients. In 1997 in a joint position statement on *Quality Care at the End of Life,* the RPA and the ASN urged nephrologists and others involved in the care of ESRD patients to obtain education and skills in palliative care. They noted that palliative care knowledge and skills were especially important for nephrologists because they treat ESRD patients who die from complications despite the continuation of dialysis or after withholding or withdrawing dialysis. For example, in 1999, 48,000 patients died from complications while continuing dialysis and 12,000 died after a decision to stop dialysis.

One issue unresolved in the 1997 position statement was whether cardiopulmonary resuscitation ought always to be provided if cardiac arrest were to occur while patients are receiving dialysis, even if individual dialysis patients preferred not to undergo it. Data suggested that as many as one-third of dialysis units performed cardiopulmonary resuscitation on all patients who arrested while on dialysis, including those who refused the procedure. The concerns driving the uniform resuscitation of dialysis patients were two: The cardiac arrest might be iatrogenic, i.e., due to a complication of the dialysis procedure; and other patients might be troubled if the dialysis team made no attempt at cardiopulmonary resuscitation.

In 1999 the Robert Wood Johnson Foundation convened a series of workgroups to evaluate how end-of-life care could be improved for special populations of patients. The Robert Wood Johnson Foundation included the ESRD population because they perceived a readiness to address end-of-life care issues among the healthcare professionals treating ESRD patients.

In its report the ESRD workgroup noted that

> most patients with end-stage renal disease, especially those who are not candidates for renal transplantation, have a significantly shortened life expectancy. In the United States, dialysis patients live about one-third as long as non-dialysis patients of the same age and gender. The unadjusted five-year probability of survival for all incident ESRD patients is only 39 percent; and for the 48 percent of incident ESRD patients who are 65 years of age or older, it is only 18 percent. Life expectancy is also shortened by comorbid conditions. 45 percent of new ESRD patients have diabetes, and many have other comorbid conditions including hypertension, congestive heart failure, ischemic heart disease, and peripheral vascular disease.… It is clear from the foregoing information that the care of ESRD patients requires expertise not only in the medical and technical aspects of maintaining patients on dialysis, but also in palliative care—encompassing pain and symptom management, advance care planning, and attention to ethical, psychosocial, and spiritual issues related to starting, continuing, withholding, and stopping dialysis. (p. 5)

The ESRD workgroup noted the following with regard to the unresolved issue of cardiopulmonary resuscitation in the dialysis unit: (1) research studies of cardiopulmonary resuscitation have indicated that the outcomes for ESRD patients are poor; (2) most dialysis patients express a preference for undergoing cardiopulmonary resuscitation, but over 90 percent believe that a dialysis patient's wish not to undergo cardiopulmonary resuscitation should be respected by dialysis unit personnel (Moss et al., 2001); and (3) it is necessary for nephrologists and other members of the renal team to educate dialysis patients about the likely outcome of cardiopulmonary resuscitation based on patients' particular medical conditions. They recommended that "dialysis units should adopt policies regarding cardiopulmonary resuscitation in the dialysis unit that respect patients' rights of self-determination, including the right to refuse cardiopulmonary resuscitation and to have a do-not-resuscitate order issued and honored" (Robert Wood Johnson Foundation, p. 10). The RPA and the ASN accepted this recommendation and revised their position statement on *Quality Care at the End of Life* in 2002 to include this and other recommendations of the ESRD workgroup.

The Effect of Reimbursement

Reimbursement has affected both dialysis techniques and quality of care provided to dialysis patients. In the 1980s cost was the federal policymakers' primary concern about the ESRD program, and federal reimbursement rates for dialysis were reduced twice. By 1989, the average reimbursement rate—adjusted for inflation—for freestanding dialysis units was 61 percent lower than it had been when the program began (Rettig and Levinsky).

When the U.S. Congress established the Medicare ESRD program, the highest estimate for cost of the program by 1977 was $250 million; the actual cost was approximately $1 billion (Fox and Swazey). At least two major reasons were held to be responsible for the higher cost: the increasing number of patients being started on dialysis, some of whom would have been *unthinkable* dialysis candidates ten years earlier, and the growth of in-center dialysis while the use of less costly home dialysis declined.

Despite inflation and increases in the costs of salaries, equipment, and supplies, there were only two modest increases in the Medicare reimbursement to dialysis providers in the 1990s. By the end of the twentieth century, the rate of reimbursement for dialysis by Medicare adjusted for inflation was only one-third of the amount in 1973. A longstanding historian of the ESRD program, Richard Rettig, observed, "No other part of Medicare has been subjected to this severe, even punitive, economic discipline" (2001, p. 16). Meanwhile, the incidence of ESRD in the United States had tripled compared to twenty years earlier. Almost 100,000 new patients were starting dialysis each year.

Conflicts of Interest

A conflict of interest occurs when there is a clash between a physician's personal financial gain and the welfare of his or her patients. While a conflict of interest generally exists for all physicians who practice fee-for-service medicine, there is a potentially greater conflict of interest for physicians who share in the ownership of for-profit dialysis units in which they treat patients. Physicians who receive a share of the profits are financially rewarded for reducing costs. Although measures to reduce costs may simply lead to greater efficiency, they may also compromise patient welfare if they entail decreasing dialysis time; purchasing cheaper, possibly less effective dialyzers and dialysis machines; and hiring fewer registered nurses, social workers, and dietitians. In the past, for-profit dialysis companies were quite open about their policy of giving physicians a financial stake in their companies. Such companies flourished under the ESRD program (Kolata).

Physicians and dialysis units are paid on a per-patient and per-treatment basis, respectively, under the ESRD program, and the acceptance rate of patients to dialysis in the United States is higher than anywhere else in the world (Hull and Parker). This higher rate has been at least partly attributed to the acceptance on dialysis in the United States of a much greater number of patients with poor prognoses. Some have argued that this high acceptance rate was a sign that nephrologists and dialysis units were seeking to maximize their incomes, while others have commented that many physicians believed they were obligated to dialyze all patients with ESRD who wanted it (Fox).

In the 1990s, the concerns about conflicts of interest heightened. Two-thirds of ESRD patients were being dialyzed in for-profit units. Short dialysis times were found disproportionately in for-profit units and associated with increased mortality. Patients treated in for-profit dialysis units were noted to have a 20 percent higher mortality rate and a referral rate for renal transplantation 26 percent lower than that for not-for-profit units (Levinsky). The nephrologist who owned all or a share of a for-profit unit was confronted with a clear conflict of interest. In responding to financial pressures created by a dialysis reimbursement rate that failed to keep up with inflation and in instituting cost-cutting measures, he or she was believed to be treading a very fine line between maintaining adequate profit to keep the dialysis unit open and compromising patient care.

A decade earlier, nephrologist and *New England Journal of Medicine* editor Arnold Relman had anticipated the predicament nephrologist owners of dialysis units would face. He had warned that the private enterprise system—the so-called new medical-industrial complex—had a particularly striking effect on the practice of dialysis, and he urged physicians to separate themselves totally from any financial participation so as to maintain their integrity as professionals (Relman). Education of nephrologists about these issues, both in training and in continuing education courses, was advocated to help them to identify present and potential conflicts of interest and resolve them in a way that places patients' interests first.

To hold dialysis units, both for-profit and non-profit, accountable for the quality of care they provide, the Medicare ESRD program through the eighteen ESRD Networks established quality indicators to measure the performance of individual dialysis units and all the dialysis units within a region. These measures monitor adequacy of dialysis, anemia management, vascular access placement, and standardized mortality ratios as well as other indicators.

Racial Disparities

Racial differences in access to effective medical procedures are known to be a problem in the United States. Black patients are less likely than white patients to undergo renal transplantation, coronary artery bypass surgery, and many other procedures. Despite the tendency to undertreatment in other areas, black patients are significantly overrepresented in the dialysis population, comprising 32 percent of all ESRD patients but only 13 percent of the United States population. There is also an overrepresentation of other

racial and ethnic minority groups in the ESRD population. The increased susceptibility of nonwhite populations to ESRD has not been fully explained and probably represents a complex interaction of genetic, cultural, and environmental influences. Disparities in treatment for racial minority ESRD patients have been noted, including the following: (1) they are less likely to be referred for home dialysis and renal transplantation; (2) they are more likely to be underdialyzed; and (3) they are more likely to have less desirable synthetic grafts (shorter patency and more complications) rather than fistulas as permanent dialysis access. Nonetheless, blacks have better survival and quality of life compared to whites, and they are also less likely to withdraw from dialysis. The better outcomes despite less than optimal treatment present an opportunity to study and further improve ESRD care for minority patients.

International Perspective

Economics plays the leading role in determining the availability of dialysis in countries throughout the world. The countries with the largest numbers of patients on dialysis are among the richest: the United States, Japan, and Germany. The number of patients per million population treated with dialysis correlates highly with the gross national product per capita. Countries with a per capita gross national product of less than $3,000 per year treat a negligible number of patients with dialysis and transplantation. Approximately three-quarters of the world's population live in these poorer countries.

In parts of the world where dialysis technology and money for healthcare are limited, dialysis is severely rationed. Two sets of criteria have been used to select patients for dialysis. In India, China, Egypt, Libya, Tunisia, Algeria, Morocco, Kenya, and South Africa, money and political influence play an important role in deciding which patients will have access to dialysis and transplantation. In Eastern Europe, ESRD patients with primary renal disease who have a lower mortality and who are more likely to be rehabilitated tend to be selected (Kjellstrand and Dossetor).

Conclusion

Dialysis was one of the earliest life-sustaining treatments. Since its inception, dialysis has raised many ethical issues to be analyzed and resolved. In the 1960s the attempt to make difficult yet socially acceptable ethical decisions about patient-selection criteria and the rationing of dialysis failed because of the use of social worth criteria. The dialysis community and others learned from this experience. In the 1990s, prompted by the dramatic expansion of the ESRD program and a belief by many that not all patients on dialysis were appropriate for it, the renal professional societies succeeded in developing patient-selection criteria—based on likelihood of benefit and shared decision making—that have been widely endorsed. Other examples of analyzed and resolved ethical issues in dialysis that are broadly applicable are the ethical justifications for allowing patients to forgo dialysis, a life-sustaining treatment, and the development of an approach to hold providers accountable when there is a major and continuing conflict of interest.

Kidney dialysis has succeeded beyond all expectations in its ability to sustain life for hundreds of thousands of patients worldwide. Refinements in the technology have allowed patients who were previously considered not to be candidates for dialysis to experience several or more years of extended life. Its success brings with it three major challenges: how to finance the expensive treatments for a larger and larger number of patients; how to maintain the quality of dialysis care in the United States with the provision of dialysis increasingly being provided by for-profit dialysis corporations who have an inherent conflict of interest; and how to humanely care for an increasingly older, frail population with multiple medical problems and a significantly shortened life expectancy.

Because of the continuing challenges it poses, dialysis will likely continue to break new ground with regard to ethical analyses that will subsequently be helpful to other modern medical technologies.

DISABILITY

• • •

I. ETHICAL AND SOCIETAL PERSPECTIVES

People who are physically or mentally disabled have many disadvantages. They may have an impairment, such as paralysis, blindness, or a psychiatric disorder, that reduces their ability to do things that nondisabled people do and may interfere with their fulfillment of socially valued roles. Also, disabled people often are subjected to various degrees of exclusion from the social and economic life of their communities. Political movements by disabled people to remove barriers and overcome discrimination, and protective legislation in several countries, have focused attention

on the controversial concept of disability and on what constitutes just and compassionate behavior toward the disabled by individuals and institutions, including private employers, providers of public services, and schools. These ethical issues are pressing for all people because everyone can be disabled by trauma and because in societies in which life expectancy is long everyone may expect some impairments in old age.

This entry analyzes the concept of disability and its links to certain other concepts (impairment, handicap, health, and disease), explains the two competing explanatory models of disability, and surveys some of the ethical controversies that pertain to the nature of disability and the relationship between a disabled person and the rest of society.

Defining Disability: Conceptual Issues

The idea of disability and these related concepts are tricky to define. The conditions that often are referred to as disabilities are varied, including sensory losses, learning difficulties, chronic systemic illnesses and their effects (such as constant fatigue and pulmonary insufficiency), mental illnesses, lack of limbs, and lack of mobility. Do all these conditions have a common feature? Does every biological abnormality qualify as a disability? Does the availability of technological aids play a role in determining whether a bodily state is a disability? To what extent does being disabled depend on the environment in which a person lives? The very definition of disability is controversial; there is no single accepted definition.

The World Health Organization (WHO) of the United Nations offered the following definitions, which have been highly influential:

> *Impairment*: Any loss or abnormality of psychological, physiological, or anatomical structure or function.
>
> *Disability*: Any restriction or lack (resulting from an impairment) of ability to perform an activity in the manner or within the range considered normal for a human being.
>
> *Handicap*: A disadvantage for a given individual, resulting from an impairment or disability, that limits or prevents the fulfillment of a role that is normal, depending on age, sex, social and cultural factors for that individual. (United Nations, 1983, quoted in Wendell)

Those definitions provide a good starting point but require fine-tuning. The distinction between impairments and disabilities is useful even though in some cases the distinction may be strained. The term *impairment* best captures a loss of or a defect in psychological, physiological, or anatomic features. Thus, paralysis of an arm muscle is an impairment, and inability to throw something is a disability brought about by that impairment, because it is a lack of the ability to perform an activity (throwing). Inability to throw a baseball is not an impairment or a disability; instead, in a person who would be expected to be able to throw a baseball it may be a handicap: a disadvantageous inability to perform a socially defined activity that is caused by an impairment and a disability.

Thus, not every impairment is disabling. An abnormal shape of the eyeball that prevents light from focusing properly on the lens is an impairment, but if the afflicted person can see perfectly well with glasses or contact lenses and carry out the same activities that other people can, that impairment is not disabling. One also can ask whether a disability is a handicap. Franklin Delano Roosevelt had a disability (he could not walk) that no doubt prevented him from fulfilling some social roles, but it did not prevent him from fulfilling the role of president of the United States, and so in that respect it was not a handicap.

Difficulties with the WHO Definitions

There are two main deficiencies in the definitions given above that should be remedied. First, they contain no account of what is normal or abnormal for human beings either in structure and function (as in the definition of impairment) or in the manner and range of performing an activity (as in the definition of disability). Second, only the definition of a handicap makes reference to disadvantage, yet intuitively, disadvantage, or at least inconvenience, is part of the concept of disability. Below are suggested improvements, although significant imperfections remain.

THE HUMANLY NORMAL AND ABNORMAL. An account of the type of abnormality necessary for the notion of impairment to be applicable is needed. What is normal human physiology, psychology, anatomic structure, and function? The topic is vast and controversial, and it is easy to go wrong.

A statistical account of normal structure and function would be misconceived. Even if all human beings were damaged in a nuclear accident, it would not be humanly normal to suffer from radiation sickness and sterility.

It is also not possible to define normal structure and function simply by listing all the body parts human beings are observed to have, what those parts are observed to do, and how they do it. This is not only because knowledge in this area is incomplete. If one simply observes human organisms, the list will include things frequently observed that never would count as normal. One would observe both

sound and decayed teeth, both painful childbirth and painful urination, and both the beating of the heart and myocardial infarction (another thing the heart is seen to do), yet the second item in each pair is abnormal. The concept of a human organ and its function is inseparable from the concept of what is normal for human beings (an evaluative, teleological concept), and any definition of normality that refers to the functions of organs assumes the concept of the normal in the attempt to define it. (The biologist's concept of the function of an organ need not depend on cultural assumptions, however. It only presupposes the distinction between normal and abnormal.)

A partial account of the normal functions and abnormalities of body parts can be derived from an understanding of their role in the survival of the species. As Norman Daniels puts it (p. 28), the biomedical sciences, including evolutionary biology, provide an account of "the design of the organism" and "its fitness to meeting biological goals" relative to which a scientist can specify some normal and abnormal phenomena. However, the usual biological goal assumed in evolutionary theory—transmission of an organism's genes to the next generation—does not entail the abnormality of many intuitively abnormal conditions, such as the diseases of extreme old age.

Rather than abandon hope of a definition, though, it is possible to adopt the following crude and incomplete standard, which suffices for the issues surrounding impairment and disability and leaves the thorniest controversies aside. A state of a human being is an abnormality of the type that can make it an impairment only if the state is such that if all human beings had had it from the beginning of human prehistory and otherwise were as they in fact are now, the human species would have been significantly less likely to survive.

This is a necessary but not a sufficient condition of a state's being abnormal. That is, all abnormal traits are ones that probably would have precluded species survival, but not all states that would have precluded species survival are abnormal. States that are abnormal fulfill certain other conditions. There is no complete list of these conditions, but here are two of them.

The first requires a subsidiary definition. Some traits assist survival when they are present in some members of a population as long as other individuals have a different trait; however, if all individuals had the trait, the population could not survive. These can be called diversity-requiring traits. An obvious one is being male or female. Having some males has been indispensable to the species's survival over time, but if all individuals were male (from prehistory), the species would have died out long ago.

The other condition excludes from the definition characteristics that are universal in but are limited to human beings of a certain developmental stage. It is normal for newborn infants to be unable to walk, for example, even though if all human beings of all ages had always been unable to walk, the species would not have survived.

The definition of abnormality can be supplemented in light of this characterization. Thus, a state of a human being is an abnormality of the type relevant to impairment only if the state is such that if all human beings had had it from the beginning of human prehistory and otherwise were as they in fact are today, the human species would have been unlikely to survive. If the state (1) is of that kind, (2) is not a diversity-requiring trait, and (3) is not a trait that is characteristic of and limited to certain stages of human development, it is abnormal.

With this understanding of abnormality, one can say, with the WHO, that an impairment is any abnormal loss or other abnormality of psychological, physiological, or anatomic structure or function. This standard ensures that the abnormalities that qualify as impairments are ones that characteristically make a difference in living a human life, the typical life of the species, whether or not they cause a great loss for any specific individual in any particular set of circumstances. Thus, extreme myopia (nearsightedness or shortsightedness) is an impairment by this definition because if all human beings had had this characteristic since prehistory and otherwise had been the same as they are today, the human species would have been unlikely to survive. A hunter-gatherer society composed entirely of severely myopic people would be doomed. Yet severe myopia may not cause serious inconvenience to a person in a modern technological society.

IMPAIRMENT AND DISABILITY. The WHO definition of disability says nothing about disadvantage, whereas intuitively that seems to be part of the concept. People would not count it as a disability if someone were unable to perform an activity in the manner normal for human beings if it were an activity that that person, or perhaps everyone, had no interest in performing in that way. It is no disability to someone who has taken a vow of celibacy or has undergone voluntary surgical sterilization that that person is biologically infertile because it does not disadvantage that person even though it is an impairment.

Instead, one can define a disability as any impairment-caused disadvantageous restriction or lack of ability to perform an activity in the manner or within the range that is normal for a human being. The relevant notion of normality is the same one identified above: that manner and range of activity without which the human species as a whole would

have been unlikely to survive. Thus, extreme myopia, although it is an impairment, is not a disability for someone who suffers no consequent disadvantage because she or he has glasses or contact lenses that enable her or him to see perfectly.

Some people argue that a disability need not be disadvantageous. Anita Silvers (1994) gives the example of the great violinist Izhak Perlman, who walks with great difficulty yet has had a life of magnificent artistic accomplishment. However, it is surely to Perlman's disadvantage to have difficulty walking, as Bonnie Steinbock (2000) notes. A particular condition may be disadvantageous even for someone who is fortunate overall.

In light of these definitions impairments may disable a person to different degrees or in different ways in different societies, depending not only on the technology available (as with severe myopia) but more generally on the modes of living prevalent in the person's society, for example, whether the society is literate, whether it is agrarian or industrial, and the forms of transportation available in it. People with impairments also may confront varied cultural obstacles. In a society in which those born with bodily defects are regarded as cursed by the gods, for example, people with congenital impairments may be shunned, barred from most vocations, and reduced to begging. For a less extreme example, in a society in which attendant care is available only to those who live in institutions people who need the help of an aide to dress or bathe must be institutionalized. Someone with the same impairment might live in his or her own home in a different society. Consequently, some have argued that disability is purely a social construct. The degree of disability may indeed vary greatly as a result of cultural factors, however, as defined here, the impairment that causes disability is not fundamentally social in nature.

Handicap

The difference between a handicap as defined by the WHO and a disability as it has been defined here is that handicap employs a different concept of normality. A handicap results from impairment or disability, but it is a disadvantage that results from the consequent inability to fulfill roles that are normal, where what is normal is determined by social and cultural factors. Some activities, such as walking and seeing, are normal for human beings regardless of cultural expectations. If one cannot perform them, one is disabled in that respect. Other activities are normal for people in a particular type of society but are not expected or needed in others. If a person cannot perform them, that person will be handicapped in one society but not in another. Reading and using a telephone are normal activities in some societies but not in others, and so the inability to perform them, for example, because one is dyslexic or deaf, is not culturally abnormal and thus is not a handicap.

However, humanly normal activities may not always be clearly distinguishable from culturally normal activities. Often people perform their normal human activities by carrying out certain social roles that are dictated by their cultural and physical environment. Susan Wendell (1996) points out that a woman with impaired vigor might be able to obtain drinking water in the way that is normal in western Canada (turning on a tap) but unable to obtain it in the way that is normal in rural Kenya (walking a long distance to a well twice daily). Consequently, the distinction between a disability and a handicap is not always sharp.

Disadvantages Resulting from Prejudice

People with disabilities tend to be looked down on, ignored, discriminated against, and otherwise badly treated. Sometimes they are denied education or medical care or excluded from employment. Sometimes they are institutionalized or sterilized against their will. Sometimes they are subjected to violence or other forms of abuse. Often, especially but not only in poor countries, their needs for food and shelter are not met. Many nondisabled individuals are uncomfortable in the presence of the disabled and therefore exclude them from social life. Thus, at times the attitudes of their fellow citizens bar disabled people from carrying out the social roles of students, employees, spouses, and parents, causing their handicaps.

Impairment, Disability, Disease, and Health

The concept of impairment is closely related to the concepts of disease and health. Health commonly is defined as the absence of disease. Chistopher Boorse (1977) defines disease as an impairment of or limitation on functional ability, identifying disease with impairment. (However, he gives a statistically based account of functional ability, which was rejected here.) Norman Daniels (1985) defines disease as a deviation from the natural functional organization of a typical member of the species. He says that in characterizing "natural functional organization," the biomedical sciences draw on evolutionary notions and "claims about the design of the species" (p. 28), yielding an account of what is humanly normal that is close to the account given here. Thus, disease and impairment are nearly equivalent. Impairment is a slightly wider category because it includes the absence of a structure, and this usually is not called a disease. An amputee may be healthy (free of disease), yet that person is impaired.

Disability has been defined as an impairment-caused disadvantageous restriction on the ability to perform normal human activities or to perform them within the normal range. Because diseases are a subset of impairments, many diseases are causes of disability provided that they impose a disadvantage on the persons who have them. Thus, an infection is both a disease and an impairment, and it may cause disability (temporary or permanent) by disadvantageously reducing the ability of an afflicted person to perform humanly normal activities. Nondisease impairments such as the absence of a limb also may cause disability.

Two Models of Disability

There are two opposing, dominant ways of conceiving of disability: the medical model and the minority group model; the latter sometimes is called the disability rights model. These are explanatory models for understanding how and why disabled people are disadvantaged and theories of the appropriate means to ameliorate those disadvantages. These two ways of representing disability influence their advocates' positions on several ethical issues.

THE MEDICAL MODEL. According to the medical model, a disabled person's lack of ability to perform normal human activities can be traced entirely to that person's impairment: the abnormalities in his or her psyche, physiology, or anatomy. A paraplegic cannot get from place to place because her legs are paralyzed; a blind person cannot read because he cannot see. Disability is a result of the state of a disabled person's body. Consequently, the best way to remove the disadvantage is to correct the impairment medically, by means of surgery, drugs, physical therapy, prosthetics, and the like. Proponents of the medical model advocate vigorous treatment to eliminate impairments, extensive research to find cures for impairments for which no treatment is available, and prevention of future impairments. Prevention should be achieved by increasing the use of existing safety devices (e.g., in automobiles), developing new ways to avoid disabling accidents and illnesses, and identifying and encouraging healthful behavior in pregnant women (such as good nutrition and not smoking) to prevent the birth of children with disabilities. Some people also support preventing the birth of affected infants by using prenatal screening and abortion of abnormal fetuses or using genetic engineering when possible.

Many corrective medical interventions are performed successfully to prevent or eliminate disability, but many impairments cannot be corrected. When medicine cannot restore normal structure or function, the extent of the incapacity may be reduced. However, in many cases this cannot be done, and the person remains impaired and disabled. The disadvantages that person experiences may be substantial. At this point the medical model has little to offer to enable a disabled person to overcome her or his disadvantage. Because the disadvantage is understood to arise from the impairment, if nothing can be done to remove the impairment, it follows that nothing can be done to overcome the disadvantage.

THE MINORITY GROUP MODEL. According to the minority group model, although disabled people have physical, sensory, or psychological impairments, the principal source of their disadvantage is not the impairments but the impact on those people of the socially created environment. Because people with impairments are few in number and lack power and influence, they make up a minority group that is not taken into account in the physical and organizational design of facilities and institutions. Consequently, they are excluded from many mainstream activities. Thus, disability and handicap are only to a small degree the result of impairments; the disadvantages they involve, which can range from inability to attend a nightclub to unemployment and poverty, are largely the result of a lack of social inclusion.

Whereas the medical model explains a paraplegic's disadvantage solely in terms of the fact that that person cannot walk, the minority group model explains it by reference to the fact that buildings and streets are built in such a way that a paraplegic cannot maneuver a wheelchair into them or through them and therefore cannot go where he or she needs to go to conduct business, acquire an education, perform a job, or engage in recreation. A paraplegic is disadvantaged because she or he cannot do those things. Anita Silvers (1995) points out that streets and buildings would be made wheelchair-accessible if the majority of people in the society moved about by means of wheelchairs. Silvers makes this statement to show that it is their minority status, not their impairment, that causes the disabled to be excluded from so much of ordinary social life.

In contrast to the medical model, the minority group model claims that a great deal can be done to overcome the disadvantage component of disability for those whose impairments are not medically correctable. Society should be altered to make it much more inclusive. To continue with the example of a person who cannot walk, buildings can be fitted with ramps and elevators, cities can provide buses and taxis with wheelchair lifts, and doorways can be widened, enabling a wheelchair user to lead an independent life that is fully integrated into the community. Thus, a wheelchair user would experience vastly less disadvantage as a result of changes in society rather than by means of medical intervention.

According to the minority group model, in nearly all societies there is rampant discrimination against the disabled. This is the case because the built environment, the chief means of information gathering, and many forms of activity are suitable only for nondisabled people. As an analogy one can imagine that unknown to the builders, a widely used building material gave off radiation that had no effect on most people but gave intolerable shocks to one small ethnic group. Members of that ethnic group thus could not enter many buildings, including places they urgently needed to go to do their banking, pay taxes, and so on. This clearly would be unfair, if unintentional, discrimination.

According to the minority group model, this is exactly the way things are. Barriers to the participation of the disabled are present both in the built environment and in cultural institutions. For example, proceedings in classrooms, courts, and legislatures are impenetrable to people with sensory impairments. According to the minority group view this state of affairs is unjust. It imposes terrible disadvantages on disabled people that could be alleviated, and because it is society that unfairly excludes the disabled, society should remediate the situation.

The tension between the more widely held medical model of disability and the minority group model helps shape some of the crucial ethical debates over the moral treatment of the disabled.

Ethical Issues

Two main categories of ethical issues pertain to disability: issues concerning the value of the lives of disabled people and issues that concern the rights disabled people have and the grounds on which they claim those rights.

THE VALUE OF THE LIVES OF DISABLED PEOPLE. The ethical issues in this category are those related to the withholding of life-prolonging medical treatment, euthanasia, physician-assisted suicide, prenatal screening and abortion of fetuses with likely birth defects, and genetic engineering to prevent impairments in future offspring. Of course, these are areas of great general ethical controversy that raise many other issues.

When nondisabled people hear descriptions of a person's impairments, especially ones that result from sudden trauma to a previously unimpaired individual, they often react by thinking, "I would not want to live like that." That is sometimes the reaction of a disabled individual to his or her own losses. Robert B. White (1975) reports that at one point after his disabling accident Dax Cowart summarized his attitude by saying, "I do not want to go on as a blind and crippled person." That type of reaction helps explain why many regard the lives of people with disabilities as not worth living. However, those who have had time to adjust to their disabilities or have always lived with them are usually very glad to be alive. Although some disabilities may deprive a person's life of value, this cannot be assumed, and such an assumption, which may be unconscious, could lead to grave wrongdoing by caregivers and the legal system.

Euthanasia, withholding of life-prolonging treatment, and physician-assisted suicide. The question whether an individual should be kept alive by medical means (for example, cardiopulmonary resuscitation) or allowed to die as the result of a disease or injury and the question whether a person's death should be brought about by his or her own agency or that of others often arise when a person is terminally ill. However, they also may arise when a person has an incurable disease or another medical condition but can be expected to live for a considerable amount of time if given fairly standard medical treatments and food and water. Justifications for withholding a standard form of life-prolonging treatment from such a person or for taking steps to bring about that person's death usually appeal to the fact that as a result of the person's wretched medical condition, life is not a good to him or her. This may be the case if the person is mentally competent and requests death (usually because the medical condition causes unbearable suffering) or if the person is in a persistent vegetative state and is unable to have experiences of any kind or is an infant too young to make decisions who faces a very bleak future.

The appeal to autonomy. The refusal of life-prolonging treatment by a mentally competent patient is justified by an appeal to individual autonomy. A patient has a moral right to refuse treatment; this is an aspect of the fundamental moral right to autonomy, including decision-making control over what happens to one's body. Some people doubt whether it is ever morally permissible for a person to exercise the right to refuse treatment for the sole purpose of hastening his or her own death. However, there is wide agreement that if a patient does refuse treatment for any reason, provided that that person is mentally competent and well informed about her or his condition and prospects, it is wrong for anyone else to force the treatment on that person against her or his will. To do so would be an act of assault.

It is far more controversial whether the right to autonomy includes the right to commit suicide (rather than only to refuse treatment), and whether once a competent patient has decided to end his or her life a physician or another person may rightly assist him or her in doing that or may deliberately end that person's life at his or her request. Some defend the legitimacy of suicide as a rational and autonomous act, at least in the face of great and irremediable

suffering that deprives life of its value. Others object to it even in such cases on the grounds that suicide is incompatible with respect for life. Physicians sometimes are asked to provide help in dying, for example, by giving lethal doses of drugs. Some argue that in cases in which the patient's life is not a good to the patient assistance with suicide is legitimate and indeed is a compassionate act. Others condemn this practice either because they condemn all suicide and judge it wrong to assist in a wrongful act or because they deem assisting with suicide incompatible with the role of a physician. Finally, some regard active euthanasia as incompatible with respect for life, indeed as murder, even when the killing is requested by the person who is to be killed. Others argue that euthanasia is morally justified when it is fully voluntary and the person's life is not worth living.

The incurable conditions that sometimes cause people to refuse life-prolonging treatment or seek physician-assisted suicide (PAS) or euthanasia (or because of which treatment is refused or euthanasia is sought on people's behalf) are often impairments and/or disabilities or are, like pain and nausea, the causes of impairments and/or disabilities. Among them are such conditions as the extensive brain damage suffered by Nancy Cruzan and diseases (and impairments) such as bone cancer, which causes disability by producing such overwhelming pain that the person cannot engage in normal activities. Thinking of a person who wishes to die as being disabled, as nearly always is the case, may change one's thinking about the ethical issues involved.

For those who oppose all euthanasia and PAS no moral conundrum arises with respect to disabilities in these areas: All such acts are wrong. For proponents of euthanasia and PAS, however, disabilities introduce some special dilemmas.

Many advocates of euthanasia and PAS tend to think of the matter as follows: Disabling conditions such as cerebral palsy, paralysis, and the type of permanent respiratory insufficiency that requires daily use of a respirator are incurable and can deprive life of its value for the afflicted person. If that person is mentally competent and refuses a life-prolonging treatment, saying that he or she prefers to die, these conditions are sufficient reason for that person to do so, and of course the request should be honored because it represents an exercise of individual autonomy. Even the opponents of euthanasia and PAS agree that treatment should not be forced on a person who is competent. If a person requests PAS or euthanasia, these are also sufficient reasons for it to be administered by willing parties according to this view. People with disabilities who seek death by starvation or the removal of a respirator have been hailed as champions of individual autonomy who attempt to exercise their rights against the resistance of officious healthcare institutions.

TWO ARGUMENTS AGAINST THE AUTONOMY-BASED APPROACH. There are two important counterarguments to this way of looking at requests to die made by people with disabilities.

The first is Carol Gill's (1992) suicide-prevention argument. Gill notes that when a nondisabled person undergoes a life crisis and subsequently shows certain behavioral signs and expresses a wish to die, that person is diagnosed with depression and is given counseling. He or she is regarded as less than fully competent because of depression and suicidal ideation. Gill observes a widespread assumption among nondisabled people, including healthcare professionals, that life with a disability is not worth living. Because of this, she argues, when someone with a disability expresses a suicidal wish, it is not classified as a symptom of curable, temporary emotional pathology. Instead, healthcare professionals regard the wish to die as rational because of their revulsion at the thought of living with a disability. They overlook standard clinical signs of depression and may disregard the presence of life crises or disappointments that are not related to the disability, such as loss of employment and divorce. Consequently, instead of providing suicide-prevention services, they encourage withdrawal of life-prolonging treatment, euthanasia, or PAS. If suicide-prevention services were provided, the disabled person might see adequate reason to live regardless of the disability, for once the depression was treated, the person would find life worthwhile. Thus, to advocate a right to die for the disabled is, at least in some cases, not to promote individual autonomy in decisions about life and death but instead to deprive the disabled of the suicide-prevention services routinely offered to nondisabled persons, a form of invidious discrimination.

The second, and related, counterargument arises more directly from the minority group model of disability. There is evidence that in some cases disabled persons seek death not because they find their impairments unendurable but because they are trapped in a dehumanizing social setting. Larry McAfee, for example, became so frustrated with his confinement to a nursing facility that he obtained a legal ruling that his ventilator be disconnected. Disabilities activists helped McAfee obtain job training and arrange to live outside the nursing home; he then decided to continue to live. According to this argument, what makes life unbearable to such people is not their impairments but the social world that subjects them to physical confinement and denies them decision-making power over their lives. Many people who are fairly severely disabled can, with assistance, do what McAfee did. However, government aid programs often refuse to provide the needed services outside an institution or the person is stymied by an unresponsive bureaucracy or excluded from jobs or housing by physical barriers or human

prejudices. Thus, the disabled person's misery is caused by the choices and policies of other people. The person may seek death as the only alternative to living without basic dignity. In this view the ethical solution is not to allow or assist in the person's death but to free the members of this minority group from the oppressive conditions under which they are forced to live by implementing policies that promote independent living.

EUTHANASIA OF NEWBORNS WITH IMPAIRMENTS. Because newborn infants cannot make informed decisions about whether to end their lives, those who grant that some euthanasia is legitimate usually argue that such decisions should be made for newborns on the basis of whether a child's life will be of value to the child. The witholding of life-prolonging treatment is treated in the same way because there is no possibility in this case of informed refusal of treatment by the patient. According to the minority group model, infants born with incurable impairments may be wrongly killed because caregivers and parents assume that their lives would be entirely unrewarding even though many people with similar disabilities lead satisfying lives.

PUBLIC POLICY. Even if euthanasia or PAS for some disabled individuals were morally justified and not a result of depression or exclusion from independent living, some authors predict that if those options were made legal and routinely available, many morally unacceptable acts would result. They cite the difficulties of judging the mental competence of suffering patients who request death. In busy or understaffed hospitals people could be put to death who did not really want to die or were not really able to make a decision about it. Those authors mention the further danger that death may be sought not for the benefit of the person who dies but for the benefit of family members overwhelmed by the responsibility of caring for or paying for the care of an incurable individual or for the benefit of insurance companies and publicly funded healthcare programs.

This position creates a conundrum: Is it acceptable to adopt a policy that denies euthanasia and PAS to some people who are morally entitled to it, resulting in their prolonged suffering, to prevent the wrongful killing of others from carelessness, poor administration, or evasion of the law? Some argue that disabled people would be particularly vulnerable to being put to death wrongly under a policy of legal euthanasia or PAS because of the tendency of nondisabled people to expect a life with disabilities to be much worse for a disabled person than it actually is, the corresponding tendency of healthcare professionals and others to overlook the needs for treatment and other services, and the costs of providing for the disabled person's needs. Any such policy must include rigorous safeguards to prevent abuses and errors, but no safeguards are foolproof.

ABNORMAL FETUSES, PRENATAL SCREENING, AND ABORTION. Testing during pregnancy for a variety of genetic and other congenital abnormalities is available in many places. Familiar examples are the test for Down's syndrome performed by means of amniocentesis or chorionic villus sampling and the blood test for the alpha-fetoprotein level to gauge the likelihood of neural tube defects. Most prospective parents seek prenatal tests with the intention of aborting the fetus or embryo if it is found to have an abnormality. The tests that exist or will exist in the near future are for types of impairments that can be fairly severe, although some exhibit a great range of severity, and tests cannot show how severely or mildly affected a child would be.

Those who regard abortion as wrong in every case or defensible only in very limited cases (e.g., to save the life of a pregnant woman) must regard abortions of impaired fetuses as immoral. Antiabortion arguments usually are based on the thesis that an unborn human being, no matter how primitive its stage of development, has a right not to be killed (and indeed to be kept alive) because it is human. If a human fetus has a right to life from conception onward by virtue of its human genome and if abortion is therefore wrong, abortion is just as wrong when a fetus is affected by spina bifida or another abnormality as it is when a fetus is normal. According to this view these fetuses are surely human, just as are adult disabled people. The most common antiabortion position holds that human fetuses are already full-fledged persons with moral rights. Thus, impaired fetuses are also persons with moral rights.

Those who argue that abortion is wrong because of a being's potential to become a person rather than as a result of its actual personhood may have some flexibility to justify exceptions for fetal abnormality. However, many abnormal fetuses have the potential to fulfill the fundamental criteria of personhood and thus could not rightly be aborted even according to the potentiality theory.

Therefore, an antiabortion position opposes nearly all abortions of impaired fetuses. Some general opponents of abortion try to defend an exception for fetal abnormalities, but it is difficult to make that position logically consistent.

Those who regard abortion as often permissible (those with a "prochoice" position) may hold a range of different views that are based on various ethical principles and countenance abortions at different stages of fetal development or for different purposes. Some regard only early abortion as acceptable, for example, before sentience; others think abortion is acceptable later in pregnancy. Some regard abortion

for frivolous reasons as unacceptable, whereas others regard it as legitimate for almost any reason as long as other criteria are fulfilled. However, most defenses of abortion attribute to an embryo or early fetus a moral status below that of persons and for that reason see nothing wrong with an early abortion chosen because the prospective parents would find it burdensome to raise a child in their circumstances. The presence of an impairment in an embryo or young fetus would count as such circumstances for many couples or pregnant women. Therefore, on the whole, according to the prochoice position, early abortion of an abnormal fetus is morally acceptable.

Furthermore, if a prochoice stance is assumed, there are positive reasons for aborting an impaired embryo or fetus. If the child were born, it might experience significant suffering, and raising a disabled child can be a great strain on parents and siblings. Indeed, a good prospective parent tries to produce a normal child rather than a disabled child and to give it advantages whenever possible. Bonnie Steinbock (2000) argues that given the prochoice assumption, selective abortion is a method of disability prevention that is comparable to a pregnant woman's taking folic acid to prevent neural tube defects. It also may be argued that the birth of disabled children is best avoided on the grounds that it drains resources from the healthcare system because those children may require multiple surgeries and other costly interventions.

THE DISABILITY RIGHTS CRITIQUE OF SELECTIVE ABORTION. Some authors who adopt a generally prochoice stance, however, argue specifically that abortion in response to fetal impairments is wrong. This has been called the disability rights critique of selective abortion. It consists of several distinct arguments, two of which are given below.

The expressive argument. The expressive argument is used both to show that the choice to abort an impaired fetus is wrong and at times that the government should not sponsor prenatal screening services. In this view aborting a fetus solely because it would develop into a disabled child expresses rejection of the disabled and perhaps exhibits the attitude that such children are undesirable or should not be born or the belief that the lives of all disabled people are miserable and lack value.

To express such an attitude is morally wrong for several reasons. For one thing the attitude is both erroneous and unfair. Many disabled people have good lives, and respect for the equal human worth of all individuals is one of the bases of morality. Also, aborting impaired fetuses, it is claimed, perpetuates bias against the disabled, just as selective abortion of female fetuses in certain societies perpetuates bias against women. Also, communicating a message of contempt to disabled people demoralizes them. Public funding of prenatal screening programs that people will use for abortion decisions does particular emotional harm because it shows public contempt and announces that society cares more about eliminating disabled people from the population than about helping those who are already born.

The main counterargument to the expressive position is that people who choose to abort impaired fetuses do not have the feelings or beliefs they are accused of expressing. Instead, their decision may be motivated by perfectly legitimate attitudes. Parents undergo special hardships in raising a disabled child that may include providing arduous or costly care well into the child's adult years. The desire to avoid those hardships is not tantamount to distaste or contempt for disabled people and does not stem from a belief that those people are all wretched. In light of the prochoice assumption, in aborting an early-term fetus with an impairment prospective parents choose not to produce a child who probably will suffer more and have more limited opportunities than a normal child does. The attempt to avoid those outcomes is part of the legitimate effort to do well for their families.

It should be noted that regardless of the actual attitudes of the agent, an action can convey an unintended but hurtful symbolic message, particularly if it is done in a context of widespread discrimination. However, this must be balanced against the central interests of adults in exercising reproductive freedom and making choices that determine the nature of their family life.

The cultural differences/social construction arguments. The arguments in this category focus on society's contribution to the phenomenon of disability. According to the minority group model, mainstream society causes much of the disadvantage inherent in disability by excluding disabled people from its central activities. Disability is socially constructed in this view. The way to eliminate the disadvantages of the disabled, then, is not to eliminate impaired people from the population through prenatal screening and abortion but to restructure society so that the impaired are included in it.

In addition, it is claimed that certain groups of disabled people form a distinct culture that should be respected. Defect-based abortion threatens to destroy that culture. This sometimes is claimed with respect to the Deaf (deaf people who identify with Deaf Culture, with a language such as American Sign as its central component). If too few congenitally deaf children are born, they will not be able to perpetuate their community.

Counterarguments to these claims turn on the shared assumption that appropriately early abortion is generally

legitimate because the fetus is not yet a person with rights. Selective abortion does not kill off members of a society or participants in a culture; it simply makes it the case that there will be fewer people eligible to join the culture in the next generation. That harm to the culture must be weighed against the disadvantages impaired children would suffer if they were born. Even if society were made more inclusive, significant disadvantages would remain.

Disability and Genetic Intervention

Developments in human genetics offer the prospect of correcting or preventing impairments by means of genetic intervention. Of course, this would eliminate only impairments that are genetically based; it is irrelevant to impairments with other causes.

One use of genetics—testing for genetic abnormalities followed by the abortion of affected fetuses—was addressed above. There are also other uses. One may screen prospective parents for deleterious genes, and the carriers may choose not to reproduce or to have children by using donor gametes or transplanted embryos. In the future one may be able to modify the somatic genome of an existing person to eliminate impairment or modify a person's germ-cell DNA (the genome of a person's eggs or sperm) to prevent disabling impairments in future generations.

Because no life is terminated in these procedures (not even that of an embryo), there is no ethical objection to them from the perspective of the right to life even among those opposed to abortion in general. The ethical concerns that arise for selective abortion against a prochoice background, however, also apply to genetic techniques that prevent the conception of impaired fetuses, although with less force. For example, choosing not to have children or to use someone else's gametes to avoid producing a disabled child might express an attitude that devalues the disabled, although merely using contraception would do that less forcefully than abortion does. Programs of gamete donation and embryo transfer and techniques for altering genes *in utero* also would reduce the size of the disabled population and the number of participants in subcultures composed of people with particular disabilities, just as abortion does.

However, techniques that "switch off" or replace deleterious genes in living people or in gametes or fetuses that will be allowed to develop have a special defense against such criticisms. First, it is hard to see what could be wrong with treating a gamete, fetus, or already-born individual to correct or prevent a disabling impairment. This would be like treating a child with antibiotics to keep an infection from causing blindness, which is surely legitimate; it is a form of healthcare. Second, individuals who were denied available interventions and went on to develop disabling impairments would have moral grounds for complaint. The claims of disabled people not to be incrementally marginalized by decreases in their numbers and not to be given a discouraging message must be weighed against the claims of other individuals to receive an intervention that spares them from grave disadvantages. To deny them this would be to make them bear a disproportionately steep cost to protect the sensibilities of others.

On the basis of either a liberal or a strictly egalitarian theory of distributive justice, Norman Daniels and others argue that citizens of an affluent industrialized society that spends heavily on healthcare have a right to a broad package of efficacious healthcare services (Daniels; Buchanan et al.). If genetic intervention in living individuals becomes a reliable form of healthcare (once it is beyond the experimental stage), it will become the type of treatment to which such citizens have a right, according to these theories (Buchanan et al.), and failure to provide it will be not only a failure of compassion but an injustice.

There are significant risks in altering the somatic-cell genes of a single individual because the biological processes involved are so complex and the environment may interact with the changed genome in unexpected ways. However, for the most part it is only the individual who is at risk. There is further risk in changing a person's germ-cell DNA so that the change is transmitted to all that person's descendants. The new genome may give rise to new impairments when it is combined with the genes of others during reproduction or in response to shifting environmental influences. Because the technology for those procedures does not exist yet, one can say only that the ethical legitimacy of germ-line intervention to prevent disability will depend on the range of risks involved in each particular procedure. Great caution here is morally obligatory.

EQUAL HUMAN RIGHTS. Western philosophers argue that all human beings, in spite of their many obvious differences in strength, intelligence, and so forth, have equal fundamental human rights. Equal human rights always are thought to include noninterference rights such as the right to autonomy or self-determination and the right to freedom. They often are thought to include rights to goods or services as well, such as the right to a minimum amount to eat or a basic education. Philosophers offer different grounds for these moral rights.

For Immanuel Kant (1996 [1797]) human beings have such rights because they possess reason, including the capacity for rational choice in regard to action. Many recent authors follow Kant in proposing as the basis for the

possession of equal rights criteria that depend on the psychological properties of the rights holder: the being's conceptual capacities, its control of its behavior, its emotions, or its capacities for reciprocal social interaction.

Social contract theories such as that of John Rawls (1971) offer a different basis for equal rights for all human beings. Jeffrie Murphy, following Rawls, says that "an individual should be understood as having a right to x if and only if a law guaranteeing x to the individual would be chosen by rational agents in the original position" (p. 8). The original position is a hypothetical situation in which a group of rational agents comes together to agree unanimously to principles and practices to govern their community. Each participant is self-interested, may care deeply about some (but not all) of the others, and knows in general what can happen in human lives but is "behind the veil of ignorance"—does not know his or her future or what his or her role in society will be. Those to whom the items in question are guaranteed need not be rational.

RIGHTS OF THE MENTALLY DISABLED. According to theories that base rights on psychological features of the prospective right holder, mentally competent people with physical disabilities have the same fundamental human rights as other competent adults because they fulfill all the criteria that have been propounded as the bases of human rights. Inability to walk or see does not deprive people of rationality, the capacity for informed choice, or the ability to interact reciprocally with others. According to contractarians, those people also have rights equal to those of the nondisabled because people in the original position know that they themselves might become physically disabled and thus would agree to protect the disabled in their possession of many goods.

In the psychologically based theories, however, a problem arises for people with severe cognitive or emotional disabilities. As Lois Weinberg (1981) points out, these people will not develop the capacities frequently cited as the grounds for equal human rights, such as the capacity for rational choice (in the severely retarded) and the capacity to interact reciprocally with others (in the sociopath). According to these philosophical theories, such individuals do not have any fundamental human rights; but that is implausible. At the very least those with mental or psychological disabilities have the basic human right not to be physically abused, and some argue that they have human rights to minimal care and an appropriate education. Giving them those things is not merely an act of compassion but also one of justice, it is argued, and hence a matter of rights.

The contractarian approach fares better. Murphy (1984) argues that rational agents behind the veil of ignorance would agree to guarantee a certain level of security and training for the mentally disabled because they know that they might become mentally disabled or might have a much-loved mentally disabled child. They would not guarantee autonomy protections to the mentally disabled but would guarantee them rights to basic food, shelter, and freedom from abuse.

AUTONOMY/NONINTERFERENCE RIGHTS AND RIGHTS TO AID. Noninterference or autonomy rights are the rights of rational persons who are capable of deciding their destinies to be left alone to do that: rights not to have others deprive them of life, liberty, or legitimately owned property (Locke, 1975 [1699]). Even for contractarians the full range of these rights belongs only to rational decision-making creatures because of their capacity to guide their behavior through their choices.

Mentally normal people with other types of disabilities are rational choosers, and so there are no grounds to deny that they have noninterference/autonomy rights. It is unjust to coerce them in the making of important life decisions, for example, to subject them to forcible sterilization. Mentally disabled people, depending on the severity of their impairments, may not live up to the standard of rational decision making needed to qualify for noninterference/autonomy rights. Some ethicists think that therefore people whose mental disabilities are significant do not have the moral right to make their own decisions about medical treatment, life-skills training, and finances. Those decisions are rightly made for them and should be made in ways that serve their interests. Others defend some autonomy rights for the mentally disabled.

Apart from noninterference rights, various authors claim that the disabled have the right to have a great assortment of goods and services provided to them by the rest of society. This may include life aids (ventilators and wheelchairs), attendant care, special education or training, the rebuilding of public structures, and income support (for food and shelter and also for healthcare in countries where healthcare is not subsidized for all). It is controversial which, if any, of these things are owed to disabled people by right and on what conceptual basis.

RIGHTS TO THE MEANS OF INCLUSION. For Anita Silvers (1994) all persons, or perhaps all who are mentally competent, have equal rights to participate fully in society on the basis of their individual dignity and self-respect. If any are excluded, justice requires that the barriers to their participation be dismantled or bridged. Thus, equality rights are the grounds on which the disabled have a right to be provided with the means of inclusion. Barriers to full participation are

conceived broadly: The lack of a teacher for the visually impaired might qualify as a barrier to a visually disabled child's full participation in her or his school. Thus, the removal of barriers consists not only in the alteration of physical structures but also in the creation of new structures or devices and the provision of trained personnel. The disabled have a right to these things solely because of their right to equal participation, which in this view is a right that everyone has. This equality right to devices and services that remove barriers does not include the right to income support, however, because people do not all equally have that right solely on the basis of their equal dignity and self-respect. Silvers (1995) argues that once disabled people are granted equal access, they will earn their own living. If a few severely disabled people have a right to subsistence support, that has a different and nonuniversal basis.

However, a contractarian view treats the right to the removal of barriers and the right to income support as being on a par. In a contractarian view both are based on the protections rational agents would agree to for their society when choosing behind the veil of ignorance.

Thus, Gregory Kavka (1992) argues on the basis of both Hobbesian and Rawlsian social-contract theory that in advanced societies people with significant disabilities have a right against society that it provide, where feasible, the accommodation, equipment, and training needed to permit the disabled to engage in the productive processes of their society and thus earn an income. The Rawlsian version of the argument says that people in the original position would agree to improve the lot of society's least-advantaged members and that the disabled are among the least advantaged because of the disadvantage inherent in their disabilities and the barriers and prejudices they face in society. The most effective way to better their lot is to give them access to self-respect, which in modern societies depends greatly on work and career identification. Income support will not provide the same basis of self-respect, and so it is not the best means to achieve this end. Thus, although Kavka argues for the subsidized removal of barriers to employment, if the provision of food and shelter were the most effective way to better the condition of the least well off, that is what he would defend. Murphy's argument, similarly appealing to the original position, defends the provision of food and shelter to the mentally disabled.

Vigorous counterarguments are made against these arguments that society should provide the disabled with the means of inclusion. Philosophers who reject Rawls's theory of distributive justice attack the relevant premises. A different sort of counterargument claims that it is too expensive to provide all the goods and services needed by the disabled. Although giving disabled people access to full social participation would enable many of them to earn a living and not depend on welfare payments, it is an economically inefficient solution, they say, because it would be cheaper to provide income support for all disabled people. Society could use the savings for other important purposes. This need not be a selfish argument; the savings could be used to provide free healthcare to the poor or to build better schools.

Various replies are offered to the efficiency objection. The basic structure of the argument is utilitarian, and it may be criticized on those grounds. The cheaper policy may increase the well-being of some elements in society, such as taxpayers and the nondisabled poor, but may yield a far lower level of well-being for the disabled than would inclusion, and no evidence is provided that the net well-being of all the persons affected will be higher with the less expensive policy. Alternatively, the argument may be rejected on grounds of justice: It may be less expensive to provide nothing but income support, but it is unjust to deny disabled people the bases of self-respect that come from inclusion in society.

Conclusion

This entry has investigated the concepts of disability, impairment, and handicap; defended partial definitions of those concepts; and related them to the concepts of disease and health. It has explained the two prevailing models for understanding disability: the medical model and the minority group model. Those conceptual analyses provided tools for surveying two groups of ethical issues pertaining to disability: issues regarding the value of the lives of the disabled and issues regarding the moral rights of disabled people. In the first category the entry examined permitting the disabled to choose death, abortion of impaired fetuses, and genetic intervention to prevent disabilities. In the second category the entry considered issues of whether the disabled have a right to various kinds of liberties and government assistance, and if so, on what grounds.

II. LEGAL ISSUES

Persons with disabilities daily face challenges beyond their individual disabilities. Social prejudice and physical barriers often pose far greater hindrances. Prejudice takes the form of the myths, stereotypes, and irrational fears that many people in society associate with impaired functioning. Barriers are those environmental factors, both physical and social, that limit the meaningful involvement of persons with disabilities in normal life activities (Herr, Gostin, and Koh). While a corpus of law has been developed in the United States to protect persons with disabilities, the passage of the Americans with Disabilities Act (ADA) of 1990 (42 U.S.C. 112101–12213 [Supp. II 1990]) marks the most important federal antidiscrimination legislation since the Civil Rights Act of 1964.

The Social Situation of Persons with Disabilities

The ADA was enacted in response to profound inequities and injustice for persons with disabilities (National Council on Disability). Americans with disabilities typically are poorer, less educated, less likely to be employed, and less likely to participate in social events than other groups in society. Social attitudes toward persons with disabilities add to their burdens. Persons with disabilities may be ignored, treated with pity or fear, adulated as *inspirations* for their efforts to overcome their disabilities, or expected to be as *normal* as possible. Moreover, Americans with disabilities have historically lacked a subculture from which to derive a collective strength, primarily due to the disparity of their disabilities and backgrounds. Disability interest groups, offshoots of civil rights groups, have filled this void in the last several decades (West).

Such prejudice and barriers raise a number of legal issues, most notably discrimination. In employment, in education, and in mobility, society often fails in its efforts to effectively accommodate persons with disabilities.

Legal Responses to Disability

Legal responses to disability range from application of constitutional theory to statutory initiatives. It would be comforting to believe that the U.S. Constitution provides meaningful protection to persons with disabilities. Sadly, the Constitution has little to offer persons with disabilities except in egregious cases. The Bill of Rights is applicable principally to government (*DeShaney v. Winnebago County Department of Social Services,* 1989). Since most forms of discrimination take place in the private sector, the Constitution is of limited applicability.

Even where state action can be demonstrated, the Supreme Court has not enunciated a coherent and compelling constitutional doctrine to protect persons with disabilities against discrimination. The Court, for example, has never found disability to be a *suspect classification,* and most government activities do not deprive persons with disabilities of a "fundamental freedom such as liberty" (*City of Cleburne, Texas v. Cleburne Living Center, Inc.,* 1985). Accordingly, the Court might be expected to uphold a state discriminatory action, provided the government could show a reasonable basis for its policy.

The Supreme Court, in one of its few constitutional decisions concerning discrimination against persons with disabilities, did suggest that it would not tolerate clear instances of prejudice or animus in government policies. In *City of Cleburne, Texas v. Cleburne Living Center*, the Court struck down a city zoning ordinance that excluded group homes for persons with mental retardation. The Court, in a particularly thorough search of the record, found no rational basis to believe that mentally retarded people would pose a special threat to the city's legitimate interest (Gostin, 1987).

A convincing constitutional argument could be made that persons with disabilities should have a high level of constitutional protection as is the case with racial minorities and women. Persons with disabilities have a similar history of exclusion and alienation by the wider society. They are often subject to discrimination on the basis of their status without regard to their abilities.

Much of the legal protection afforded to persons with disabilities is under federal and state law. Statutory initiatives in disability law fall into three general categories: (1) programs and services; (2) income maintenance; and (3) civil rights. Such statutes incrementally have sought the legislative goals of full participation and independence for persons with disabilities. While state laws vary in scope and effect, at the

federal level three main acts shaped the corpus of disability law prior to enactment of the ADA.

The federal Rehabilitation Act (29 U.S.C. 791–794 [1988 and Supp. I 1989]), enacted in 1973, covers federally funded entities (and continues to cover all federal employees). Section 504 of this act (broadened by amendments in 1987) prohibits discrimination against otherwise qualified disabled persons in any federally funded program, executive agency, or the Postal Service. Sections 501 and 503 require affirmative action hiring plans in the federal government and certain large federal contractors.

The Individuals with Disabilities Education Act (IDEA) (42 U.S.C. 6000–-6081 [1975]; 20 U.S.C. 1400 *et seq.* [1991]), enacted in 1975 and amended in 1990, mandates a free and appropriate education for all children with disabilities, encouraging integration (*mainstreaming*) whenever possible.

The Fair Housing Amendments Act of 1988 (42 U.S.C. 3601–3619 [1988]) ensures that persons with disabilities are a protected class in housing discrimination cases, and mandates access requirements for new housing and adaptation requirements for existing housing to ensure that the housing needs of disabled persons are met. This act continues to cover housing discrimination in place of specific provisions in the ADA.

The Americans with Disabilities Act of 1990

While these initiatives were a start, they failed to address cohesively the needs and rights of persons with disabilities. The ADA is a strong response to the needs and rights of persons with disabilities, needs and rights articulated by the growing voice of disability interest groups in America. It offers a potentially important vehicle for safeguarding the rights of persons with disabilities, but the judiciary has been whittling away its protections over recent years (Gostin, 2002).

More specifically, as an outgrowth of civil rights law, the ADA serves as a legal tool because of its broad scope and unique ability to adopt the visions of both equality and special treatment. The ADA recognizes that a person's disabilities often have little to do with his or her inabilities. Often it is society's reactions to the person with disabilities or society's structural barriers that disable the person. The mandate of civil rights law is to destroy those negative reactions and dismantle those barriers in order to restore equal opportunity and full participation in daily life activities with dignity, not charity. The ADA strives to achieve this objective.

The act prohibits discrimination against qualified persons with disabilities in employment, public services, public accommodations, and telecommunications. The principal change in federal law is that the ADA applies to all covered entities, whether or not they receive federal funding. The impact of the ADA on public health departments and communicable-disease law (Gostin, 1991b) and on the healthcare system (Gostin and Beyer) is significant. It will also have a significant impact on other important areas of bioethics, including the duty to treat, the right to health-benefit coverage, and medical testing and examinations by employers (Parmet).

Although the specific titles of the ADA have slightly different provisions, a finding of discrimination is based on adverse treatment of a person (1) with a *disability* who is (2) *qualified* or who (3) would be qualified if *reasonable accommodations* or modifications were made available.

Disability is defined broadly to mean "a physical or mental impairment that substantially limits one or more of the major life activities," a record of such impairment, or being regarded as having such impairment (section 3). The definition of disability theoretically covers a wide range of medical conditions. The courts had construed the Rehabilitation Act to include a wide-range of disabilities that are both genetic (e.g., Down syndrome [*Bowen v. American Hospital Association*], muscular dystrophy [S. Rep. no. 116]); or cystic fibrosis [*Gerben v. Holsclaw*] and multifactorial (e.g., heart disease, schizophrenia, or arthritis [S. Rep. no. 116]). Disability was also construed to include diseases that are communicable (e.g., tuberculosis [*School Board of Nassau County, Florida v. Arline*], hepatitis [*New York State Association of Retarded Children v. Carey*], or syphilis); as well as those that are not (e.g., cerebral palsy [*Alexander v. Choate*], or diabetes [S. Rep. no. 116]). However, a person who is currently using illegal drugs is not considered disabled, but is covered once he or she has been successfully rehabilitated and is no longer using drugs (section 510). Similarly, a range of socially disapproved behavior disorders are excluded from protection, such as most gender-identity disorders, pedophilia, exhibitionism, voyeurism, compulsive gambling, kleptomania, pyromania, and psychoactive drug-use disorders (section 511).

Moreover, a person is disabled if he or she has a *record* of, or is *regarded* as, being disabled, even if there is no actual disability (*Southeastern Community College v. Davis*). A record indicates that a person has, for example, a history of disability, thus protecting persons who have recovered from a disability or disease, such as cancer survivors.

The term regarded includes individuals who do not have disabilities but are treated as if they did. This concept protects people who are discriminated against in the false belief that they are disabled. It would be inequitable for a

defendant who intended to discriminate on the basis of disability to successfully raise the defense that the person claiming discrimination was not, in fact, disabled. This provision is particularly important for individuals who are perceived to have stigmatizing or disfiguring conditions such as HIV, leprosy, or severe burns (S. Rep. no. 116).

Although the ADA theoretically covers a wide range of persons with disabilities, the Supreme Court has been significantly narrowing its scope. The first Supreme Court opinion on the ADA was quite hopeful. In its decision in *Bragdon v. Abbott* (1998), the Court held that a person with purely asymptomatic HIV infection was *disabled* within the meaning of the Act.

The *Bragdon* decision makes it more likely that, in the future, the courts will find persons with asymptomatic HIV infection protected under the ADA. The question remains, however, whether other health conditions will satisfy the ADA's definition of disability. As explained above, courts deciding cases under the Rehabilitation Act did not view the definition of disability as a strict obstacle for plaintiffs. The issues did not turn on whether an individual *had* a disability, but rather on whether the disability was the *cause* of the adverse action, or on whether the action was *justified* because a person's disability rendered her unqualified for a job or ineligible for a service. The judicial approach in disability cases was similar to the approach when individuals claim discrimination based on their race or gender. When making decisions regarding race or gender discrimination, courts do not engage in searching inquiries into whether the individual is *really a woman,* or *really an African-American.* Rather, these cases are often lost because individuals are unable to prove they have been discriminated against *because* of their race or gender (Feldblum, 1996).

Nothing during passage of the ADA suggested that courts would adopt a narrow definition of disability. But the legal landscape has changed dramatically (D'Agostino). Courts deciding ADA cases have arrived at a restricted definition of disability through two principal methods. First, many courts analyze whether a plaintiff is substantially limited in the major life activity of working. Courts often conclude that the impairment is not sufficiently limiting because there is a range of jobs that the individual can still perform. This narrow view makes little sense because the ADA was designed to prohibit discrimination against people with disabilities who *can* work, but who are nonetheless discriminated against.

Even if an individual's claim that her impairment limits a major life activity *other* than working is accepted, there is a second method by which courts have restricted coverage under the ADA. Courts scrutinize whether the individual's impairment *substantially* limits a *major* life activity. In *Toyota Motor Manufacturing Kentucky v. Williams* (2002), the Supreme Court adopted a narrow construction of "major life activity." The Court found that a medical diagnosis of carpal tunnel syndrome was not sufficient to qualify a person as disabled; nor is evidence that the person cannot perform "isolated, unimportant, or particularly difficult manual tasks."

Courts have also restricted coverage under the ADA by asking whether the impairment of a major life activity is "substantial." The Supreme Court requires that the impairment be "considerable." For example, in *Albertsons v. Kirkinburg* (1999) the Supreme Court held that a person with monocular vision is not disabled because the condition is not serious enough to substantially restrict his life activities.

The Supreme Court not only requires a substantial limitation in a major life activity, but it also requires that corrective and mitigating measures be considered in determining whether an individual is disabled. In *Sutton v. United Airlines, Inc.* (1999) the Court held that severely myopic job applicants for airline pilot positions are not disabled because eyeglasses or contact lenses mitigate their impairment. Similarly, in *Murphy v. United Parcel Service, Inc.* (1999) the Court held that a driver with high blood pressure is not disabled because his condition could be mitigated with medication. The Court did not claim that individuals with myopia or high blood pressure are not qualified to be pilots or drivers. Rather, the Court held that since the plaintiffs were not disabled, their qualifications for the job were not even relevant considerations under the ADA. Thus, in an ironic twist, although the ADA's goal is to provide anti-discrimination protection to individuals who (perhaps because they are taking medication) are qualified for jobs and eligible for services, such individuals are denied protection precisely because their medical conditions are under control.

The third prong of the definition of disability—which protects individuals who are *regarded as* having a substantially limiting impairment—has been applied quite restrictively by courts. Indeed, the Supreme Court in *Sutton* suggested that the employer or service provider must actually believe the person is substantially limited in a major life activity before receiving protection against discrimination. Thus, a person fired due to irrational fear or prejudice will not receive protection under the ADA provided the employer does not think the individual has a substantial physical or mental limitation.

A person is *qualified* if he or she is capable of meeting the essential performance or eligibility criteria for the particular position, service, or benefit. Thus, a person with a

disability is not protected unless he or she is otherwise qualified to hold the job or to receive the service or benefit.

Qualification standards can include a requirement that the person with a disability does "not pose a direct threat to the health or safety of others" (sections 103[b], 302 [b][3]). The *direct threat* standard means that persons can be excluded from jobs, public accommodations, or public services if necessary to prevent a *significant risk* to others (*School Board of Nassau County, Florida v. Arline,* 1987). The significant risk standard originally applied only to persons with infectious disease. However, it was extended by the House Judiciary Committee to all persons with disabilities (H.R. Conference Report no. 101–596).

In order to determine, for example, that a person with mental illness poses a significant risk to others, evidence of specific dangerous behavior must be presented. In the context of infectious diseases such as tuberculosis, the Supreme Court laid down four criteria to determine significant risk:

1. the mode of transmission;
2. the duration of infectiousness;
3. the probability of the risk;
4. the severity of the harm (*School Board of Nassau County, Florida v. Arline*).

The Supreme Court in *Chevron U.S.A. Inc. v. Echazabal* (2002), held that a person with a disability is not "qualified" if she poses a direct threat to herself. This is a form of paternalism that is not in the language of the ADA, but had been supported by the Equal Employment Opportunities Commission. Allowing an employer to balance the benefits and risks for an individual, rather than allotting that power to the individual, opens the door to unfair treatment whenever an employer has reason to believe that workplace conditions or activities may be harmful.

The ADA requires reasonable accommodations or modifications for otherwise qualified individuals (sections 102[b][5], 302[b][2][A][ii]). This requires adaptation of facilities to make them accessible, modification of equipment to make it usable, and job restructuring to provide more flexible schedules for persons who need medical treatment (section 101[9]). To accommodate otherwise qualified persons with infectious conditions, an entity might have to reduce or eliminate the risk of transmission. Employers, for example, might be required to provide infection control and training to reduce nosocomial (disease or condition acquired in the hospital) or blood-borne infections. An employer, however, is not forced to endure an undue hardship that would alter the fundamental nature of the business or would be disproportionately costly. The Eighth Circuit Court of Appeals, for example, held that a school for persons with mental retardation was not obliged to vaccinate employees in order reasonably to accommodate a student who was an active carrier of hepatitis B virus (*Kohl v. Woodhaven Learning Center,* 1989).

Conceptual Foundations of Disability Law

Conceptually, disability law follows two distinct traditions—equal treatment (based on civil rights law) and special treatment (based on social welfare law). The equal treatment perspective means that persons with disabilities should be treated as if their disabilities do not matter. Accordingly, the law mandates businesses, public accommodations, public services, transportation, and communications authorities not to discriminate. This concept of equal treatment is powerfully articulated in the law. At the same time disability law also requires special treatment. The law requires the aforementioned entities to adopt a concept of affirmative action that focuses on the person's disabilities, as well as on societal barriers to equal treatment (Feldblum, 1993). The ADA requires reasonable accommodations or modifications designed to enable or empower the person with disabilities to take his or her rightful place in society. The law, therefore, insists on special treatment when that is necessary to allow a person to perform a job, enter a public building, or receive public service. As the Supreme Court observed over two decades ago, "Sometimes the greatest discrimination can lie in treating things that are different as though they were exactly alike" (*Jenness, et al. v. Fortson*, p. 442).

Disability law, however, does not take either the equal treatment or the special treatment principle to its logical extension. With respect to equal treatment, the Supreme Court has dismantled the statute to such an extent that the ADA does not provide an effective remedy for many individuals with a disability. With respect to special treatment, the ADA does not allocate tax dollars to enable the person to participate equally in society, beyond use of government funds for *reasonable accommodations* in such areas as public transportation. Nor does it require covered entities to spend unlimited amounts to provide equal access and opportunities for persons with disabilities.

Conclusion: A New Vision

The ADA promised to revolutionize the way we view the law's protection and empowerment of persons with disabilities. No longer were we supposed to see persons with disabilities through the lens of charity, sympathy, or benign discretion. Now we were supposed to see persons with disabilities through the lens of civil rights law. Under civil rights law persons with disabilities should not have to not ask

for societal favors. They should be able to demand an equal place in a society that has long been structured—physically and sociologically—by and for the able-bodied.

This promise and vision, however, have been sharply curtailed by the Supreme Court. It is no longer realistic to believe that persons with disabilities will receive the same kind of civil rights protection as, say, African Americans and women. For that to happen, Congress will have to amend the ADA to express the vision of true inclusion and protection against discrimination for all Americans with a disability.

DIVIDED LOYALTIES IN MENTAL HEALTHCARE

• • •

Physicians have traditionally understood their primarily loyalty as being to the patients they serve. This tradition goes back to at least to the time healers left behind their shamanistic roots, some twenty-five centuries ago. So important is this sacred commitment that it is enshrined in Hippocratic Oath, with which physicians and the public often identify the medical profession. The relationship between physician and patient is understood as a fiduciary relationship, meaning it is based on trust. Other healthcare professions—and indeed other professions—have modeled their self-understanding on this sort of promise to benefit those served.

Situations do arise in which physicians and other professionals experience divided loyalties—divided between allegiance to the patient and allegiance to some other interest. This has traditionally been spoken of as "the dual-agent (or double-agent) problem." A physician or therapist is a dual agent, for example, if he or she owes an allegiance to an employer as well as the patient. In situations of divided loyalties the integrity of a physician's judgment or action may be compromised. Classic examples of this occur when a physician (especially a psychiatrist) works for the military or for a state or federal institution, where confidences cannot be guaranteed. Increasingly, physicians and other providers find themselves asked to serve the broader interests of society; that is, the interests of populations rather than individuals. This is especially true for those working for large organizations, such as health maintenance organizations (HMOs), managed-care organizations, or nationalized health services. In these situations, the physician must recognize an obligation to society, making it more difficult to buffer the unique concern for each individual patient.

From the moral point of view, most dual-agent situations are best seen as cases of conflicting loyalties or clashing duties. The doctor must choose one duty over another (Macklin, 1982). Perhaps most problematic are situations in which the patient assumes (because of the weight of the professions' patient-centered ethic) that the doctor is working for the patients' best interest. A psychiatrist in a pre-arraignment examination might be able to elicit more information then a police interrogation simply by presenting a trusting demeanor. But if the message is not "I am here to help you," then the purpose of the examination should be directly stated. An administrative evaluation in a student health service should clearly state, "You are being evaluated at the request of the dean, who will receive a report of my findings." A health professional should not give the impression that everything a person says is confidential if that is not the case.

While cases in psychiatry and mental health have received the most attention, this attention has increased awareness of the problem of divided loyalties in virtually all areas of healthcare. A quick literature search for "divided loyalties" on the Internet returns results from the following specialties: nursing (Winslow; Dinc and Ulusoy; Chao; Tabik, 1996), ophthalmology (Addison), sports medicine (Sim), occupational medicine (Walsh), physical therapy (Lurie; Bruckner), military medicine (Howe; Camp; Pearn; Hines), transplant medicine (Bennett; Tabik, 1994), clinical researchers (Miller), aviation medicine (McCrary), infectious diseases, obstetrics (Plambeck), student health and those doing administrative evaluations and disability evaluations (Lomas and Berman), and house physicians and residents (Morris; La Puma), as well as psychiatrists, forensic psychiatrists and physicians, and child psychiatrists and pediatricians. Issues of privacy, especially the privacy of medical records, cut across all disciplines in the information age, as do issues of cost containment, reimbursement, and healthcare funding. While all these disciplines face situations of divided loyalties, perhaps nowhere is the conflict more dramatic than it is in nursing, where loyalties have undergone a transformation from loyalty to the individual physician for whom and with whom a nurse works, to the healthcare institution that employs the nurse, to patients more generally, and finally to the principles of medical ethics that inform the values of all professions.

Background and History

Divided-loyalty dilemmas have been most blatant in efforts at social control. Since mental healthcare often deals with deviance in behavior, its conceptions run parallel to society's conceptions of social behavior, personal worth, and morality. Thus, in certain situations, there may be great pressure for mental-health professionals to label patients on the basis of social, ethical, or legal norms, and not on clearly established clinical or laboratory evidence of psychopathology.

Doctors are influenced in their activity and judgment by sociocultural context, by the ideology implicit in their professional training, and by the economic and organizational constraints of the setting in which they practice. Their practice involves multiple and, at times, competing professional roles with different social and ethical requirements,

but often with no clear definition of boundaries (Mechanic). The practitioner must always ask the crucial question: Whom do I represent and whom do I serve? History is replete with cases showing that the patient is not always the primary one represented.

Extreme cases put the more mundane cases into perspective. Psychiatrists in the former Soviet Union (as well as in other Eastern European countries and in the People's Republic of China) have come under scrutiny for hospitalizing political dissidents and labeling them psychiatrically impaired (Bloch and Reddaway). Physicians in the military governments of Latin American have (perhaps under coercion themselves) cooperated with the torture of political prisoners, a situation that also occurred in South Africa during the period of apartheid. Nazi physicians conducted experiments in concentration camps that would have previously been unimaginable, giving rise to the safeguards of informed consent now required (Drob; Lifton, 1976, 1986). Nazi doctors acted completely contrary to their own moral and professional commitments, serving the ideology of the state and not their patients. These historic lessons make the need to examine divided loyalties all the more urgent.

The use of psychiatry as an instrument of social control had a long history in the former Soviet Union. Soviet authorities chose to have dissenters from official governmental policy labeled with mental illness designations such as schizophrenia, "sluggish schizophrenia," or paranoid development of the personality. The labeling of persons as mentally ill is an effective way to discredit their beliefs and actions, and to maintain control over those persons of whom a government disapproves.

Although the situation in the former Soviet Union was extreme, there have been examples in other societies in which psychiatry has been used (or abused) to stifle nonconformity, serving the interest of someone other than the patient. Notorious examples include the poet Ezra Pound and the actress Frances Farmer, both of whom where involuntarily hospitalized for political extremism (Arnold).

In cases of controversial religious movements, distressed families have sought help from mental health professionals to "rescue" and "deprogram" their children from such groups or cults. The mental health professional may be caught in a divided-loyalty dilemma between family values and religious liberties, possibly medicalizing religious conversions and then treating them as illnesses (Post). On the other hand, vulnerable young people may be particularly susceptible to coercive group pressure, and mental health professionals have traditionally acted in the "best interest of the child" for autonomous growth and development.

The question of divided loyalty can readily arise in matters of confidentiality. Mental health professionals cherish confidentiality as a prerequisite for psychotherapeutic work, but what is an appropriate limit to confidentiality when a patient reveals plans that might endanger others? This question came dramatically to public attention in 1974, when Tatiana Tarasoff, a college student, was murdered. Lawsuits were subsequently brought by the student's parents against the university, the campus police, and the psychotherapist who had failed to warn Tarasoff of threats made against her life by a fellow student (and patient of the therapist) who had fallen in love with her and whose love was unrequited. The therapist had alerted campus police to the danger his patient posed, but they arrested him, found him harmless, and released him.

The military is an organization whose needs and interests may compete with those of the patient. In the military, mental-health professionals are committed to serving society by supporting their commanders in carrying out military operations (Howe). The psychiatrist who returns a soldier to mental health may be returning him to a battlefield where he could be killed. Robert Jay Lifton highlights this ethical conflict by showing that the soldier's very sanity in seeking escape from the environment via a psychiatric judgment of instability renders him eligible for the continuing madness of killing and dying (a perfect example of Joseph Heller's "Catch-22"). Even in military situations, mental health professionals retain obligations to their profession. Further, their clinical effectiveness requires that they give high priority to the needs and interests of the military personnel they treat. In most cases, the mental health professional's ambiguous position in military medicine as a dual agent allows the person to believe that he or she is participating in both the care of patients and the public interest (Howe).

The prison system has also been the setting for a variety of divided-loyalty dilemmas. The professional may be called upon to evaluate an accused person's competency to stand trial. If treated, the person may become competent to stand trial, but left untreated the psychosis may prevent the person from participating in his or her own defense. In capital cases this can be a matter of life or death. How does a physician understand this obligation to the patient when providing treatment, particularly antipsychotic medication that may ultimately lead to conviction and death?

Conflicting obligations can easily arise in situations where doctors ask their own patients to participate in clinical research. While most doctors comply with their primary obligation to deliver the best possible care to their patients, the demands of adhering to a strict research design can create obligations that compete with those of giving good medical

care. The research-oriented physician must maintain special ethical vigilance to assure that the patients' interest comes first, a vigilance that is reinforced by external review of research consent procedures.

Ethical Analysis and Resolution

A first step in resolving divided loyalties is to think of loyalty as an attachment or allegiance to a person or cause, and to see it as expressing a coherent meaning that unifies one's personal and professional conduct (Dwyer). Loyalties develop with the assumption of roles and relationships both inside and outside of professional practice. The professional's identity is connected with the primary role of restoring the patient to health. In approaching a divided-loyalty dilemma, it is necessary to articulate and reflect on the meaning of one's commitments in order to determine how these commitments ought to be ordered or reconciled in a particular case.

A basic principle of medical practice is that health professionals should be loyal to their patients and be advocates for them. This commitment does not always avoid conflict. For example, even when health professionals devote themselves exclusively to the good of the patient and show no allegiance to other persons or causes, conflicts may still arise between what the professional sees as good treatment and what the patient wants and sees as good treatment.

The roots of the confidentiality concept are essentially ethical and not legal, and from the earliest days of medical practice, respect for the patient's confidences has been considered an important part of the obligation owed by the physician to the patient. Communications told in secret and in trust have been guarded and respected. In a situation such as the Tarasoff case, however, while acknowledging the desirability of maintaining patients' confidences, one sees a strong competing ethical obligation. When a patient intends harm to another person, or when information is required for the adjudication of a dispute in court, physicians are faced with the claim that societal interests should take precedence. While absolute confidentiality is no longer the expectation, arguments for protecting and extending confidentiality, even in the face of competing demands, remain strong. The arguments usually rest on both ethical and utilitarian grounds and center on the moral good reflected in protecting private utterances. The arguments relate to the belief that confidentiality promotes desirable goals, such as encouraging potential patients to seek medical care and allowing patients to unburden themselves and provide all the information essential for the doctor to help them. In a healthcare system such as that in the United States, the practitioner's relationship to the patient is fiduciary—that is, he or she acts for the benefit of the patient. Can modifications be made that do not compromise the fiduciary relationship? Can the doctor–patient relationship be extended to support affirmative duties not only to the patient but also for the benefit of third parties? Ralph Slovenko, an attorney-psychologist, answers this question in the affirmative, stating that a psychiatrist's loyalty to the patient and responsibility for treating the professional relationship with respect and honor do not negate responsibilities to third parties, to the rest of the profession, to science, or to society. Slovenko goes on to say, however, that how these other duties are accepted, how the patient is kept informed, and how the patient is cared for when other duties are carried out can either introduce or help to avoid a divided-loyalty dilemma.

Joan Rinas and Sheila Clyne-Jackson recommend a forthright stance in preventing dual-agent dilemmas. They argue that the mental health professional has obligations to all parties with whom he or she has a relationship. These duties include notifying all parties of their rights, the professional's specific obligations to each party, potential and realistic conflicts that may arise, and limitations in knowledge and service. If, on exchange of this information, the mental health professional concludes that he or she is not the appropriate one to provide the requested service, the patient or the third party should be referred to a professional appropriate and qualified to perform the desired function. Participants in a Hastings Center symposium on double agentry made a similar set of recommendations for addressing divided-loyalty dilemmas (Steinfels and Levine).

The answer to what appears to be a divided-loyalty dilemma in court cases may rest on a particular type of disclosure. Where the psychiatrist is functioning as a friend of the court, the primary loyalty is not to the patient but to society as embodied in the judicial system. In such settings, the doctor–patient relationship does not exist in the traditional sense. Both doctor and patient must understand this from the outset. Divided-loyalty dilemmas are prevented when the psychiatrist advises all parties involved that the relevant materials they provide will be used in the court proceedings and that he or she is functioning as a consultant to the court (Goldzband).

Financial Considerations

Divided loyalties are becoming more prevalent due to efforts at cost containment and the rationing of health services. Society is demanding that healthcare costs be controlled. In response, careful protocols are being developed as to what services can be given, and for how long they can be given.

These cost-containment methods may interfere with what patients realistically need to remedy their health problems, and can therefore compromise the ethical principle of doctor as patient advocate. Ruth Macklin emphasizes that whether doctors cut costs voluntarily in treating their patients or are required to adhere to policies instituted by others, their ability to advocate vigorously for their patients' medical needs is weakened. When rationing becomes a factor in physicians' treatment decisions, such as which patients will be admitted to the hospital and for how long, physicians are forced into a divided-loyalty conflict. Further, the care obligation embraced by medical ethics cannot be accomplished without permitting a physician to strive for "a robust patient–physician relationship, patient well-being, and avoidance of harm" (Wolf, p. 38).

Conclusion

Conflicting responsibilities, contradictory goals, hidden scenarios, and unsigned contracts existing in the changing world of both the patient and the professional serve as reminders that ideal resolutions may be unattainable in many divided-loyalty dilemmas. Professionals must be very sensitive to the possibility that they may become double agents in the routines of their everyday practice with its many ambiguities and subtleties.

Further, review and examination of dual-agent issues should be a continuing obligation of mental health professionals, for that is one way to prevent these issues from disrupting the doctor-patient relationship. These are issues that often come before professional ethics committees, which keep them alive through education, codes, and professional discipline.

In cases of divided loyalties, physicians and other health professionals should give the patient their primary loyalty, and other allegiances should be subordinated to that of the patient. Where this is not possible, any conflicting allegiance should be explicitly disclosed. The goal of maintaining trust is essential for the therapeutic relationship, and anything that erodes that goal diminishes not only the therapy or the treatment, but also the therapist and the profession he or she represents.

DNA IDENTIFICATION

• • •

In 1985, Alex J. Jeffries and his colleagues demonstrated that patterns of molecular markers in human DNA, or *DNA fingerprints,* could serve as uniquely identifying personal traits. This discovery was quickly applied by the criminal justice system, as way of definitively connecting suspects with blood, tissue, or semen from crime scenes. Shortly thereafter, governments at the state and national levels began authorizing the collection of DNA samples from individuals convicted of violent crimes who were considered at high risk for recidivism. By 1998, all fifty states in the United States had enacted such laws, and the U.S. Federal Bureau of Investigation (FBI) was able to launch a national electronic database of DNA profiles from convicted criminals for use in future cases (Hoyle). In the interim, the collection of DNA for personal identification purposes has already become mandatory within the military and has become a

mainstay of civilian efforts to clarify the identities of children and kidnap victims, to investigate family lineages, and even to authenticate religious relics. On the horizon, lies the question that civil libertarians anticipate with dread: Why not store personally identifying genetic information on everyone as a matter of course, for the advances in public safety and personal security that can be gained thereby?

Photographs and traditional fingerprints have, of course, also been taken, collected, and used for all these same purposes in the past. But unlike photography and manual fingerprinting, collecting individually identifying DNA patterns (iDNAfication) does involve taking bits of people's bodies from them: nucleated cells and their complements of DNA molecules. For those concerned about the ethical and legal status of body tissues and an individual's ability to control what happens to him or her through use of that tissue, this corporeal side of iDNAfication raises an interesting challenge. Clearly, questions of personal privacy are involved. But unlike most other disputes over body tissues, the issues here are not primarily matters of personal sovereignty.

For example, unlike involuntary sterilization or forced surgeries, the central concern with mandatory iDNAfication does not seem to be the violation of a person's bodily integrity. Compared with the other infringements of personal freedom that legitimately accompany legal arrest, providing a saliva or cheek swab sample seems negligibly invasive (Schultz). Moreover, unlike the creation of marketable human cell lines or the commercialization of organ procurement, it is not the exploitation or misappropriation of the person's body for others's gain that is centrally troubling either. Manual fingerprints and photographs also exploit suspects's bodies in order to incriminate them, without raising special privacy concerns. Moreover, consider the fact that it does not matter to an identical twin whether a DNA sample under scrutiny actually comes from him or his sibling: To the extent that the genetic information it contains describes both their bodies, the privacy of each is endangered.

In fact, the major moral concern about iDNAfication has little to do with whether the DNA analyzed is a piece of the person being identified, the property of the person being identified, or even is forcibly extracted from the person being identified. In most iDNAfication contexts, these physical, proprietary, and decisional privacy considerations are beside the point. Rather, the important feature of iDNAfication is what the DNA analyzed can *disclose about* the person being identified. It is, in other words, individuals's informational privacy that is at stake in the prospect of widespread iDNAfication, and it is in those terms that the policy challenge of iDNAfication should be framed. What should society be allowed to learn about its citizens in the course of attempting to identify them?

Taking up this challenge means taking seriously the precedents set by society's use of photography and manual fingerprinting, since their primary impact on personal privacy also lies in the identifying information they record rather than the nature of their acquisition. If the collection of mandatory *mug shots* and fingerprint impressions are taken as benchmarks of social acceptance for at least some identification purposes, any iDNAfication methods that conveyed no more personal information than those techniques should also be socially acceptable, for at least the same range of purposes. Thus, where fingerprints of arrestees, inmates, employees and recruits are now taken legitimately, performing iDNAfication should also be justified, if its informational privacy risks were equivalent. Similarly, if society accepts the personal disclosures involved in using photographs on drivers's licenses and identification cards, it should be willing, in theory, to expose an equivalent range of genetic information in any legitimate forms of iDNAfication. One approach to the general challenge of iDNAfication, then, would be to ask the following question: If the ways in which photographs and manual fingerprints are used for legitimate identification purposes are accepted, under what circumstances, if any, might forms of iDNAfication meet the standard those practices set for the disclosure of personal information?

Personal Privacy Considerations

A number of personal privacy risks of iDNAfication have been described and anticipated in the design of some iDNAfication programs. Thus, for example, many have pointed out that if the DNA sequences used as the components of an iDNAfication profile are taken from the regions of the human genome that code for proteins, important biological information about their sources could be revealed, including information about their paternity, current health status, and potential health risks (U.S. Congress Office of Technology Assessment (OTA), National Academy of Sciences). Any risk of disclosing sensitive personal information of these sorts would clearly increase the intrusiveness of iDNAfication beyond that of traditional fingerprinting and photography. In addition, it could expose the person being described to the possibility of discrimination on the basis of a disclosed genotype (Bereano; DeGorgey; Scheck; Sankar) Fortunately, this is a privacy risk that can be almost entirely eliminated by two simple precautions: One need only avoid analyzing biologically informative DNA, and destroy the DNA samples upon analysis.

The first precaution can be accomplished by restricting the sections of DNA that are amplified, analyzed and utilized in the iDNAfication profile to the non-coding regions of DNA between our functional genes. By definition, markers selected from these regions will not disclose any biologically significant information. Rather, like fingerprints, they could merely provide a unique pattern to match in seeking to identify an unknown person. Even photographs are useful mainly as patterns to match, rather than for what they can independently tell us about the person pictured in them. Serendipitously, individual variation is also vastly more pronounced in this so called junk DNA (since mutations can accumulate in these sections without having any adverse effect on genomic function), making it more attractive for iDNAfication purposes on scientific grounds as well.

Thus, the FBI, in establishing standardized forensic iDNAfication markers for use by state laboratories contributing DNA profiles to the latter's National DNA Index System (NDIS), has focused on a set of thirteen loci from non-coding regions that contain series of repeated nucleotide sequences whose length is highly variable between individuals (Hoyle). The exclusive use of these markers in any iDNAfication program would forestall most genetic privacy concerns linked to the biological information content of the DNA profile itself.

The second important step to insuring the genetic privacy of iDNAfication is to destroy the physical samples of DNA once DNA profiles have been generated from them. As long as the DNA samples themselves are retained, the risk remains that they could be retested for their biological informational content. Thus, in its report on forensic DNA analysis, the National Academy of Sciences in 1990 recommended that even samples taken from convicted offenders be destroyed promptly upon analysis, and the FBI has designed its national iDNAfication collection as a databank, not a DNA bank, including only the electronic profiles of non-coding DNA markers (Murch and Budowle).

This second precaution has not been adopted by forensic laboratories at the state level, or by the military at the federal level. Most of these laboratories plan to bank their actual DNA samples indefinitely, on the grounds that the samples may need to be retested as new markers or testing technologies become standard (McEwen). The Department of Defense is storing dried blood samples from its recruits, for genotyping only in the event that the recruits later turn up missing in combat. This effectively undercuts the privacy protections afforded by using non-coding markers in the iDNAfication profile itself, and immediately elevates the privacy risk of any iDNAfication program well beyond that of ordinary fingerprinting. Even if, *contra* the National Academy of Sciences, this increased risk were tolerable for convicted offenders, it should not be for military recruits, government employees, or arrestees, since the potential intrusion goes well beyond what is required for identification.

Social Policy Considerations

Despite the initial hopes of early enthusiasts like English scientist Francis Galton (1822–1911), large collections of ordinary fingerprints have never been useful for much else besides individual identification. (Rabinow) The informational potential of the human genome, however, does require the designers of iDNAfication systems to consider in advance the range of uses they should accommodate. Even when a DNA profile collection is committed exclusively to use for personal identification purposes, several policy choices present themselves: (1) Should the system be designed to support any type of research involving the stored information? (2) Should the system be designed to aid in the identification of the sources of new DNA samples without clear matches in the database?, and (3) Should the system be designed to support electronic *dragnet* screening of the population in search of particular individuals? In the context of the expanding uses of iDNAfication, these choices raise some important social policy issues that go well beyond issues of personal privacy.

RESEARCH USES. Among the legislatively authorized uses of the existing iDNAfication databanks is their use for various kinds of research. For example, many state statutes, following the FBI's legislative guidelines, provide for the use of convicted offender iDNAfication data in research by state forensic scientists designed to improve iDNAfication techniques and protocols. Although the state statutes vary widely in the security procedures they mandate for containing this research within the crime laboratories and protecting the identities of the sample sources, if they were to implement the protections recommended by the FBI (Murch and Budowle) using such samples would raise few direct privacy issues. However, it is worth noting that to the extent that this research requires access to physical DNA samples, it provides the main impetus for retaining samples in state crime labs after the database profiles have been generated. This opens the door for other research uses of the collection. For example, Alabama allows the use of anonymous DNA samples from its convicted offender collection "to provide data relative to the causation, detection and prevention of disease or disability" and "to assist in other humanitarian endeavors including but not limited to educational research or medical research or development." (Alabama Laws [1994] 1st Spec Sess Act 94–100).

Alabama's generosity towards researchers is presumably premised on the view that the *anonymity* of the samples provides adequate protection of the sources's privacy, and frees the state from having to worry about the usual elements of biomedical research, like informed consent. But on the contrary, from the perspective of research ethics, these samples are not anonymous, nor even *anonymized,* since the iDNAfication database is itself the key to identifying the source of any given sample. Since that existing linkage makes it technically possible to benefit and harm the sample donors with the results of such research, all the usual biomedical research protections should apply (Clayton et. al.). In addition to these personal privacy issues, moreover, open-ended research on iDNAfication samples also poses broader questions of research justice. Collections of DNA samples from criminals or soldiers, for example, are likely to be perceived as particularly rich research resources by those interested in studying genetic factors involved in antisocial or aggressive behavior. Unfortunately, our social experience with such research has not been good (Marsh and Katz). Repeatedly, such studies have succumbed to ascertainment biases that ultimately mischaracterize—and stigmatize—groups of people that are disproportionately represented in the systems under study for social reasons. Two forms of injustice tend to flow from these results. First, genetic claims about individual research subjects, like those concerning XYY syndrome in the 1970s, become generalized to an entire class, simultaneously pathologizing behavior and stigmatizing bearers of the genetic trait. This has the effect of both undercutting personal responsibility and legitimizing draconian medical responses to the targeted behavior, like eugenic sterilization. Second, genetic studies tend to misdirect attention from the overwhelming social causes of the behaviors they purport to explain, by encouraging a determinism that suggests that efforts at social reform are ultimately futile. Where this misdirection reinforces existing social policy inequities, it is likely to have an even more pronounced effect (Wasserman).

PROFILING USES. The third kind of databank that is part of a comprehensive iDNAfication system (in addition to the identified DNA profile collection and the aggregate population polymorphism frequencies database) is an open case file: a collection of DNA profiles taken from crime scenes or battlefields or plane crash sites that come from as yet unidentified sources. Obviously, this collection needs to be comparable to the identified reference collection, which means the same markers should be used to compose the profiles in both. With these collections, however, investigators will be especially tempted to glean as much information as they can from their genetic analyses in their efforts to compose a profile of their missing sample source. One of the areas of highest interest has been in non-coding polymorphisms that would allow investigators to estimate the *ethnic affiliation* of a sample source (Shriver, et al.). These investigators call their markers *population specific alleles* (PSAs), and the ethnic populations they mark are, once again, just our traditional races: European-Americans, African-Americans, native Americans, and Asian Americans. Should these PSAs be included in or excluded from the panel of markers established for our universal, humanitarian iDNAfication system? Including them would allow the system to support an open case file that could take advantage of the additional information to narrow the search for sample sources. It would also, presumably, take the guesswork out of deciding which racial reference group to assess a particular sample against.

Of course, including PSAs in iDNAfication profiles would elevate the informational content of the profile beyond that of a traditional fingerprint, constituting more of an intrusion on privacy. Moreover, it would do so by reporting a particularly socially sensitive feature of the arrestee: their probable race. But photographs also can reveal race, and we sanction collecting them for identification purposes. How would this be different?

Photography is an illuminating analogy here. Photographs show only the superficial distinctions that we use socially to categorize a person's ethnic affiliation. They leave that categorization itself up to the observer, and make no claims about its merits. Thanks to our large-scale hybridization, in other words, *passing* for one race or another is still possible in mug shots. PSAs, on the other hand, are defined in terms of our society's racial categories, and purport to be able to *appropriately classify* even interethnic individuals into their true (ancestral) categories.

This has several implications. First, it means that genuine secrets might be revealed through PSA screening: for example, shifts in the social (racial) status of the arrestee or her ancestors that have nothing to do with their arrest, but which, if interpreted as normative, could cause psychological and social harm to the individuals and their families by upsetting their social identities. In that sense, PSAs are more threatening to privacy than photographs. Second, as the scientists's own hopes for appropriately classifying hybrids shows, it is hard not make the logical mistake of moving from the use of social categories to define the PSAs to then using PSAs to define our social categories. This mistake raises two important issues about the use of PSAs in iDNAfication schemes.

First, it risks exacerbating racism by reinventing in statistical and molecular terms the arbitrary social apparatus of the *blood quantum* and *the One Drop Rule*: Under PSA screening, one's proportional racial endowment could be

quantified, and carrying the defining polymorphisms for any given race would warrant (statistically) *affiliating* one with it for official identification purposes, regardless of one's superficial social identity. In the wake of a program of iDNAfication in which thousands of American's would have their PSAs determined, this could have powerful social consequences. In fact, our bad experiences with other forms of *low tech* racial profiling in law enforcement has already led to court decisions prohibiting the practice as unconstitutional under the Equal Protection clause (Johnson).

The second danger in estimating ethnic affiliation through PSAs is the way it facilitates the reification of (fundamentally unjust) social categories as biological realities. If PSAs are not *genes for race,* they are at least differentially associated with the people we classify in particular races. Genetic association, however, in the public and scientific mind, often comes to imply causation that implies in turn the objective reality of the effect. In other words, if PSAs correlate with racially defined populations, they must be linked somehow with the defining genes of those populations, and if the racial populations have defining genes, races must be real and separable biological entities, not just social constructions. Our society has had recurrent experience with this kind of *hardening of the categories,* all of which has been detrimental to the least well off (Duster) because it fosters a particular form of social harm: the erosion of our sense of solidarity as a community and our empathy for members of other groups, leading to what one scholar has called social policies moral abandonment (Wasserman). Any widespread iDNAfication program that involved PSA-based ethnic affiliation estimations would run the real risk of exacerbating that harm, by fostering the public perception that PSA-based profiles revealed real racial assignments.

DRAGNET USES. Finally, there is a third set of choices about the range of use to which any arrestee iDNAfication system should be put. Given our commitment to the presumption of innocence, should such a system accommodate *sweep searches* of its stored profiles in the pursuit of a criminal suspect? Obviously, in addition to the precise identification of sample sources, the principal purpose of the existing convicted offender iDNAfication databanks in law enforcement is to aid in the identification of suspects by matching unidentified DNA samples from a crime scene with an identified profile in the collection. If in fact we kept the informational content of arrestee iDNAfication under the *pattern matching* standard of manual fingerprinting, could we really complain about police searches of arrestee iDNAfication databases for the same purpose?

On one hand, it is clear that some dragnet uses of iDNAfication would not be acceptable in the United States. Critics of current forensic iDNAfication programs often point to the 1987 British case in which every male resident in three Leicestershire villages was asked to voluntarily provide a DNA sample to the police in an (ultimately successful) effort to identify a murderer, as an cautionary sign of things to come (Wambaugh). However, given the coercive nature of such a request (police made house calls on those failing to appear for sampling), its effect of shifting the presumption of innocence to one of guilt, its lack of adequate probable cause, and the U.S. Supreme Court's rejection of similar uses of manual fingerprinting, it seems implausible that such a sampling practice would be constitutionally sanctioned in the United States.

However, what if the dragnet were only a matter of searching a database of DNA profiles previously collected by the state for the identification of arrestees? In supporting the existing convicted offender iDNAfication databases, the courts have argued that the public interest in prosecuting crime outweighs any presumption of innocence that criminals may have in future cases, thus justifying the reuse of their DNA fingerprints for forensic matching (*Jones v. Murray,* 1991). Moreover, we already store and reuse arrest photographs and manual fingerprints, even from those arrestees subsequently cleared of their charges, in attempting to identify suspects in future cases. Why should arrestee DNA fingerprints be handled differently?

Here is where the uniquely biological side of iDNAfication reenters the analysis, with its increased claims of physical privacy. U.S. courts have ruled that systematic analyses of tissue samples and body products (as opposed to photos and fingerprints) of suspects (as opposed to convicted criminals) are the sorts of searches that are protected by the Fourth Amendment, even when the samples are already in the state's hands. This suggests that, although one's arrest presumes enough probable cause to justify sampling for *identification* purposes, arrestees have not forfeited as much of their presumption of innocence and the physical privacy that attends it as convicted offenders have, whose samples can be searched at will by the state. If these decisions are accepted as precedents for iDNAfication, efforts to screen forensic DNA against a database of arrestee profiles from citizens who have no convictions would also have to pass the Fourth Amendment's tests, and show probable cause for each attempted match.

Moreover, if anything, the bar to dragnet searches of arrestee iDNAfication collections should be set higher than the bar to searching other tissue samples and body products, because DNA profile matching actually poses a greater risk to privacy than other forms of tissue typing. This is because, unlike both fingerprint and urinalysis screening, the process of matching a forensic sample against an iDNAfication

database can reveal familial relationships as well as identities. Unlike fingerprints and photographs, in which the environmental vagaries of human development usually work to obscure any convincing evidence of kinship, DNA profiles can demonstrate those relationships in clear genetic terms.

Thus, when non-coding nuclear DNA markers are used to profile a forensic specimen, the siblings, parents, and children of the specimen source will all show partial matches with the specimen. Their appearance in an arrestee iDNAfication database will not make them direct suspects, because of the mismatching elements of the profile. But their matching elements can reveal that they are related to the suspect, and so will flag their family for further investigation by the police. Moreover, when mitochondrial DNA is used for genotyping, the resulting profiles will almost always be completely shared by the DNA source's mother and siblings, and by her mother and all her siblings as well: They are all essentially mitochondrial clones. In these cases, the appearance of family members in an arrestee database might even make them immediate suspects for investigation. In any case, the disclosure of the identities of a suspect's relatives is not something that fingerprint searches accomplish, which means that iDNAfication puts more personal information at risk. It therefore poses a greater threat to the privacy of both the arrestees and their kin. Moreover, experience from clinical DNA testing within families demonstrates that even in a supportive context, the disclosure of familial relationships can have tremendous psychosocial impact on family members (Juengst). To have those relationships disclosed publicly in the context of a criminal investigation only amplifies the risk that the impact will be negative on both the sample sources and their kin.

It is interesting to note in this regard that some states's convicted offender iDNAfication databanking statutes already include provisions mandating the expungement of a person's DNA profile, and the destruction of their samples, if their convictions are overturned or dismissed on appeal (McEwen and Reilly). The only circumstance in which that this happens with traditional fingerprints is in case of juvenile acquittals, where expungement is justified in terms of the burden of an early criminal record on the life prospects of the acquitted. This suggests that having one's DNA on file with the state is also recognized, at least in some states, to carry privacy risks to the individual that are unfair to impose on citizens cleared of criminal guilt, in the same way it is unfair to impose a criminal record on a reformed youth. But if that is true of those whose convictions are overturned, it should be equally true for those who are never convicted in the first place (Nelkin and Andews).

DNR (DO NOT RESUSCITATE)

• • •

In its most simple form, "DNR" is a physician's order directing a clinician to withhold any efforts to resuscitate a patient in the event of a respiratory or cardiac arrest. The literal form, *do not resuscitate,* is more precisely worded as *do not attempt resuscitation.* While originally intended for hospitalized patients, the concept of withholding resuscitative efforts has since been extended to include patients in nursing homes, children with incurable genetic or progressive neurologic diseases, and terminally ill patients in the home or hospice setting.

More broadly, the DNR order has become a part of the ritual of death in American society. For the patient, a DNR order (or the absence of a DNR order) establishes how death will likely ensue. The introduction of DNR orders also marked a pivotal change in the practice of medicine, for it was the first order to direct the withholding of treatment. DNR orders are so commonplace and widely accepted in everyday practice that nearly all physicians and nurses have had some experience in determining whether to invoke or adhere to the order when it is written.

History

Although commonplace and widely accepted today, the development of the do-not-resuscitate order was, and remains, controversial on several fundamental issues at the intersection of medicine and ethics. As with artificial (mechanical) ventilation and artificial nutrition and hydration, the development of advanced cardiopulmonary resuscitation (CPR) techniques created decision points regarding treatment alternatives for both dying patients and their caretakers that had not previously been confronted.

Prior to 1960 there was little that physicians could do for a patient in the event of sudden cardiac arrest. In that year, surgeons at Johns Hopkins Medical Center reported a technique for closed-chest massage combined with "artificial respiration" and designed specifically for patients suffering anesthesia-induced cardiac arrest. This condition was especially conducive to closed-chest massage because it often occurred in otherwise healthy patients who needed only short-term circulatory support while the adverse effects of anesthesia were resolved. In the context for which it was designed—transient and easily reversible conditions in otherwise healthy individuals—the technique at first appeared miraculous for its effectiveness and simplicity. A 1960 article in the *Journal of the American Medical Association* stated: "Anyone, anywhere, can now initiate cardiac resuscitative procedures. All that is needed are two hands" (Kouwenhoven, Jude, and Knickerbocker, pp. 1064–1067).

Partly because of its simplicity, and partly because of uncertainty over who might benefit from the performance of CPR, it soon became the rule and not the exception that any hospitalized patient experiencing cardiac arrest underwent a trial of resuscitative efforts. These attempts often transiently restored physiologic stability, but too often also resulted in prolonged patient suffering. By the late 1960s, articles began appearing in the medical literature describing the agony that many terminally ill patients experienced from repeated resuscitations that only prolonged the dying process (see Symmers).

Soon a covert decision-making process evolved among clinicians regarding the resuscitation decision. When physicians and nurses responded to situations in which they believed that CPR would not be beneficial, they either refused to call a *code blue* or performed a less than full resuscitation attempt. New terms, such as *slow code* and *Hollywood code,* entered the vocabulary of the hospital culture as these partial or half-hearted resuscitation efforts became more pervasive.

Lacking an established mechanism for advanced decision making about resuscitation, some hospitals developed

their own peculiar means of communicating who would not receive a full resuscitation attempt in the event of cardiopulmonary arrest. Decisions were concealed as purple dots on the medical record, written as cryptic initials in the patient's chart, or in some cases simply communicated as verbal orders passed on from shift to shift.

The absence of an open decision-making framework about resuscitation decisions was increasingly recognized as a significant problem in need of a solution. Unilateral decision making by clinicians in this context effectively circumvented the autonomy of the patient and prevented the full consideration of legitimate options by the involved parties prior to a crisis. From the patient's perspective, this covert decision making resulted in errors in both directions: some patients received a resuscitation attempt in circumstances where they did not desire it, while others did not receive a resuscitation attempt in circumstances where they would have desired it.

In 1976 the first hospital policies on orders not to resuscitate were published in the medical literature (see Rabkin). These policies mandated a formal process of advance planning with the patient or patient's surrogate on the decision of whether to attempt resuscitation, and also stipulated formal documentation of the rationale for this decision in the medical record. In 1974 the American Heart Association (AHA) became the first professional organization to propose that decisions not to resuscitate be formally documented in progress notes and communicated to the clinical staff. Moreover, the AHA position on DNR stated that "CPR is not indicated in certain situations, such as in cases of terminal irreversible illness where death is not unexpected" (American Heart Association).

Ethical Perspective

Parallel to the development of the DNR order in the medical community was the emergence of a broad societal consensus on patient's rights. The conceptual foundation of this consensus was the recognition that the wishes and values of the patient should have priority over those of medical professionals in most healthcare decisions.

An influential President's Commission further advocated that patients in cardiac arrest are presumed to have given consent to CPR (that is, a resuscitation attempt is favored in nearly all instances). By extension the commission argued that the context in which the presumption favoring CPR may be overridden must be explicit, and must be justified by being in accord with a patient's competent choice or by serving the incompetent patient's well-being (President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research). Since that time nearly all states have adopted specific statues on the DNR order. The bioethics community, however, has not embraced this view without dissent.

The assumption that CPR is generally beneficial and should be withheld only by exception has been seriously challenged. CPR, the argument goes, is often not beneficial and was never intended to be the standard of care for all situations of cardiac arrest (four of the five patients in the original Johns Hopkins report experienced an unanticipated cardiac arrest in the setting of anesthesia). From this perspective, CPR, like any treatment, should only be offered to those patients for whom it is medically indicated—physicians are not ethically bound to seek consent to refrain from a procedure that is not medically indicated.

Few issues have been more contentious than whether a physician may determine, without patient or surrogate consent, that CPR is not indicated. Some hospitals have adopted a "don't ask, don't tell" approach to this question by allowing *unilateral* or *futility-based* DNR orders without asking or informing the patient of the decision. Still other policies employ a "don't ask, do tell" approach, where unilateral DNR orders can be written at the discretion of the attending physician, who then informs the patient or patient's family of the decision.

Attempts have been made within the medical profession to define *futile, nonbeneficial, inappropriate,* or *not indicated* in specific terms, such as lack of physiological effect or low likelihood of survival. The assumption underlying this approach is that physicians are best qualified to determine whether and when a medical therapy is indicated. Others advocate procedural resolution pathways, in the belief that it is not possible to achieve consensus on an accepted definition of what constitutes futile medical treatment. This approach assumes that end-of-life decisions inherently involve value-laden choices that people will not always agree on.

Who ultimately decides when a treatment is indicated? The original foundation of the consent process in medicine is the principle that permission is needed "to touch," even when the intent of the person who seeks "to touch" is solely to promote health and treat illness. Because the DNR order is an order not to touch—when that touch may be both highly invasive and life-preserving—only a properly informed patient can decide whether touching is wanted or not. This determination is ultimately a value judgment made by the patient, utilizing information as to efficacy (or futility) provided by the physician.

Conclusion

The introduction of the DNR order brought an open decision-making framework to the resuscitation decision, and also did much to put appropriate restraints on the universal application of cardiopulmonary resuscitation for the dying patient. Yet, DNR orders focus upon what will not be done for the patient, as opposed to what should be done for the patient. These deficiencies are being addressed through the palliative care movement, which recognizes that good care at the end of life depends much more on what therapies are provide than upon those that are not.

DOUBLE EFFECT, PRINCIPLE OR DOCTRINE OF

• • •

Originating in Roman Catholic scholastic moral philosophy, the Principle of Double Effect (hereafter referred to as the PDE or Double Effect) is still widely discussed in the bioethics literature on euthanasia, palliative care, physician assisted suicide, suicide and abortion (Barry; Quill, Lo et al.; Manfredi, Morrison et al.; Stempsey; Kamm, 1999; McIntosh; Shaw). It has also been applied to a range of other issues, including organ donation and transplantation (DuBois). Due in large part to these bioethics discussions, the PDE has been the subject of a resurgence of interest in moral and political philosophy generally. Double Effect has been debated in the philosophy of law as germane to discussions of, among other things, murder, self-defense, capital punishment, and suicide (Frey; Hart; Finnis, 1991, 1995; Aulisio, 1996). In social and political philosophy, it has been put forth as an important principle for rights theory (Quinn, 1989; Bole), and as a partial justification for affirmative action (Cooney). A traditional military ethics application of Double Effect, to distinguish between strategic and terror bombing, remains a subject of debate today as well (Bratman; Kamm, 2000). In addition, the PDE's central distinction, intention/foresight, has been the subject of rigorous analysis in the philosophy of action (Robins; Bratman; Aulisio, 1995; Brand; Harman).

Double Effect is typically applied to conflict situations in which any action (or course of actions) will result in numerous effects, good and bad. Traditionally a four-part principle, contemporary versions of the PDE are usually formulated as two-part principles, along the following lines: An action with multiple effects, good and bad, is permissible if and only if (1) one is not committed to intending evil (bad effects) either as end or means, and (2) there is proportionate reason for bringing about the evil (bad effects). The first

condition, a non-consequentialist intention condition, is lexically prior to the second. Most proponents of the PDE consider the second condition, the proportionate reason condition, to be consequentialist in nature while allowing for other considerations as well.

Paradigm Applications

In the Roman Catholic bioethics literature, the PDE has long been invoked to deal with cases of maternal-fetal conflict to distinguish between permissible interventions that may result in the death of the fetus and abortion, which is absolutely forbidden (Barry). Consider the following set of maternal-fetal conflict paradigm cases.

Paradigm 1: Therapeutic Hysterectomy. A thirty-three year old pregnant woman is diagnosed with a highly aggressive form of uterine cancer ten weeks into her pregnancy. The woman is a devout Roman Catholic, strongly opposed to abortion, and is under care at a Catholic hospital. If the woman were not pregnant, her doctors would recommend a therapeutic hysterectomy to prevent the spread of cancer.

Paradigm 2: Hypertensive Pregnancy. A thirty-nine year old woman is diagnosed with dangerously life threatening high blood pressure seventeen weeks into her pregnancy. The woman is a devout Roman Catholic, strongly opposed to abortion, and is under care at a Catholic hospital. An abortion would alleviate the hypertension and remove the threat to the woman's life.

Though it may come as a surprise to some, those familiar with the Roman Catholic double effect literature will know that the therapeutic hysterectomy proposed in the first case above has long been considered permissible by orthodox Roman Catholic moralists. Indeed, this is viewed as a paradigm instance of a *permissible* action under the PDE (Healy; Kelly; O'Donnell). On the traditional view, the physician's intended *end* would be *saving the life of the mother* by stopping the spread of cancer through her intended *means* of removing the cancerous uterus. Fetal death, on the traditional view, would properly be described as a foreseen but unintended (bad) side effect of the (good) act of saving the mother's life.

In contrast, the case of the hypertensive pregnancy has long been considered a paradigm instance of an action that fails the PDE. In particular, the abortion has traditionally been interpreted as the intended means to the good end of saving the life of the mother, thus failing the PDE's lexically prior intention condition (Healy; Kelly; O'Donnell).

The following scenarios illustrate another set of paradigm applications of the PDE, that is, to distinguish between palliative care and euthanasia:

Paradigm 3: Morphine Drip. David, a forty-nine year old HIV patient, is terminally ill and in constant pain. After much discussion with his partner, family, friends and care team, David has decided that he wants only comfort care. He is adamant that he be kept comfortable. David is placed on a morphine drip, which is then periodically adjusted to alleviate David's discomfort. David's physician knows that continued titration to alleviate David's discomfort runs the risk of hastening or even causing death given David's weakened state. David's physician continues to adjust the morphine drip to keep David comfortable.

Paradigm 4: Lethal Overdose. David, a forty-nine year old HIV patient, is terminally ill and in constant pain. After much discussion with his partner, family, friends and care team, David has decided that he no longer wants to go on living. After saying his good-byes to his partner, family, and friends, David asks his physician to give him a lethal injection of morphine. David's physician gives him a lethal overdose of morphine.

Traditionally, Paradigm 3, the Morphine Drip, has been considered permissible under the PDE, while Paradigm 4, the Lethal Overdose, has been considered impermissible. Why? In Paradigm 3, on the traditional view, David's physician's intended end is to alleviate David's pain. The intended means to this end is the administration of a palliative medication, morphine. Given David's excruciating pain and terminal illness, David's physician has proportionate reason to titrate to pain even though he knows this may hasten or even cause death. On the traditional view, should David die, his death is taken to be a foreseen, but unintended, side effect of the doctor's action (Healy; Kelly; O'Donnell).

In Paradigm 4, David's physician has the same end (i.e., to alleviate David's pain). His means, however, is to give David a lethal injection (i.e., to kill him). On the traditional view, Paradigm 4 is taken to fail the intention condition of the PDE because David's death, the bad effect, is intended by his physician as the means to alleviating David's pain. Paradigm 4 is, on the traditional view, a classic instance of mercy killing (Healy; Kelly; O'Donnell).

The application of the PDE to these, and other, types of cases has been challenged. These challenges generally fall into one of three categories: conceptual tenability, practical applicability, and moral significance. Since challenges to the conceptual tenability and practical applicability of the PDE are largely matters for the philosophy of action, they extend well beyond the scope of this entry. In the bioethics literature, challenges to the PDE have focused on its moral significance outside of the absolutist moral framework within which it emerged. In order to understand this type of

challenge, however, it is important to consider the historical origins of the PDE.

Historical Origins

In its traditional form, the PDE has four conditions:

1. The act to be done must be good in itself or at least indifferent.
2. The good intended must not be obtained by means of the evil effect.
3. The evil effect must not be intended for itself, but only permitted.
4. There must be proportionately grave reason for permitting the evil effect. (Fagothey)

Most trace the origins of this traditional four-part PDE and its two-part contemporary successor to St. Thomas Aquinas's (1224–1274) discussion of killing in self-defense (Aquinas; Mangan). Aquinas notes that the Christian tradition had, until his time, almost universally forbidden killing in self-defense. This prohibition probably stemmed from a teaching of St. Augustine (354–430) in *De Libero* that Christians should not kill others to save themselves because bodily life is that which "they ought to despise" (I, 5 PL 32, 1228). In his justification of killing in self-defense, Aquinas invoked what later became the essential conditions of the PDE. He argued that:

> A single act may have two effects, of which only one is intended, while the other is incidental to that intention. *But the way in which a moral act is to be classified depends on what is intended,* not what goes beyond such an intention. Therefore, from the act of a person defending himself a twofold effect can follow: one, the saving of one's own life; the other the killing of the aggressor. (IIaIIae, q.64, a.7)

Implicit here is the crucial distinction upon which the PDE depends, namely intention/foresight. An act of self-defense is classified as such provided that it is the saving of oneself and not the killing of the aggressor that is intended. If the killing was intended (*intendere*), and not merely foreseen (*praeter intentionem*), then, for Aquinas, the act would properly be classified as homicide.

It would seem that both conditions one and three of the traditional PDE might be elicited from this passage. Condition three forbids the intending of an evil effect *for itself* (as an end). Yet if acts are to be classified according to what is intended, then a violation of condition three (intending the evil as an end) will also be a violation of condition one (the act will be classified as bad in itself). Furthermore, condition two, that the good intended not be obtained by means of the evil, though not explicitly stated, can be understood as a plausible explication of conditions one and three as one who intends an end may also be taken as intending the means to his or her end.

Not to have intended evil is a necessary, but not sufficient, condition of justified self-defense for Aquinas. In the same section he offers a second condition:

> An act that is properly motivated may, nevertheless, become vitiated if it is not *proportionate* to the end intended. And this is why somebody who uses more violence than is necessary to defend himself will be doing something wrong. (IIaIIae, q.64, a.7)

What became the fourth condition of the traditional PDE, the proportionality principle, can be elicited from this passage. Though it is not obvious from this passage, nor from the broader context of Aquinas's work, that proportionate is meant to refer to the measure of good and bad effects, later moralists interpreted the condition in this way.

Double Effect and Contemporary Bioethics

As noted at the outset, the contemporary bioethics literature generally treats Double Effect as a two-part principle. Interestingly, the two-part contemporary PDE, as the preceding discussion suggests, is closer to its Thomistic origins. Though its traditional applications to abortion, euthanasia, self-defense and suicide (particularly physician assisted suicide) continue to be discussed, the PDE has been applied to some novel contemporary bioethics cases, such as the separation of conjoined twins and the use of embryos in research, as well (Coughlan and Anscombe). The strong resurgence of interest in Double Effect in bioethics, however, is directly attributable to the rise of the palliative care movement (Cantor and Thomas; Cavanaugh; Quill, Lo et al.; Manfredi, Morrison et al.; Patterson and Hodges; Preston; Shorr; Gilbert and Kirkham; Sulmasy and Pellegrino; Hawryluck and Harvey; Nuccetelli and Seay; Sulmasy; Bernat; Luce and Alpers; Thorns). Indeed, the vast majority of contemporary bioethics discussion of Double Effect has centered its application to *terminal sedation* which, though controversial in some quarters, is usually little more than a logical extension of the morphine drip case considered above (Paradigm 3) (Krakauer, Penson et al.; Wein). A somewhat novel application of Double Effect in terminal sedation is illustrated by the following case.

Terminal Sedation: Agonal Breathing. Mrs. Jones, an eighty-two year old white female, is a vent dependent terminally ill cancer patient. She is conscious and deemed to have decision capacity upon psychiatric evaluation. Though her pain is well controlled, she requests to be removed from

the ventilator. She also requests to first be sedated so that she will not have the experience of not being able to breathe once ventilator support is withdrawn.

The use of palliative medicine in the case of Mrs. Jones can plausibly be construed as satisfying the PDE. Here the use of palliative medicine is intended to alleviate the discomfort of agonal breathing and the attendant suffering of Mrs. Jones should she have to experience this. Critics have argued that invoking Double Effect in these types of cases is a thinly veiled attempt to avoid the charge of intentional killing (Quill, Dresser et al.; Kuhse). Such critics argue that, rather than invoking Double Effect as a rationalization for palliative care, it should be acknowledged that there are times when the intentional mercy killing (euthanasia) is appropriate, thus rendering Double Effect concerns irrelevant.

Double Effect and Moral Relevance: Curious Artifact or Bulwark?

Many critics of Double Effect and even some of its proponents have focused on its Roman Catholic origins, questioning its moral relevance outside of absolutist Roman Catholicism (Boyle 1991a, 1991b; Quill, Dresser et al.). Indeed, this is the most common challenge articulated in the bioethics literature. What, then, can be said of the moral relevance of the PDE outside of absolutist Roman Catholicism? Should bioethicists outside of Roman Catholic moral tradition view the PDE as little more than the curious invention of sectarian casuistry?

To understand this challenge, it is important to highlight the fact that the Roman Catholic moral tradition, in which the PDE emerged, absolutely prohibits certain types or classes of action, including active euthanasia, abortion, murder, and suicide (Boyle, 1991b). In such a tradition, the question of appropriate act description and classification is of paramount importance. The intention condition of the PDE helps to delimit what counts as falling into a given class of action (recall Aquinas's claim, cited above, that the way an act is to be classified depends on intention). Provided an act does not fall into one of the absolutely forbidden classes of action, one may then apply the proportionate reason condition to help determine the permissibility of bringing about the evil effect. Thus, the moral relevance of the PDE and, in particular, of the intention/foresight distinction, is easy to establish in the context of Roman Catholicism with its absolute prohibitions on certain types of acts.

The claim that Double Effect is morally relevant only within the context of absolutist Roman Catholicism is highly problematic. As discussed above, the most fundamental element of the PDE is a conceptual distinction between intention and foresight. Arguably, the normative significance of *any* conceptual distinction will depend on the normative framework within which the distinction is operative (Aulisio, 1996, 1997). The central distinction of PDE, intention/foresight, is embedded in ordinary language and common morality, and is arguably important for certain areas of Anglo-American law despite its emphasis on individual autonomy (e.g., law of attempts, distinction between murder one and manslaughter; etc.) (Aulisio, 1996). More importantly, any moral framework, absolutist or not, that incorporates deontic constraints, formulated in terms of intention, on consequentialist considerations may have use of the intention/foresight distinction (and, therefore, the PDE) (Nagel; Kagan; Quinn, 1993; Beauchamp; Kamm, 2001).

If the preceding discussion is on target, given the wide variety of moral frameworks that incorporate deontic constraints formulated in terms of intention, it seems likely that the PDE will continue to be relevant to a range of bioethics issues. This does not mean that proponents of the PDE can rest easily, however. Serious challenges to the PDE remain. Chief among these are challenges to the conceptual tenability and practical applicability of the intention/foresight distinction, and the need for an adequate theory of intention to address these challenges. Though interesting and important in their own right, it seems unlikely that these matters will inhibit continued vigorous bioethics debate concerning the application of the PDE to vexing cases.

E

EASTERN ORTHODOX CHRISTIANITY, BIOETHICS IN

• • •

The Eastern Orthodox church considers itself identical with the Church established by Jesus Christ and believes itself to be guided by the Holy Spirit, continuing that ecclesial reality into the present age as an organic historical, theological, liturgical continuity and unity with the apostolic Church of the first century. Historically, it sees itself as identical with the "One, Holy, Catholic, and Apostolic Church" that suffered the "Great Schism" in 1054 that led to the division of Christendom into Eastern and Western Christianity.

The Orthodox church is organized hierarchically, with an ordained clergy and bishops. A number of national and ethnic Orthodox churches, under the leadership of patriarchs, are united by tradition, doctrine, and spirit rather than by authority, although the Ecumenical Patriarch of Constantinople is accorded a primacy of honor. The church's identity is rooted in the experience of the Holy Spirit in all aspects of its life and in a doctrinal perspective that serves as a matrix for its ethical teachings (Ware; Pelikan). In the sphere of bioethics, this theological matrix forms a coherent source of values for bioethical decision making. At its center is the view that life is a gift of God that should be protected, transmitted, cultivated, cared for, fulfilled in God, and considered a sacred reality. Consequently, there is a high regard for the concerns usually identified with the field of bioethics.

Doctrine and Ethics

In Orthodox belief, the teaching of the church is found in the Old and New Testaments, the writings of the church fathers, and all aspects of the synodical, canonical, liturgical, and spiritual tradition of faith as lived, experienced, and reflected upon in the consciousness of the church, for which the general name "holy tradition" is used.

The Eastern Orthodox church understands ultimate reality to be the Holy Trinity, or God who is a triune unity of persons: the Father, source of the other two fully divine persons; the Son, forever born of the Father; and the Holy Spirit, forever proceeding from the Father. Thus, ultimate uncreated and uncontingent reality is a community of divine persons living in perpetual love and unity.

This divine reality created all else that exists, visible and invisible, as contingent reality. Human beings are created as a composite of body and spirit, as well as in the "image and likeness" of the Holy Trinity. "Image" refers to those characteristics that distinguish humanity from the rest of the created world: intelligence, creativity, the ability to love, self-determination, and moral perceptivity. "Likeness" refers to the potential open to such a creature to become "God-like." This potential for deification, or *theosis,* has been lost through the choice of human beings to separate themselves from communion with God and their fellow human beings; that is to say, sin is a part of the human condition. Though weakened and distorted, the "image" remains and differentiates human existence from the rest of creation.

The work of redemption and salvation is accomplished by God through the Son, the second person of the Holy Trinity who took on human nature (except for sin) in the person of Jesus Christ. He taught, healed, gave direction, and offered himself upon the cross for the sins of humanity, and conquered the powers of death, sin, and evil through his resurrection from the dead. This saving work, accomplished for all humanity and all creation, is appropriated by each

human person through faith and baptism, and manifested in continuous acts of self-determination in communion with the Holy Spirit. This cooperation between the human and divine in the process of growth toward the fulfillment of God-likeness is referred to as synergy.

The locus for this appropriation is the Church—specifically, its sacramental and spiritual life. The sacraments, or "mysteries," use both material and spiritual elements, as does the life of spiritual discipline known as "struggle" and "asceticism" (*agona* and *askesis*). Both foster a communion of love between the Holy Trinity and the human being, among human beings, and between humans and the nonhuman creation, making possible continuous growth toward God-likeness, which is full human existence.

Though in this earthly life growth toward Godlikeness can be continuous, it is never completed. In the Eastern Orthodox worldview, the eternal Kingdom of God provides a transcendent referent for everything. The Kingdom is not only yet to come in the "last days," but is now a present reality through Christ's resurrection and the presence of the Holy Spirit. Within this spiritual reality, the goal of human life is understood to be an ongoing process of increasing communion with God, other persons, and creation. This forms the matrix for Orthodox Christian ethics and provides it with the materials and perspectives for articulating the "ought" dimensions of the church's teaching (Mantzaridis).

Among the more important aspects of these teachings for bioethics are (1) the supreme value of love for God and neighbor; (2) an understanding that sees nature fallen but also capable of providing basic norms for living through a foundational and elementary natural moral law; (3) the close relationship of material and spiritual dimensions of human existence and their appropriate relationship and integration; (4) the capacity for self-determination by human beings to make moral decisions and act on them; and (5) the criterion of movement toward God-likeness—all within a framework that is both this and other-world focused.

In practice, ethical norms are arrived at in holy tradition and by contemporary Orthodox ethicists by defining moral questions within this context of faith in a search for ethical guidelines that embody the good, the right, and the fitting (Harakas, 1983).

Bodily Health

Concern for the health of the body, though not central, has a significant place in Eastern Orthodox ethics (Harakas, 1986a). Orthodox Christian ethics calls for "a healthy mind and a healthy spirit with a healthy body." The body is neither merely an instrument nor simply a dwelling place of the spirit. It is a constituent part of human existence, and requires attention for the sake of the whole human being. Thus, in its sinful condition, the body can also be a source of destructive tendencies that need to be controlled and channeled. This is one of the works of asceticism, which seeks to place the body under control of the mind and the spirit. But asceticism is never understood as a dualistic condemnation of the body. As a good creation, under the direction of the proper values, the body is seen as worthy of nurturing care. Thus, everything that contributes to the well-being of the body should be practiced in proper measure, and whatever is harmful to the health of the body ought to be avoided. The Eastern Christian patristic tradition is consistent in this concern (Constantelos; Darling).

Practices that contribute to bodily health and well-being are ethically required. Adequate nourishment, proper exercise, and other good health habits are fitting and appropriate, while practices that harm the body are considered not simply unhealthful, but also immoral. Abuse of the body is morally inappropriate. Both body and mind are abused through overindulgence of alcohol and the use of narcotics for nontherapeutic purposes. Orthodox teaching holds that persons who might be attracted to these passions need to exercise their ethical powers in a form of ascetic practice to overcome their dependence upon them as part of their growth toward God-likeness.

Healing Illness

When illness occurs, Orthodox Christianity affirms an ethical duty to struggle against sickness, which if unaddressed can lead to death. The moral requirement to care for the health of the body indicates it is appropriate to use healing methods that will enhance health and maintain life. Two means are used concurrently: spiritual healing and different forms of medicine. The first is embodied in nearly all services of the church, in particular, the sacrament of healing, or holy unction. There is also a continuing tradition of multiple forms of prayer and saintly intercessions for the healing of body and soul.

The church does not see spiritual healing as exclusive nor as competitive with scientific medicine. In the fourth century, Saint John Chrysostom, one of the great church fathers, frequently referred to his need for medical attention and medications. In his letters to Olympias, he not only speaks of his own use of medications but advises others to use them as well. Saint Basil, another great fourth-century church father, underwent various forms of therapy for his illnesses. In fact, both of these church fathers had studied

medicine. Basil offers a classic Christian appreciation of the physician and the medical profession:

> Truly, humanity is the concern of all of you who follow the profession of medicine. And it seems to me that he who would prefer your profession to all other life pursuits would make a proper choice, not straying from the right, if really the most precious of all things, life, is painful and undesirable unless it can be possessed with health. And your profession is the supply vein of health. (Epistle 189, To Eustathius, the Court Physician fourth century, p. 228)

Recent studies have highlighted the Eastern Orthodox church's concern with healing, both in its medical and spiritual dimensions. Orthodox monks established the hospital as a place of healing, a tradition maintained by Orthodox monasticism for almost a thousand years, until it was taken over by the medical establishment (Miller; Scarborough; Harakas, 1990).

Bioethical Concerns and Methods

Bioethics as a distinct discipline is only a few decades old, but some topics included in the discipline, such as abortion, have been addressed by the Christian tradition over the centuries. Many bioethical issues are new, however, and the Orthodox church's views concerning them have yet to be officially stated. The method contemporary Orthodox ethicists use to determine Eastern Orthodox perspectives on bioethical questions is the same as the general method used to make ethical decisions. The general doctrinal stance and ethos of the church form the larger context, delineating basic perspectives. The church requires further study, however, to assess the moral dimensions of newly created bioethical questions.

The ethicist concerned with bioethical questions then consults the tradition, which embodies the mind of the church: Scripture, patristic writings, decisions of the ecumenical councils and other synods, the received doctrinal teachings of the church, canon law, ascetical writings, monastic *typika* (constitutions of monastic establishments), liturgical texts and traditions, *exomologetaria* (penitential books), the exercises of *economia* (a process of judgment that allows for consideration of circumstances in a particular case, but without setting precedents for future normative decision making), and theological studies, for specific references that exhibit the mind of the church in concrete ethical situations. The "mind of the church" is understood as the consciousness of the people of God, together with the formulation of theological opinion, in conjunction with the decisions of the church in local, regional, and ecumenical synods, conceived and experienced as arising from the guidance of the Holy Spirit. It is a mindset, rather than a set of rules or propositions. The purpose of examining these sources is to determine whether these sources speak either directly, or indirectly, or by analogy, to new questions of bioethics. The historical contexts of these specific sources are kept in mind, and will serve to condition contemporary judgments.

Both general and specific applications can then be made and expressed as theological opinion on topics in bioethics. These views, however, are tentative, until the mind of the church specifically decides. Wherever this has already occurred, it will be noted below. Otherwise, what follows should be understood as thoughtfully considered theological opinion, subject to correction by the mind of the church (Harakas, 1980,1986b).

The Protection of Life

Orthodox thought holds that life is a gift from God, given to creation and to human beings as a trust to be preserved and protected. Just as the care for one's health is a moral duty for the individual, society's concern for public health is also a moral imperative. The first large division of concern is that existing life be protected. This can be expressed in a number of ethical positions characteristic of an Orthodox perspective.

The protection of life has been a value pursued throughout history by the church. During the early days of the rise and spread of Christianity, abortion was widely practiced in the Roman Empire. The Church, based on its respect for life, condemned this practice in its canon law as a form of murder. The Church considered abortion particularly heinous because of the defenseless and innocent condition of the victim (Kowalczyk). Of course, no moral stance is absolute. In Orthodox traditional teaching, however, abortion is nearly always judged to be wrong. There can be unusual circumstances, such as an ectopic pregnancy that threatens the life of the mother, that might be judged prudentially as calling for an abortion, but such situations are rare.

Historically related to the rejection of abortion was a condemnation of the exposure of infants, that is, their abandonment, a practice that caused their death or led to their exploitation by unscrupulous persons who profited from forcing children into prostitution or begging. These are severe examples of child abuse that unfortunately have continued into the modern age. Every such case, historic or contemporary, violates the moral requirement that adults care for children in a loving and supportive manner.

Modern Medical Technology and Ethics

The development of medical science and technology has raised many new issues, however. Studying these issues from within the mind of the church has produced a body of positions that are expressive of the church's commitment to the protection of life. Some of these follow.

ALLOCATION OF MEDICAL RESOURCES. A bioethical question that finds a response in the concern for the protection of life is the issue of the allocation of scarce medical resources. A healthcare system that fosters the widest possible distribution of healthcare opportunities is the most morally responsible, since it reflects the common human situation before God.

PROFESSIONAL-PATIENT RELATIONSHIPS. In the area of the relationships of providers and recipients of healthcare, the church affirms the existence of patients' rights and requires that the medical profession honor them. The full human dignity of every person under treatment should be among the controlling values of healthcare providers, manifested in their concern to maintain the patient's privacy, obtain informed consent for medical procedures, develop wholesome personal contacts between the patient and the medical team members, and treat the patient as a total human being rather than an object of medical procedures.

HUMAN EXPERIMENTATION. Because of the role it plays in the development of medical therapies and the possible cure of individual persons, human experimentation must be conducted and is morally justified by an appeal to the value of the protection of life. Wherever possible, however, such experimentation should fulfill the following minimal conditions: The patient should be informed of the risks involved and should accept participation in the experiment freely and without coercion, and the experiment should have potential benefit for the patient. Increased knowledge should be secondary to the welfare of the patient.

ORGAN TRANSPLANTATION. Protection of life finds intense application in the area of organ transplantation. This topic may serve as a somewhat more extensive example of Orthodox bioethical reflection. Organ transplantation was unknown in the ancient world. Some Orthodox Christians consider it wrong, a violation of the integrity of the body. Significant as this consideration is, it does not outweigh the value of concern for the welfare of the neighbor, especially since organs for transplants are generally donated by persons who are philanthropically motivated for the protection of life. The sale of organs is seen as commercializing human body parts and therefore unworthy, and is prohibited by a concern for the protection of life and its dignity.

There are two categories of potential donors: the living and the dead. Usually, the potential living donor of a duplicated organ is a relative. In such cases, concern for the well-being of the patient may place undue pressure upon the potential donor. No one has an absolute moral duty to give an organ. Healthcare professionals must respect the integrity of the potential donor as well as the potential recipient. Yet it is certainly an expression of God-likeness for a person to give an organ when motivated by caring concern and love for the potential recipient. Ethical consideration must be given to the physical and emotional consequences upon both donor and recipient and weighed in conjunction with all other factors. When these are generally positive, the option for organ donation by a living person has much to commend it.

In the case of donation of organs from the dead, some of the same considerations hold, while several new issues arise. Organs can be donated in anticipation of death. Some states, for example, encourage people to declare their donation of particular organs (liver, kidney, cornea) in conjunction with the issuance of auto licenses. There do not appear to be serious objections to this practice; many Orthodox consider it praiseworthy. When no expressed wish is known, permission of donation should be sought from relatives. Their refusal should be respected.

Persons may donate organs through bequests associated with their wills. This choice should be made known to responsible survivors before death. In 1989, for example, the Greek Orthodox Archbishop of Athens announced in the press that he had made provision for the donation of his eyes after his death.

BODY DONATION TO SCIENCE. Similarly connected with the protection of life is the issue of donating one's body to science. Much of the answer from an Orthodox Christian perspective has to do with what the representatives of science will do with it. Giving one's body to science means, in nearly all cases, that it will be used for the education of medical students. There has been a bias against this practice in many countries because at the same time that the personal identity of the body is destroyed, the body itself is treated without respect. The alternative to using donated bodies for medical education, however, is that medical students and young physicians will learn surgical skills on living patients. The concern for the protection of life could not, thus, totally disapprove of the practice of body donation. In principle, then, giving one's body for medical education cannot be ethically prohibited. But medical schools should strive to create an atmosphere of reverence and respect for the bodily remains of persons given for this purpose. In some medical

schools, this already takes place; in most, it has not. Potential donors of their bodies should inquire about procedures and refuse to donate their bodies to schools that do not show adequate respect for the body. Usually this means making arrangements for ecclesial burial of the remains after their educational use.

THE AGED. The protection of life covers the whole life span. The Orthodox church has always had a special respect and appreciation for the aged. Industrial society, with its smaller, nuclear families, has tended to isolate the aged from the rest of society. The aging themselves ought not to accept such marginalization passively. They should continue to live active and fulfilling lives, with as much independence of movement and self-directed activity as possible. Spiritually, growth in the life of Christ continues to be important. Repentance, prayer, communion with God, service to others, and loving care for others are important in this and every age bracket.

Children and relatives should do everything possible to enhance the quality of life for their aging parents and relatives. But in cases of debilitating conditions and illnesses, it may be necessary to institutionalize them. Many Orthodox Christians feel that this is an abandonment of their moral responsibilities to their parents. If institutionalization is a way of abdicating one's responsibilities to parents for the sake of convenience, then it is wrong. However, it is often the best solution. Even when it is morally indicated, the important values remain; in a nursing home or outside of it, children still have the obligation to express love, care, and respect for their parents.

DEATH. Concern for the protection of life is also present at the end of life. Death should come of itself, without human intervention. God gives us life; God should be allowed to take it away. Proponents of so-called euthanasia hold that persons should be allowed and may even be obliged to end their earthly lives when "life is not worth living." In the church's judgment, this is a form of suicide, which the church condemns. If one does this to another person, it is a case of murder. Orthodox Christian ethics rejects euthanasia as morally wrong.

Modern medical practice has raised some related issues, however. The possibility that vital signs can be maintained artificially, even after death has occurred, raises the complex question of turning off "life-sustaining" machines after brain death is diagnosed. The tradition has never supported heroic intervention in situations where death is imminent and no further therapies exist. It has been Eastern Orthodox practice not only to allow a person to die but also to actively pray for it when, according to the best medical judgment available, a person is struggling to die. If a person is clinically dead but his or her vital organs are kept functioning by mechanical means, turning off the machines is not considered euthanasia. Until the determination of clinical death, both physician and family should seek to maintain the comfort of the patient. Spiritually, all should provide the dying person opportunities for repentance and reconciliation with God and with his or her fellows (Breck, 1989).

SUFFERING. In all serious medical situations, suffering should be relieved as much as possible; this is especially true for the Orthodox patient who has participated in the sacraments of Holy Confession and Holy Communion. Pain that cannot be relieved should be accepted in as redemptive a way as possible. For the church, a "good death" (in Greek, *euthanasia*) is one in which the human being accepts death with hope and confidence in God, in communion with him, as a member of his kingdom, and with a conscience that is at peace. Genuine humanity is achievable even on the deathbed.

The Transmission of Life

The Eastern Orthodox approach to marriage provides the context for discussing procreative and sexual issues. The church sees marriage as a sacramental dimension of human life, with ecclesial and interpersonal dimensions and purposes (Guroian). The Orthodox church sees both men and women as equal before God as human beings and as persons called to grow toward God-likeness. Both men and women are persons in their own right before God and may be endowed with many potentialities that ought to be developed as part of their human growth. Yet the special sacramental relationship of marriage, procreation, and child rearing gives to women, in the mind of the church, a special role. Accompanying it is the role of husband and father in constituting a marriage and creating a family. Most of the bioethical issues regarding the transmission of life arise out of this marital and familial perspective in Orthodox thought.

REPRODUCTIVE TECHNOLOGIES. Artificial insemination assists spouses to procreate when they cannot conceive through normal sexual intercourse. In such cases, the sperm of the husband is artificially introduced into the wife's childbearing organs. There are differences of opinion in the Orthodox church regarding this procedure. A major objection is that this is a totally unnatural practice. But since other "unnatural practices" such as cooking food, wearing clothes, using technical devices such as eye-glasses and hearing aids, and performing or undergoing surgery are considered morally acceptable, this argument loses much of its force.

More cogent is the argument that artificial insemination separates "baby-making" from "love-making," which is a way of emphasizing the unity of the spiritual and bodily dimensions of marriage. In the case of artificial insemination by husband (AIH), the personal, social, and spiritual context seems to indicate that AIH is morally acceptable. The opposite holds true when the semen of a donor is used (AID). The intrusion of a third party in providing the semen violates the psychosomatic unity of the marital couple.

The same pattern of ethical reflection applies to other procedures, such as artificial inovulation and in vitro fertilization. If the sperm and ovum come from the spouses themselves, and the wife bears the child to term, ethical objections to these procedures are lessened. Often, however, fertilized ova are discarded in the procedures. The majority of Orthodox consider this a form of abortion. Others hold that for abortion to take place, implantation in the womb must have previously occurred. Nevertheless, surrogate mothers, egg donation, and sperm donation from parties outside the marriage find no place in an ethical approach that places heavy emphasis on the wholeness and unity of the bodily and spiritual aspects of human life, and of the marital relationship in particular.

STERILIZATION. Where sterilization is intended to encourage promiscuous sexual living, Orthodox Christianity disapproves. A strong ethical case can be made for it when there are medical indications that a pregnancy would be life-threatening to the wife. An as yet unexplored ethical area is the case of almost all older, yet still fertile, married couples, for whom there is a significant likelihood that the children of their mature love would be bearers of serious genetic diseases.

GENETICS. Genetic counseling seeks to provide information to a couple before they conceive children so that potentially serious conditions in newborns can be foreknown. Genetic counseling is also related to genetic screening of population groups that might be carriers of particular genetic illnesses. Genetic screening refines and makes more accurate the earlier practices of the church and of society that sought to reduce the incidence of deformed and deficient children, through the restriction of marriages between persons closely related genetically.

As a procedure that would reduce the number of persons entering into marriages with dangerously high chances for the transmission of genetic illnesses, these procedures ought to be strongly encouraged. Premarital genetic screening of young people with Mediterranean backgrounds, where there is a relatively high incidence of thalessemia B and Tay-Sachs disease, might guide them in the selection of spouses. Once a child is conceived and growing in the womb, however, the church could not consider the termination of the pregnancy as anything other than abortion. An impaired child is still the image of God with a right to life (Harakas, 1982). Since the church strenuously opposes abortion, prenatal diagnostic information indicating the prospective birth of a genetically deformed child cannot justify ending the life of the baby in the womb. Instead, this information serves to prepare the parents to receive their child with the love, acceptance, and courage required to care for such an exceptional baby.

GENETIC ENGINEERING. Concern with genetic engineering as an aspect of the transmission of life provokes a conflicting reaction among Orthodox Christian ethicists. Some Orthodox ethicists value the potential therapeutic possibilities of genetic engineering. In this case, the treatment of the genome to correct deficiencies is looked at positively, as a form of medical therapy. Nevertheless, there is concern when these same techniques are thought of as means for eugenic goals. The potential for misuse and abuse make Orthodox Christian reactions very cautious (Breck, 1991).

Conclusion

The common denominator in all these issues is the high regard and concern of the church for human life as a gift of God. Eastern Orthodox Christianity takes a conservative approach to these issues, seeing in them a dimension of the holy and relating them to transcendent values and concerns. Only an intense respect for human life can curb the modern tendencies to destroy human life both before birth and as it approaches its end. The human person, from the very moment of conception and implantation in the womb, is dependent upon others for life and sustenance. It is in the community of the living—especially as it relates to the source of life, God in Trinity—that life is conceived, nurtured, developed, and fulfilled in communion with God. The trust that each person has in others for the continued well-being of his or her own life forms a basis for generalization. Eastern Orthodox ethics, consequently, functions with a pro-life bias that honors and respects the life of each person as a divine gift that requires protection, transmission, development, and enhancement.

ECONOMIC CONCEPTS IN HEALTHCARE

• • •

Healthcare has always been an economic activity; people invest time and other resources in it, and they trade for it with each other. It is thus amenable to economic analysis—understanding the demand for it, its supply, its price, and their interrelationship. Economic analysis, of course, does not merely discern what the supply, demand, and price for healthcare in private or public markets are. It also attempts to understand why they are what they are: What behavior on the part of suppliers affects the demand for healthcare? How does a particular insurance framework affect supply and demand? And so on. Moreover, economic analysis is indispensable in the larger attempt to improve healthcare—to make it more efficient, for example, so that people can accomplish more with their investment in healthcare, or more in life generally with their resources.

The economics of healthcare, in fact, has grown into an established specialty within professional economics. Though virtually every good is in some sense an *economic good,* economists have been quick to notice some differences with healthcare. Final demand seems to be more supplier-created in the case of healthcare than it is with most goods; both the shape of health services and their price are very directly influenced by providers. Other forms of what economists call *market failure* occur in healthcare—for example, when people with a considerable demand for healthcare do not receive services because their high risk to insurers drives prices for even the most basic insurance to unaffordable levels.

As people have become increasingly concerned about rising cost, economic concepts have gained greater general currency in society's consideration of healthcare. Price is seldom *no object,* and the search for efficiency is vigorous. This entry on economic concepts in healthcare will:

1. Clarify the differences between two important forms of efficiency analysis in healthcare;
2. Articulate some of the difficulties in devising and using a common unit of health benefit;
3. Examine the monetary evaluation of one health benefit, life extension;

4. Focus on some of the fundamental moral difficulties that the demand for efficiency poses for clinical practice; and
5. Briefly explore the notions of *externality* and *public good* and their role in health policy.

Many other economic concepts apply to healthcare, but these are some that obviously raise ethical issues and are therefore most appropriate to include in this volume. Throughout, however, it will be important to keep in mind that economists, qua economists, usually think of their primary task as describing the world, not saying what it ought to be.

One should also note that although many economic concepts may appear to be more at home in capitalist than in centralized, collectivist, or socialist economies, they virtually always have a role to play in those other economies, too. For example, cost-effectiveness and cost-benefit analysis are used at least as much in socialist as in more capitalist healthcare systems. While the economic concepts developed here may not be ideology-free, they are hardly confined to free-market frameworks.

Cost-Effectiveness, Cost-Benefit, and Risk-Benefit Analysis

Efficiency involves the basic economic concept of *opportunity cost*: the value sacrificed by not pursuing alternatives that might have been pursued with the same resources. When the value of any alternative use is less than the value of the current service, the current one is efficient; when the value of some alternative is greater, the current service is inefficient. In thinking of the possible alternative uses, our sights can be set either narrowly or broadly. If we focus just on other options in healthcare, wondering whether we can get *more benefit* for our given healthcare dollars, or whether we can get the *same health benefit more cheaply,* we are engaged in cost-effectiveness analysis (CEA). If, on the other hand, we are comparing an investment in healthcare with *all the other things* we might have done with the same time, effort, and money, we are engaged in cost-benefit analysis (CBA). CEA asks whether the money spent on a particular program or course of treatment could produce healthier or longer lives if it were spent on other forms of care. CBA involves an even more difficult query: whether the money we spend on a particular portion of healthcare is *matched* by the benefit. We determine that by asking in turn whether, spent elsewhere, it could produce greater value of another sort, not just healthier or longer lives.

Both kinds of analysis are important. We want to get the most health and life for our investment in healthcare (CEA), but we also want neither to be so occupied with other investments that we ignore improvements in health that would be worth more to us, nor to pass up other things in life because we are investing too much in relatively unproductive healthcare (CBA). CEA is the less ambitious enterprise: We compare different healthcare services, detecting either final differences in expense to achieve the same health benefit or differences in some health benefit (for example, added years of life, and reductions in morbidity). That itself is a tall order, but it is less daunting than CBA. CBA is difficult, of course, because the advantages gained from such other investments often seem incommensurable with health and longevity. Improvements *within* healthcare, though, often seem terribly incommensurable, too: How do we really compare the values of non-life-extending hip replacement, for instance, and life-extending dialysis or transplants?

Formal, economic CBA puts into common *monetary* terms the various benefits of the endeavors in life that are being compared—a life saved with healthcare is seen to have a value, let us say, of $1 million. With the benefits thus monetarized, the conceptual package of resource trading is tied together; we are able to compare the benefits of healthcare and those of other endeavors with each other in the same terms (i.e., monetary ones). If benefits are assigned a monetary value, then, since costs have been stated from the beginning in monetary terms, we can ascertain straightforwardly whether the benefits are worth the costs. If, for example, it will likely take three $500,000 liver transplants to get one lifesaving success, and if a life saved has a monetary value of $1 million, then the transplants cost more than the life they save is worth. Whether we are achieving actual *value for money*—efficiency—now gets an explicit answer (though critics will doubt that we can ever sustain the judgment that a life saved has a monetary value of *only* $1 million).

Another, less formalized kind of analysis is *risk-benefit analysis*: One compares the probabilities of harm presented by a certain course of action with its likely benefits. If another procedure is likely to produce similar benefits with less risk, the latter is obviously preferable. It is not always clear, however, when one risk is *less* than another; the two may be risks of different things—one, say, of paralysis and the other of chronic pain. Moreover, one procedure may harbor lower risk but also promise fewer health benefits; again we are left with non-comparables. Unlike CEA, the beneficial effects in risk-benefit analysis are not all measured on a common scale, and unlike CBA, the benefits are not put in the same terms as the costs or risks.

We use the economic tools of CEA and CBA to discern potential improvements in efficiency. The existence of a

potential efficiency improvement, however, does not by itself tell us that we should pursue it. Efficiency is only one goal; we might also need to consider the fairness of distributing goods and resources in the most efficient way. Economists, though, will be quick to note efficiency's especially great moral force in two sorts of circumstance: where the new, more efficient distribution is *Pareto superior* (someone gains, and no one loses), or where the gain to some is sufficient to allow them to compensate the *losers* back to their reference point and still retain some net benefit for themselves. If, for example, so many people gain from water fluoridation that they are better enough off even after being taxed to provide a really ample compensation fund for those who suffer some side effect, then all, even the *losers,* gain by fluoridation.

Health Benefit Units: Well-Years or Quality-Adjusted Life Years (QALYs)

CEA, unlike CBA, does not venture answers to the question of how much money to spend for a given health benefit. It does, however, attempt ambitious as well as modest comparisons within healthcare. What it needs to be able to do this is a common unit of health benefit. In some contexts this will quite naturally be present; suppose we are comparing the respective prolongations of life provided by bypass grafts and coronary *medical management* (drug therapy). The more difficult task for CEA comes in translating widely different health benefits into a common conceptual currency. The notion developed for this purpose goes by various labels: a *well-year,* a *quality-adjusted life year* (QALY, pronounced to rhyme with *holly*), or *health-state utility.* The essential idea is a unit that combines mortality with quality of life considerations—*a year of healthy life,* as one defender of QALYs puts it. We can then compare not only life-prolonging measures with each other but also measures that enhance quality with those that prolong life—hip replacements with kidney dialysis, for example. And then we can also track the health of a population, calculating changes in per capita *years of healthy life.*

Having available a unit that combines mortality and morbidity will be immensely useful if we are trying to maximize the *health benefit* of a given amount of resources invested in healthcare. Suppose dialysis patients' self-stated quality of life is 0.8 (where 0 is death and 1.0 is normal healthy life). They would gain 8.0 QALYs from ten years on $40,000-a-year dialysis, a cost-benefit ratio of $50,000 per QALY. Suppose hip replacements improve fifteen years of life from 0.9 quality ranking to 0.99. That will be a 1.35 QALY gain for the $10,000 operation, a cost of less than $7,500 per QALY. To achieve greater efficiency, we apparently should expand the use of hip replacements and look toward reducing dialysis.

A sizable literature of CEA has developed, not only studies of particular procedures but also discussions about the construction of common units of health benefit. Take the QALY. Questions abound. Whom does one ask to discern quality-of-life rankings for different sorts of health states—patients with the problems, or other citizens and subscribers who are less dominated by their desire to escape their immediate health need? What questions do we ask them? Those building the QALY and well-year frameworks have used *time trade-off* (how much shorter a life in good health would you still find preferable to a longer lifetime with the disability or distress you are ranking?), *standard gamble* (what risk of death would you accept in return for being assured that if you did survive, you would be entirely cured?), and several others. Whatever question people are asked, it should convey as accurately as possible what might be called the *QALY bargain*: their exposure to a greater risk of being allowed to die should they have an incurable, low-ranking condition, in return for a better chance of being helped to significant recovery or saved for prospectively normal health.

The moral argument for using some such common health benefit unit is more than just some narrow focus on aggregate economic efficiency per se. The major moral argument by many health economists for using both quality adjustment and longevity extension in a serious attempt to maximize the benefit that a plan or an entire healthcare system produces is that it is people themselves who implicitly quality-rank their own lives and thus consent to the allocation priorities that QALYs or well-years generate. Critics charge, however, that maximizing years of healthy life in our lifesaving policies systematically fails to respect the individual with an admittedly lower quality of life. To what interpersonal trade-offs have people consented, even when it might involve themselves? Suppose you yourself now prefer, as you did previously, a shorter, healthier life to a longer, less healthy one. You are now an accident victim who could survive, though paraplegic, while someone else could be saved for more complete recovery. Admittedly, you yourself prefer a life with recovery to one with paraplegia, and you would be willing to take a significant risk of dying from a therapy that promised significant recovery if it succeeded. You do not admit, though (and you never have admitted), that when life itself is on the line, a life with paraplegia is any less valuable to the person whose life it is than life without that disability. *Compared with death,* your paraplegic life could still be as valuable *to you* as anyone else's *better* life is *to*

them—that is, you want to go on living as fervently as the nondisabled person does.

Some analysts, in attempting to incorporate points such as this and other ethical criticisms of QALYs, have emphasized a standard distinction in economics, that between individual utility and societal (or *social*) value. Individual utilities convey information about the welfare of an individual, while social values constitute preferences or evaluative claims about communities or relationships between persons. People hold social values, just as they also have preferences about their own lives. For example, they typically believe that those who are more severely ill should get a given healthcare service first before another who is not as severely ill, even if in either case the care produces equivalent improvement in those two persons' individual utilities. They also typically believe that even if the individual utility of a given number of years of life extension is arguably greater for someone in full health than it is for someone with a significant chronic illness, the value of saving either of their lives is equal. Using the *person trade-off* technique for eliciting such social values, some economists and policy analysts (Nord; Menzel et al) have argued for extending empirical value measurement to so-called *cost-value analysis* (CVA). Whether a model for health resource allocation developed along such lines will prove to be ethically superior to standard health economic analysis that focuses on individual utility units such as QALYs will undoubtedly be vigorously debated in the coming decade.

Common health benefit units will undoubtedly continue to be developed and used. Their contested character only indicates that the process of economic analysis into which they fit, systemwide CEA, is itself a morally contested vision for healthcare.

The Monetary Value of Life

CBA, in contrast to CEA, demands the assignment of monetary value to the benefits of a program or procedure. The health benefit whose monetarization has received the most explicit attention in the literature of CBA is life itself. Economic evaluation of life itself, as superficial and distorting as it may sound, is in one sense now an ordinary phenomenon. Now that a great number of effective but often costly means of preserving life are available, we inevitably and repeatedly pass up potential lifesaving measures for other good things, and money mediates those trade-offs. In CBA, however, one goes further and assigns a *particular* monetary value, or range of monetary values, to life. Is that value $200,000 or $2,000,000? Other questions abound. Is the monetary value of a relatively short remaining segment of life (a year, say) simply an arithmetic proportion of the whole life's value? If we assume that the length of different people's lives that remains to be saved or preserved is equal, is the economic value of their lives the same, or does it vary—for example, with income level, wealth, or future earning power? And if it does vary, should we still use those varying values or instead some common average in doing CBA of healthcare?

Independent of the debates on those questions, economists have developed two main models for translating empirical data into an economic value of life: discounted future earnings (DFE), also known as *human capital,* and willingness to pay (WTP). DFE looks at the future earnings forgone when a person dies. In the economy, those earnings are what is lost when a person dies, so that from the perspective of the *whole economy* (if we can speak of any such thing), it would be self-defeating not to save a life for $200,000 if the value of the person's earnings (after discounting the future figures back to present value) was more than that. While such DFE calculations continue to be used in some CBAs in healthcare, DFE has been largely surpassed in economists' work by WTP. In WTP the value of life is taken to be a direct function of people's willingness to use resources to increase their chances of survival. Suppose one annually demands an extra $500, and only $500 extra, to work in an occupation that runs an additional 1 in 1,000 risk of dying. Then according to WTP, $500,000 (1,000 × $500) is the monetary value one puts on one's life. Within the context of CBA, this would mean it would be inefficient to devote more than $500,000 per statistical life saved to healthcare that eliminates prospective risks of death.

In economic theory, WTP is generally regarded as the superior model; it captures the range of life's subjective, intangible values that DFE seems to ignore. Generally people spend money for reasons of subjective preference satisfaction quite independent of monetary return. That is, economic value incorporates consumption values, not just investment. Despite that firm basis in underlying economic theory, WTP has raised a host of objections. For one thing, questions arise similar to those that afflict DFE. Just as there are in DFEs, there are wide variations in willingness to pay—largely based on people's wealth and income. May those variations in value legitimately affect what is spent on lifesaving measures? If their effect is legitimate, is that only for services privately purchased, or also for those funded publicly? Defenders of WTP have articulated many responses to handle these and other critical questions, but the model may still seem suspicious. Any statement to the effect that "it was efficient not to save his life (now lost)—it was worth only $500,000" is not easily accepted. Consequently, despite its professional popularity, WTP has hardly gained widespread moral acceptance for actual use in health-policy.

The basic problem is simply that in the end the world is such a different place for a loser than it is for a winner. Suppose one refuses to pay more than $500 (when one could) for a CAT scan or magnetic resonance image (MRI) that one knows is likely to eliminate a 1-in-1,000 portion of the risk of dying from one's malady, and that then one later dies because of that decision. Of course one has in some sense consented to what happened, but one never thought anything remotely like "$500,000—no more—is the value of my life," the life that after the fact is irretrievably lost. The move that economists make in WTP to get from an initial trade-off between money and risk to the value of a real, irreplaceable life is puzzling. One critic has claimed that in principle only valuations of life made directly in the face of death are correct reflections of the actual economic value of life (Broome). And as another contributor to this discussion has noted, we do not know of anyone "who would honestly agree to accept any sum of money to enter a gamble in which, if at the first toss of a coin it came down heads, he would be summarily executed" (Mishan, p. 159–160). Some conclude from this that CBA can set no rational limit on what to spend to save a life because no particular finite amount of money is adequate to represent the real value of life.

Even if this point about the actual value of a life is correct, however, it may not render WTP estimates of the value of life irrelevant for use in health policy. In the context of setting policy about whether to include a certain service in our package of insurance, we cannot just assume that the later perspective of an individual immediately in the face of death is the correct one from which to make decisions. Such a perspective may be proper for the legal system to adopt in awarding compensation for wrongful death, for there we are trying to compensate people for losses actually incurred. But perhaps healthcare decisions ought to be made from an earlier perspective. In modern medical economies, after all, most people either subscribe to private insurance plans or are covered by public ones. Once insured, whether in private or public arrangements, subscribers and patients as well as providers find themselves with strong incentive to overuse care and underestimate opportunity costs. Why should we not address the problem of controlling the use of care in the face of these value-distorting incentives at the point in the decision process, *insuring,* where the major cost-expansion pressure starts? In the context of CBA for health policy, while it may not be necessary to claim that willingness to risk life shows us the *value of life,* willingness to risk may still be appropriate to use in any case. Perhaps what is important in decisions to invest resources in healthcare is only that what gets referred to as *the monetary value of the benefits* should be derived from people's decisions to bind themselves in advance to certain restrictions on the provision of care. The problem with WTP may then be narrower: Many of the *values of life* generated by WTP are not sufficiently close to the actual decisions of people to take risk by limiting their own investment in lifesaving. That would render any resulting CBAs that used them crude and ungrounded, but would not necessarily seal the fate generally of WTP-using CBA.

It is possible that as a formal method of analysis, CBA will never have great influence. Even if that is true, however, the larger enterprise of less formal CBA will remain an active and crucial dimension of the broader attempt to find the proper place of healthcare in our lives overall.

The Difficulties That Economic Concepts Pose for Clinical Practice

Suppose that economic efficiency analysis, whether of the CEA, CBA, or other less formalized sort, lays the groundwork for recommendations about the kind and amount of healthcare to use—fewer diagnostic MRIs in certain low-yield situations and very cautious introduction of new, expensive drugs, for example, and more hip replacements and much more assertive and widely diffused prenatal care. The former, service-reducing steps would not constitute the elimination of merely wasteful procedures that generate no net health benefit. They would constitute something much harder: *genuine rationing,* in which some patients did not get what for them would be optimal care. How does such rationing for efficiency relate to the ethical obligations of healthcare providers? The traditional (at least traditionally professed) ethic of physicians is one of loyalty to individual patients. Generally, in turn, that loyalty is interpreted to mean beneficence: doing whatever benefits a patient the most, within the limits of what the competent patient willingly accepts. If healthcare is to be rationed in order to control the resources it consumes, however, will the basic clinical ethic have to change? This potential clash between traditional ethical obligations and the economic and social demands of the *new medicine* in an age of scarcity is one of the central foci of ethical controversies in medicine as we enter the twenty-first century.

One can divide the potential views here into *incompatibilist* and *reconciliationist* camps: those who think that the demands of societywide (or at least large-group) efficiency cannot be reconciled with the ethical obligations of practitioners, and those who think they can be. The incompatibilists will end up in two different positions: (1) the "well, then, to hell with morality" view in which one is willing to pursue economic efficiency anyhow; and (2) the anti-efficiency stance that opposes rationing in the name of a morality of strict beneficence toward individual patients. Reconciliationist views will also come in distinctly different

sorts. (1) Parties more distant from the patient than clinicians should make all rationing decisions, and clinicians should then ration only within pre-determined practice guidelines—the separation-of-roles position. (2) As a provider, one's proper loyalty to a patient, though not dominated by efficiency, is to the patient as a member of a just society; this then enables the clinician to ration with a clean conscience if based on considerations of fairness and justice (Brennan). (3) Patients are larger, autonomous persons; rationing can then be grounded in the consent of the pre-patient subscriber to restrictions on his or her later care (Menzel, 1990). (Why would the patient consent?—to reserve resources for other, more value-producing activities in life.)

The strength of the incompatibilist views may seem to be that they call a spade a spade, but their abiding weakness is that they just dam up the conflict and create later, greater tensions. The reconciliationist views, on the other hand, deal constructively with the conflict and allow conscientious clinical medicine to find roots in a more cost-controlled, socially acceptable aggregate of healthcare. Their weakness may be the great difficulties they face in actual use. The separate-roles view requires extremely clear formulation of detailed care-rationing practice guidelines in abstraction from the medically relevant particulars of individual patients; by contrast, *bedside rationing* in which clinicians make substantive rationing decisions may be preferable and necessary (Ubel). The patient-in-a-just-society model requires a great degree of agreement on what constitutes a just society. And the prior-consent-of-patients solution requires not only accurate readings of what restrictions people are actually willing to bind themselves to beforehand but also a willingness of subscribers and citizens to think seriously about resource trade-offs beforehand and then abide honestly by the results even when that places them on the short end of rationing's stick.

Undoubtedly this discussion is not about to reach immediate resolution soon in societies that are enamored of ever-expanding healthcare technologies, pride themselves on respecting individual patients, and are determined to steward their resources wisely.

Externalities and Public Goods

Externalities and public goods play a prominent role in economics-informed discussions of public policy. Externalities are costs or benefits of a behavior not borne by or accruing to the actor, but by or to others. They pose a distinct problem for the achievement of efficiency in market economies. If I am making and selling an item whose production involves harms or burdens to others for which I do not have to pay, I will be able to price the product under its true cost and sell it more easily. The solution is to correct incentives by imposing a tax on the item equivalent to its external cost (or a subsidy equivalent to its external benefit). Even better, one could give the proceeds of that tax to the parties harmed by the item's use or production. Externalities, then, immediately propel us into public-policy decisions about taxes and subsidies.

Public goods also directly raise questions of public regulation and taxation. A *public good* in the economist's sense is one whose benefits accrue even to those who do not buy it. If you clean up your yard, I benefit from a somewhat better appearance on the block regardless of whether I clean up my own or help you clean up yours. Or if a large number of people contribute to an educational system in the community, I get some of the benefits of the more civilized culture and productive economy that result even if I never contribute anything. The benefit is thus public and nonexclusive: Once a certain mass of contributors is in place, it is difficult if not impossible to exclude from the benefits an individual who chooses not to contribute. Standard examples of public goods include many of the basic functions of the modern state (public safety, national defense, education, public health, and the reduction of pollution). Thus, public goods constitute a primary justification of the state's coercive power. If I contribute not a penny to a police force, for example, I will still receive most of its benefits; if not taxed, I can thus *free-ride* on others' willingness to fund public safety. The obvious solution is for the collective to tax me my fair share.

The use of both public goods and externalities is undoubtedly on the rise in discussions of healthcare. Note just two examples of the interesting contexts in which these concepts come up.

An example of externalities is the taxing of health-complicating products such as tobacco and alcohol. Smoking and excessive drinking undoubtedly increase certain costs to others—healthcare expenditures for smoking- and drinking-related diseases; lost work time; displeasure, sadness, and pain in dealing with others' destruction of their social and biological lives; and even direct loss of life (from passive smoking, drunk driving, etc.). These externalities provide part of the momentum behind the movement to increase taxes on tobacco and alcohol. Note, however, that the empirical picture can be much more complicated, and in the case of tobacco it certainly is. First-impression, informal cost analysis of smoking (and many published academic studies as well) leads us to think that smokers cost nonsmokers a great deal of money. That conclusion ignores, however, two hidden *savings* of smoking that accrue to others: Because smokers die earlier, and generally near the end of their

earning years or shortly thereafter, they save others the pension payouts and the unrelated healthcare expenditures they would have incurred had they lived longer, without losing that saving through significantly reduced earnings. One leading study, in fact, concludes that all the costs that smokers impose on others, including losses from fires and the costs of the U.S. tobacco subsidies justify only a cigarette tax of $.37 per pack (Manning et al.). The typically higher taxes that actually obtain in most states cannot then be justified by any empirically well-grounded externalities argument, nor can the state governments' claims to settlements of hundreds of billions of dollars from tobacco companies (Viscusi). This is not the last word on the net external costs of smoking, but it illustrates the subtleties and hidden costs that increasingly sophisticated economic analysis reveals. Economic analysis may turn up equally surprising results in the future as we turn increasingly to prevention in the hope of controlling healthcare costs; prevention that saves healthcare expense in one respect may lose those gains as its longer-living beneficiaries draw more pension payouts and end up incurring higher aggregate costs of illness in their longer lives.

An example of public goods is sharing in the costs of a healthcare system that provides access to those who otherwise cannot pay. Suppose most people think a good society provides basic care to those who cannot afford it, and that they believe that the financial burdens of the medical misfortunes that people cannot have been expected to control by their own choices ought to be shared equally by well and ill. It is then possible to analyze the situation in the traditional and conservative terms of public goods and the prevention of free-riding. If a considerable amount of charity care is societally provided and access is thus improved, I gain both the security of knowing that I will be helped if I become poor or sick, and the satisfaction of knowing that I live in a society that does not neglect its poor and ill. If I do not contribute financially to make this more secure and arguably better society possible, I free-ride on the largess of others. This free-riding situation generates an essentially conservative justification for requiring people to pay into an insurance pool even when they think they are safe.

Many other interesting and controversial instances of the use of these and other economic concepts in the analysis of healthcare could be cited. Without being targeted accurately on identifiable pockets of market failure, tax breaks for health-insurance premiums would seem to create incentives for inefficient overinvestment in healthcare. If physicians significantly create demand for their own services, their incomes will need to be regulated either by the government or by market forces at work among health plans using salary or capitation payments (as distinct from fee for service) to compensate physicians. And so on and so forth. More generally, how to discern what constitutes efficiency in the investment of resources in healthcare, how to arrange incentives to stimulate efficient use of care, and how the achievement of efficiency is to be compared with the realization of other values central to the whole healthcare enterprise constitute the challenge that economic concepts bring to healthcare in the twenty-first century.

ELECTROCONVULSIVE THERAPY

• • •

Electroconvulsive therapy (ECT) is a highly efficacious treatment in psychiatry (Crowe, Abrams), and yet there is ethical controversy about its use. Some have claimed that ECT should be outlawed because it seriously impairs memory; others, that ECT is best viewed as a crude form of behavior control that psychiatrists frequently coerce patients to accept. Still others claim that, even if coercion is not employed, depressed patients are rarely, if ever, competent to give valid consent to the treatment (Breggin). The complaint is also sometimes voiced that ECT is given more frequently to women patients than to men. There is also ample evidence that, in earlier years, ECT was given in ways that are not used today: higher amounts of electrical current, and sometimes daily or several-times-daily treatments. Undoubtedly, this harmed some patients (Breggin). Probably because of concerns like these, one state, California, has passed legislation making it difficult for psychiatrists to employ ECT without satisfying many administrative regulations (California Welfare and Institutions Code). There also exist several activist groups that are opposed to all ECT and have even tried to criminalize the administration of ECT. Daniel Smith provides an excellent summary of these groups's arguments and activities in his 2001 article "Shock and Disbelief."

The nature of the treatment itself understandably frightens some persons, and there have been gruesome depictions of it in popular films and novels (Kesey). The notion of passing an electrical current through the brain, stimulating a cerebral seizure and causing unconsciousness, may seem forbidding, particularly in view of the fact that ECT's therapeutic mechanism of action remains largely unknown. There are, however, many effective treatments in medicine whose mechanisms are unknown, and there are probably many surgical treatments that would seem equally forbidding if they were observed by a layperson. In appraising the ethical legitimacy of ECT as a treatment, it is important to ask the same questions about ECT that are asked about any treatment: Of what does it consist, what is the likelihood that it will help, what kinds of harm can it cause; and how does its spectrum of benefits and harms compare with those of alternative plausible treatments?

ECT Treatment

There are several excellent reviews of the history, clinical indications, and likely harms and benefits of ECT (Abrams; American Psychiatric Association Task Force on Electroconvulsive Therapy (APA Task Force); Crowe; Ottosson). The essential feature of the treatment is the induction of a cerebral seizure (which is easily measured via concomitant electroencephalography) by means of electrodes attached to the scalp. Current is applied through the electrodes for a fraction of a second. The two electrodes may

be attached to the right and left temples (bilateral ECT), inducing a seizure in both hemispheres of the brain, or to anterior and posterior placements on only one side (unilateral ECT), limiting the seizure to that side. Patients are premedicated with a muscle relaxant and anesthetized with a short-acting barbiturate general anesthetic. Patients remain unconscious after the treatment for about five minutes and are usually mildly confused for an hour or so after they awaken. They have no memory of the treatment itself. Treatments are usually given two or three times weekly for two to four weeks.

ECT was used originally as a treatment for schizophrenia on the basis of the now-discredited belief that epilepsy, which ECT was thought to mimic, and schizophrenia did not occur in the same persons. It is used chiefly with patients suffering from severe depression; most psychiatrists suggest its use to patients only when drug treatment and/or psychotherapy have not helped. ECT is also used occasionally with bipolar patients suffering from a life-threatening degree of manic excitement, or to schizophrenic patients suffering from a catatonic stupor, when these conditions do not improve with drug therapy.

Efficacy and Side Effects

The effectiveness of ECT in reversing severe depression seems beyond dispute (Abrams; Crowe; APA Task Force): Many large studies show a significant recovery from depression in 80 to 90 percent of patients who receive ECT, as compared with 50 to 60 percent of depressed patients who respond to antidepressant medication. Patients who do not respond to drugs show a high response rate to ECT: about 50 to 60 percent recover. No study comparing the differential effects of drugs and ECT has ever found that drugs have a greater therapeutic effect. ECT also works more quickly than drugs: Patients who improve typically begin to do so after about one week; drugs, if they work, typically take three to four weeks, sometimes longer, to have a significant effect. Many studies have shown that unilateral and bilateral ECT are equally effective treatments, although a minority have found unilateral ECT to be on average less effective. However unilateral ECT also causes, on average, less cognitive confusion during treatment and less residual memory impairment afterward.

Although ECT can cause death, it does so infrequently that it is difficult to reliably estimate a mortality rate. The largest modern report (Heshe and Roeder) studied 3,438 courses of treatment (22,210 ECTs), and only one death occurred. The APA Task Force estimates a death rate of 1 in 10,000 patients and 1 in 80,000 treatments. When ECT does cause death, it is usually cardiovascular in origin and is related to the use of a general barbiturate anesthesia.

The principal adverse effect of ECT on some patients is to cause one or another kind of memory impairment. Two of these kinds of memory impairment are limited. During the two to three weeks that treatments are given, memory and other cognitive functions are usually mildly to moderately impaired because of the ongoing seizures. Moreover in later years patients are often unable to recall many events that took place shortly before, during, and shortly after the two- to three-week course of treatment. Neither of these effects bothers most patients, as long as they understand ahead of time that they will occur.

The more important and controversial question is how often ECT causes an ongoing, permanent deficit in memory function (an anterograde amnesia). If and when it does, it is possible that the treatment has damaged parts of the brain underlying memory function. This has proven to be an elusive research problem, despite dozens of studies, many quite sophisticated, that have been carried out (Taylor et al., Abrams). Among the many methodological problems involved in doing this research (Strayhorn) is the fact that depression itself often causes cognitive impairment, including memory dysfunction. In fact studies of the effect of ECT on memory have repeatedly shown that the majority of patients actually report improved memory function after ECT, probably due to the diminution of their depression (APA Task Force).

A small minority of patients—the exact percentage seems unknown—do report mild, ongoing, permanent memory problems after ECT; nearly all of them rate the memory problem as annoying but not serious. However, when patients treated with ECT are compared with appropriate control groups, no deterioration in performance on objective tests of memory ability has ever been found. Nonetheless a very small number of patients, perhaps 1 to 2 percent, complain of serious ongoing memory problems. Memory complaints occur more frequently after bilateral than unilateral ECT, which has led many commentators to recommend that unilateral treatment generally be given, and that bilateral treatment be used only in serious conditions and after unilateral ECT has failed.

Ethical Issues

Is ECT so harmful that it should be outlawed? Very few persons maintain this position. ECT has an extremely small risk of causing death. It probably also has a small risk of

causing chronic mild memory impairment, and a very small risk of causing chronic serious memory impairment. It is frequently used, however, in clinical settings where other treatments have failed and where the patient is suffering intensely and may be at risk of dying. Severe depression is a miserable and a serious illness: The three-year death rate in untreated or undertreated patients is about 10 percent, while in treated patients, it is about 2 percent (Avery and Winokur). Even if the risks of ECT were substantially greater than they are, it would still be rational in the clinical setting of severe depression for patients to consent to receiving ECT.

As with all other treatments in medicine, the possible harms and benefits of ECT should be explained to the patient during the consent process. The risk of death and of chronic memory dysfunction should be mentioned specifically. The APA Task Force also stipulates that a discussion should be included, during the consent process, "of the relative merits and risks of the different stimulus electrode placements and the specific choice that has been made for the patient. The patient's understanding of the data presented should be appraised, questions should be encouraged, and ample time for decision making should be allowed. Patients should be free to change their minds about receiving ECT, either before the treatments start or once they are under way" (pp. 5–6).

ECT is often suggested to patients only after other treatments have failed. However, although it has slight risks, ECT has several advantages over other treatments: It works more quickly, in a higher percentage of cases, and it does not have the annoying and, for some cardiac patients, possibly dangerous side effects of many antidepressant drugs. Following the general notion that part of an adequate valid consent process is to inform patients of any available rational treatment options (Gert et al.), a strong argument can be made that, from the outset of treatment, seriously depressed patients should be offered ECT as one therapeutic option (Culver et al.). The APA Task Force states: "As a major treatment in psychiatry with well-defined indications, ECT should not be reserved for use only as a *last resort.*"

Do psychiatrists often coerce patients into receiving ECT? This seems doubtful, but there are no data addressing this question. In the overwhelming majority of cases, psychiatrists should not force any treatment on a patient. Nonetheless there are very rare clinical situations in which it is ethically justified to give ECT to patients who refuse it (Group for the Advancement of Psychiatry): for example, patients in danger of dying from a severe depression that has not been responsive to other forms of treatment (Merskey). But this is a special instance of the general ethical issue of justified paternalistic treatment, and no special rules should apply to psychiatric patients or to ECT (Gert et al.).

There seems no reason to believe that the consent or the refusal depressed patients give to undergo ECT is not in most cases valid. If a patient is given adequate information about the treatment, if he or she understands and appreciates this information, and if the patient's choice is not forced, then the decision is valid and, in almost all cases, should be respected. Most psychiatrists would assert that the great majority of depressed patients are like the great majority of all patients: They feel bad, they would like to feel better, and if presented with information about available treatment options, they try to make a rational choice.

Is ECT disproportionally and unjustly given to women patients? There are no data that address this question, and it would be useful to obtain them. However, given the fact that women suffer from clinically significant depression two to three times more frequently than men (Willner), the critical question is not whether more women in total receive ECT, as would be expected, but whether ECT is given at a higher rate to women than to equally depressed men.

EMBRYO AND FETUS

• • •

I. DEVELOPMENT FROM FERTILIZATION TO BIRTH

The ethical relevance of studying human development appears when one asks which stages of the human life cycle embody significant ethical concerns. Between birth and death, the human organism is a person, equipped with the full measure of basic human rights. This much is not really controversial, and the debate primarily concerns the prenatal phase of development. Do human rights accrue to the unborn all at once, for instance at fertilization? Do they instead arise in a gradual manner, based on the various progressive steps through which the prenatal human organism acquires significant person–like properties? Besides personal rights, are there other ethically–significant values and properties that would justify a respectful treatment of embryos and fetuses? An understanding of prenatal development is a necessary, albeit in no way sufficient, condition for addressing these issues successfully.

To understand the basic biology of any sexually reproducing organism, one needs to grasp the primary concept of the life cycle. The life cycle of humans includes fertilization, cleavage, gastrulation, organogenesis, fetal development, birth, child development and puberty, gametogenesis and again fertilization. It is through the germ–line that the life cycle persists from generation to generation. On the other hand, the somatic cells (which comprise all the cells of the fetus, child, and adult that are not directly involved in reproduction) belong to an inherently mortal entity, the human organism, whose fate is senescence and death. One turn of the life cycle defines one generation. Fertilization and birth define the beginning and end of the prenatal phase of development, which is comprised of two stages: embryonic and fetal.

The embryonic phase initiates with fertilization, the meeting of the male (sperm) and female (oocyte) gametes, giving rise to the zygote. At fertilization, a new, diploid genome arises from the combination of the two haploid genomes included in the gametes. The zygote divides several times (cleavage stage) to form a blastocyst. The cells of the blastocyst, called blastomeres, are separated into two parts: an outer layer, called the *trophoblast,* that eventually contributes to the placenta; and an inner cell mass that contributes to the future embryo. About six days after fertilization, the blastocyst attaches to the endometrium (the epithelial lining of the uterus). This marks the beginning of pregnancy and further development depends on intricate biochemical exchanges with the woman's body. While the trophoblast invades the uterine wall, the inner cell mass undergoes further stepwise differentiation processes that lead to the formation of the embryonic epiblast (the precursor of the actual human individual) and several extraembryonic structures (Figure 1). The embryo then undergoes gastrulation, the process that starts with the formation of the *primitive streak.* This is the crucial developmental step, common to all

animals but the most primitive invertebrates, by which the three basic germ layers of the embryo are formed. These are called ectoderm, mesoderm, and endoderm.

From the third to the eighth week, the process of organogenesis involves the differentiation of the three germ–layers into specific tissues and primordial organs. The earliest stage in organogenesis is called neurulation and starts when a specific area of ectoderm turns into the primordium of the nervous system. During organogenesis, many genes that are crucial to development are activated, and complex cell–to–cell signals insure the proper differentiation of various cell types, as well as the movement and migration of cells to their proper places in the developing embryo. For some cell types, this involves long–range navigation. For instance, the gamete precursors must travel from their initial position near the yolk sac to the primordial gonads.

At the end of the embryonic phase, many important organ systems are in place, at least in rudimentary form. The fetal phase is characterized by further differentiation and maturation of tissues and organs, as well as considerable growth, especially towards the end of pregnancy. In the late fetal phase, the nervous system undergoes an acceleration of synapse formation and maturation of the brain, which is increasingly sensitive to outside cues. This process continues well after birth.

Specific Developmental Stages in Detail

Especially in early development, specific developmental processes seem more meaningful than others in the ethical debate about the moral status of human prenatal life. These are described in more detail.

GAMETOGENESIS AND FERTILIZATION. The embryo is usually defined as coming into existence at fertilization and becoming a fetus when organogenesis is completed (eight weeks after fertilization). These borders are not sharply defined. The definition of an embryo thus cannot avoid being operational and context–dependent. The term *conceptus* is useful to denote any entity resulting from fertilization, when no reference to a more specific stage is intended. An additional complication results from the significant overlap between the final stages of female gametogenesis, fertilization, and initial cleavage.

Gametogenesis involves a special type of cell division called meiosis. When primordial germ cells (which are diploid—i.e., they have two complete sets of chromosomes) enter meiosis, their DNA is duplicated so that there are now four copies of each type of chromosome (a condition called tetraploidy). In the first meiotic division, there are genetic exchanges within each group of homologous chromosomes, which then separate into diploid daughter cells. In the second meiotic division, there is no further round of DNA duplication. Each chromosome in a pair is allotted to a separate daughter cell, now haploid. Each primordial germ cell thus gives rise to four daughter haploid cells.

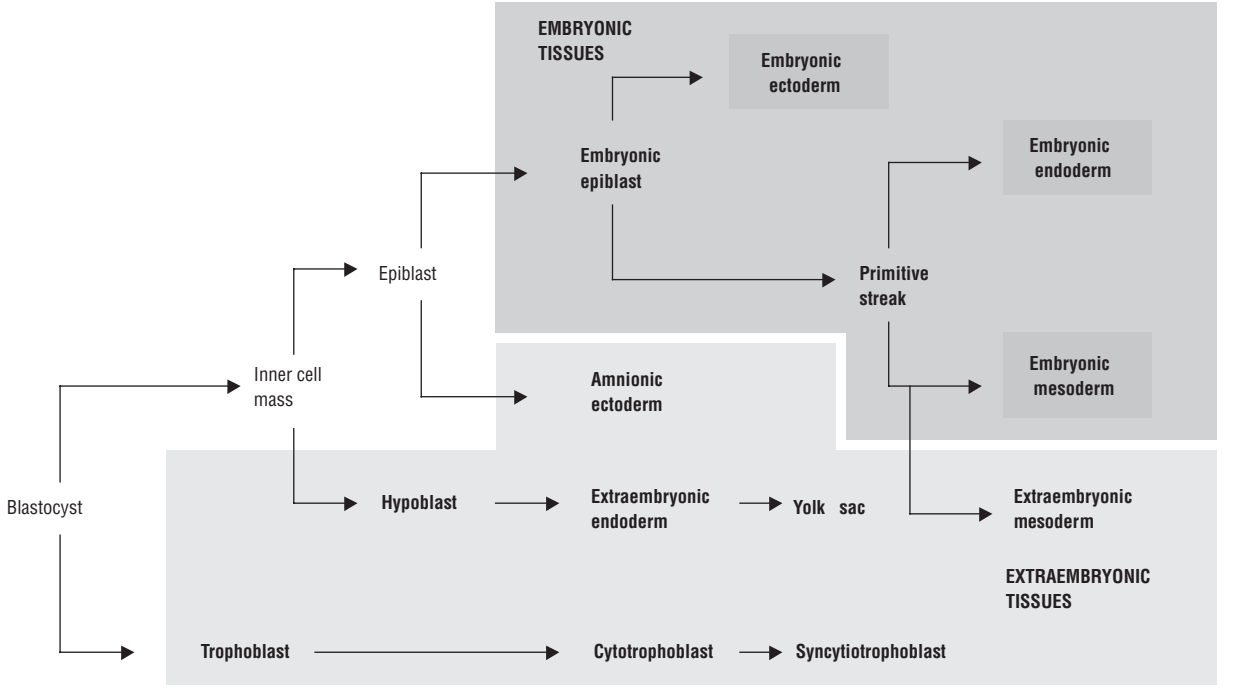
In the male, all four cells resulting from meiosis ultimately become functional spermatozoa. In contrast, in the female, only one of the daughter cells becomes an oocyte, the other three cells are discarded as polar bodies. In addition, female meiosis is not completed until after fertilization has occurred. During each ovarian cycle of the sexually mature female, one oocyte progresses partially through meiosis but is arrested in the middle of the second meiotic division at the time it is discharged from the mature ovarian follicle into the oviduct. If the oocyte is fertilized, meiosis is completed. Within the newly fertilized egg, the male and female pronuclei undergo a protracted migration towards each other, while DNA is duplicated within both. Thereafter, both nuclear envelopes disappear and the chromosomes derived from the male and female gamete are involved in the first cleavage division. Thus the first genuine diploid nucleus is observed at the two–cell stage only (30 hours after initial contact of sperm and oocyte). While fertilization usually occurs close to the ovary, the conceptus is gently nudged towards the uterus, a voyage lasting about five days.

Both through recombination of gene segments during the first meiotic division, and through random assortment of homologous chromosomes in gametes, genetic novelty is generated. In other words, gametes are genetically distinctive in relation to their diploid progenitors and do not simply reflect the genetic structure of their parent organism. In a sense, gametes are distinctive "individuals" in relation to the organism that produces them. Fertilization creates genetic novelty of a different sort, by combining two independent paternal genomes. The zygote is genetically distinctive because it represents the meeting of two independent parental lineages. Thus genetic novelty appears twice per turn of the human life cycle.

CLEAVAGE, PLURIPOTENTIALITY, AND TWINNING. During cleavage, the zygote divides into smaller embryonic cells. At the 16–cell stage, the embryo is called a morula and a first differentiation into two cell types is initiated. The trophoblast is the cell layer that will soon connect with the uterine wall, whereas the inner cell mass includes the cells of the later stage embryo. At the blastocyst stage, a central cavity (blastocoel) is formed. If a blastomere is removed from the inner cell

FIGURE 1

Derivation of Tissues in Human Embryos



SOURCE: Gilbert, 2000.

mass of a blastocyst (as, for instance, in preimplantation diagnosis), the blastocyst is still able to produce a complete late embryo and fetus. This illustrates a fundamental principle called regulation, or regulative development. Within the early embryo, cell fates are not definitely fixed but largely depend on interactions with neighboring cells, so that development adjusts to the presence or absence of specific environmental cues. The molecular basis and the genes responsible for these cues are increasingly well known.

At the blastocyst stage, the inner mass cells are pluripotent (i.e., they have developmental plasticity) and are able to participate in the formation of most cell types of the adult organism, as shown for instance by experiments with cultured immortalized blastomeres, called embryonic stem cells. Recent research does suggest that individual blastomeres acquire some degree of molecular specificity quite early. However, this inherent "bias" that tends to drive every blastomere towards a specific cellular fate can easily be overridden at this stage.

Around day 6, the blastocyst has hatched from the surrounding zona pellucida (the outer envelope of the ovum) and is ready for implantation. As it attaches to the endometrium, two distinctive layers appear in the inner cell mass. The ventral layer (hypoblast) contributes to the primitive yolk sac. The dorsal layer soon differentiates between the embryonic epiblast that will contribute to the embryo–to–be, and the amniotic ectoderm lining the newly appearing amniotic cavity (day 7–8). This two–layered structure is called the embryonic disk. All this happens as the blastocyst burrows deeper into the uterus wall and the trophoblast comes into close contact with maternal blood vessels. The trophoblast also produces human chorionic gonadotropin (hCG), which is the substance detected in pregnancy tests and is essential to the maintenance of pregnancy. Abnormal conceptuses are very common until that stage and are eliminated, usually without detectable signs of pregnancy. Inversely, fertilization occasionally results in a hydatidiform mole. This structure consists of trophoblastic tissue and therefore mimics the early events of pregnancy (hCG is produced), without their being any actual embryonic tissue present.

The term *pre–embryo* was often used to mark the embryonic stages described so far. This term is sometimes shunned in contemporary discourse, as it has been suspected

to be a semantic trick to downgrade the standing of the very early embryo. Yet even writers like Richard A. McCormick belonging to the Catholic tradition, sets great store by the moral standing of the earliest forms of prenatal development, have expressed doubts about the validity of this suspicion (1991). More importantly, doing away with the term "pre–embryo" does not solve the two underlying conceptual problems that this term addresses. The first ensues from the cellular genealogy linking the zygote to the later stage embryo and fetus. Only a small part of the very early embryo is an actual precursor to the late embryo, fetus, and born child. Whatever terminology one wishes to use, no account of early development can avoid sentences such as this, written by Thomas W. Sadler in 2000, "[t]he inner cell mass gives rise to tissues of the *embryo proper*," or terms such as the *embryo–to–be.* This is an inescapable consequence of the fact that the late embryo includes only a small subset of all the cells that originate with the zygote and blastocyst (Figure 1 shows the complex genealogy of embryonic and extraembryonic tissues in human development). The second problem arises from the fact that the early embryo has a degree of freedom as regards its final numerical identity. Until about 12 days after fertilization, twinning can occur. In other words, until that stage, a single embryo still has the potential to divide in two embryos, ultimately developing into two separate persons. Therefore there is no intrinsic one–to–one relationship between the zygote and the late embryo, as there is between the late embryo, the fetus, and the born human.

GASTRULATION. Gastrulation begins with a wave of cellular movements that start at the tail end of the embryo and extend progressively forward. Future endoderm and mesoderm cells slip inside the embryonic disk through a groove called the primitive streak (day 14). The anterior end of the streak is called the node. Of the cells that migrate inside the streak, some form the endoderm and others will lie atop the endoderm and form the mesoderm. Finally, those cells that remain in their initial position on the surface of the embryonic disk become the ectoderm. Gastrulation sets the overall organization of the embryo in a definitive way. The main axes (anterior–posterior, left–right) are defined under the control of two central signaling centers: the node (which is the equivalent of the organizer discovered by embryologists working on frog and chick embryos) and the anterior visceral endoderm.

Recent data from molecular genetics have partially uncovered the molecular basis of axis determination. The determination of the anterior–posterior axis involves the HOX genes, a set of four gene complexes. Since HOX genes located at the "front end" of a HOX complex are expressed at the "front end" of the embryo, the arrangement of the various genes within each complex remarkably reflects the place at which they are expressed in the embryo along the anterior–posterior axis. The four HOX complexes thus provide four "genetic images" of the lengthwise arrangement of embryonic structures. The left–right asymmetry of the embryo (and thus of the future body plan) is thought to originate with specific cells in the node. In a way that is not fully understood, these cells induce a cascade of protein signals that is different on the left and right side of the embryo. This results in the synthesis of controlling factors that are laterally restricted. It is supposed that these controlling factors and other factors direct the development of asymmetric organs accordingly.

Through gastrulation, the embryo arises as a defined entity endowed with a much higher level of organic unity than at any stage before. The laying down of the head–to–tail axis and other defined spatial features, as well as the loss of pluripotentiality in many cell lineages, mark the beginning of a single individual human organism and thus provide one of the first important dimensions of the ontological continuity typical of the born human.

LATER DEVELOPMENTAL STEPS. In the initial step in organogenesis, the midline axial section of mesoderm—the notochord—instructs the overlying ectoderm to turn into the neural plaque. This structure soon wraps around to form the primitive neural tube, out of which the central nervous system will eventually grow. By the beginning of the fetal period (eighth week), the rudiments of the heart, blood and blood vessels, the major segments of the skeleton and associated muscle groups, the limbs, and many other structures are in place. It is noteworthy that although the primordial nervous system is one of the earliest organ systems to emerge in development, it takes the longest time to mature. Synaptogenesis (the formation of –contacts between nerve cells) starts on a grand scale only late in pregnancy and continues well after birth. This is important to keep in mind when interpreting early movements of the fetus, visualized more and more accurately by ultrasonography. These movements reflect the maturation of local neuromuscular structures and are not due to significant brain function, since there is no "brain" in the sense of the later, much more developed anatomic and functional structure called by that name. This is different later in pregnancy, when fetal movement is more reactive to the environment and when it becomes arguably legitimate to interpret it as "behavior," insofar as it reflects the increased functional capabilities of the central nervous system. Finally, the concept of *viability* basically reflects the ability of fetal lungs and kidneys to

support extrauterine life, which is impossible before the twenty-second week.

As mentioned before, the differentiation and migration of early gametes also occurs during the embryonic phase. This separation of the germ cell lineage from all other cell lineages marks a bifurcation in the life cycle. Unlike somatic cells, gamete precursors have a chance of becoming gametes and participating in fertilization, thus contributing to the next generation. In a way, the germ cell lineage is eternal through successive turns of the life cycle, whereas the rest of the embryo, the sum total of somatic cells, is inherently mortal.

Extracorporeal Embryos

Science fiction fantasies about the artificial uterus notwithstanding, only the very first stages of human development can occur outside the female body. Since 1978, in vitro fertilization followed by embryo transfer has been a common treatment of fertility problems. The growth of ovarian follicles is stimulated by the administration of gonadotropins. Oocytes are then collected by laparoscopy and placed in an appropriate culture medium. Sperm is added and cleavage occurs in culture until the blastocyst is transferred in the uterus.

With in vitro fertilization, the early embryo became much more accessible to human intervention, and this has raised ethically perplexing possibilities. Interventional research on early embryos has become possible, raising the question of whether it is ethical to produce human embryos for research purposes, or whether research should be done, if at all, only on "spare" embryos. These occur when some embryos are no longer needed for fertility treatment, even though they resulted from in vitro fertilization performed with therapeutic intent. Additionally, progress in genetic testing techniques using very small amounts of DNA has made preimplantation diagnosis of genetic abnormalities possible. Single blastomeres are removed from in vitro blastocysts, their DNA amplified by polymerase chain reaction (PCR), and subjected to genetic tests with appropriate DNA probes. (Thanks to regulative development, the missing blastomere is soon compensated for.) In this way, embryos can be screened for certain genetic defects and only those free of defects chosen for embryo transfer. This procedure is sometimes suspected of being eugenic, and the controversy around it has led to it being outlawed in certain countries including Germany and Switzerland.

Developmental Steps and Moral Status

The biological processes around fertilization and early embryonic development are often accorded considerable relevance in ethical debates, making a detailed description of these processes necessary. This descriptive effort, however, is not based on the belief that "the facts speak for themselves." They emphatically do not. In fact, many ethical controversies about the ethics of in vitro fertilization, embryo research, therapeutic cloning, abortion and the like, are less about ethics in the strict sense as they are about expressing divergent interpretations of biology. The marshalling of biological fact to support apodictic statements of moral status involves many, usually unspoken, "bridge principles." These principles involve highly complex notions, such as unity, individuality, potentiality, and continuity. It is a common misconception that these theoretical concepts constitute stable, common–sense notions that are merely applied to biological entities and processes. In actuality, these concepts are themselves given new meanings and qualifications in the very process of using them to make sense of biological facts. Between the realm of ontological categories and the empirical domain of biology, there is a two–way street.

It is often said that "human life begins at fertilization." Strictly speaking, this statement is meaningless. Human life does not begin at any point of the human life cycle; it persists through successive generations. The ethically relevant question to ask is at what stage a human individual is first endowed with important ethical value and correlative rights against harm. The difficulty is that no particular step stands forth as a self–evident developmental marker, both because developmental events that appear as sharp discontinuities turn out to be protracted processes upon closer scrutiny (for instance, fertilization is a process, not an instantaneous event), and because the highlighting of one developmental process over another necessarily involves more or less plausible philosophical assumptions.

Three different concepts of individuality appear to be relevant:

- genomic individuality as established trough fertilization;
- numerical identity, defined once twinning is no longer possible;
- identity of the self, as sustained by a functional central nervous system.

Fertilization is important because it newly connects two parental lineages that were independent until then. The meeting of sperm and oocyte gives rise to a uniquely novel diploid genome that is not subject to further change. It will be the genome of the future person or persons arising from this particular fertilization. This fact is often misinterpreted according to a hylomorphic interpretation of the genome, where the latter becomes the formal cause of the future human being (Mauron). (Hylomorphism is the aristotelian and scholastic teaching that concrete objects, especially

living things, result from a combination of form [morphê] and substance [hylê].) This interpretation suggests the notion that fertilization is the single crucial step, since the new genome appears at that point. This interpretation fails, not only because of the inherent conceptual problems of the hylomorphic view, but also because there exist biological facts such as twinning and genetic mosaicism that show that there is little connection between genomic individuality as such and personal identity. Monozygotic or identical twins are separate persons, even though they share "the same" genome, that originated from "the same" fertilization. This shows that genomic individuality does not provide any basis for the most essential property of personal identity, namely numerical identity through time. To be one and same person through changes in one's biography is an essential ingredient of any workable concept of the person, and the biological basis for this property does not originate before gastrulation. In fact, much of the organic singularity and coordinated functioning as one organism (rather than several potential organisms) is established only at that stage.

However, one may want a richer interpretation of this basic criterion of personal identity. Having a biography of one's own is not just being the same individual through time, but also experiencing a continuity of mental states, which is linked to an at least minimally–functioning central nervous system. In fact, nothing is more central to the modern conception of the self than the functional persistence of a central nervous system that provides the material substrate of an individual subjective biography. For this biographical, or subjective, identity, it is difficult to quote a definitive starting point. It is plausible to place it in late pregnancy, when the earliest possibility of a continuing self seems to be given, but there is no absolute certainty in this claim.

Conclusion

Ethical reasoning on this topic often shows a common pattern: one takes moral concepts that belong to uncontroversial persons (such as grown humans) and tries to apply them backwards to the fetus and embryo. However, importing intuitions pertaining to the ethics of personal rights and interests onto various forms of prenatal life is increasingly fraught with conceptual difficulties as one moves towards earlier stages. Indeed, the most perplexing problem in bridging human developmental biology and statements of moral standing is perhaps that traditional moral categories tend to be "all–or–none" concepts (either one is a person or not, and if so, one is equal in basic rights to all persons), whereas developmental biology shows mostly gradual change and tends to resolve what appear to be discrete borders into continuities. One obvious and popular answer to this quandary is to make ethical standing a gradually increasing property of the developing human organism. On the other hand, one may query the underlying assumption that there is a one–dimensional measure of ethical concern. Further reflection may benefit from a recognition that ethical concerns about human prenatal life are multidimensional, and sometimes qualitatively, not just quantitatively, different from the person–centered systems of ethical values and duties.

II. EMBRYO RESEARCH

In previous editions of this encyclopedia, the topic of embryo research was included within the entry on fetal research. However, during the latter part of the twentieth century the issues arising from research involving in vitro fertilized embryos became sharply distinguished from issues in research with already-implanted fetuses. Moreover, new

technologies such as the development of embryonic stem cells and the possibility of human cloning raised new ethical concerns in relation to research involving human embryos.

This entry will address the history of human embryo research, public policy on embryo research in the United States and internationally, moral considerations, particularly the debate on the moral status of the human embryo, and the relevance of ethical distinctions that have been proposed, such as the distinction between research use of surplus embryos versus embryos created specifically for research.

The Research Subject

Scientifically the product of conception is called an *embryo* until eight weeks of gestational age, when the name changes to *fetus.* However, contemporary discussions of embryo research customarily restrict the term embryo to the earliest stages of human development before implantation in the uterus occurs. This terminology is supported by the U.S. federal regulations on fetal research, which define the fetus as "the product of conception from implantation until delivery," thus excluding non-implanted embryos from the regulations (45 CFR 46.202).

In practical terms the embryo as subject of research is the embryo in the laboratory, generally the result of in vitro fertilization (IVF), but possibly developed by other means, for example, through flushing naturally-fertilized eggs from the fallopian tube, or through somatic cell nuclear transfer (SCNT) of a body cell into an enucleated egg, a type of cloning procedure.

A variety of terms has been proposed for the embryo as subject of research:

the *preembryo,*
the *preimplantation embryo,*
the *embryo ex utero,*
the *early embryo.*

In this entry the simple term *embryo* will be used, with the understanding that it refers to the embryo in the laboratory that has not undergone transfer to a woman. Some commentators maintain that only embryos resulting from fertilization of eggs by sperm are properly called embryos. This question will be addressed in later sections when it is relevant.

Early History of Embryo Research

Until the 1990s most research involving human embryos was directed toward improving the chances for pregnancy in laboratory-assisted conception. These investigations, in turn, were based on many years of research with animal models, where virtually all research in the United States has been supported with federal funding. It was hoped that procedures developed in animal studies could later be applied to human reproduction and embryology, especially to the understanding and alleviation of human infertility.

Attempts at laboratory fertilization of human oocytes (precursor eggs) showed some promise as early as 1944 in the work of American obstetrician-gynecologist John Rock and scientist Miriam Menkin. From that time until the birth of the first child conceived through IVF in 1978, various approaches were tried in order to achieve a pregnancy and live birth. The work of Robert Edwards, British reproductive endocrinologist, culminated in the birth of Louise Brown after he collaborated with Patrick Steptoe, an obstetrician who utilized laporoscopy for viewing and recovering a mature ovarian follicle containing an oocyte capable of fertilization.

According to embryologist Jonathan Van Blerkom, most current methods used in laboratory-based treatment of infertility have evolved from those used by Edwards and Steptoe and their predecessors. According to Van Blerkom, this work "established the basic science foundation of clinical IVF" (p. 9). Without these four decades of research on fertilizing oocytes, accompanied by study of the early cleavage and development of fertilized eggs or zygotes, the clinical practice of IVF, which is an almost universally accepted primary treatment for infertility, would not exist.

U.S. Funding and Regulation of Embryo Research

In 1975 the U.S. National Commission for the Protection of Human Subjects recommended guidelines for federal funding of research involving human fetuses, but stipulated that these guidelines did not cover research on IVF or on embryos resulting from IVF. It proposed that an Ethical Advisory Board be appointed to review such protocols, and this recommendation was incorporated into federal regulations. In 1978 an Ethics Advisory Board (EAB) was appointed to recommend a policy on federal funding for research involving IVF.

In its 1979 report the EAB concluded that research on IVF was ethically acceptable for federal funding under these conditions: that all federally funded research is directed toward establishing the safety and efficacy of IVF; all gametes used to develop embryos in research protocols are provided by married couples; and no embryos are preserved in the laboratory beyond fourteen days of development. The EAB's rationale was based on two main points. First, it

would be irresponsible to offer clinical IVF without doing the studies necessary to insure its safety and efficacy. Second, given the high rate of embryo loss in natural procreation, a similar rate of loss could be tolerated for the goal of eventually achieving pregnancies and births.

The EAB did not distinguish between embryos created for research purposes and embryos remaining from infertility treatment. In fact, the board implied that at times it might be necessary to create embryos with no intent to transfer them to a woman. For the sake of safety, the results of new types of procedures would have to be studied in the laboratory before the procedures were offered clinically. It would be unethical to transfer to a woman the embryos resulting from unvalidated novel procedures.

The EAB report elicited an outpouring of letters opposing embryo research, and its recommendations were never implemented. When the EAB charter expired in 1980, a subsequent board was not appointed, thus leaving no body to review proposals for federal funding of IVF and embryo research. This situation effectively created a moratorium on federal funding in the United States, though it did not affect research that was privately funded.

Public Policy in Other Countries

It is not possible to review all legislation and policy recommendations throughout the world, but two early initiatives are of particular interest. They come from countries that share a common law tradition with the United States, Australia (Victoria), and the United Kingdom.

AUSTRALIA (VICTORIA). The earliest comprehensive legislation on reproductive technologies was enacted in the State of Victoria, Australia in 1984. The Infertility (Medical Procedures) Act addressed embryo research by prohibiting research that might damage the embryo or make it unfit for implantation. This prohibition appeared to outlaw any IVF or embryo research that was not directed toward benefiting each individual embryo.

In 1986 the review committee established by the act received a proposal for research on the microinjection of a single sperm into an egg. In their application the investigators suggested a novel approach for circumventing the prohibition on embryo research. They proposed to examine the egg after the sperm had penetrated it, but before the genetic contributions of the sperm and egg had fused at the stage known as syngamy. Arguing that fertilization was not completed until syngamy had occurred, researchers claimed that the law did not apply until the time of syngamy, thus giving them approximately twenty-two hours after sperm penetration for conducting their studies.

Since the review committee was uncertain as to whether the 1984 act allowed this interpretation, it recommended that the act be amended to clarify that research was permissible if it ended by the time of syngamy, even if the research destroyed the embryo's potential for implantation. The act was amended according to this recommendation in 1987.

UNITED KINGDOM. The issue of the regulation of reproductive technologies and embryo research was particularly pressing in the United Kingdom because of the publicity given to the birth of Louise Brown in England in 1978. The Warnock Committee was appointed to study the matter, and its 1984 report recommended national regulation of assisted reproduction. It also recommended that research on embryos resulting from IVF be permitted up to the fourteenth day after fertilization, under the jurisdiction of a licensing body.

Based on the Warnock Report, the Human Fertilisation and Embryology Act (HFE Act) of 1990 commissioned a standing body, the Human Fertilisation and Embryology Authority (HFEA), to develop standards for licensing clinical facilities and research protocols, and mechanisms for auditing and oversight. Initially research protocols were restricted to the study of infertility, the causes of congenital diseases, and the detection of gene or chromosome abnormalities in embryos.

Since its establishment in 1991 the HFEA has addressed new types of procedures and research through public consultation processes as well as the advice of experts. If a matter was beyond the scope of authority of the HFEA, it was referred to Parliament. In January 2001 Parliament extended the HFE Act to permit embryo research directed at increasing knowledge about treatments for serious diseases. This provision would allow the HFEA to issue licenses for research on embryonic stem cells, including stem cells derived from blastocysts resulting from somatic cell nuclear replacement (SCNR). However, the Pro-Life Alliance brought a challenge to this provision, arguing that the HFE Act applied only to embryos resulting from the fertilization of eggs by sperm. Despite a Court of Appeal ruling against the Pro-Life Alliance, in June 2002 the House of Lords agreed to hear a final appeal of the case. In March 2003 the House of Lords ruled that the HFE Act applied to all types of embryos, and hence the HFEA had authority over research with embryos created by nuclear transfer as well as embryos resulting from fertilization by sperm.

The U.S. Human Embryo Research Panel

After nearly twenty years of moratorium on federal funding of research involving IVF, the U.S. Congress in 1993 revoked the requirement of EAB review. Through the

National Institutes of Health (NIH) Revitalization Act of 1993, Congress explicitly permitted the NIH to fund research on assisted reproductive technologies with the goal of improving the understanding and treatment of infertility.

Since research on IVF includes the study of IVF-fertilized embryos, the research authorized by Congress included research involving human embryos. Recognizing the controversial issues raised by this research, NIH decided to conduct an examination of ethical issues before funding any research proposals. Consequently, the Director of NIH appointed the Human Embryo Research Panel (HERP) to provide advice and recommendations.

In developing its position and recommendations, the panel focused on two distinct sources of guidance: viewpoints on the moral status of the early human embryo, and ethical standards governing research involving human subjects. It considered a wide range of possible views on the moral status of the embryo, from the position that full human personhood is attained at fertilization, to the argument that personhood requires self-consciousness and is not attained until after birth. In the end, all nineteen members of the panel agreed to the following statement:

> Although the preimplantation embryo warrants serious moral consideration as a developing form of human life, it does not have the same moral status as an infant or child. (Human Embryo Research Panel, p. x)

This conclusion implied that the preimplantation embryo is not a full human subject and thus is not a fully protectable human being. As a result, some research that might be destructive to the embryo could be acceptable for federal funding. But the panel also asserted that the human embryo "warrants serious moral consideration," requiring that it be treated differently from mere human cells or animal embryos. The panel proposed restrictions on embryo research that would express such moral consideration, for example, that human embryos be used in research only as a last resort, that the number of embryos used be carefully limited, and that embryos not be allowed to develop longer than required by a specific research protocol, and in no case longer than fourteen days of development.

In applying the ethical standards governing research involving human subjects, panel members invoked the criteria used by Institutional Review Boards (IRBs) in approving research protocols. Donors of eggs, sperm, or embryos were to be informed of the specific goals, procedures, and risks of research projects. Risks to donors, particularly egg donors, were to be minimized. Eggs for research could be donated only by women who were undergoing diagnostic or therapeutic procedures where egg retrieval would present little additional risk.

The most controversial issue facing the panel was the question of whether human oocytes could be fertilized solely for research purposes. The panel decided to allow such fertilization only under very special circumstances, most particularly, if certain research by its very nature could not otherwise be conducted. For example, research on the laboratory maturation of human oocytes, which could eliminate the need for egg donors as well as infertile women to be subjected to high levels of hormonal stimulation, requires study as to whether such oocytes can be successfully fertilized.

The panel's limited acceptance of the fertilization of oocytes for research purposes aroused strong criticism, and President Bill Clinton immediately announced his opposition.

The Aftermath in the United States and Beyond

Despite President Clinton's directive that NIH not fund research involving the creation of embryos, most types of research on IVF and human embryos were still eligible for federal funding. However, in its next appropriations bill Congress reversed its previous stance and prohibited NIH from funding any research that might involve damaging or destroying human embryos. In 2003 this prohibition was still in effect.

During the 1990s scientific advances raised new questions regarding research with human embryos. In 1998 the first embryonic stem cell lines were developed from the inner cell mass of human blastocysts, and at the same time, similar stem cell lines were produced from the germ cell tissue of aborted fetuses. Deriving stem cells from blastocysts was clearly prohibited for federal funding. However, the derivation of stem cells from the tissue of aborted fetuses was eligible for federal funding under previous legislation (U.S. Public Law 103–43, Manier).

Another discovery was the successful cloning of a variety of nonhuman animals from adult cells, beginning with the cloning of the sheep Dolly in 1997. Research on human cloning arguably involves research on human embryos. These embryos are produced by transfer of somatic cell nuclei into enucleated oocytes, rather than through fertilization of eggs by sperm, yet their development and potential appear to be similar to those of fertilized eggs. Thus cloning research raises similar ethical questions.

The day after the announcement of the cloning of Dolly, President Clinton instructed the National Bioethics Advisory Commission (NBAC) to undertake a thorough review of the technology and to report within ninety days.

Given this short deadline, it is understandable that NBAC had to focus on issues specific to the cloning process. In particular, NBAC decided to "not revisit … the issues surrounding embryo research," since the topic had "recently received careful attention by a National Institutes of Health panel, the Administration, and Congress" (Shapiro).

In contrast, when the President's Council on Bioethics appointed by President George W. Bush issued its report on cloning in 2002, it called for a broader debate on the entire topic of human embryo research. The ten-member majority of the council wanted cloning discussed "in the proper context of embryo research in general and not just that of cloning" (p. 133). Both the majority and minority reports call attention to the fact that human embryo research of all types remains essentially unregulated in the private sector, with the minority noting that "it seems inappropriate to halt promising embryo research in one arena (cloned embryos) while it proceeds essentially unregulated in others" (p. 143).

In the United States, public policy at the national level is focused on what types of research are eligible for public funding. There is essentially no regulation of research in the private sector. This situation contrasts sharply with that of most other countries, where laws apply to all research, regardless of the funding source.

As of April 2003, Germany, Austria, and Ireland prohibit embryo research unless intended to benefit the individual embryo subject. Germany does allow some importation of established stem cell lines for research. France prohibits any embryo research that would harm the embryo. However, in January 2002 the French assembly passed a bill that, if enacted, would permit research using surplus embryos originally created for reproductive purposes. Sweden allows research on surplus embryos up to day fourteen, including research on deriving stem cell lines. Creating IVF embryos solely for research is prohibited, but creating embryos through nuclear transfer is not mentioned in Swedish law and thus has an uncertain legal status. The United Kingdom arguably has the most permissive policies on embryo research within the European Union. It explicitly sanctions the granting of licenses to create embryos, including cloned embryos, for specific research projects.

Because of the diverse views and policies of its member states, the European Union has taken an intermediate position, providing support for research on surplus embryos in countries where that is permitted, but discouraging the creation of embryos for research. In April 2003 the European parliament voted for a ban on cloning or otherwise creating embryos for stem cell research. However, this decision becomes law only if approved by all fifteen member states of the European Union.

In May 2002 the Assisted Human Reproduction Act was introduced into the Canadian Parliament. The act prohibits the creation of a human clone for any purpose. It also prohibits the creation of an IVF embryo for research purposes with the exception of "improving or providing instruction in assisted reproduction procedures." In April 2003 the bill was in its third reading in the House of Commons.

In some non-Western countries, embryo research is proceeding with few restrictions. Chinese laboratories are forging ahead with cloning research to develop stem cells. Though Chinese scientists have been slow to publish their work, they may well be ahead of their Western counterparts (Leggett and Regalado). India has developed a number of internationally recognized stem cell lines, and scientists are developing additional lines. Dr. Firuza Parikh, Director of Reliance Life Sciences in Bombay, links their success to the absence of cultural and political opposition to embryo research (Lakshmi).

The Moral Status of the Early Embryo

In contrast to China and India, most Western countries are deeply divided over ethical issues related to embryo research. Does the embryo merit full protectability from the moment of fertilization, or does it gradually attain full protectability as it moves through a series of developmental stages? If fertilization is not the point of greatest moral significance, is there some later developmental marker beyond which embryo research ought not be conducted?

FERTILIZATION. Fertilization of egg by sperm marks the initiation of a new and unique genotype, that of a human being distinct from either of its progenitors. The zygote or fertilized egg not only contains the plan or blueprint for a new human being, but it has the potential within itself to develop into that human being.

Based on these facts, many would argue that the zygote is a full human being from the moment it comes into existence. This view would preclude any research that might be harmful or destructive to an embryo, unless intended to be therapeutic for that embryo or to improve its chances for implantation. This position has received able defense in contemporary terms by opponents of embryo research (McCarthy and Moraczewski).

It is possible to hold this position while acknowledging that fertilization is a process rather than an instantaneous event, and hence that the new human life begins only when the process of fertilization is completed. At least two possible candidates marking the completion of fertilization have been suggested. The first is the time of syngamy, when the

chromosomes from the male and female gametes unite to form the genotype of the embryo. Since syngamy is not completed until about twenty-four hours after the sperm penetrates the egg, this view would allow some study of the early development of the embryo.

A second proposal maintains that the embryo does not begin its life as a new human being until the regulation of its development switches from oocyte genes to embryonic genes. In 1988 Peter Braude and colleagues showed that this occurs at the six- to eight-cell stage, approximately two days after penetration of egg by sperm. Arguably the embryo begins its own life distinct from that of the oocyte at the time that its own internal regulatory mechanism begins to function. This interpretation would allow investigation of questions such as why a large proportion of embryos are arrested in their development during the earliest cell divisions (Van Blerkom).

Such variant views of the process of fertilization do not counter the claim that the human being begins its life at fertilization. Rather, they provide differing interpretations as to what constitutes fertilization, under the assumption that the formation or activation of the unique genotype of the new organism is the crucial event.

IMPLANTATION. Implantation is the process by which the embryo imbeds itself in the uterine wall and begins to take nourishment from the woman, thus marking the beginning of pregnancy. It is at this time that the U.S. federal regulations define the product of conception as a fetus, and the research regulations begin to apply (45 CFR 46.201–207).

From a moral point of view, some have argued that the IVF embryo lacks the potential to develop into a human being as long as it is simply maintained in culture in the laboratory. Only those embryos that are transferred to women and that implant successfully acquire the potential for development. This type of argument has been utilized by politicians like U.S. Senator Orrin Hatch, who support some forms of embryo research while they take pro-life positions in relation to abortion. In his testimony to a Congressional subcommittee in July 2001, Hatch stated, "I believe that a human's life begins in the womb, not in a petri dish or refrigerator."

This view can be linked to a philosophic distinction between *possible* persons, entities that could possibly develop into persons if certain actions were taken with respect to them, and *potential* persons, entities that will develop into persons in the normal course of events unless something happens or is done to interrupt that development. The embryo in the laboratory or freezer is a possible person that might develop into a person if action were taken to transfer it to a uterus. The already-implanted embryo or fetus is a potential person that, under normal circumstances, will continue to develop into a person. Proponents of this distinction argue that while we may have a moral obligation not to interfere with the development of a potential person, we do not have a similar obligation to bring every possible person into existence (Singer and Dawson; Tauer 1997a).

PRIMITIVE STREAK. In the late twentieth century, scholars were faced with biological data about early embryonic development that led to new perspectives on the ontological and moral status of the early embryo. Particularly within the Catholic tradition, writers such as Norman Ford, John Mahoney, Richard McCormick, and Karl Rahner developed arguments questioning whether the zygote or early embryo is a full human being or human person. Their arguments appealed to the following points:

1. Twinning of the embryo is possible until implantation, and at least through the morula stage, several embryos may aggregate (recombine) to form one embryo. Thus the embryo lacks developmental individuation at this early stage. Philosophic arguments that rely on the continuity of personal identity and religious arguments based on ensoulment must deal with the phenomena of twinning and recombination, which occur naturally and can also be induced scientifically.
2. Until the blastocyst stage at approximately five days after fertilization, the cells of the embryo are totipotent or completely undifferentiated. Each cell has the capacity to differentiate into any of the cell or tissue types of the fetus, or more likely, not to become part of the fetus at all but rather to form placental and other extra-embryonic tissues. The early embryo is a collection of undifferentiated cells rather than an organized individual.
3. At approximately fourteen days after fertilization, the primitive streak appears, the groove along the midline of the embryonic disk that establishes in the embryo its cranio-caudal (head-to-tail) and left-right axes. The primitive streak marks the beginning of the differentiation of cells into the various tissues and organs of the human body, and thus initiates the development of the embryo proper (the cells that will become the fetus) as an organized, unified entity. The primitive streak is also the precursor of the neural system.
4. In normal procreation, during the period between fertilization and the completion of implantation a large proportion of embryos (generally estimated at over 50%) are discarded naturally. Karl Rahner argues that it is implausible that such a large number of human beings could come into existence

> and disappear without anyone's knowing about it. Others have argued that given nature's prodigality with human embryos, it ought to be morally acceptable to allow similar types of embryonic losses in research as part of the effort to achieve healthy pregnancies.

These sorts of arguments have been utilized in public policy debates since 1978, and the appearance of the primitive streak has come to be accepted internationally as a marker carrying moral significance. The prohibition of embryo research after fourteen days of development is almost universally accepted.

Opponents of embryo research have responded to claims that the early embryo is not yet a full human being. These commentators find arguments based on twinning and recombination, totipotency of cells, and embryo loss to be unpersuasive (Ashley; Ashley and Moraczewski; Mirkes). In its 2002 report on cloning, the majority members of the U.S. President's Council on Bioethics questioned the significance of the primitive streak as a moral marker, stating:

> Because the embryo's human and individual genetic identity is present from the start, nothing that happens later … —at fourteen days or any other time—is responsible for suddenly conferring a novel human individuality or identity. (p. 97)

GASTRULATION AND NEURULATION. Some persons regard the initiation of the neural system or the presence of brain activity to be the most significant marker for the beginning of the life of a human being. This view is based on the belief that the brain is the essential organ underlying our specifically human capacities. It also represents an effort to identify a criterion at the beginning of human life that is analogous to the criterion of whole-brain death marking the end of life. For those who regard the presence of sentience as a necessary condition for personhood, the neural system is significant since sentience is impossible in the absence of any neural structures.

While there is debate as to the stage at which brain activity first occurs, it is certain that there is no brain activity before fourteen days of gestational age. The emergence of the primitive streak marks the very beginning of the development of the nervous system. If the presence of neural structures is the significant criterion for the beginning of a human life, then it might be permissible to extend embryo research slightly beyond fourteen days of development.

Several possible cut-off points have been suggested. By the completion of *gastrulation* at about seventeen days, the three germ layers of the embryo are in place, with cells of each layer committed to forming tissues and organs of one of three types. Subsequent neural development leads to the beginning of *closure of the neural tube* around twenty-one days, with the primitive nervous system in place by the completion of *neurulation* around twenty-eight days.

However, given the widespread consensus that fourteen days of gestational age is a morally defensible boundary for embryo research, there has been limited discussion of extending research to a later embryonic stage.

Other Moral Considerations

Those who believe that the human embryo is a fully protectable human being have no choice but to oppose embryo research that could not ethically be performed on infants or children. But those who maintain that the early embryo is not yet a full human being, still have to determine how that embryo ought to be treated.

Some have proposed severely restrictive criteria for embryo research. Norman Ford, after providing painstaking arguments to support the conclusion that the embryo cannot be a human individual until fourteen days after fertilization, acknowledges that he could be wrong. In his view, the Catholic Church is right to insist on the principle that "human embryos should be treated as persons," even if they may not be (2001, p. 160). In other words, as long as there is any degree of uncertainty regarding the moral status of the embryo, it must be absolutely inviolate.

A more commonly held view is that the human embryo has an intermediate sort of moral status. While it is not a fully protectable human being, it is not merely cells or tissue. Proponents of this view are generally willing to permit some embryo research with restrictions that acknowledge that the embryo is nascent human life or a developing form of human life. Our ethical obligation toward the embryo is often characterized as *respect* or *profound respect.*

Proponents as well as opponents of embryo research have questioned the concept of respect as a guide for human embryo research. John Robertson, an advocate of scientific freedom with respect to embryo research, believes the notion of respect carries mainly symbolic significance. Hence its practical ramifications are vague, potentially allowing a wide range of types of research. Daniel Callahan, in an essay opposing most embryo research, wonders how one shows respect for a living being while intending to end its life and future potential, even if done for a good purpose such as research on infertility or disease.

In an effort to express respect for the special status of the human embryo, public policy bodies have stipulated conditions for embryo research that are considerably more restrictive than policies on research with human cells or animal

embryos. For example, research must have important scientific or medical goals and may involve human embryos only when the research cannot be conducted in any other way. Research projects should be restricted to the smallest number of embryos that is feasible, and for the shortest possible time period. Careful records and security must be utilized to ensure that no embryos are diverted for unapproved purposes and that none are sold.

Bringing Embryos into Existence for Research

One of the most contentious issues in embryo ethics is the question of whether it is ever justifiable to bring human embryos into existence specifically for research purposes. Many would argue that research use of surplus embryos remaining after the completion of infertility treatment is ethically acceptable, since these embryos are destined to be destroyed in any case. At the same time, they may hold that the development of embryos for research purposes, so-called research embryos, is not morally justified.

The development of embryos for research purposes has been characterized as a novel practice that requires particular justification. Referring to embryos created through nuclear cell transfer, the President's Council on Bioethics in 2002 claimed that such research creation of embryos would constitute crossing a "major moral boundary" (p. 132). Yet decades of research on human IVF beginning in the 1930s required investigation of various methods of laboratory fertilization, followed by study of cleaving fertilized eggs to determine their normality before transfer to a woman was even considered (Soupart and Strong; Edwards and Steptoe).

Commentators agree that there is no ontological or intrinsic distinction between surplus embryos remaining after infertility treatment and research embryos developed specifically for study. Arguments that support a moral distinction must identify other morally relevant factors. The concept of respect is often invoked, as is the notion of *intent.*

Respect for the special status of the embryo seems to require that embryos be treated as entities of intrinsic value. When embryos are created purely for research purposes, they become instruments for purposes that have nothing to do with the embryos themselves. In Kantian terms, the embryos are used solely as means for the welfare of others rather than as ends in themselves. The practice of creating research embryos thus results in treating embryos as commodities, equivalent to mere cells or tissues.

In contrast, the intent to procreate justifies the development of embryos in the laboratory. Even when a large number of eggs is fertilized in an IVF procedure, each fertilized egg has an equal chance of being transferred to a woman and developing into a human being. Thus each zygote is equally respected for its procreative potential.

It is only because some of the embryos cannot be transferred (because of the decision of the progenitors, or because there simply are too many of them) that they become surplus embryos and are destined for destruction. It is arguably permissible to derive some good from the inevitable destruction of these embryos by using them in research. In doing so, one may be said to be choosing the *lesser evil.*

These arguments have been countered by a number of considerations.

It may be true that respect for the special status of the human embryo requires that it be treated differently from mere human tissue. But the concept of respect is vague and undetermined, so that a wide range of concrete interpretations is plausible. The claim that respect precludes all creation of research embryos gives heavy weight to one interpretation of the concept at the expense of any countervailing considerations. Research projects that include the development of embryos may promise significant benefits for relieving the suffering of living human beings. These benefits could outweigh a particular interpretation of respect.

While procreative intent may justify the creation of embryos in the laboratory, it is plausible that other sorts of purposes could provide equally valid justifications. The treatment of infertility, an elective medical procedure, may even hold lesser moral significance than the development of cures for life-threatening or significantly disabling diseases and trauma outcomes. Hence such goals may also justify the creation of embryos.

Moreover, surplus embryos do not appear purely by chance. Clinicians frequently make a decision to fertilize large numbers of eggs in order to optimize the chances of establishing a pregnancy. The initial intent is not to give every zygote the opportunity for implantation, but to achieve one or more pregnancies and births, as desired by the progenitors. A later decision to direct unused embryos to research cannot be justified by the principle of the lesser evil, since the existence of surplus embryos should have been anticipated. This situation was deliberately caused and could have been avoided. Thus it is invalid to invoke the principle of the lesser evil to justify use of surplus embryos in research, while maintaining that any creation of research embryos is prohibited.

Parthenogenesis

A potentially non-controversial process for developing morulas and blastocysts for research is the activation of oocytes

without use of sperm or transfer of somatic cell nuclei. Such activation can be achieved through electrostimulation or chemicals in a process called parthenogenesis. The resulting cleaving eggs, called *parthenotes,* may develop much like normal embryos at least to the blastocyst stage. Although no human parthenotes have progressed this far, in February 2002 scientists announced that they had developed monkey parthenote blastocysts and established stable stem cell lines from them (Cibelli, et al.).

Scientists believe "there is a profound and intrinsic biological barrier that prevents mammalian parthenotes from developing to advanced fetal stages" (Human Embryo Research Panel, p. 20). On this assumption, parthenogenic morulas or blastocysts lack the intrinsic potential to become human beings. If this potential is a defining aspect of the human embryo and the basis for its special moral status, then human parthenotes are not human embryos and should not arouse the same sorts of moral concerns. Thus they may offer an attractive alternative for research.

III. STEM CELL RESEARCH AND THERAPY

In this entry we review the ethical and legal issues that arise in the context of stem cell research and therapy. Stem cells have attracted both immense scientific interest and equal ethical and legal concern because of their capacity to "specialize" and become virtually any part of the organism into which they are introduced. Thus if introduced into the brain they become brain cells, if into the cardiovascular system they become cells of that type and so on. They also appear to be able to trigger cell regeneration and colonize damaged tissue effecting "repair" in situ. Thus if such cells are made compatible with the genome of a host using cloning techniques they could in principle repair and regenerate damaged tissue and halt or even cure many diseases. This holds out both great promise and causes great unease in equal measure. Here we examine both the scientific promise and the extent to which ethical and legal safeguards may be appropriate.

Ethical Issues

The ethical aspects of human stem cell research raise a wide variety of important and controversial issues. Many of these issues have to do with the different sources from which stem cells may be obtained. Stem cells are at present obtained from adults, umbilical cord blood, and fetal and embryonic tissue. Although there are widely differing views regarding the ethics of sourcing stem cells in these ways, there is general consensus that embryos are the best source of stem cells for therapeutic purposes—a consensus that may of course change as the science develops. If spare embryos or aborted fetuses may be used as sources for stem cells, there is a further question: Should embryos or fetuses be deliberately produced in order to be sources of stem cells, whether or not they are also intended to survive stem cell harvesting and grow into healthy adults?

The European Group on Ethics in Science and New Technologies, which advises the European Commission, has highlighted the women's rights issues involved in stem cell research. It is particularly worth bearing in mind that women, as the most proximate sources of embryonic and fetal material and hence also of cord blood, may be under special pressures and indeed risks if these are to be the sources of stem cells.

The issue of free and informed consent, both of donors and recipients, raises special problems. Because embryos and fetuses can hardly consent to their role in sourcing stem cells, the question of who may give consent for the use of fetal or embryonic material is important, particularly because the usual basis for parental consent is hardly appropriate. This basis involves a judgment about what is in the best interests of the individual, and because, in most cases, the individual in question will not survive, the test is irrelevant (Harris, 2002a). Competent risk–benefit assessment is vital, and particular attention needs to be paid to appropriate ethical standards in the conduct of research on human subjects. Other issues concern the anonymity of the donors, the security and safety of cell banks, and the confidentiality and privacy of the genetic information and the tissue the banks contain. Finally, there are issues of remuneration for those taking part and of the transport and security of human tissue and genetic material and information across borders both within the European Union (EU) and worldwide. While these issues are important, they are well understood in biomedical ethics, and with the exception of the issue of consent, they do not raise special issues in connection with stem cell research and therapy (U.K. Human Genetics Commission).

Before considering the ethics of such use in detail, it is important to first explore the possible therapeutic and research uses of stem cells and also the imperatives for research and therapy.

WHY EMBRYONIC STEM CELLS? Embryonic stem cells were first grown in culture in February 1998 by James A. Thomson of the University of Wisconsin. In November of that year Thomson and his colleagues announced in the journal *Science* that such human embryonic stem cells formed a wide variety of recognizable tissues when transplanted into mice. Roger A. Pedersen, writing in 1999, noted potential applications of these stem cells:

> Research on embryonic stem cells will ultimately lead to techniques for generating cells that can be employed in therapies, not just for heart attacks, but for many conditions in which tissue is damaged.
>
> If it were possible to control the differentiation of human embryonic stem cells in culture the resulting cells could potentially help repair damage

caused by congestive heart failure, Parkinson's disease, diabetes, and other afflictions. They could prove especially valuable for treating conditions affecting the heart and the islets of the pancreas, which retain few or no stem cells in an adult and so cannot renew themselves naturally.

Stem cells, then, might eventually enable us to grow tailor-made human organs. Furthermore, using cloning technology of the type that produced Dolly the sheep, these organs could be made individually compatible with their designated recipients. In addition to tailor-made organs or parts of organs, such as heart valves, it may be possible to use embryonic stem cells to colonize damaged parts of the body, including the brain, and to promote the repair and regrowth of damaged tissue. These possibilities have long been theoretically understood, but it is only now with the isolation of human embryonic stem cells that their benefits are being seriously considered.

Stem cells for therapy. It is difficult to estimate how many people might benefit from the products of stem cell research should it be permitted and prove fruitful. Most sources agree that the most proximate use of human embryonic stem cell therapy would for Parkinson's disease, a common neurological disease that has a disastrous effect on the quality of life of those afflicted with it. In the United Kingdom around 120,000 individuals have Parkinson's, and the Parkinson's Disease Foundation estimates that the disease affects between 1 million and 1.5 million Americans. Another source speculates that "the true prevalence of idiopathic Parkinson's disease in London may be around 200 per 100,000" (Schrag, Ben-Shlomo, and Quinn). Untold human misery and suffering could be stemmed if Parkinson's disease became treatable. If treatments become available for congestive heart failure and diabetes, for example, and if, as many believe, tailor-made transplant organs will eventually be possible, then literally millions of people worldwide will be treated using stem cell therapy.

When a possible new therapy holds out promise of dramatic cures, caution is of course advised, if only to dampen false hopes of an early treatment. For the sake of all those awaiting therapy, however, it is equally important to pursue the research that might lead to therapy with all vigor. To fail to do so would be to deny people who might benefit the possibility of therapy.

Immortality

Finally we should note the possibility of therapies that would extend life, perhaps even to the point at which humans might become in some sense "immortal." This, albeit futuristic dimension of stem cell research raises important issues that are worth serious consideration. Many scientists now believe that death is not inevitable that that the process whereby cells seem to be programmed to age and die is a contingent "accident" of human development which can in principle and perhaps in fact be reversed and part of that reversal may flow from the regenerative power of stem cells. Immortality has been discussed at length elsewhere but we should, before turning to the ethics of stem cell research and therapy note one important possible consequence of life extending procedures.

Human Evolution and Species Protection

Human Embryonic Stem Cell research in general, but the immortalizing properties of such research in particular raises another acute question. If we become substantially longer lived and healthier, and certainly if we transformed ourselves from "mortals" into "immortals" we would have changed our fundamental nature. One of the common defining characteristics of a human being is our mortality. Indeed in English we are "mortals"—persons; not "immortals" or Gods, demi-gods or devils. Is there then any moral reason to stay as we are simply because it is "as we are"? Is there something sacrosanct about the human life form? Do we have moral reasons against further evolution whether it is "natural" Darwinian evolution, or evolution determined by conscious choice?

One choice that may confront us is as to whether or not to attempt treatments that might enhance human functioning, so-called "enhancement therapies." For example it may be that because of their regenerative capacities stem cells inserted into the brain to repair damage might in a normal brain have the effect of enhancing brain function. Again it would be difficult if the therapies are proved safe in the case of brain damaged patients to resist requests for their use as enhancement therapies. What after all could be unethical about improving brain function? We don't consider it unethical to choose schools on the basis of their (admittedly doubtful) claims to achieve this, why would a more efficient method seem problematic?

We should not of course attempt to change human nature for the worse and we must be very sure that in making any modifications we would in fact be changing it for the better, and that we can do so safely, without unwanted side-effects. However if we could change the genome of human beings, say by adding a new manufactured and synthetic gene sequence which would protect us from most major diseases and allow us to live on average twenty five per cent longer with a healthy life throughout our allotted time,

many would want to benefit from this. In high-income countries human beings now do live on average twenty five per cent longer than they did 100 years ago and this is usually cited as an unmitigated advantage of "progress." The point is sometimes made that so long as humans continued to be able to procreate after any modifications, which changed our nature, we would still be, in the biological sense, members of the same species. But, the point is not whether we remain members of the same species in some narrow biological sense but whether we have changed our nature and perhaps with it our conception of normal species functioning.

THE ETHICS OF STEM CELL RESEARCH. Stem cell research is of ethical significance for three major reasons:

1. It will for the foreseeable future involve the use and sacrifice of human embryos.
2. Because of the regenerative properties of stem cells, stem cell therapy may always be more than therapeutic—it may involve the enhancement of human functioning and indeed the extension of the human lifespan.
3. So-called therapeutic cloning, the use of cell nuclear replacement to make the stem cells clones of the genome of their intended recipient, involves the creation of cloned pluripotent (cells that have the power to become almost any part of the resulting organism—hence pluri-potent)and possibly totipotent cells (cells which have the power to become any part of the resulting organism including the whole organism), which some people find objectionable.

In other venues, John Harris has discussed in detail the ethics of genetic enhancement (Harris, 1992, 1998a) and the ethics of cloning (Harris, 1997, 1998b, 1999b). The focus of this entry, however, is on objections to the use of embryos and fetuses as sources of stem cells.

Because aborted fetuses and preimplantation embryos are currently the most promising sources of stem cells for research and therapeutic purposes, the recovery and use of stem cells for current practical purposes seems to turn crucially on the moral status of the embryo and the fetus. There have, however, been a number of developments that show promise for the recovery and use of adult stem cells. It was reported in 2002 that Catherine Verfaillie and her group at the University of Minnesota had successful isolated adult stem cells from bone marrow and that these seemed to have pluripotent properties (capable of development in many ways but not in all ways and not capable of becoming a new separate creature), like most human embryonic stem cells have. Simultaneously, *Nature Online* published a paper from Ron McKay at the U.S. National Institutes of Health showing the promise of embryo-derived cells in the treatment of Parkinson's disease.

Such findings indicate the importance of pursuing both lines of research in parallel. The dangers of abjuring embryo research in the hope that adult stem cells will be found to do the job adequately is highly dangerous and problematic for a number of reasons. First, it is not yet known whether adult cells will prove as good as embryonic cells for therapeutic purposes; there is simply much more accumulated data about and much more therapeutic promise for embryonic stem cells. Second, it might turn out that adult cells will be good for some therapeutic purposes and embryonic stem cells for others. Third, whereas scientists have already discovered that virtually any gene in embryonic stem cells can be modified or replaced, this has not yet been established to hold for adult stem cells. Finally, it would be an irresponsible gamble with human lives to back one source of cells rather than another and to make people wait and possibly die while what is still the less favored source of stem cells is further developed. This means that the ethics of embryonic stem cells is still a vital and pressing problem and cannot for the foreseeable future be bypassed by a concentration on adult stem cells.

RESOLVING THE ETHICS OF RECOVERING STEM CELLS FROM EMBRYOS. There are three more or less contentious ways of resolving the question of whether it is ethically permissible to use the embryo or the fetus as a source of material, including stem cells, for research and therapy. The three methods involve: (1) solving the vexing question of the moral status of the embryo; (2) invoking the principle of waste avoidance; and (3) showing that those who profess to accord full moral status to the embryo either cannot consistently do so or do not in fact believe (despite what they profess) that it has that status. Regarding the first of these, it is difficult to determine whether there will ever be sufficiently convincing arguments available for this question to be finally resolved in the sense of securing the agreement of all rational beings to a particular view of the matter (Harris, 1985, 1999a). Putting aside this contentious issue, then, the other two issues will be discussed below.

The principle of waste avoidance. This widely shared principle states that it is right to benefit people if we can, that it is wrong to harm them, and that faced with the opportunity to use resources for a beneficial purpose when the alternative is that those resources will be wasted, we have powerful moral reasons to avoid waste and do good instead.

That it is surely better to do something good than to do nothing good should be reemphasized. It is difficult to find

arguments in support of the idea that it could be better (more ethical) to allow embryonic or fetal material to go to waste than to use it for some good purpose. It must, logically, be better to do something good than to do nothing good, just as it must be better to make good use of something than to allow it to be wasted.

It does not of course follow from this that it is ethical to create embryos specifically for the purposes of deriving stem cells from them. Nevertheless, in all circumstances in which "spare" embryos have been produced that cannot, or will not, be used for reproduction, because they have no chance of developing into normal adult human beings, it must be ethical to use such embryos as sources of stem cells or therapeutic material or for research purposes.

Does anyone really believe that embryos are moral persons? One way in which stem cell research and therapy using human embryos might be successfully defended is to draw a distinction between what people say and what they do, or rather to point out that there may be an inconsistency between the beliefs and values of people as revealed by their statements on the one hand and by the way they behave on the other. Although many people, including most so-called pro-life or right-to-life supporters, are prone to make encouraging noises about the moral importance of embryos, and even sometimes talk as if embryos have, and must be accorded, the same moral status as human adults, such people very seldom, if ever, behave as if they remotely believe any such thing. Taking for the moment as unproblematic the idea, made famous by the Greek philosopher Socrates (c. 470–399 B.C.E.), that "to know the good is to do the good," many pro-life advocates do not behave consistently with their professed beliefs about what is good. A few examples must suffice.

One would expect that those who give full moral status to the embryo, who regard it as a person, would both protect embryos with the same energy and conviction as they would their fellow adults and mourn an embryo's loss with equal solemnity and concern. This, however, they do not do. It is true that some extreme pro-life advocates in the United States have taken to murdering obstetricians who perform abortions, but those same individuals are almost always inconsistent in some or all of the following ways.

For every live birth, up to five embryos die in early miscarriages. Although this fact is widely known and represents massive carnage, pro-life groups have not been active in campaigning for medical research to stem the tide of this terrible slaughter. Equally well known is that, for the same reasons, the menstrual flow of sexually active women often contains embryos. Funeral rights are not usually routinely performed over sanitary towels, although they often contain embryos. In the case of spare embryos created by assisted reproductive technologies, there has not been the creation of a group of pro-life women offering their uteruses as homes for these surplus embryos. In his 1992 book, *Wonderwoman and Superman,* John Harris had to invent a fictitious quasi-religious order of women, "The Sisters of the Embryo," who would stand ready to offer a gestating uterus to receive unwanted embryos because (surprisingly given the large numbers of pro-life women available) there has never been such a movement. Indeed, anyone engaging in unprotected intercourse runs substantial risk of creating an embryo that must die, and yet few people think that this fact affords them a reason either to refrain from unprotected intercourse or to press for medical research to prevent this tragic waste of human life.

Finally, it is notorious that many pro-life supporters, including many Catholics, are prepared to permit abortions in exceptional circumstances, for example, to save the life of the mother or in the case of rape. In the former situation, however, the right course of action for those who believe the embryo has full moral status is to give equal chances to the embryo and the mother (perhaps by tossing a coin) in cases where one may survive but not both. In the case of rape, because the embryo is innocent of the crime and has therefore done nothing to compromise its moral status, the permitting of abortion by those who give full status to the embryo is simply incoherent (Richards).

These cases provide reasons for thinking that even if the views of those who believe the embryo to have the same moral status as normal adult human beings cannot be conclusively shown to be fallacious, it can at least be shown that these views are inconsistent with practice and that the "theory" is therefore not really believed by those who profess it or indeed that it is not actually compatible with the lives that human beings must, of necessity, lead.

Legal and Regulatory Issues

A draft United Nations (UN) convention to prohibit human reproductive cloning seeks to augment the advisory regulatory approach enshrined in the Universal Declaration on the Human Genome and Human Rights. The latter was developed by the United Nations Educational, Scientific and Cultural Organization (UNESCO), adopted unanimously by its 186 states on November 11, 1997, and adopted by the UN General Assembly on March 10, 1999 (via Resolution 53/152). Article 11 of the UNESCO Declaration states (in part): "Practices which are contrary to human dignity, such as reproductive cloning of human

beings, shall not be permitted." The limitations of this provision were revealed in a report by the director-general of UNESCO. The report concluded that "this prohibition concerns the reproductive cloning of human beings and should not be interpreted as prohibiting other applications of cloning" (UNESCO, 1999, p. 13).

The Council of Europe's Convention for the Protection of Human Rights and Dignity of the Human Being with regard to the Application of Biology and Medicine (1997; known as the Convention on Human Rights and Biomedicine), to which the United Kingdom is not a signatory, does provide some form of protection for the human embryo. Thus, Article 18(1) provides the following: "Where the law allows research on embryos in vitro, it shall ensure adequate protection of the embryo," and Article 18(2) states, "The creation of human embryos for research purposes is prohibited." Under Article 36, countries—such as the United Kingdom—that have a preexisting law may make a reservation to the convention based on that existing law. Those countries that have no preexisting law on the embryo and that sign the convention will be hindered or prohibited from sanctioning embryo research, unless they formally withdraw from the convention, pass the new permissive law, and then re-sign (as has happened with Finland and Greece).

In the United Kingdom, the appending of the Human Rights Act of 1998, which brought U.K. domestic law closer to the provisions of the Convention on Human Rights and Biomedicine, has provoked some commentators to focus on the provisions of Article 2 as having potentially significant effect on domestic abortion law and hence the status of the embryo in law. Article 2 stipulates the following: "Everyone's right to life shall be protected by law." Whether this will afford any greater degree of recognition to the fetus, let alone to the embryo, is unlikely.

No European consensus exists on abortion, (or, as Table 1 shows, on embryo research), and the European Commission and the European Court of Human Rights have been reluctant to pronounce substantively on whether the protection in Article 2 of the convention extends to the fetus. In the light of these differing laws, a state will have what is called under European human rights legislation a wide "margin of appreciation" with regard to the convention on the issue of abortion, and hence, it is thought, on the status of the embryo (Decision Reports of the European Commission of Human Rights, Application 17004/90 H v Norway 73 DR 155 (1992) E Com HR.).

The European Court of Human Rights has yet to rule on whether the term *everyone* includes a fetus. In *Open Door Counselling & Dublin Well Woman v. Ireland,* the European Commission had recognized the possibility that Article 2 might in certain circumstances offer protection to a fetus, but they took the point no further.

THE UNITED KINGDOM POSITION. Important distinctions must be drawn in the law's treatment of human cloning. The first distinction is between *reproductive cloning,* which is designed to result in the birth of a live human being genetically identical to another, and *therapeutic cloning,* in which an embryo is cloned for research purposes and will not be permitted to develop into a fetus or a live birth. The second essential distinction is that between two different cloning techniques: The first of these (when applied to *human* cloning) involves replacing the nucleus of an embryonic cell with a nucleus taken from another human embryonic or adult cell, and it is known as cell nuclear replacement (CNR).

The HFE Act of 1990. The Human Fertilisation and Embryology Act of 1990 (HFE Act) contains a clear prohibition on the first technique. Section 3(3)(d) states that a license granted under the act "cannot authorise … replacing a nucleus of a cell of an embryo with a nucleus taken from a cell of any person, embryo or subsequent development of an embryo." CNR, on the other hand, is not *expressly* prohibited by the act, nor is "embryo splitting," a process that can occur naturally at a very early stage of embryonic development, forming identical twins, but which can also be done in vitro to produce identical, cloned embryos. The form of CNR whereby the nucleus of an oocyte is replaced with a nucleus from an *adult* cell was beyond the bounds of scientific credibility when the 1990 legislation was being debated and drafted.

The legal status of CNR in the United Kingdom is, therefore, unclear. The regulatory framework of the HFE Act rests on a definition in section 1(1)(a), in which an embryo is defined as "a live human embryo where fertilisation is complete." This definition's emphasis on the process of fertilization (an emphasis repeated throughout the act) raises the possibility that embryos created by CNR fall outside the scope of the act and that accordingly their creation and use is unregulated. In their 1998 report, *Cloning Issues in Human Reproduction,* the Human Genetics Advisory Commission (HGAC) and the Human Fertilisation and Embryology Authority (HFEA) argued for a *purposive* rather than a *literal* interpretation of the definition. Through such an approach, organisms created by CNR would fall within the statutory definition of *embryo* on the basis that Parliament clearly intended to regulate the creation and use of embryos outside the human body, and that excluding organisms created by

TABLE 1

Legislation on Reproductive/Therapeutic Cloning, Embryo Research, and Stem Cell Research, 2003

Country	Reproductive Cloning Allowed	Therapeutic Cloning (SCNT*) Allowed	(General) Research on Embryos Allowed	Stem Cell Research on Spare Embryos Allowed	Legislative Source(s)
Argentina	No				Decree No. 200 of March 1997: A Prohibition of Human Cloning Research
Australia (federal)	No	No	Yes	Yes	Research Involving Human Embryos Act of 2002; Prohibition of Human Cloning Act of 2002 (Embryos created before April 5, 2002, may be used for stem cell embryo research; Subject to license)
Austria	No	Possibly	No	No	Reproductive Medicine Law of 1992 (Embryos may be created for (Cf. Import) reproductive purposes only)
Brazil			Yes	Yes	Law 8974/95, Normative Instruction by National Technical Committee of Biosecurity
Canada	No	No	Yes	Yes	CIHR Guidelines; Bill C-13, An Act Respecting Assisted Human Reproductive Technologies and Related Research (Surplus embryos only; Subject to license)

SOURCE: Compiled from various sources by Authors.

CNR from the definition in the HFE Act would frustrate this legislative intention.

It is important here to immediately observe three things:

1. CNR is not specifically prohibited by the HFE Act.
2. The same is true of embryo splitting.
3. The HFEA gave careful consideration to embryo splitting as an additional possible form of infertility treatment in 1994, when its potential use at the two- or four-cell embryonic stage was discussed. After considering the social and ethical issues involved, the HFEA decided to ban embryo splitting as a possible fertility treatment. The HFEA, however, did not make a similar prohibition with respect to CNR research.

Is somatic CNR specifically covered by the wording of section 3(3)(d) of the HFE Act? And, as CNR does not involve fertilization, does section ("No person shall bring about the creation of an embryo … except in pursuance of a licence") 3(1) apply either? Is CNR regulated at all by the HFE Act? At least from a moral point of view, and taking what could be called a purposive or result-oriented approach, it may be possible to reconcile the CNR embryo with embryos created in vitro. From this, it would follow that there is no particular difficulty in accepting the view with which the HFEA works—that the creation of embryos through CNR is *already* brought within the scheme of the HFE Act by an extended interpretation of section 1.

Section 1(1)(a) reads in full: "In this Act, *except where otherwise stated* (a) embryo means a live human embryo where fertilisation is complete" (emphasis added). The emphasized words make it plain that the legislators could have provided otherwise for embryos created other than by in vitro fertilization to be included within the statute, but evidently they did not. To read the statute as providing for embryos created by CNR is to read it as providing that an embryo means a live human embryo where fertilization is complete, *unless the context otherwise requires.*

The* Quintavalle *case. In the early 2000s, a legal challenge by the Pro-Life Alliance, a U.K. lobbying group, tested the question of whether the HFE Act can be interpreted purposively to include organisms produced by CNR. In the High Court (*Regina [on the Application of Quintavalle] v. Secretary of State for Health,* 2001), the claimant submitted simply that an embryo that has not been produced by fertilization cannot be "an embryo where fertilization is complete" in terms of section 1(1)(a) of the HFE Act. The Secretary of State for Health argued for a purposive construction of this section, whereby the definition would be expanded to include embryos produced other than by fertilization. The judge decided that such a purposive approach would "involve an impermissible rewriting and extension of the definition" (*Quintavalle,* 2001, para. 62). In immediate response to this, the government introduced the Human Reproductive Cloning Act of 2001, under which it is an offense to place, in a woman, a human embryo that has been created by any method other than fertilization.

In the Court of Appeal (*Regina [on the Application of Quintavalle] v. Secretary of State for Health,* 2002), the Secretary of State continued to argue that section 1(1)(a) must be given a "strained" construction in order to give effect to the obvious intention of Parliament. The claimant disagreed that the intentions of Parliament with regard to CNR can be thought to have been clear when the technique was unheard of at the time the HFE Act was enacted. Furthermore, the claimant pointed out, had Parliament known of the CNR technique, they may well have decided to include it in the prohibition on cloning included in section 3(3)(d).

In upholding the appeal, the court placed particular emphasis on two considerations. First, it observed the dictum of Lord Wilberforce, in his dissenting judgment in the case of *Royal College of Nursing of the United Kingdom v. Department of Health and Social Security* (1981), that:

> Where a new state of affairs, or a fresh set of facts bearing on policy, comes into existence, the courts have to consider whether they fall within the Parliamentary intention. They may be held to do so, if they fall within the same genus of facts as those to which the expressed policy has been formulated. (*Royal College of Nursing,* p. 822)

The court decided, regarding "genus of facts," that the fact that an embryo was created by fertilization had not been a factor of particular relevance to the desirability of regulation when the HFE Act was envisaged, and that, furthermore, the embryo created by CNR is "morphologically and functionally indistinguishable" (*Quintavalle,* 2002, p. 639) from the embryo created by fertilization. The relevant point was taken to be the capacity to develop into a human being, which is shared by both.

The second point the court emphasized related to the policy of the HFE Act. Rejecting the argument that Parliament's intention was undiscoverable and that CNR, if possible at the time, may have been prohibited under s3(3)(d), the court decided that the rationale behind that prohibition was

> to prevent the production artificially of two or more genetically identical individuals. This policy would be put in jeopardy if the creation and use

> of embryos by cell nuclear replacement were unregulated. It would be furthered by making the production of embryos by cell nuclear replacement subject to the regulatory regime under the Act, for it is inconceivable that the licensing authority would permit such an embryo to be used for the purpose of reproduction. (*Quintavalle,* 2002, pp. 641–642)

In the final appeal to the House of Lords (*Regina [on the Application of Quintavalle] v. Secretary of State for Health* 2003), the decision of the Court of Appeal was unanimously sustained. In his leading judgment Lord Bingham upheld the Court of Appeal's endorsement of the dictum in *Royal College of Nursing,* saying that this "may now be treated as authoritative" (*Quintavalle,* 2003, para. 10). Indeed, following the House of Lords' judgment in *Quintavalle,* the passage in question can be regarded as enshrining a new rule of statutory interpretation.

The House of Lords' decision (and the Court of Appeal ruling that it upheld) is highly contestable, on several grounds. First, the clarity of the statutory language in section 1(1)(a) casts doubt on either court's freedom to use a purposive approach to interpreting it; moreover, the 2001 act prohibiting human reproductive cloning was in force when the appeal was considered, so the court's view that a purposive approach was necessary to prevent the production of genetically identical individuals is surprising. Second, embryos produced by the process prohibited in section 3(3)(d) would *also* be "morphologically and functionally indistinguishable," in the words of the Court of Appeal, from embryos produced by fertilization, just as are embryos produced by CNR, and yet Parliament adopted a different regulatory approach to *their* creation and use. This being so, the assumption that Parliament intended to treat all "morphologically and functionally indistinguishable" embryos alike seems mistaken. Finally, in its consideration of *genus,* the House of Lords seems to have replicated the Court of Appeal's erroneous conflation of the term's legal application (to facts) and its scientific sense.

The current research purposes specified in the HFE Act relate only to research that could be envisaged at that time. It is nevertheless difficult to argue that they were based on immutable moral criteria, and indeed the existence in the HFE Act of the power to broaden the research purposes in due course supports this view. Additional research purposes were in fact added by important new regulations that were enacted in 2001, as is discussed below. In all types of embryo research under consideration it has to be accepted that the embryo cannot itself receive any benefit. The embryo is used instrumentally—as a means to an end—and will be destroyed. This is, in any event, an inevitable outcome for all spare embryos whether donated for research under the currently allowed research purposes or no longer required for treatment. If the arguments of the Warnock Committee (established in 1982 by the U.K. government to report and advise on developments in human fertilization and embryology, in its report published in 1984), are accepted, the issue to be considered is one of balance: whether the research has the potential to lead to significant health benefits for others and whether the use of embryos at a very early stage of their development in such research is necessary to realize those benefits.

The post*-Quintavalle *situation. So far as CNR research within the United Kingdom is concerned, the legislation now draws a line at the point of implantation by prohibiting the placing in a woman of "a human embryo which has been created otherwise than by fertilisation." Until the Court of Appeal reversed the High Court decision, a decision confirmed by the House of Lords, it would not have been unlawful to do CNR work preparatory to implantation. After the reversal, however, research involving CNR embryos is lawful only when authorized by a license granted by the HFEA, and so long as the Human Reproductive Cloning Act remains in place it is inconceivable that the HFEA would license research directed at human reproductive cloning.

A license authorizing specific research under the HFE Act may be granted by the HFEA for a maximum period of three years. Any research license may be made subject to conditions imposed by HFEA and specified in the license, and any authority to bring about the creation of an embryo, keep or use an embryo, or mix human sperm with a hamster or other specified animal's egg may specify how those activities may be carried out. Each research protocol must be shown to relate, broadly, to one of the existing categories of research aim, and then again only if the authority is satisfied that the research is "necessary for the purposes of the research" (Schedule 2, para. 3[5]). These research aims are:

- Promoting advances in the treatment of infertility
- Increasing knowledge about the causes of congenital disease
- Increasing knowledge about the causes of miscarriage
- Developing more effective techniques of contraception
- Developing methods for detecting the presence of gene or chromosome abnormalities in embryos before implantation
- Increasing knowledge about the creation and development of embryos and enabling such knowledge to be applied

The Human Fertilisation and Embryology (Research Purposes) Regulations of 2001 extended these original purposes. These regulations provided for three further purposes for which research licenses may be authorized:

(a) increasing knowledge about the development of embryos;
(b) increasing knowledge about serious disease, or
(c) enabling any such knowledge to be applied in developing treatments for serious disease.

THE EUROPEAN DIMENSION. The Council of Europe's Convention on Human Rights and Biomedicine (1997), along with its Additional Protocol on the Prohibition of Cloning Human Beings (1998), which covers only *reproductive* human cloning, is an important document. Ten of the fifteen EU countries have now signed the convention, despite what some have seen as its (almost necessary) limitations.

The protocol makes what was implicit in the convention explicit by declaring that "[a]ny intervention seeking to create a human being genetically identical to another human being, whether living or dead, is prohibited" (Article 1[1]). Because "genetically identical" is defined as "sharing with another the same nuclear gene set" (Article 1[2]), somatic CNR is included within this prohibition. The term *human being* is not defined in the convention, and because *human being* is unlikely to be interpreted to include embryonic human life, some countries, in signing the convention and its protocol, have added their own interpretative statements. For example, the Netherlands, in doing so, stated that "[i]n relation to Article 1 of the Protocol, the Government of the Kingdom of the Netherlands declares that it interprets the term 'human beings' as referring exclusively to a human individual, i.e., a human being who has been born."

In its report titled "Ethical Aspects of Human Stem Cell Research and Use," however, the European Group on Ethics in Science and New Technologies advised that, at present, "the creation of embryos by somatic cell nuclear transfer ['therapeutic cloning'] for research on stem cell therapy would be premature" because there are alternative sources of human stem cells.

EXAMPLES OF OTHER JURISDICTIONS' LEGAL APPROACHES. In the United States, regulation of human cloning and embryo research has been undertaken or debated at both the national and state levels. At the federal level, there is a rigid separation between the public and private sectors. Little if any regulation applies to research involving the use of human embryos if it is funded by the private sector, although the U.S. Food and Drug Administration has asserted jurisdiction over reproductive cloning whenever safety issues are raised.

Federal attempts to regulate cloning have the support of President George W. Bush, who, on April 10, 2002, called on the U.S. Senate to endorse the Human Cloning Prohibition Act, which would ban all human cloning in the United States, including the cloning of embryos for research. This bill was nearly identical to the bipartisan legislation that passed the U.S. House of Representatives by more than a 100-vote margin in 2001.

This announcement supplemented the one issued on August 9, 2001, regarding stem cell research. In the latter, Bush resolved that federal funding of research using the more than sixty existing stem cell lines from genetically diverse populations around the world that have already been derived would be permitted, but that he would not sanction or encourage the destruction of additional human embryos. Henceforth, federal funds could be used only for research on existing stem cell lines that were derived: (1) with the informed consent of the donors; (2) from excess embryos created solely for reproductive purposes; and (3) without any financial inducements to the donors. In order to ensure that federal funds are used to support only stem cell research that is scientifically sound, legal, and ethical, the U.S. National Institutes of Health was charged with examining the derivation of all existing stem cell lines and creating a registry of those lines that satisfy these criteria. A further result was that federal funds cannot be used for: (1) the derivation or use of stem cell lines derived from newly destroyed embryos; (2) the creation of any human embryos for research purposes; or (3) the cloning of human embryos for any purpose.

In Canada, a similar approach was taken in February 2002. In Australia, the Research Involving Embryos and Prohibition of Human Cloning Act of 2002 was introduced into Federal Parliament in June 2002. There are three main elements to the bill: a ban on human cloning, a ban on certain other practices relating to reproductive technologies, and a system of regulatory oversight for the use of excess embryos created through assisted reproductive technologies that would otherwise have been destroyed. The legislation would establish a system of licensing, administered by the National Health and Medical Research Council.

IV. RELIGIOUS PERSPECTIVES

Even for those who are not actively religious, nascent human life evokes awe and a sense of being in the presence of primal powers of creation. In the procreation of all species, from plants to domestic pets, religious consciousness often senses the divine at play in the natural. In human procreation in particular, human beings not only observe but also participate in that power, and by conceiving and giving birth humans play a small but profoundly personal role in creation.

There is little wonder, then, that for millennia, religious texts have spoken of human procreation with tones of wonder. In the Hebrew Scriptures, Psalm 139 reads in part:

> For thou didst form my inward parts,
> thou didst knit me together in my mother's womb.
> I praise thee, for thou art fearful and wonderful.
> Wonderful are thy works!
> Thou knowest me right well;
> my frame was not hidden from thee,
> when I was being made in secret,
> intricately wrought in the depths of the earth.
> Thy eyes beheld my unformed substance … (Psalms 139:13–16a)

In ancient Hebrew thought, procreation is the realm of divine prerogative. The protracted struggle for monotheism is in part a rejection of the idea, probably widespread in the ancient world, that fertility is itself divine. Hebrew monotheism could not tolerate lesser gods, such as fertility. In the name of one God, the prophets insisted that though mysterious, fertility is one of many processes of nature entirely under God's control. Various forms of polytheism in the ancient world saw these processes as deities in themselves, often female, and the success of monotheism is in some respects a desacralization and a defeminization of these processes. But such a desacralization goes only so far. For the ancient Hebrew monotheist, the one supreme God is intimately and personally present in these processes, making them anything but merely natural.

From Creation to Procreation

As an arena of divine presence, nascent life must be held in respect, for if it is God's work, its development must not be thwarted nor its condition questioned. According to the prophet Isaiah, God declares:

> Woe to you who strive with your Maker,
> earthen vessels with the potter!
> Does the clay say to the one who fashions it, "What are you making"?
> or "Your work has no handles"?
> Woe to anyone who says to a father, "What are you begetting?"
> Or to a woman, "With what are you in labor?" (Isa. 45:9–10)

Because procreation is the work of God, it is unseemly to question how or when it occurs, much less speculate about God's competence in making humankind.

Ancient biblical culture is also characterized by the command to propagate (Genesis 1:28) and thus by a strongly reinforced desire for children. In addition to any innate yearning or social pressure for offspring, the infertile in biblical culture no doubt feared being seen as disobedient, and several biblical stories contain impassioned pleas for children. The most notably such plea is that of postmenopausal Sarah, the wife of Abraham, who according to the story subsequently gives birth to Isaac from whom all Israel descends. That God can cause this to happen against nature is taken as evidence of God's supremacy over nature.

In view of the involvement of God in procreation and of the command to populate the earth, it is somewhat surprising that Hebrew Scripture says little or nothing about the moral status of human life in utero. Exodus, chapter 21, discusses the legal consequences that follow from an accidental miscarriage: "When men strive together, and hurt a woman with child, so that there is a miscarriage, and yet no harm follows, the one who hurt her shall be fined, according as the woman's husband shall lay upon him; and he shall pay as the judges determine. If any harm follows, then you shall give life for life …" (Exod. 21: 22–23).

While the text leaves much unsaid, it does prescribe different penalties for causing a miscarriage (a fine) and for causing the women's death (a capital offense), suggesting that these are offenses of a substantially different magnitude. Strictly speaking the scope here is limited to miscarriage or unintentional abortion, so its applicability to an intended abortion is subject to debate.

Early Judaism

In Judaism at the beginning of the common era, this text was interpreted in various ways. In most interpretations, developing life was not generally regarded as possessing the legal status of a person, but abortion was nonetheless opposed, in part because of its interference with creation, in part because it violated the command to reproduce, and in part because it deprived the family (in particular the father) of something of

value in the birth of another child. Generally speaking, Judaism objected to the widespread acceptance of abortion (and even of infanticide) in the ancient world, even if it did not see abortion as a highly serious offense.

In the translation of this Hebrew text into Greek, a significant mistranslation occurred. Where the original says "no harm," the translators substituted "no form," thereby introducing into religious debate the distinction between the unformed and the formed fetus. The widely influential Jewish scholar Philo (c. 20 B.C.E.–c. 50 C.E.), for instance, distinguished between formed and unformed fetus, and early Christianity picked up this distinction.

Christian Origins

The New Testament itself takes no position on abortion or on the status of embryonic or fetal life, although some scholars feel that negative references to *pharmakeia* in several passages specifically refer to abortifacient drugs and not to medicine generally. As in Judaism, the core Scriptures of Christianity ignore the moral questions of fetal life and of abortion. But to say that because the New Testament does not address abortion, it says nothing *theological* about fetal life, is wrong. Two of the four Gospels (Matthew and Luke) devote substantial attention to the miraculous conception not just of Jesus but also of his forerunner, John the Baptist. According to the story, John's mother Elizabeth is too old to conceive, but in keeping with a tradition that goes back to Sarah, she conceives because of God's involvement and for the sake of God's purposes. Mary, the mother of Jesus, is Elizabeth's cousin, and in the story of the "virgin birth" (or more precisely the "virginal conception") the tradition of miraculous conceptions reaches its culmination. God is so immediately involved in the details of this human conception that a human sperm is replaced by a miracle. The virgin birth is often the subject of theological puzzlement by scholars but is widely, if only sentimentally, affirmed by many ordinary Christians to this day. One must not underestimate the significance of this tradition in forming Christian attitudes toward embryonic and fetal life.

Not unexpectedly, therefore, as Christianity developed and distinguished itself from Judaism, it opposed abortion more strongly than Judaism or than the teachings of the New Testament itself. In some early post–New Testament writings, abortion is equated with murder. For instance, an early writing known as the *Didache* comments on abortion by listing it among the commandments: "You shall not commit murder … you shall not murder a child by abortion nor kill that which is born" (2:2). This text not only prohibits abortion, but, by identifying it with murder, also implies that fetal life is fully human or personal. Another early text, the *Letter of Barnabas,* uses essentially the same terms: "Thou shalt not kill the fetus by an abortion or commit infanticide" (19:5). These texts, critically important in shaping the early Christian conscience, expressed agreement in considering abortion as murder and as elevating its prohibition to the status of commandment. Furthermore, the claim that God is fully present in the human life of Jesus, even in utero, at once divided Christian from Jew and drove the Christian to a new consciousness of the value of nascent life.

Form and Soul

Even so, early Christian writers often retained the distinction between the formed and unformed fetus, implying that the unformed fetus possesses a lesser status than one that is fully formed. One of the first Latin Christian theologians, Tertullian, who lived around 200 C.E., opposed abortion but implied in his writings that there is a distinction of significance between the formed and unformed embryo. In chapter 37 of his treatise *On the Soul,* Tertullian wrote: "The embryo therefore becomes a human being in the womb from the moment that its form is completed."

One way to defend the distinction between formed and unformed is to hold that the human soul is added to the developing fetus when it attains a recognizably human shape. The metaphysics of the fourth century B.C.E. Greek philosopher Aristotle, which links soul and form, was often used here for support. Thus, what begins as an empirical question—does the fetus have a human shape?—becomes entwined with a religious and metaphysical question of whether the fetus has a soul, and at what stage this is so. The joining of the soul to the developing organism, a process called ensoulment, thus became a subject of intense religious debate among Christian theologians.

This debate was never resolved and in fact quickly became entangled in conflicting Christian views of the human soul, its origin, and the nature of its relationship to the human body, all set against the backdrop of competing philosophical options. In this regard Tertullian held a view peculiar among Christians that the soul is not a spiritual but a material substance and is transmitted sexually rather than created by God. Most other theologians of the early church saw the soul as a spiritual substance. In contrast, however, to philosophical views that accepted a dualism of soul and body, Christian theologians generally agreed that body and soul, though metaphysically distinct, are functionally inseparable. In death, the soul is not freed from the body, as the Greek philosopher Plato (c. 428–c. 347 B.C.E.) contended, but awaits the resurrection of the body in order that

both soul and body might be transformed together into a glorified mode of immortal existence. Speculation about ensoulment, therefore, was always grounded on this insistence on the unity of soul with body.

Unity of Soul and Body

The widely influential Gregory of Nyssa (c. 335–c. 394), for instance, held so strongly to the unity of soul and body that he could not imagine the body developing at all without the soul being present. In a work called *On the Making of Man,* Gregory wrote: "As man is one, the being consisting of soul and body, we are to suppose that the beginning of his existence is one, common to both parts so that it is not true to say either that the soul exists before the body, or that the body exists without the soul, but that there is one beginning of both" (chap. 29). According to Gregory, at every stage of human development, from inception to resurrection, body and soul function as one.

In the same work, Gregory elaborates on the development of the soul with the body:

> For as the body proceeds from a very small original to the perfect state, so also the operation of the soul, growing in correspondence with the subject, gains and increases with it. For at its first formation there comes first of all its power of growth and nutriment alone, as though it were some root buried in the ground; for the limited nature of the recipient does not admit of more; then, as the plant comes forth to the light and shows its shoot to the sun, the gift of sensibility blossoms in addition, but when at last it is ripened and has grown up to its proper height, the power of reason begins to shine forth like a fruit, not appearing in its whole vigour all at once, but by care increasing with the perfection of the instrument, bearing always as much fruit as the powers of the subject allow. (chap. 29)

In Gregory's view, there is no moment or process of ensoulment subsequent to conception. Existence and ensoulment are one.

Augustine's Options

As Gregory of Nyssa profoundly influenced the development of Greek Christianity and thus of the subsequent Orthodox Churches, so Augustine (354–430) deeply shaped Western or Latin Christianity, which at the Reformation (beginning about 1520) became Catholicism and Protestantism. Augustine, whose influence can scarcely be exaggerated, accepted the distinction between the formed and unformed fetus. In addition he tended to be more dualistic in his thinking, and he therefore accepted greater discontinuity between soul and body than did Gregory or other Eastern theologians.

Although Augustine was not generally indecisive on theological and moral matters, he remained undecided throughout his life on the question of the origin of the human soul and the way it is joined with the human body. One possibility (called *creationism*) is that God creates the soul at around the time of conception or somewhat later and joins it to the developing body. By allowing separate origins for the soul and the body, this view makes possible the idea that for a time, the body develops without a human soul being present, something Gregory flatly rejected. The other possibility that Augustine considered (called *traducianism*) is that soul and body come into existence together, that is to say, at conception, when both are transmitted together from one generation to the next. Tertullian accepted traducianism, and perhaps for that reason, other Western theologians see it as degrading the soul by making it material rather than spiritual in substance.

Both Augustine's indecision and his speculations remain influential in Western Christianity. Concerning the pastoral question of whether the results of miscarriage or abortion will share in the general human destiny of immortality, Augustine wrote in the *Enchiridion:*

> … with respect to the resurrection of the body … comes the question about abortive fetuses, which are indeed "born" in the mother's womb, but are never so that they could be "reborn." For, if we say that there is a resurrection for them, then we can agree that at least as much is true of fetuses that are fully formed. But, with regard to undeveloped fetuses, who would not more readily think that they perish, like seeds that did not germinate? (23:84–85)

Here Augustine accepts the distinction between formed and unformed and uses it in the ultimate theological context—the question of what is human in the resurrection. He also uses it to clarify his opposition to abortion. For him, destroying the formed fetus is murder, whereas destroying the unformed fetus is a lesser offense.

When it comes to the deeper theoretical question of the beginning of human life, Augustine admits his uncertainty in the *Enchiridion:*

> On this score, a corollary question may be most carefully discussed by the most learned men, and still I do not know that any man can answer it, namely: When does a human being begin to live in the womb? Is there some form of hidden life, not yet apparent in the motions of a living thing? To

> deny, for example, that those fetuses ever lived at all which are cut away limb by limb and cast out of the wombs of pregnant women, lest the mothers die also if the fetuses were left there dead, would seem much too rash. (23:86)

The Development of Catholic Thought

In time creationism, with its dualistic tendencies, became the majority view in the Western or Latin church, and it was often combined with the idea that the soul was not joined to the body until formation. The reintroduction of Aristotle into Western thought brought new subtleties to the discussion. Thomas Aquinas, whose integration of Aristotle into Christian theology in the thirteenth century was at first controversial but was subsequently seen as authoritative for Catholics, combined creationism with the view that the soul undergoes transition. At its beginning, the embryo does not have a human soul, merely the kind of soul common to all forms of life and responsible for growth and development. Only when fetal development advances to a stage that resembles human form is it possible for the human soul to be present. The human or intellectual soul is immaterial and must be created by God, who joins it to the developing fetus. At that moment of ensoulment, the fetus becomes human or attains hominization, and its moral claim to life is absolute.

Thomas's position is dependent upon an empirical observation of Aristotle, who concluded that the human soul is present at forty days after conception for males and ninety for females. Because the soul was thought to animate the body, "quickening," or the feeling of fetal movement, was taken as a sign that ensoulment had occurred. Until 1869, the Catholic Church recognized a distinction between the ensouled and the unensouled fetus, insisting on a higher penalty for the destruction of the former.

Into the Modern Era

Protestantism, which in its various forms became separate from the Catholic Church in the sixteenth century, tended to take a more strict view against abortion than the Catholics, opposite to the modern situation. This is perhaps because of the Protestant return to early church standards and its rejection of much of the previous thousand years of church tradition, particularly in philosophical theology. Early followers of Martin Luther and John Calvin (leaders of the Reformation) held views that resembled those of Gregory of Nyssa more than those of Thomas Aquinas. In time, however, theological and philosophical considerations reentered Protestant discussion, along with both an encounter with new scientific discoveries in biology and embryology and a general tendency in Protestantism to accommodate contemporary culture whenever reasonably possible. As a result, by the twentieth century, Protestantism was largely tolerant of abortion even while discouraging its members from obtaining one for less than urgent reasons.

During this same period, Catholic teaching moved in the opposite direction. Scientific discoveries (and in some cases, misinterpretation of data, such as the view that the earliest embryo is fully shaped like a tiny human being) led Catholic theologians to challenge their own previous view of delayed hominization and to propose in its place a new theory of immediate hominization. This idea gained popularity after 1700, until, in 1869, Catholic canon law removed the distinction between the ensouled and the unensouled fetus, thereby implying but not asserting that immediate hominization is the correct view. The key point, however, is that the abortion of an unformed fetus is to be regarded as the moral equivalent of the abortion of a formed fetus, and therefore abortion is murder at any stage. With this development, Catholic moral teaching became absolute, whereas Catholic theology remained somewhat open to various perspectives on the metaphysical status of the embryo. As a result, Catholic morals and theology developed somewhat independently, based in part on the claim that moral certainty does not require doctrinal clarity.

Current Catholic Teaching

In 1987 the Catholic Church provided guidance on reproductive medicine and embryo research in *Donum vitae* (Respect for human life). *Donum vitae* poses and then answers a key question: "how could a human individual not be a human person? The Magisterium has not expressly committed itself to an affirmation of a philosophical nature, but it constantly reaffirms the moral condemnation of any kind of procured abortion" (Congregation for the Doctrine of the Faith, 1987, part I, no. 1). In other words, immediate hominization is not affirmed doctrinally but its implications are fully asserted morally, not just for abortion some weeks into a pregnancy but in regard to the embryo at the earliest moment. *Donum vitae* insists:

> The human being must be respected—as a person—from the very first instant of his existence.… Thus the fruit of human generation, from the first moment of its existence, that is to say from the moment the zygote has formed, demands the unconditional respect that is morally due to the human being in his bodily and spiritual totality. The human being is to be respected and treated as a person from the moment of conception; and therefore from that same moment his rights as a person must be recognized, among which in the first place

> is the inviolable right of every innocent human being to life. (Congregation for the Doctrine of the Faith, 1987, part I, no. 1)

Again asserting moral certainty while avoiding doctrinal conclusiveness, the Catholic Church in 1974 issued its *Declaration on Procured Abortion,* which states: "This declaration expressly leaves aside the question of the moment when the spiritual soul is infused. There is not a unanimous tradition on this point and authors are as yet in disagreement" (Sacred Congregation, p. 13). This statement almost invites debate on dogma while shutting the door to reconsideration of moral teaching.

Dogma and Debate

The discussion of the theology of nascent human life has been vigorous among Catholic scholars and some Protestants. Recent scientific discoveries in genetics and embryology have been considered in the debate, particularly relating to whether the human embryo prior to about fourteen days can be said to be an individual. There is general agreement, according to a 1984 article by Carol A. Tauer, that "the stage of individual has been seen as a morally relevant marker because it appears that only individuals can be wrongfully killed or otherwise injured" (p. 5).

While genetics and embryology support the idea that the newly conceived embryo is a genetically unique human life, three other biological considerations have been raised to argue against the idea that the early embryo is an individual: The embryo might divide into two (twinning); an embryo might join with another genetically unique embryo to form a chimera, which then continues to develop as one human individual; and as many as 75 percent of all human conceptions fail to survive. In a 1990 article, Thomas A. Shannon and Allan B. Wolter argued that "something human and individual is not a human person until he or she is a human individual, that is, not until after the process of individual is completed. Neither the zygote nor the blastocyst is an ontological individual, even though it is genetically unique and distinct from the parents" (p. 613).

A related question is whether the embryo, which lacks most human qualities, nonetheless typically anticipates their development and thus must be said to possess them potentially, or to have potentiality. If so, does that potentiality confer a status to the embryo as one who must be regarded morally as already possessing what is only its potential? Furthermore, if the embryo is out of the body (and thus unable to actualize its potential), does it possess a lower status? Or if the embryo is somehow biologically incapable of developing, either because of a natural or technologically induced impairment, does it likewise lack whatever value potentiality confers? These questions remain open.

Given that Catholic theologians hold various views on the individuation or personhood of the embryo, how can Catholic moral certainty be possible? Much depends, of course, on the conclusion one draws from the variety of views. One might conclude that when various views are held, one should err on the side of caution, give the embryo the benefit of any doubt, and treat it as if it were a human person. Others conclude that in light of the evidence, it cannot be a human person and that therefore, aside from the authority of the church, there is no obligation to treat it as such.

Protestant Perspectives

Protestants, in the late-twentieth century, were generally supportive of the right of women to choose an abortion, even though they adopted a cautious approach of limiting to the most serious reasons the circumstances under which this right could be exercised. For instance, the Presbyterian Church (U.S.A.), in a 2000 publication, outlined a position similar to that of other traditional denominations:

> The considered decision of a woman to terminate a pregnancy can be a morally acceptable, though certainly not the only or required, decision. Possible justifying circumstances would include medical indications of severe physical or mental deformity, conception as a result of rape or incest, or conditions under which the physical or mental health of either woman or child would be gravely threatened. (p. 431)

This is not to suggest that the members of these denominations are in strong agreement with the official position, and in fact there is some reason to believe that support for these positions is eroding. In addition, the character of Protestantism has been changing in the United States, with the rapid growth of evangelical, independent, and charismatic churches that often criticize traditional denominations for being too accommodating to secular culture on matters such as abortion. As a result, even those who fully support the right of women to choose an abortion as a matter of public policy are recognizing that at the same time, they must acknowledge the moral value of what is lost. Furthermore, some African-American Christians are suspicious of abortion for the additional reason that it appears to them to be a way to limit their numbers.

Prominent Protestants have also stood in opposition to abortion. Karl Barth, often seen as the most important Protestant theologian of the twentieth century, objected to

abortion, while Stanley Hauerwas, perhaps the most influential Protestant theologian in the United States at the beginning of the twenty-first century, is also critical of abortion along with other accommodations to modern culture.

Whether tolerating abortion under limited circumstances or condemning it in almost all cases, contemporary Protestants tend to agree among themselves that questions of ensoulment are too dualistic for Christian faith, at least in its Biblical roots. They see human life, as a whole and from beginning to end, as a gift of God that we dare not refuse lest we reject our own humanity. In some respects the views of recent Protestants have more in common with those of Gregory of Nyssa than with recent Catholic debate, and thus Protestants agree with Orthodox theologian John Breck's assessment that Orthodoxy would "take issue with the Catholic Church's doctrine of ensoulment, at least as it has been expressed in Aristotelian and Thomistic terms … [as] dualistic to Orthodox ears" (p. 140). While Orthodoxy has no doubt about when the unitary gift of human life begins (that is, at conception), Protestants by virtue of their institutional structure and communal ethos will surely continue to disagree, some siding with Orthodoxy and practically with Catholicism, others siding with Judaism and Islam.

Special notice should be paid to the perspective of the Church of Jesus Christ of Latter Day Saints, commonly known as the Mormons. While dependent in many ways upon the views of Christianity and Judaism, and sharing scriptures with these traditions, Mormonism develops a somewhat distinct view. Mormons have tended to be restrictive if not prohibitive on abortion, although not necessarily seeing it as murder. Furthermore, as Lester E. Bush observes, Mormonism does not hold to a dogma on the embryo or the fetus, but tends to see each human person or soul as the dynamic interplay between the biological and the spiritual. Somewhere in the process of fetal development, usually at quickening or at birth but not at conception, spirit is present and thus the developing life is a person deserving absolute protection. Given the size of the Latter Day Saints, these views have considerable political significance in the United States.

Judaism, Islam, and Buddhism
