MEDICAL CODES AND OATHS

• • •

I. HISTORY

The following is a revision and update of the first-edition article "Codes of Medical Ethics: History" by Donald Konold. Portions of the first-edition article appear in the revised version.

In the ethics of healthcare, explicit statements of ethical standards have been formulated for physicians and members of the other health professions, for persons conducting medical experiments involving human subjects, for administrators, and for patients and other laypeople who make healthcare decisions. These have often been written by members of the relevant practitioner group, but they may also be written by members of religious, cultural, national, or international bodies. While codes of ethics have long been regarded as the classic expression of these directives, various principles and rules have also been stated in the form of prayers, oaths, creeds, institutional directives, and statements. Prayers state a very personal commitment of duty; oaths publicly pledge the oath taker to uphold specified responsibilities; and codes provide more comprehensive standards to guide the practicing health practitioner, patient, or other decision maker. Each form of ethical statement implies a moral imperative, either to be accepted by the individual personally or to be enforced by a practitioner organization, religious community, or governmental body.

While practitioner bodies have often assumed responsibility for writing their own codes of ethics for their members, governmental, religious, and cultural bodies have also claimed authority to articulate the moral norms of conduct in healthcare. Disputes over who has the authority to articulate codifications of ethical duties in the medical sphere reveal important controversies over who can legitimately claim moral authority in determining what these duties are. This article first examines prayers, oaths, and codes written by health providers or practitioner groups, and then examines those written outside the profession.

Documents Created by Practitioners

MEDICAL PRAYERS. Healthcare providers in all ages have composed prayers expressing gratitude for divine blessings and asking for divine inspiration in their practitioner conduct. Such prayers signify that the writer stands within a religious tradition and grounds medical duties in that religion's moral framework.

An ancient Greek poem that has the quality of a prayer or a hymn was found inscribed on a monument in a sanctuary of Asclepias, originally on the south slope of the Acropolis. According to the poem, the physician should be "like God: savior equally of slaves, of paupers, of rich men, of princes, and to all a brother, such help he would give" (Etziony, p. 21).

Likewise, ancient Jewish sources include texts extolling the physician's healing. An early Jewish prayer was written by the early-twelfth-century Spanish poet, philosopher, and physician Yehuda Halevi (Etziony). The most widely acclaimed Jewish example is the Daily Prayer of a Physician, once ascribed to the Jewish physician and philosopher Moses Maimonides (1135–1204) but now believed to be the work of the eighteenth-century German Jewish physician

Marcus Herz (Rosner). In the manner of most medical prayers, the Daily Prayer asks for courage, determination, and inspiration to enable the physician to develop skills, meet responsibilities, and heal patients. It commits the physician to place duty to patients above the physician's own concerns and places the physician's healing in clear subordination to divine authority.

Many examples of Christian prayers of physicians exist from ancient and medieval times. More modern prayers sometimes reflect more eclectic, nondenominational perspectives. The theology expressed in the prayers of these physicians, who, theologically, are laypeople, is sometimes not an authoritative reflection of the tradition in which they stand.

OATHS FOR PHYSICIANS. In the ancient world physicians often expressed their ethical commitments in the form of oaths, which were an integral part of the initiation ceremony for medical apprentices. Like many medical prayers, ancient oaths reflect the physician's belief that success in the healing profession required an alliance with the deity in the treatment of disease. The ancient oaths often beseech the deity to inspire physicians to fulfill their moral obligations, reward those who honor their sacred trust, and punish those who violate it.

One of the oldest of these oaths, a medical student's oath taken from the *Charaka Samhita* manuscript of ancient India, contains concepts that had pervaded Indian ethical thought for many centuries before their inclusion in the oath at about the beginning of the common era (Menon and Haberman). Pledging the medical student to live the life of an ascetic and a virtual slave of his preceptor in accordance with Indian custom for apprenticeships, the path requires personal sacrifice and commitment to duty from the student comparable to the physician's responsibilities to patients. By the terms of the oath, the student physician is to place the patient's needs above personal considerations, serving day and night with heart and soul; abstaining from drunkenness, crime, and adultery; and scrupulously observing practitioner secrecy.

In sharp contrast to the medical ethics of the Western world, the Indian oath obliges the physician to deny services to enemies of his ruler, evildoers, unattended women, and those on the point of death. Ancient Indian thought condemned aid to anyone who was immoral or was involved in any circumstance that might suggest illicit sexual contact; it also condemned interference with the process of dying. Despite these differences, the oath of the Indian student reveals significant parallels between the medical ethics of India and those of the Western world, which may suggest a diffusion of ideas, probably from India to the West.

The most enduring medical oath of Western civilization is the Oath of Hippocrates. Despite its renown, its origin is obscure. It is a part of the Hippocratic Collection, which was catalogued and edited by a group of Alexandrian librarians sometime after the fourth century C.E. Copies of these writings available to modern scholars, however, date from the tenth to the fifteenth centuries C.E. and do not preserve the original text with verbal accuracy. None of the manuscripts in this collection can be positively verified as genuine works of the great Greek physician, and clearly the documents are the products of many contributors, with the earliest predating the latest by at least a century.

Twentieth-century scholars, especially Ludwig Edelstein (1943), have suggested that the oath conforms closely to the teachings of Pythagoras (fourth century B.C.E.). He noted the similarities with the principal ethical beliefs of the Pythagoreans, which included reincarnation, avoidance of shedding of blood, prohibition on taking of life, and commitment to sexual purity and secrecy. Edelstein held that the oath was composed by a group of Pythagoreans who practiced the healing arts. More recent historians of medical ethics have argued over whether the dependency is as close as Edelstein maintained, suggesting that the influence of other philosophical/ethical traditions may also be present (Carrick). Nevertheless, some degree of affinity of Hippocratic with Pythagorean thought is generally conceded. The oath, in accord with Pythagorean ethics, proclaims a more strict morality for physicians than was established by Greek law, Platonic or Aristotelian ethics, or common Greek medical practice.

The Oath of Hippocrates consists of two parts, the first serving as a contractual agreement between pupil and teacher and the second constituting an ethical code. The opening sentences pledge the novice physician (invariably a male) to become an adopted member of his teacher's family, to help support his teacher and his teacher's children in case of need, and to instruct his teacher's children free of charge. The oath forbids sharing the precepts and medical knowledge with anyone who has not taken the oath. Since familial bonds between teacher and pupil implied careful selection of those admitted to the family group, the covenant enabled physicians to prevent unworthy persons from entering the profession and to keep tight control on knowledge transmission.

The ethical code contained in the Oath of Hippocrates places restrictions on the medical techniques of the physician and defines relations with the patient's family. One who takes the oath pledges, "I will apply dietetic measures for the benefit of the sick according to my ability and judgment; I will keep them from harm and injustice" (Edelstein, 1943, p. 3). He also agrees to refuse to dispense poisons or abortive remedies, and to leave surgery (including lithotomy or

removal of a stone from the urinary bladder) to those trained in that art. He makes the commitment that "whatever houses I may visit, I will come for the benefit of the sick, remaining free of all intentional injustice" (Edelstein, 1943, p. 3). The taker of the oath swears to abstain from sexual relations with all those in the houses the physician enters. Regarding confidentiality, in an ambiguously qualified way, the physician promises not to disclose that "which on no account one must spread abroad." The oath ends with a plea for reward that is unusually self-serving for a code of ethics: that if the physician keeps the oath he be "honored with fame among all men for all time to come." If he transgresses it, "may the opposite of all this be my lot" (Edelstein, 1943, p. 3).

The oath's provisions contrast sharply with what is otherwise known about ancient Greek medical practice, which permitted physicians to abet suicide and infanticide and to perform surgery. They introduced an element of respect for slave as well as freeman and, even though the secrecy requirement is qualified, it is extended outside the practitioner relationship. These precepts, though they represent the thought of only a small group of medical practitioners, extended their influence beyond the importance of the Hippocratic school of medicine in the ancient world.

For centuries following the appearance of the Hippocratic oath, the practitioners of the medical art showed no inclination to accept it. Hellenistic physicians ignored its injunctions without compunction. It is sometimes held that the rise of Christianity, which had certain ethical positions similar to Hippocratic ethics, is responsible for the ascendancy of the Hippocratic oath (Edelstein, 1943; Carrick). There is, however, very little evidence of early Christian interest in the Hippocratic oath; increasingly there is emphasis on important ethical differences between the Hippocratic and Christian traditions (Veatch and Mason). Medical historian Owsei Temkin has identified considerable tension between Hippocratic and Christian medicine and their ethical commitments. One exception to this generalization is the fourth-century Christian figure Jerome, who explicitly mentions the Hippocratic oath, but in doing so he points out that the Christian physician's obligation is even more stringent.

Precisely what happened to bring the oath into prominence during the Middle Ages is uncertain. Perhaps the early post-Constantinian Christian culture found similarities between Christian and Hippocratic views, as has been suggested. A strong case can be made, however, that although there were significant differences between Greco-Roman and Christian medical ethics, lay physicians were simply not sufficiently schooled in Christian theology to perceive them. One way or another, increased attention to the oath led to renewed interest in it. Modifications were introduced in order to bring it somewhat more into harmony with Christian ideological concepts and practices. This could be taken either as evidence to support the convergence hypothesis or to support the contrary claim that the oath had to be corrected significantly to bring it into harmony with Christian thought.

The earliest of these extant revisions, titled "From the Oath According to Hippocrates Insofar as a Christian May Swear It" (dating from the tenth or eleventh century), substitutes a statement of Christian adoration of God for the references to the Greek deities in the original oath and replaces its covenant with a statement of teaching responsibilities based on Christian brotherhood, pledging the physician to teach the medical art to whomever wants to learn it (Jones; Leake). The injunction against surgery does not appear in this version of the oath. No reason is known for its omission, but later Christian versions do contain it. The appeal for reward and honor for the physician should he follow the oath is abandoned, probably because it is inconsistent with Christian views of grace.

The Oath of Asaf, from the seventh-century *Sefer Asaf* manuscripts of the oldest Hebrew medical work, reveals Hippocratic influences in its injunctions against administering poisons or abortifacient drugs, performing surgery, committing adultery, and betraying practitioner confidences (Rosner and Muntner). Like the medieval Christian oaths, it is consistent with Talmudic ethics and instructs physicians to give special consideration to the poor and needy, a concern absent from the Hippocratic oath. A revision of the Oath of Hippocrates also appeared in medieval Muslim literature, where the only significant changes replaced references to Greek gods with statements in harmony with Islamic theology. The oath in its original form was also known to Christian and Muslim scholars; however, among the Christian church fathers, only rare mention is made of it. The texts that do refer to the oath reveal a perception of a difference between Hippocratic and Christian medicine.

Following the transition from medieval to modern Western civilization, the Oath of Hippocrates apparently continued to be a model for ethical pledges by physicians. Its legacy is ambiguous. On the one hand, it repudiates exploitation of the sick, often the most vulnerable. On the other hand, it locates all authority about what constitutes a benefit in the physician's "ability and judgment." In this way, the oath has sanctioned a medical paternalism throughout the ages that is in conflict with the modern assertion of the right of patients to determine for themselves the benefits they seek from medical care.

Western medical schools in the eighteenth and nineteenth centuries, seeking to impart high ethical ideals to their students, administered oaths to their graduates. It is unclear whether or how often the Hippocratic oath itself was used, but certainly the typical oaths, such as that of the great medical school of Montpellier, incorporated Hippocratic ideas (Etziony).

Our knowledge of professional medical ethics in the early modern period is very limited. Historians have not done enough specific research in European and American medical schools and professional societies to know what local religious, philosophical, and political influences helped shape medical education. Additional research is underway. The received tradition holds that Western medical schools, seeking to commit their students to the pursuit of high ethical ideas, continued a tradition begun in the Middle Ages of incorporating Hippocratic concepts in oaths for their graduates, especially the covenant's requirement for the physician to instruct his teacher's children and the ethical injunctions for secrecy and against administering harmful drugs. During the nineteenth century, some medical schools in the United States required their graduates to take the Hippocratic oath in its original form, and that continued to be a common practice in the twentieth century, even though many of the oath's provisions were archaic or offensive to some of the students. A study published in 1991 found that 60 of 141 U.S. medical schools administered the Hippocratic oath (Dickstein et al.).

A document patterned after the Oath of Hippocrates appeared in 1948, when the newly organized World Medical Association (WMA) adopted the Declaration of Geneva. In 1991 forty-seven U.S. medical schools used it (Dickstein et al.). (Of the remainder, fourteen schools used the Prayer of Maimonides or more recently written oaths.) The declaration attempts to make the original oath applicable to modern conditions of medical practice and diverse cultural, religious, and ethnic groups in the world community. In doing so, it raises serious questions of how any one single ethical text could be made appropriate for a wide range of religious and cultural groups that clearly have fundamental differences, not only about significant medical ethical controversies, but also about the very foundations and meanings of ethical propositions. The Declaration of Geneva is a secular oath that contains no reference to religious tenets or loyalties, thus appealing to secular physicians while perhaps offending those who continue to ground their ethics in some particular religious framework.

Although the claim is made that the Declaration of Geneva simply updates the Hippocratic oath, the reformulation clearly involves significant differences. The declaration commits the physician to make the patient's health his or her first consideration, a provision reminiscent of the Hippocratic oath's pledge to use dietetic measures for the benefit of the sick. But in addition to the secularization of the declaration by the removal of the religious references, the 1948 text deletes the pledge to refuse to reveal information to those who have not taken the oath. The loose Hippocratic pledge of confidentiality is replaced with an exceptionless pledge, one that conflicts with the increasingly recognized necessity of disclosing in order to protect third parties from serious threats of harm, as well as with the more paternalistic exceptions seen in many modern interpretations of the oath. The oath's surgical restriction is also omitted from the declaration, as is the injunction against sexual contact with those in the patient's household.

The physician of the declaration vows not to let considerations of religion, nationality, race, party politics, or social standing interfere with his duty to his patient. Obviously, those who conceived and adopted the declaration found united support for clearer condemnation of these prejudices than the original oath provided. In sharp contrast, however, the declaration's statement of the physician's responsibility regarding suicide, mercy killing, and abortion is obscured in generalities that conceal modern controversy on these matters among physicians and laypeople alike. The physician of the declaration pledges only to maintain respect for human life from the time of conception and not to use medical knowledge in ways that are contrary to the laws of humanity. While the Declaration of Geneva has found some acceptance among medical professional groups, it has not been endorsed by significant national professional associations, and it certainly conflicts with the ethical precepts of many secular and religious groups in both East and West.

PRACTITIONER CODES. Physicians of the modern world have not been content with the spiritual inspiration of prayers and the moral commitments of medical oaths. The large medical institutions of urban society have required complex relationships among medical personnel who demand detailed procedures to prevent embarrassing ethical controversy and disruption of services. Lengthy treatises on medical subjects, which had enlightened physicians on ethical matters since the earliest times, were not easy to cite by paragraph and line and frequently concealed ethical instruction in needless verbiage. Reducing these essays to lists of rules, proponents of practitioner control produced elaborate ethical codes.

A code is an ordered collection of injunctions and prohibitions, usually created by an authoritative body and adopted as a statement of ideals and rules for a group or organization. The modern idea of codes derives ultimately from the Renaissance ideal of rationalizing Roman law,

putting the diverse parts into some order and stating briefly and clearly the essence of the rule. Sometimes individually authored documents, such as the work of Sun Szu-miao and Thomas Percival discussed below, have taken on the status of systematic codifications.

One of the earliest codes of medical ethics appeared in China, where the Oath of Hippocrates never made a significant impression. From the seventh century, an indigenous Chinese tradition in medical ethics developed in works by Sun Szu-miao. Generally regarded as Taoist, his writing stresses the importance of preserving life and the subordination of self-interest to compassion for the patient. It reflects the differentiation of an elite group of physicians referred to as "great physicians" and marks the emergence of a group claiming special medical authority. A Confucian response authored by Lu Chih (754–805) attacks this elitist trend, indicating medicine should be the responsibility of all persons. This tradition received clear expression in the Five Admonitions and Ten Maxims listed by Ch'en Shih-kung in a seventeenth-century treatise on surgery (Unschuld). Along with much guidance for social intercourse, Ch'en's precepts instruct physicians to give equal treatment to patients of all ranks, to keep expenses modest, and to treat the poor without charge, providing the same services regardless of the amount of payment. Above all, the physician is to know the principles of Confucianism. The key Confucian virtues are compassion and "applied humaneness," terms that do not enter Western medical ethics until the twentieth century.

These instructions continue to characterize Chinese medical ethics in modern times, but they have had little influence elsewhere. Although they bear some resemblance to ethical concepts in Western medicine, there are significant differences and little evidence of crossfertilization.

In the West, the Royal College of Physicians provides an interesting example of a professional code. In the first Statutes of the College in 1555, and in the revision of 1647, there is a section entitled, *De statutis moralibus seu penalibus.* This contains precepts requiring good behavior in the meetings of the college, regular attendance and, in addition, proper etiquette between several physicians called into consultation. They admonish physicians not to disparage or accuse one another in public, but only before the college. They also prohibit physicians from telling their patients and the public the names and composition of medicines, "lest the people be harmed by abuse of them" (Clark, p. 384).

A treatise published in 1803 by Thomas Percival, an eminent physician of Manchester, England, strongly influenced the development of codes of medical ethics (Leake; Baker et al., 1993; Baker, 1993). Originally prepared in 1794 to mediate a dispute among surgeons, physicians, and apothecaries in Manchester, and expanded in 1803 to include physicians in general practice, *Medical Ethics; or, A Code of Institutes and Precepts Adapted to the Professional Conduct of Physicians and Surgeons* expresses standards of morality and etiquette that were in sharp contrast to the quarrelsome conduct of British practitioners of that era. Percival's treatise places emphasis on the professional relationships of physicians to one another; to hospital personnel, apothecaries, and others engaged in the care of the sick; and to the law.

In its advice to physicians to treat patients with the eighteenth-century virtues of "tenderness, steadiness, condescension, and authority," it conveys the attitudes of the English gentleman philanthropically bestowing benefits on patients who are expected to show proper gratitude. Percival's *Medical Ethics* stands in the Hippocratic tradition, but begins to acknowledge obligations of physicians to the society as well as to patients. Unlike the Hippocratic oath, Percival holds both surgery and medicine as acceptable practices.

As befits a volume having its origins in a local dispute among professions, a principal concern of Percival's *Medical Ethics* is with the etiquette of professional conduct. It offers elaborate procedures for consultation among physicians in difficult cases and for preservation of distinction of rank in relationships between junior and senior physicians on hospital faculties and in consultations. It cautions physicians to display respect for one another, to avoid criticizing the practice of their colleagues, to conceal professional differences from the public, and not to steal patients from one another. In justifying these procedures, Percival reasoned that criticism of the profession was usually unfounded and always degrading both to the doctors criticized and to the profession. In most of its provisions, Percival's *Medical Ethics* suggests a modified utilitarian philosophy, calling for individual physicians to conduct themselves in a manner that would enhance public respect for the entire medical profession.

Among the earliest American writings in physician-authored ethics were those by Columbia University physician Samuel Bard and revolutionary patriot Benjamin Rush; early codes were also prepared by the medical associations of the cities of Boston and Baltimore and the state of New York. When the American Medical Association (AMA) was organized in 1847, it adopted a code of ethics drawn from Percival's *Medical Ethics* as well as these other sources. The code of ethics made no mention of etiquette for hospital staff and barely referred to the relations of physicians with pharmacists and courts of law, but it expanded and elaborated the principles for physicians in private practice, even

presuming to include a statement of obligations of patients and the public to physicians.

The medical profession in the United States faced a crisis in public confidence in 1847. Medical licensure laws in most states had been repealed with the result that uneducated practitioners and charlatans had begun to compete for patients with educated physicians. In addition, a vigorous debate raged between various schools of medical science over which was the correct or orthodox system. Proponents of the code of ethics hoped that the public would cooperate with allopathic physicians in establishing standards for medical practice that would reinstate public respect for the medical profession.

The code of ethics contained a variety of restrictions on open competition among physicians. It branded as quacks all medical practitioners who lacked orthodox training, claimed special ability, patented instruments or medicine, used secret remedies, or criticized other practitioners. In doing so, it also became a weapon in the internal dispute among physicians of different schools, particularly challenging the homeopaths. The requirement of orthodox training made outcasts of physicians who belonged to medical sects such as the homeopaths, the eclectics, the Thomsonians, and later the osteopaths and chiropractors. Since each sect claimed superior results from its form of treatment, practitioners with sectarian designations were guilty of claiming superior ability as well as handicapped by their incomplete education.

Charging that these offenses resulted from selfishness and efforts to discredit rivals, the code of ethics also demanded that reputable physicians avoid any appearance of soliciting the patient of another doctor. Although these provisions united the profession against heterodoxy and quackery, the prohibition on claims of special ability produced conflict between general practitioners and aspiring specialists. This ethical rule ceased to cause dissension only after the establishment of specialist organizations to certify the credentials of their members and after specialization won sufficient acceptance to permit physicians to restrict practice to their specialties.

The code of ethics provided orthodox physicians with one means of exposing those undeserving of confidence. It stated that physicians should not consult professionally with anyone who lacked a license to practice or was not in good professional standing. Since professional standing was determined by the local medical societies, this provision had the effect of substituting a collective professional judgment for that of individual physicians and patients, thus superseding the Hippocratic oath's focus on the individual physician's judgment. In those cases where the patient insisted on inviting a consultant who was not approved by the local medical organization, the attending physician would have to retire from the case in order to retain professional standing. While physicians argued that they could not fulfill their obligation to patients if they admitted a right for fraudulent practitioners to advise in any capacity, their ethics required that they withdraw, thus giving full charge of the case to the allegedly unqualified practitioner. Moreover, the majority of physicians found the consultation restriction a useful means for excluding many qualified physicians from association with the dominant organization. Thus the codes served a monopolistic function as instruments for restraint of trade. Before 1870, regular medical societies excluded from membership and forbade consultations with female physicians and Negro physicians and, throughout the latter half of the century, with physicians who adopted a sectarian designation, even if they were certified by licensing boards. Because of mounting criticism, the consultation restriction was eliminated from the code of ethics in 1903, but its spirit was revived by a 1924 resolution of the American Medical Association forbidding voluntary association of its members with cultists. In effect, the AMA code, so vociferously debated in the nineteenth century was double edged: It did state, in Percivalian terms, certain ideals of good practice, but at the same time, it was an instrument to create a monopoly.

Establishment of the World Medical Association in 1948 encouraged physicians to develop international standards of medical ethics. The new organization adopted an International Code of Medical Ethics (International Code) in 1949, which attempted to summarize the most important principles of medical ethics. Since 1900, certification laws had reduced the prevalence of unqualified medical practitioners, and scientific advances had increased the effectiveness of trained physicians. By mid-century, physicians were directing their attention more to the actual treatment of patients and less to the formality of relations between one doctor and another, or between doctor and patient. The International Code reflects these new concerns in a shift away from the detailed regulations of the preceding 150 years. In place of elaborate etiquette for consultations and other medical confrontations, it recommends only that physicians behave toward colleagues as they would have colleagues behave toward them, that they call specialists in difficult cases, and that they not entice each other's patients. It warns against the profit motive and prohibits unauthorized advertising, medical care plans that deprive the physician of professional independence, fee splitting or rebates with or without the patient's knowledge, and refusal to treat emergency cases. It also commits physicians to honor professional secrecy in an unqualified way, an obligation that

continues after the death of the patient, according to an amendment to the code adopted in 1968.

The International Code only hints at the ethical problems of abortion and euthanasia by asserting the physician's responsibility to preserve life. It does, however, warn specifically against any action that would weaken the patient's resistance without therapeutic justification. Applicable to the dying patient and experimental subject alike, this standard requires the physician to consider the patient's well-being above all else. The International Code also recognizes the need for adequate testing of innovations by urging great caution in publishing discoveries and therapeutic methods not recognized by the profession.

Using the International Code of Ethics as an example, the American Medical Association reduced its elaborate code to ten one-sentence Principles of Medical Ethics in 1957 (Ten Principles). This was intended as an epitome rather than a reduction. ("Every basic principle has been preserved," according to the Council that submitted the draft.) It retained the essentially Hippocratic focus on benefit of the patient, but added that the responsibilities of the physician extend also to the society.

Most of these principles had been anticipated in the International Code, but there are a few noteworthy exceptions. Reflecting a continuing distrust of sectarian practitioners by regular physicians in the United States, the 1957 principles warn against professional association with unscientific practitioners. They also oblige physicians who are AMA members to expose the legal and ethical violations of other doctors. Instead of warning against premature publication of discoveries, the 1957 principles urge physicians to make their attainments available to patients and colleagues. Finally, while reaffirming the principle of confidentiality, the 1957 principles authorize physicians to violate this principle when required by law or to advance the welfare of the individual or the community. This provision suggests more discretionary authority for the physician than do the codes of most nations and the World Medical Association, which emphasize the inviolability of professional secrecy.

By the late 1970s, there was again dissatisfaction with the principles. A special committee was appointed to prepare a new draft that would clarify and update the language, eliminate reference to gender, and seek a "proper and reasonable balance between professional standards and contemporary legal standards in our changing society" (American Medical Association, 1989, p. viii). The report submitting the new version acknowledged the increasing recognition of laypeople's role in defining the moral terms of the patient–physician relation. Nevertheless, the new code was prepared and adopted by a group made up entirely of members of the association. The new principles affirm the virtues of compassion and respect for human dignity. It, for the first time, shifts to the use of the language of "rights," saying that "a physician shall respect the rights of patients, of colleagues, and of other health professionals" (p. ix). It generally removes the traditional Hippocratic paternalistic authorization for physicians to act for the benefit of the patient according to the physician's judgment. For example, it permits breaking confidentiality only "within the constraints of the law" (p. ix).

Scientific advances and changing social standards in recent decades have raised ethical questions in a number of areas that are not adequately covered by existing general codes. The Council on Ethical and Judicial Affairs of the American Medical Association regularly issues opinions that elaborate (and occasionally contradict) the principles adopted by the AMA's legislative body, the House of Delegates. In recent years, other medical organizations, such as the American College of Physicians, have prepared and issued codes of ethics for their members.

Codes from Outside the Profession

GOVERNMENTAL CODES. In the twentieth century, a number of national governments have incorporated ethical codes into legal statutes governing the medical profession, to be enforced by an official, publicly appointed medical board. The precepts in these codes sometimes accord with the broader principles of the Percival tradition, but many provisions deal with problems of recent origin and reflect a modern concern for both public and individual welfare.

Some of these codes deal with single subjects. For example, the Nuremberg Code, which is the product of international law, deals with medical research on human subjects. In the United States, the federal government's regulations on the same subject function as a code of conduct as does the Belmont Report, a set of ethical principles on research developed by the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research (1978).

Underlying the development of these codes is a fundamental issue of ethics: Is the professional group or the general public responsible for deciding what the ethical norms of the lay–professional relation should be? Even if the profession is deemed the proper authority for determining what constitutes ethical conduct, it is not clear exactly who should have the authority to speak for the profession and what the content of the codes should be. Some functions of

the codes are clearly more for public relations and control of competition rather than for articulation of ethical norms. Many provisions that clearly are normative in content are still controversial. It is increasingly doubtful that the organized professional associations should have the authority to speak even for the profession as a whole (including the large numbers of physicians who are not members of the organizations) and that these groups should have any authority to speak on ethical matters that affect laypeople.

While modern medical ethics has often presumed that the profession should define its own code of conduct, this has not always been the case. Religious as well as governmental groups have sometimes claimed this prerogative. Increasingly, professional groups as well as laypeople are insisting that judgments about ethics are not the exclusive province of the professions and that the norms of lay–professional relations should be grounded in cultural, philosophical, or religious commitments.

A government-sponsored medical oath was adopted in the former Soviet Union, where its Presidium approved the Oath of Soviet Physicians in 1971. Modeled after an oath that had been used at the University of Moscow since 1961, the Soviet oath pledged the physician to conduct himself in accordance with communist principles and to order his responsibility to the Soviet government. This commitment to political creed and government was unique among medical oaths. The Soviet oath did not neglect other moral obligations, however; it instructed the physician to honor professional secrets, constantly improve knowledge and skill, always be available to calls for medical care or advice, and dedicate all knowledge and strength to professional activities. Like other recent oaths, the Soviet oath voiced virtually the same ideal of humanitarian duty to individual patients that appears in the earliest medical creeds, but it also pledged the physician to serve the interests of society.

Postcommunist Russia is undergoing a major reassessment of its healthcare policies, including its medical ethics (Tichtchenko and Yudin). In November of 1991, the Russian Supreme Soviet adopted the Declaration of Rights and Liberties of Citizens, which includes the principle of voluntary consent for participation in medical experiments and declares a right of every citizen to qualified medical care in the state healthcare system.

The Russian Medical Academy has developed a "Solemn Oath" (1993) to replace the Oath of the Soviet Physician. The new oath is a modernized revision of the Hippocratic oath. Approved by the Minister of Health in 1992, it is an official government document, not merely the product of a professional medical association.

NONGOVERNMENTAL GROUPS. Throughout history, codes, prayers, and oaths dealing with medical ethics have also been sponsored by private groups, religious bodies, and consumer groups that do not represent the medical profession.

For centuries, the Catholic church has articulated moral views about medical matters including abortion, euthanasia, and fertility control. These have appeared, at least since the medieval era, in systematic theological treatises, cases of conscience (collections analyzing morally perplexing cases), and in the theology manuals of the early modern era (Kelly; Griese). Formal codes of medical ethics, such as the Ethical and Religious Directives for Catholic Health Facilities prepared by the United States Catholic Conference (1975; Griese), are not only considered binding on Catholics but also affect non-Catholics who are associated with Catholic health facilities and others who find their reasoning persuasive.

The statements of the directives on secrecy, consent, organ transplantation, and terminal care closely resemble those of other codes. It prohibits abortion, except when justified by the principle of double effect, that is, when it is an unintended result of a procedure employed to protect the mother. It prohibits both male and female sterilization except in the treatment of a serious pathological condition, and it prohibits artificial insemination. Thus, the directives articulate the Vatican's "Instruction on Respect for Human Life" (Sacred Congregation for the Doctrine of the Faith).

The modern consumer movement has also influenced the ethics of medical practice. As hospitalization became a major consumer service, consumers increasingly demanded the right of patients to minimum standards of care and respect. In 1972, the American Hospital Association responded to consumer pressure and adopted "A Patient's Bill of Rights," which pertains primarily to hospitals but involves physicians with several responsibilities to patients ("Statement," 1973). A physician who subscribes to the bill of rights is obligated, with limited exceptions, to keep the hospitalized patient informed of diagnosis, treatment, and prognosis, to instruct the patient fully regarding possible consequences and alternatives before obtaining consent for medical procedures, to honor a patient's refusal to consent to treatment to the extent permitted by law, to protect the patient's right to confidentiality and privacy from physicians and staff not involved in his or her case, and to instruct the patient of his or her care requirements after discharge. These standards represent a significant departure from the traditional paternalism prevailing in the patient–physician relationship.

Still, the Patient's Bill of Rights was generated by a professionally dominated group. On some issues, such as

informed consent, it actually incorporates traditional paternalistic exception clauses that might be rejected by those emphasizing the rights of patients. Other bills of rights have been developed such as those for nursing home patients, the mentally retarded, children, and other vulnerable groups. It is not clear how the statements of these documents are to be sanctioned, since no mechanisms of enforcement are specified.

Conclusion

The difficulties that confront professional leaders, patients, surrogates, and public policymakers who undertake the establishment of ethical standards on new issues reflect the conflicts in fundamental values inherent in diverse views of medical ethics. The traditional professional ethics of physicians places great emphasis on the virtue of benevolence and the physician's responsibilities to serve the patient. This tradition honors the individuality of the patient–physician relationship, professional secrecy, and the physician's duty to promote the patient's welfare. In these and other matters, ethical formulations by physicians have been paternalistic, making the physician the dominant party in determining which action will best further both the physician's and the patient's interests. Codes prepared by interests outside the medical profession (including those written by religious and governmental bodies) have advanced other philosophical tenets as foundations for medical ethics. Some of these codes have focused on justice or equity in allocating resources. This has resulted in mounting ethical confusion as physicians become subject to competing ethical authorities with conflicting standards.

Responsibility for the development of ethical guidelines relative to the physician–patient relationship may be shifting from the physician to the society as a whole. In those contingencies not anticipated by accepted guidelines, the responsibility for ethical criteria rests partly with the individual physician, partly with patients, and partly with society's general ethical standards. Future success in the use of codes to control medical practice may well depend on an accommodation of the ethical norms of physicians with those of the larger society.

II. ETHICAL ANALYSIS

The following is a revision and update of the first-edition article "Codes of Medical Ethics: Ethical Analysis" by the same author.

Codes, oaths, and prayers of medical ethics have emerged over the centuries from disparate sources, representing disparate societies, time periods, organizations, and perspectives. It is not surprising that they differ significantly in style and content. This article will examine systemically the ethical content of this divergent collection of documents from the earliest to contemporary times. In the Appendix, the reader will find the texts of codes and additional bibliography of codes and commentaries on codes for ethics of the medical and other health professions.

Ethical analysis of the codes of medical ethics creates problems. Such codes are not fully developed, systemic theories of medical ethics. On the other hand, the codes, at least the modern ones, are normally the product of much discussion, debate, and review. These codes, along with the historical documents that have had lasting significance, can reasonably be expected to reflect the basic ethical views of the organizations that have endorsed them.

When one turns to the substance of the codes, especially the codes written by physicians, one can identify what might be called a central ethical obligation, a basic principle that provides the physician with a core moral stance for resolving ethical dilemmas. Striking features are the presence of contradictions among the codes and the controversial nature of these central ethics.

Hippocratic Oath

Modern Western medical ethics has reiterated the central ethic of the Hippocratic oath into the twentieth century. The core ethic of the Hippocratic oath is the physician's pledge to do what he or she thinks will benefit the patient. This is repeated twice in the oath, once as applied to matters of diet, and once when referring to visits to the homes of patients.

The principle that the physician's first obligation is to do what the individual physician thinks will benefit the sick person is picked up in the Declaration of Geneva, where the physician swears, "The health of my patient will be my first consideration," and in the International Code of Medical

Ethics of the World Medical Association (WMA), which proclaims, "A physician shall owe his patients complete loyalty and all the resources of his science." Likewise, the postcommunist Russian oath has the physician pledge, in Hippocratic fashion, to work always for the patient's good (Solemn Oath of a Physician of Russia).

THE HIPPOCRATIC OATH'S INDIVIDUALISM. The first characteristic of the Hippocratic ethic is that it is individualistic; it concentrates only on the benefit to the individual patient. In contrast, classical utilitarian ethics of the tradition of Jeremy Bentham (1748–1832), John Stuart Mill (1806–1873), and G. E. Moore (1873–1958) would consider such a narrow focus on consequences for the patient to be ethically unjustified, unless it would serve the greater good of the greater number in the long run. They would consider benefits to all persons and to society as a whole. There is no evidence that the Hippocratic authors or their twentieth-century counterparts had such an indirect utilitarianism in mind. Rather, they seem to hold that the physician has a special ethical obligation to benefit his or her patient, independent of the net consequences for others who are not patients. The real test comes in cases in which the physician believes that one course will produce the most good in total, but another course will most benefit the patient. A physician who feels required to choose the course most beneficial to the patient is faithfully following the oath and rejecting the utilitarian alternative.

The American Medical Association (AMA), in its 1957 Principles of Medical Ethics, did not accept the Hippocratic individualism. It instructs the AMA physician that "the principle objective of the medical profession is to render service to humanity." The tenth principle made this interpretation unambiguous:

> The honored ideals of the medical profession imply that the responsibilities of the physician extend not only to the individual, but also to society where these responsibilities deserve his interest and participation in activities which have the purpose of improving both the health and the well-being of the individual and the community.

This focus on the community continued in the major revision of 1980. The last principle of that version is, "A physician shall recognize a responsibility to participate in activities contributing to an improved community" (American Medical Association, 1989, p. ix).

Here the AMA is closer to the now-abandoned Soviet physicians' oath of 1971 than to the Oath of Hippocrates. The Soviet physician more boldly swore "to work conscientiously wherever the interests of society will require it" and "to conduct all my actions according to the principles of the Communistic morale, to always keep in mind the high calling of the Soviet physician, and the high responsibility I have to my people and to the Soviet government." By contrast, the postcommunist Russian oath reverts to the pure Hippocratic focus on the good of the individual patient, abandoning any reference to the interests of the community or state (Solemn Oath of a Physician of Russia). The Criteria for Medical Ethics of the Ministry of Health of the People's Republic of China (1989) are actually closer to the postcommunist Russian oath and its Hippocratic ancestors by focusing on the interests of the patient. It lacks any appeal to the duty of the physician to the community that is seen in the AMA and the Soviet oaths.

THE HIPPOCRATIC OATH'S PATERNALISM. The central ethic of the Hippocratic tradition is also paternalistic. The physician is to benefit his or her patient "according to my ability and judgement" (Edelstein, 1943, p. 3).

Addressing the meaning of the injunction to protect the patient from mischief and injustice, Edelstein concludes that the oath means that "the physician must protect his patient from the mischief and injustice which he may inflict upon himself if his diet is not properly chosen" (Edelstein, 1943, p. 24).

This paternalism is also seen in the provision of the Hippocratic oath that medical knowledge is to be kept secret and not disclosed to people outside the Hippocratic group. A similar provision is seen in a sixteenth-century Japanese medical code called the Seventeen Rules of Enjuin, which actually required that, if a successor trained in the School of Enjuin could not be found upon retirement or death, the medical books of the school had to be returned to the school.

Physicians, according to Percival (1740–1804) (who also shared in this Hippocratic paternalism), should study not only tenderness and steadiness but also "condescension and authority, as to inspire the minds of their patients with gratitude, respect, and confidence" (Leake, p. 71). The AMA principles of 1957 and the 1959 British Medical Association (BMA) codes held that medical confidences could be broken if, in the judgment of the physician, it was in the patient's interest for them to be broken.

THE HIPPOCRATIC OATH'S FOCUS ON CONSEQUENCES. Finally, one sees the controversy of the Hippocratic patient-benefiting ethic when it is contrasted with other theories that can be called nonconsequentialist, that is, ethical theories in which certain principles are taken to be simply inherently right-making or where certain claims are taken to be "inalienable rights." Holders of views in which there are

certain characteristics of actions that make them inherently tend toward being right (other things being equal) or holders of the view that certain things, such as life, liberty, and the pursuit of happiness, are "inalienable rights" would have to reject the ethic of doing what one thinks will benefit the patient. At least they would reject patient benefit in cases where benefiting the patient will be at the expense of fulfilling prima facie duties or respecting basic rights of the patient.

There may be a paradox in the Hippocratic oath. The physician is to do what he or she thinks will benefit the patient but is not to give an abortive remedy or a deadly drug and is not to "use the knife, not even on sufferers from stone." What is the physician to do who believes that giving a deadly drug or an abortifacient remedy, or using the knife, will benefit the patient? Perhaps this apparent contradiction is resolved by the belief of the Pythagorean physician that such actions can never be beneficial to the patient. In that case, the oath simply spells out some rules that guide the physician in deciding what will be beneficial. More likely, however, these actions are seen as inherently wrong even if they might be of benefit. If so, then the Hippocratic ethic abandons its consequentialism, at least for these cases.

Codes Written by Groups Outside the Medical Profession

Many of the more recent codes written by governmental and religious groups have not shown these characteristics of individualism, paternalism, and consequentialism. The Nuremberg Code (1947), one of the first codes relevant to medical ethics emerging in international law, could have addressed the problem of abuse of human subjects in medical research by retreating to Hippocratic individualism, thus making all use of subjects for purposes of gaining knowledge immoral (because, by definition, doing something for the pursuit of general knowledge is not acting for the purpose of benefiting the patient). It did not. Instead it acknowledged the legitimacy of physician participation in efforts to benefit society by doing research on human subjects. It introduced protections for those subjects by abandoning the exclusive focus on consequences—on producing benefits and avoiding harms—and replacing it with an ethic that speaks in terms of duties and responsibilities, including the duty to ensure that the subjects give their informed consent.

Other codes coming from governmental and religious sources adopted the language of rights as a way of signaling their break with the professional medical ethical traditions that focus exclusively on consequences. This focus on rights is influenced heavily by the tradition of the liberal political philosophy of John Locke, Thomas Hobbes, Jean Jacques Rousseau, and the authors of the Bill of Rights of the United States Constitution. It is a moral tradition significantly different from that of the traditional, professionally written medical codes.

The focus on rights and duties includes an emphasis on the right to give informed and voluntary consent not only for research but for all clinical, medical treatments. Consent, grounded in the moral principle of autonomy and the legal notion of self-determination, is totally absent from the classical codes written by medical professional groups. The introduction of the perspective of rights and duties, and the underlying moral notion of respect for persons (including the principle of autonomy), signals a rejection of both traditional Hippocratic paternalism and consequentialism. It also provides a way of moving away from pure individualism, incorporating a more social ethic without lapsing into a social utilitarianism that would completely subordinate the individual to the aggregate social good.

The first healthcare association that used the language of rights was the International Council of Nurses' Code for Nurses (1973, reaffirmed 1989). Still using gender-specific language, it nevertheless signaled a revolution in the philosophical orientation of professional codes when it said, "Inherent in nursing is respect for life, dignity and rights of man." This use of "rights" language also appeared in the American Nurses' Association (ANA) code revision in 1976, when it proclaimed (with more gender-neutral language), "Each client has the moral right to determine what will be done with his/her person." By making self-determination of clients its first principle, the ANA announced it was the first organization of healthcare professionals to abandon Hippocratic paternalism and exclusive focus on consequences. However, ambivalence persists; after announcing that self-determination is its first principle, it says that "the nurse's primary commitment is to the health, welfare, and safety of the client" (American Nurses' Association, 1985, p. 6). At this juncture, the nursing profession seemed unable to decide whether to abandon Hippocratic paternalism in favor of respect for rights of self-determination or remain Hippocratic.

The AMA followed this pattern in its 1980 revision. It begins to use rights language saying, "A physician shall respect the rights of patients, of colleagues, and of other health professionals" (American Medical Association, 1989, p. ix). It commits the physician for the first time to deal honestly with patients, reversing the long-standing, more paternalistic approach in which physicians were expected to withhold information when they believed it might harm the patient. Yet, it still proclaims the Hippocratic notion that the AMA's ethical statements are developed "primarily for

the benefit of the patient," and not, apparently, to protect the patient's rights.

Specific Ethical Injunctions

The strictures against abortion, euthanasia, and surgery in the Hippocratic oath are examples of specific injunctions that occur from time to time in the codes and oaths of medical and physician ethics. Code-by-code comparison of these injunctions reveals interesting differences. The conflict among the codes on the question of confidentiality is perhaps the most dramatic.

CONFIDENTIALITY. The Hippocratic injunction on breaking confidentiality is sometimes taken to forbid breaking medical confidences. The text is really much more ambiguous. It says, "Whatever I may see or hear in the course of treatment in regard to the life of men, which on no account one must speak abroad, I will keep to myself holding such things shameful to be spoken about." The individual physician, however, is left with the question of just which things he or she hears "on no account must be spoken abroad." Possibly physicians are to use the "patient-benefiting" criterion for deciding when breaking the confidence is appropriate. That was the explicit principle in the 1959 version of the BMA code, which said:

> The complications of modern life sometimes create difficulties for the doctor in the application of this principle of confidentiality, and on certain occasions it may be necessary to acquiesce in some modification. Always, however, the overriding consideration must be the adoption of a line of conduct that will benefit the patient, or protect his interests.

The World Medical Association's International Code of Medical Ethics (1949, amended 1968 and 1983) and the Declaration of Geneva (1948, amended 1968 and 1983) both close any such patient-benefiting loophole in the confidentiality principle. They simply require "absolute secrecy," much as did the ancient Jewish Oath of Asaph. No exception is considered even in a case where the physician has learned that the patient is about to commit mass murder. The Ethical and Religious Directives for Catholic Health Facilities (1975) is almost as blunt. It requires that

> professional secrecy must be carefully fulfilled not only as regards the information on the patient's charts and records but also as regards confidential matters learned in the exercise of professional duties.

In keeping with their more social commitment to the welfare of others as well as the patient, the now outdated 1957 American Medical Association Principles (1957, revised 1971), and the American Psychiatric Association's (1973), which were based on them, were quite explicit in providing three exceptions to the general principle of confidentiality:

> A physician may not reveal the confidences entrusted to him in the course of medical attendance, or the deficiencies he may observe in the character of his patients, unless he is required to do so by law or unless it becomes necessary in order to protect the welfare of the individual or of the society.

Confidences could be broken not only when the physician thought it would benefit the patient but also when he or she thought it would benefit society or when it was required by law, for example, informing the police of a bullet wound incurred in a crime. The ethical problem of such broad exceptions, of course, is not only the paternalism of the patient-benefiting exclusion but also the potential subordination of the patient's interests and rights to the interests of the society.

The BMA was confronted by a particularly difficult case in which the physician disclosed to the parents of a sixteen-year-old that she was taking birth-control pills. He defended the breaking of the confidence on the grounds that he thought it was for her benefit. Since this was explicitly permitted by the BMA code at the time, the General Medical Council acquitted him of the charge of unprofessional conduct. After that case, the BMA in 1971 amended its confidentiality principle and became the first to recognize the patient's right to confidence in cases where the patient and the physician disagreed. The new position stated that "if, in the opinion of the doctor, disclosure of confidential information to a third party seems to be in the best medical interest of the patient, it is the doctor's duty to make every effort to allow the information to be given to the third party, but where the patient refuses, that refusal must be respected."

However, in the years that followed, the BMA's position seems to have reverted to a modified version of the old policy permitting disclosures "if it is in the patient's own interest that information should be disclosed but it is either impossible, or medically undesirable in the patient's own interest, to seek his consent" (British Medical Association, 1988, p. 21). The BMA also has added a provision permitting disclosure for social purposes when it is necessary to safeguard the national interest or when the doctor has an "overriding duty to society."

ABORTION. On the controversial subject of abortion, groups authoring codes have followed the ethical stances of their subcultures. The Hippocratic oath follows the Pythagorean

prohibition on abortion, even though abortion was not considered unethical in the broader Greek culture (Edelstein, 1943). In the Oath of Asaph, the early medieval Jewish medical initiate is instructed, "Do not prepare any potion that may cause a woman who has conceived in adultery to miscarry." The 1975 Ethical and Religious Directives for (U.S.) Catholic Health Facilities follow, consciously and precisely, a traditional, theological explanation of official church teaching, devoting seven of forty-three principles to the subject. Directly intended termination of pregnancy before viability is never permitted nor is the directly intended destruction of a viable fetus. Treatments not intended to terminate a pregnancy but which nonetheless have that effect are permitted, provided there is a proportionately serious pathological condition of the mother and the treatments cannot be safely postponed until after the fetus is viable.

When the cultural base of the group writing the code is very broad, the code is predictably less specific about the ethics of abortion. The Declaration of Geneva said, "I will maintain the utmost respect for human life from the time of conception," without directly prohibiting abortion. Its 1983 revision softened the position even further, changing "from the time of conception" to "from its beginning" (Declaration of Geneva, 1948, amended 1968 and 1983). The WMA's International Code in its draft, but not in its finally adopted form, stated, "Therapeutic abortion may only be performed if the conscience of the doctors and the national laws permit." The American Nurses' Association (ANA), which also represents individuals with a wide variety of viewpoints, similarly avoids direct comments. In its code, revised in 1968 and in effect prior to the 1976 revision, the ANA says that "the nurse's respect for the worth and dignity of the individual human being extends throughout the entire life cycle, from *birth* to death" (italics added). The implication may be that fetal life is not included. A 1966 statement approved by the ANA Board of Directors recognizes "the right of individuals and families to select and use such methods for family planning as are consistent with their own creeds and mores," again appealing to individual conscience. Is the combined implication a toleration of the nurse's participation in abortion?

EUTHANASIA. An explicit obligation to preserve life is strikingly absent from the codes of ethics, both professional and public. In light of a widely held view that the duty, or one of the duties, of the physician is to preserve life, one would expect to find this duty emphasized. The only explicit, well-known reference is the weak formulation in the International Code (1949, amended 1968 and 1983), which says that "a physician shall always bear in mind the obligation of preserving human life." This obligation to "bear in mind" rather than explicitly attempt to preserve life is a very soft injunction, especially when combined with the patient-benefiting principle the code emphasizes.

Proscribing active killing is much more common in the codes, as might be expected from the general ethical prohibition on active killing, even for mercy, in many cultures and subcultures. The Hippocratic oath's formula is, "I will neither give a deadly drug to anybody if asked for it, nor will I make a suggestion to this effect." Interpretation of this prohibition is controversial. Some take it to forbid any criminal, malevolent homicide. What seems more likely, however, is a prohibition against merciful killing or assisting in suicide. While suicide, especially in the face of medical suffering, was not uncommon in ancient society, it was forbidden by the Pythagorean cult. This fact is cited by Edelstein in his defense of the hypothesis that the Hippocratic oath is a Pythagorean document (1943). According to the *Caraka Samhita,* acts "causing another's death" were one of the few things the Indian medical student should not do at his teacher's behest. The oath of Asaph instructs the Jewish medical student to "take heed that you not kill any man with a root decoction."

In the professionally written codes or those of the Catholic church, however, the prohibition against assisting in an act of killing has never been extended to apply to cooperating in withdrawal from treatment. The distinction between active killing and withdrawal of certain treatments is clear in the Ethical and Religious Directives for Catholic Health Facilities, according to which "the directly intended termination of any patient's life, even at his own request, is always morally wrong," and "euthanasia ('mercy killing') in all its forms is forbidden." The directives go on, however, to say that while "failure to supply the ordinary means of preserving life is equivalent to euthanasia … neither the physician nor the patient is obliged to use extraordinary means." Nor is it considered euthanasia "to give a dying person sedatives or analgesics for the alleviation of pain, when such a measure is judged necessary, even though they may deprive the patient of the use of reason, or shorten his life."

The AMA states in its Judicial Council Opinions that "the physician should not intentionally cause death" (American Medical Association, 1989, p. 13). At the same time, it acknowledges the legitimacy of forgoing life-sustaining treatment in accord with the preferences of the patient or surrogate. The postcommunist Russian oath, following the original Hippocratic language, commits the Russian physician never to give a deadly drug.

The distinction between active killing and forgoing treatment is made clearer when rights language is used, as in A Patient's Bill of Rights (1973), written under the auspices of the American Hospital Association. That document proclaims that "the patient has the right to refuse treatment to the extent permitted by law," presumably even if the result will be the death of the patient. However, there is clearly no corresponding right to drugs that will actively hasten death.

TRUTH-TELLING. One conspicuous conflict between the patient-benefiting principle and the more deontological ethical theories is over the question of what one ought to tell a dying patient. Historically, many of the professional codes are simply silent, presumably expecting the patient-benefiting principle to apply. The Indian oath of the *Caraka Samhita* is explicit: "Even knowing that the patient's span of life has come to its close, it shall not be mentioned by thee there, where if so done, it would cause shock to the patient or to others." The 1847 version of the AMA code instructs: "A physician should not be forward to make gloomy prognostications … but he should not fail, on proper occasions, to give to the friends of the patient timely notice of danger, when it really occurs; and even to the patient himself, if absolutely necessary." The violation of confidentiality in communicating to family or friends before informing patients either is not noticed or is justified on patient-benefiting grounds. Using the patient-benefiting principle as a basis for withholding the truth is traditional in professional physician ethics. The 1847 code makes the grounding explicit: "It is, therefore, a sacred duty … to avoid all things [that] have a tendency to discourage the patient and to depress his spirits."

The latent paternalism that justifies withholding information from patients for their own good is retained even in the period after 1980 when the AMA principles themselves pledge unqualified honesty. In the AMA Council on Ethical and Judicial Affairs' interpretation, an exception can be made to the requirement of informed consent "when risk-disclosure poses such a serious psychological threat of detriment to the patient as to be medically contraindicated" (American Medical Association, 1989, p. 32).

Even the authors of "A Patient's Bill of Rights" seem to yield to the paternalistic patient-benefiting principle when it conflicts with the patient's right to know. The bill first states that "the patient has the right to obtain from his physician complete current information concerning his diagnosis, treatment, and prognosis in terms the patient can be reasonably expected to understand." But it then qualifies this by stating, "When it is not medically advisable to give such information to the patient, the information should be made available to the appropriate person in his behalf." The potential conflicts of such an exception with the right to privacy or the right to receive information necessary for informed consent are not discussed. By contrast, U.S. courts and many codes generated outside the Hippocratic tradition insist that information be adequate for the patient to make a self-determining choice, even if that information is potentially upsetting.

JUSTICE IN DELIVERING HEALTHCARE. Many of the codes of physician and other medical ethics have some reference to the duty to deliver healthcare justly or equitably. The Hippocratic oath uses a term, *adiki'e,* often translated into English as "justice," but it really means "wrongdoing" more generally; it does not refer to equality of treatment or equitable distribution of benefits. The statement in the Hippocratic oath that physicians must abstain from sexual relations with males and females, free and slave, during a medical visit is as close as the text comes to a pledge of equal treatment.

The ancient Chinese medical ethical codes are much more far-reaching in emphasizing equal treatment of rich and poor. The commandments written by Chen Shi-Kung, a seventeenth-century physician, include the explicit commitment that "physicians should be ever ready to respond to any calls of patients, high or low, rich or poor."

Equality of access seems generally recognized as an ideal in many modern codes even if it is absent in the Hippocratic original. The twentieth-century Declaration of Geneva holds forth this ideal: "I will not permit considerations of religion, nationality, race, party politics, or social standing to intervene between my duty and my patient." The American Nurses' Association code declares, "The nurse provides services with respect for the dignity of man, unrestricted by considerations of nationality, race, creed, color, or status." The AMA recognizes that society must make decisions regarding the allocation of limited healthcare resources and urges that they be allocated on the basis of "fair, socially acceptable, and humane criteria." At the same time, it emphasizes that the physician's duty is "to do all that he can for the benefit of his individual patient" (American Medical Association, 1989, p. 3). The postcommunist Russian oath, by contrast, pledges never to deny medical assistance to anybody and to provide care with equal diligence to patients regardless of means or national or religious affiliation.

The Ethics of Professional Relations

In contrast with the lay or public codes or bills of rights, virtually all professional codes devote significant attention to relationships among professionals. The Hippocratic oath begins with a covenant by which the new physician pledges

"to hold him who has taught me this art as equal to my parents and to live my life in partnership with him, and if he is in need of money to give him a share of mine, and to regard his offspring as equal to my brothers in male lineage and to take them this art—if they desire to learn it—without fee and covenant." It includes a pledge to keep secrets, much as any initiation ritual into a cult might.

The longest of the three sections of the AMA code of 1847 is devoted to "the duties of physicians to each other and to the profession at large." Since many of the codes emerged at a point historically when the profession was separating itself from others claiming to offer treatments and cures, there is often, even to modern times, strong language forbidding association with those not properly members of the group. The American Osteopathic Association, for instance, requires that a physician "shall practice in accordance with the body of systemized knowledge related to the healing arts and shall avoid professional association with individuals or organizations which do not practice or conduct organization affairs in accordance with such knowledge."

In terms of the sociology of the professions, it has been suggested that restraints on advertising, rules structuring referral of patients, instruction on the ways of handling an incompetent member of the profession, or exclusion of those not properly initiated into the profession have important functions in maintaining the professional monopoly. Apart from their role in protecting professional interests, however, it is also pertinent to analyze them as sets of ethical obligations.

Three different kinds of ethical arguments may underlie the detailed formulations of professional obligations to other professionals. First, such duties to one's colleagues may be defended on what could be called "universal" grounds. That would be the case if the ethical principles claimed as the foundation of such intraprofessional obligations are principles generally recognized by all persons. For instance, the AMA code of 1847 states detailed rules regarding professional consultation prohibiting "exclusion from fellowship" of duly licensed practitioners and requiring punctuality in visits of physicians when they hold consultations as well as secrecy and confidentiality so that the patient will not be aware of consultants' disagreements. These standards for consultation are defended on the grounds that "the good of the patient is the sole object in view." Although it is not generally argued, there is a presumption that rational patients should accept this principle. We have seen, however, that the principle of patient benefit is quite controversial when put up against competing ethical principles.

A second foundation for intraprofessional duties might be a special ethic for a special group, which nonmembers would not be expected to share or even understand. This would be the case, for example, if the profession is viewed as a kind of club or fraternity that invents its own norms and applies them only to its own members. The ethic of a profession is in part the ethic of fraternal loyalty, of special obligation to one's adopted brothers. The professional obligation may be seen deriving from the professional nexus rather than from some more universal source. It is a special ethic of a special cult.

The ethic of the AMA's 1847 code, like the ethic of the code written by Percival, is an ethic of dignity and honor among gentlemen: "There is no profession, from the members of which greater purity of character and a higher standard of moral excellence are required, than the medical." The discussion of duties of physicians to each other begins with the admonition that "every individual, entering the profession, as he becomes thereby entitled to all its privileges and immunities, incurs an obligation to exert his best abilities to maintain its dignity and honor, to exalt its standing, and to extend the bound of its usefulness." The text goes on to entreat the physician to avoid "all contumelious and sarcastic remarks relative to the faculty, as a body; and while by unwearied diligence, he resorts to every honorable means of enriching the science, he should entertain a due respect for his seniors, who have, by their labors, brought it to the elevated condition in which he finds it."

This gentlemanly ethic of honor and purity (the Hippocratic phrase is "purity and holiness") gives rise to special ethical burdens for the medical profession that the layperson cannot be expected to grasp. Professional "courtesy" (gratuitous services for practitioners, their wives, and their children) should probably be understood in these terms. "Courtesy" is an ethical expectation for members of the brotherhood.

A third possible foundation confounds the two. It could be that professional duties are defended as being in the public interest (or in some other manner consistent with a more universal ethic), but that only members of the profession can be expected to understand this to be so. Advertising, for instance, could be attacked, as it is in the AMA's 1847 code, as "derogatory to the dignity of the profession," but it is defended as necessary to separate the profession from "the ordinary practices of empirics." The authors might well hold that it is really in the public interest that the separation be made, but also concede that only members of the profession could see the necessity of that separation.

If there are special ethical obligations for members of the profession that in principle cannot be recognized from outside the professional group, it follows that there are likely to be conflicts between the profession's formulation of its ethical obligation and the broader public's formulation. The

issue is not the existence of different ethical responsibilities attaching to different roles, but rather a disagreement between the profession and the broader public over what constitutes the proper behavior of the professional in his or her specific professional role. Even if a profession agrees that it has a special duty to preserve life or limit advertising, it is still an open question whether the public wants physicians always to act on that norm. If the professional group holds that there is a special professional source of norms, then conflict is predictable.

A specific example of such conflict involves the ethics of advertising. Many professional codes, in the manner of the 1847 AMA code, prohibit or restrict advertising by members of the profession. The 1957 Principles of Medical Ethics of the AMA claim that "this principle protects the public from the advertiser and salesman of medical care by establishing an easily discernible and generally recognized distinction between him and the ethical physician." While such prohibitions on advertising might be seen as the behavior of a cartel restraining price competition, it is also possible that physicians really believe that they are engaged in a service that must not be peddled as a commodity. Whether the medical profession sees such advertising as unethical or not, the public may see restraint on advertising as unethical. At stake are not only two different perceptions of ways to maximize benefits to potential patients, but also two sources of ethical norms—one from within the professional nexus and the other from the broader society. In this regard, an important transition occurred when the committee responsible for the 1980 revision of the AMA principles acknowledged that increasingly the public will be determining the norms for moral conduct in the lay–professional relationship.

Conclusion

The codes, oaths, prayers, and bills of rights derive from disparate contexts, representing differing professional groups, public agencies, and private, lay organizations such as churches and patients' groups. It is not surprising that radically different ethical conclusions are reached and that they are based on radically different fundamental ethical theories and methods of ethical reasoning.

One critical problem faced by health professionals as well as laypeople is what ethical directives should be decisive when an individual professes identification with more than one group. A health professional may also be a member of a religious or cultural group that has an ethical framework relevant to the moral problems faced by the individual. For example, if the ANA position can be interpreted as endorsing the nurse's tolerance of a woman's right to choose abortion, what is the Catholic nurse to do, or what is a nurse who works in a Catholic health facility to do if he or she believes in the right of the individual to select methods for family planning? These conflicts for individuals who are simultaneously members of more than one group, each of which has authored a code, arise for many ethical issues in healthcare. Moreover, individuals may reach conclusions of conscience that fail to conform to any codes of ethics whether written by healthcare professions or by religious, cultural, or governmental groups. An active understanding of the ethical differences among these codes is needed to begin developing a response.

MEDICAL EDUCATION

• • •

When this subject was addressed in the first edition of this encyclopedia, the paucity of systematic analyses of the ethical issues peculiar to medical education was underscored (Pellegrino, 1978). In recent years, this deficiency has gradually been redressed, so that today, a considerable body of literature is available. This entry is therefore a substantial revision of the first. The emphasis has shifted from underlying values to more specific, normative issues, particularly in clinical education.

Ethical issues arise in medical education because of the special societal role of medical schools, the necessary intermingling of patient care with education, and the conflicts that may arise because of the obligations among students, patients, faculty members, and society. Similar ethical issues are present in the education of nurses, dentists, and the allied health professions.

The Social Mandate of Medical Schools

Medical schools occupy a unique moral position in society. They are mandated to meet society's need for a continuous supply of competent practitioners who can care for the sick and promote the public's health. For this reason, medical schools are supported as loci for the advancement and transmission of medical knowledge and are granted authority to select who shall study medicine, what shall be studied, and what standards of performance shall be established.

To achieve these goals, medical schools require certain special privileges, for example, to dissect human bodies, to provide "hands on" practical experience for students in the care of sick people, and to conduct human experimentation. These practices would be criminal were they not socially mandated for a good purpose. When medical schools, students, and faculty avail themselves of these privileges, they enter an implicit covenant with society to use them for the purposes for which they are granted.

To fulfill this social covenant, medical schools and their faculties must perform a tripartite function with respect to medical knowledge: 1) they must preserve, validate, and expand it by research; 2) transmit it to the next generation by teaching; and 3) apply it by practice in the care of the sick. However, these three functions have different aims. The aim of research is truth that requires dedication to objectivity, freedom of inquiry, rigorous design, as well as peer review and publication. The aim of teaching is learning that requires dedication to student welfare, competent pedagogy, and opportunities for students to practice their skills. The aim of practice is the welfare of the patient that requires dedication to compassion, competence, and ethical concern for the vulnerability, dignity, and autonomy of the sick person.

In the past, these three functions were less often in conflict with each other than they are today. This conflict is the result of several factors in the evolution of medical education since the late nineteenth century. The first factor is the realization of the power of the physical and biological sciences to advance medical knowledge and their integration into medical education. Second is the incorporation of teaching hospitals into medical schools for the clinical education of medical students (Flexner). Third is the increasing reliance on practice income to support salaries of

medical teachers. Previously, teachers had been self-supporting practitioners from the community, while only a few were university-funded full-time teachers. Today's "tenure track" clinical faculty member is expected to excel in research, to support himself or herself financially through practice and overhead cost recovery from grants, and to teach at the bedside. Each function has its own legitimacy, but taken together, these functions conflict with each other.

Ethical Obligations of Medical Schools

The ethical obligations of medical schools as societal entities are defined in terms of the constituencies they serve: society, faculty, student body, and patients (Pellegrino, 1976).

Medical schools have been granted a virtual monopoly over the number of students they admit and the number of training places in the various specialties in teaching hospitals. Medical schools are the sole portal into the practice of the profession and, as a result, medical schools incur a responsibility to match the kind and number of physicians they produce with the needs of society. This requires a socially responsive appraisal by medical schools of the way resources are used and curricula are designed, as well as how faculty rewards are distributed. Societal aims sometimes can, and do, conflict with a medical school's pursuit of esteem among its peers, which usually comes not through renown in teaching or the quality of practitioners it produces, but excellence in producing research and academic leaders.

Another important obligation of medical schools is to ensure that graduates are competent to enter postgraduate training and are free of obvious traits of character that would make them dangerous practitioners. Today, most of those admitted to medical school graduate and obtain licenses. Few fail, particularly in the clinical years. This places an obligation on medical schools to evaluate not only a student's knowledge and skill, but some facets of his or her character as well. Close supervision by clinical teachers is mandatory if dubious character traits are to be detected. Educators must balance fairness in their evaluations of students against their obligations to protect future patients from unsafe or dishonest practitioners.

Another societal responsibility of medical schools is to ensure equal opportunity for admission to all qualified students. Despite early progress, there is recent evidence of retrenchment in the support, financial and otherwise, available for minority student recruitment in the United States and in Great Britain (Hanft and White; Esmail and Everington). Subtle forms of discrimination probably still exist in the interview process where it is difficult to detect and prove (Connolly). Gender discrimination and sexism are no longer legally tolerable, but remain a persistent social problem (Hostler and Gressard). Academic administrators and faculty members are morally obliged to ensure equitable treatment of all applicants and must assume collective responsibility for inequities and injustice. In doing so, medical schools must thread their way carefully through an ethical maze of competing claims for preferential treatment and reverse discrimination.

Ethical obligations exist in the relationship between medical schools and faculty members. Faculties are owed freedom of inquiry in research and teaching, justice in hiring, tenure, promotion, compensation, and redress for injury or grievances. Faculty members in turn are morally responsible for the quality of their instruction, for fairness in the evaluation of students, and for properly apportioning their time and effort between teaching and personally remunerative activities such as clinical practice and consultation. Imbalance among these activities compromises the societal responsibilities of a medical faculty.

Faculty and administration are therefore obligated to detect inadequate teachers and to rehabilitate and reassign them or terminate their appointments when necessary. Tenure is among the most privileged benefits of academic life. The obligation to use it responsibly rests squarely on faculty members and administrators.

Incidents of scientific fraud, abuse of consulting and travel privileges, and conflicts of interest are cause for legitimate public concern. While the number is small, such abuses by faculty members invite external limitations and regulation of privileges that can interfere with the educational mission. The ethics of medical academia cannot be a private matter since the moral behavior of academics affects students, patients, the use of public funds, and the quality of fulfillment of the medical school's covenant with society.

Some Ethical Issues Peculiar to Clinical Education

The ethical issues outlined thus far are particular only in part to medical education. What is unique is the medical school's engagement in clinical education, i.e., in providing "hands on" experience for students in the actual care of patients. It is here that serious conflict may arise between patient care and student learning.

Physicians since Hippocrates have taught their students from actual cases. Usually, this was accomplished by preceptorship with a practicing physician or by case demonstrations to entire classes of students. In the mid-nineteenth century, it was a rare school that incorporated more intimate involvement in the care of patients in its teaching (Ludmerer). Toward the end of the same century, William Osler involved

students more directly as clinical clerks at the Johns Hopkins Hospital, where they " … lived and worked … as part of its machinery, as an essential part of the work of the wards" (Osler, p. 389). This practice lagged in other schools until the reform of education in 1910 (Ludmerer). Since then, however, it has become standard pedagogic practice.

Today, clinical education centers on practical experience under supervision at every level, from medical school through postgraduate specialty training to lifelong continuing education. Until recently, the merits of this training have been so much taken for granted that the ethical conflicts inherent in the process have been neglected (Fry; Pilowski).

Clinical education by its nature unavoidably puts the aims of caring for patients into potential conflict with the aims of teaching and learning. The involvement of medical students, interns, and residents in patient care slows the process of care, increases its discomforts and fragmentation, and, at times, poses significant danger to the patient. With close supervision by experienced clinical teachers, these potential conflicts are tolerable. The clinical teacher therefore carries a double responsibility for balancing the quality of his or her pedagogy with the quality of patient care.

The moral status of medical students is ambiguous. They are physicians in utero, that is, in a developmental state of competence to provide care. When they enter medical school they are laypersons. When they graduate they are physicians, still in need of further training before they can become safe and competent practitioners. During this process, they take on progressive degrees of responsibility associated with the privilege of caring for patients, although their capacity to fulfill that responsibility is limited.

Patients come to university hospitals primarily to receive optimal treatment, not to be subjects of teaching. They may understand in a general way what being in a teaching hospital means. This in no way suggests, as some assume, that patients give implicit consent to become "teaching material." Patients in teaching hospitals preserve their moral right to know the relative degrees of competence of those caring for them. They have a right to give informed consent to any procedures and to know whether an untrained or partially trained person will perform that procedure. When unskilled students participate in procedures, patients are owed appropriate supervision by someone of significantly greater competence who can protect their safety.

Medical students, therefore, should disclose the fact that they are students to avoid the attributions of knowledge and trust patients still associate with anyone bearing the title "doctor" (Greer; Ganos; Brody; Liepman). They should be introduced as students by their supervisors before procedures like spinal taps and chest taps are performed. For their part, students as well as their supervisors must thoroughly acquaint themselves with the procedures in question and must observe a sufficient number performed by experienced clinicians. Students are under an obligation to refrain from conducting a procedure until these requirements are met and to resist the "see one, do one" philosophy of some clinical teachers. They must also receive instruction on how to obtain a morally and legally valid consent (Johnson et al.).

Students must also be sensitive enough to discontinue even the simplest procedures, such as a venipuncture, if their efforts cause discomfort (Williams and Fost). These injunctions are particularly important in highly personal and sensitive situations such as learning to do vaginal or rectal examinations (Bewley et al.; and Lawton et al.).

Medical students also face problems of personal ethical integrity with respect to abortion, treating patients with acquired immunodeficiency syndrome (AIDS), and attitudes toward the poor (Christakis and Feudtner; Dans; Crandall et al.; Currey et al.; Holleman). They may observe unethical or unacceptable behavior of teachers or colleagues (Morris). The extent of their responsibility and the real possibility of punitive treatment if students "blow the whistle" is a difficult, unresolved, but genuine ethical issue. Students may cheat on exams or see others do so (Rozance; Stimmel). By virtue of their presence at the bedside as members of the "team," they may be drawn prematurely into advising about the ethics of other colleagues. Helping students to deal with these moral dilemmas poses a new challenge to students and to their clinical teachers. This is a crucial part of the ethical maturation of the student (Drew; Andre; Wiesemann).

Two final examples of recently debated ethical dilemmas center on the moral status of dead human bodies and of animals of other species similar to humans. To what extent may recently dead human bodies be used to teach intubation, resuscitation, and tracheostomy? Who can, or should, give permission? May it be presumed? Is it necessary at all (Benfield et al.; Iserson)? Are the moral rights of other animal species to be considered so that they never or rarely should be used in teaching or research? Do computer models or tissue and cell preparations adequately replace animal experimentation?

Conclusion

Despite the sanction society gives to clinical education, there are important ethical obligations that limit this privilege. In no sense can learning by practice be a "right" of medical students or medical schools no matter how high the tuition or the degree of social utility. The privileges of clinical education cannot be bought at any price by the student, or

granted even for good purpose by the medical school. Only a social mandate can legitimize the invasions of privacy a medical education entails.

The ethical issues of clinical education have just begun to receive the ethical scrutiny they deserve. Fundamental conceptual issues like the moral status of medical students, dead bodies, and animals are coupled with very practical issues regarding student–faculty and student–patient relationships. Clearer guidelines are needed to deal with the ethical issues characteristic of clinical education. We can expect the literature on this topic to expand in size, sophistication, and importance in the immediate future.

MEDICAL ETHICS, HISTORY OF AFRICA

• • •

I. SUB-SAHARAN COUNTRIES

The geographic region of sub-Saharan Africa includes all the African countries immediately below the Sahara Desert, together with all the associated island states but excluding the Republic of South Africa. Although the latter is within the region, it is excluded from this text in view of the heavy influence that apartheid exerted on indigenous African cultures. All the countries considered are bound by the Tropic of Cancer on the north and the Tropic of Capricorn on the south. In addition to a multitude of indigenous languages, the majority of the countries are either Anglophone or Francophone; five are Lusophone (Portuguese-speaking).

Medical ethics in sub-Saharan Africa is extremely complicated and cannot be considered homogeneous in any sense. This is because the vast geographic area (almost 23 million square kilometers, or about nine million square miles) contains forty-three independent countries with innumerable sociocultural groupings. Many of the countries are nation-states only superficially, since their borders enclose ethnic groups that have little in common with their fellow citizens, being more closely affiliated with groups in other countries. Quite apart from the matter of indigenous cultures, these countries were under the domination of European colonial powers that sought to impose their cultures upon local cultures. Some countries gained political independence only in the 1980s, and in some supposedly independent countries (Angola, Mozambique, Sudan) civil strife based on ethnic differences has raged throughout most of their independent period. The interaction between an externally introduced culture and a local one is more complicated in the field of medicine than in any other. The differences in urban-center development in East Africa and West Africa demonstrate the role that colonial power had in influencing cultural and ethical values (Larson).

Traditional and Scientific Methods

Some of the countries have had contact with scientifically based European medicine for less than 50 years, and others for little more than 100 years. The development of medical ethics in all the African countries has therefore tended to follow the existing European ethical values, principally those of France and Great Britain, the two dominant colonial powers. European medical professionals, faced with traditional African medical practice, took the position that all such medical practices and values, as well as their practitioners, were bad. Traditional African healers were considered no more than quacks and deceivers and therefore were either ignored or actively persecuted. Even the traditional midwives or "birth attendants," as they are now known, who from time immemorial have provided help to women at a most difficult time, were looked upon with disfavor. To a certain extent such attitudes were underwritten by the beliefs and practices of the colonizers' religion, Christianity. Since much of traditional healing relied on the intervention of gods and spirits, which Christians found abhorrent, the practice of traditional healing was strongly discouraged. Furthermore, European medical ethics required that European doctors not associate with practitioners whose training and beliefs differed from their own.

With the rise of black consciousness and the acceptance of the notion that blackness is not a sign of inferiority, African peoples have begun to reappropriate the medical knowledge gained over centuries by traditional medicine and medical practice. In some countries laws have been passed recognizing traditional medical practice as legal and effective. This process has been very slow. Many African medical schools still do not offer any instruction in traditional medicine, and where interest exists, it is only at a

research level. Financial grants have been made for research into the methods and preparations of traditional medicine. In a few instances medical scientists are actively involved with traditional practitioners.

This new collaboration between traditional and imported medical practice is likely to be furthered by the indigenization of African churches and the improvement of the quality of their leadership. Previously, priests and ministers in the majority of churches had been inadequately trained, and they tended to assume a patronizing approach to their congregants. Now, a growing number can be considered well educated; some can even be viewed as theologians who are able to help formulate the churches' views on subjects of such crucial importance as the conflict between traditional and modern medical practice. Medical professionals in the majority of countries now feel relatively free to develop new ways of practice and to work with traditional birth attendants, herbalists, and other healers without fear of losing either the respect or the comradeship of colleagues in Europe.

Traditional and Western practices are seeing crossover training in the areas of psychiatry, childbirth, and grassroots education. Much of traditional medicine touches on the realm of psychiatry. Involvement of traditional practitioners in psychiatric treatment makes for a more humane treatment and much better integration of patients into society (Lambo). Among other efforts that may be cited is the involvement of the University of Ghana Medical School in training programs for traditional birth attendants. In many countries the medical schools (Makerere University in Uganda, University of Nairobi in Kenya, and University of Yaounde in Cameroon, for example) are striving to identify relevant practices within their own societies, such as use of peer groups to educate members of their societies on health-related issues. These medical schools are, therefore, embarking on programs that identify and preserve traditional practices considered valuable (Jelliffe and Bennett). In these programs, traditional practices considered harmless or beneficial are to be permitted, and those practices considered truly harmful are to be eliminated.

Standards for Medical Practice

Most English-speaking countries have general medical councils or boards responsible for registration, accreditation, and supervision of medical practice. In most of these countries the boards of control are generally quite distinct from the ministries of health (Kenya Government). Many of these medical councils or boards, however, have fashioned policies more responsive to western European norms and needs than to African ones. These boards have had little time to devote to the development of ethical guidelines relevant to social and cultural conditions peculiar to life within African countries. Some principles remain fundamental, however: Privacy of the patient is respected, and so is confidentiality, although here and there disclosure is required by the government for various reasons, including payment for medical service, granting of sick leave by employers, and mandatory registration of births and deaths.

Healthcare Service

There are very few scientifically trained medical personnel in Africa. The ratio of scientifically trained doctors to population ranges from 1:3,000 in such better-off cities as Dakar (Senegal), Accra (Ghana), and Nairobi (Kenya) to 1:200,000 in some poorer rural areas, such as most of the Northern Region of Nigeria and all of the immediate sub-Saharan countries including Mauritania, Mali, Burkina Faso, Niger, and Chad, which are sometimes referred to as the Sahel. There are countries within which there may not be a single specialist in any recognized field of medicine. This immediately raises the issue of what kind of medicine is most suitable in such conditions.

European medicine has developed and gained the reputation of being "one-on-one" medicine, and it also has concentrated more on curative than on preventive medicine. In Africa, on the other hand, the practice of one-on-one medicine, if it is accepted as the ideal, means excluding 80 to 90 percent or more of the population, who have no access to Western-oriented medical facilities. Such medical practice also places an inhuman load on the few medical practitioners and quickly reduces them to no more than purveyors of drugs and injections. Fendall sees this as the "quantity versus quality" dilemma, although not all agree with his view.

Doctors in Africa are now being asked to view their role in light of certain priorities—the first being promotive and preventive health services and the second being curative—in terms of individual patient treatment in offices or hospitals. In attempting to respond to the first priority, many have pointed out that not much can be done until medical practice is so arranged that the community is both the consumer and the provider of its own healthcare. This can be done only if delegation of healthcare to nonphysician personnel, such as traditional birth attendants and community leaders, is done on a basis of genuine need. The debate will continue, but almost all the new medical schools have agreed that doctors' training should be responsive to the needs of the community and to the organization and priorities set by ministries of health.

Many African countries depend on the use of paramedical personnel in the running of health services at the level of

primary healthcare. Paramedics are often the only healthcare personnel available at this level. They include clinical officers, laboratory technologists, public-health technicians, environmental health officers, and various kinds of nurses. They are usually trained at medical training colleges, which are non-university, diploma-awarding institutions established in countries including Zambia, Kenya, and Tanzania. Apart from the nurses, who take an oath at graduation, paramedical personnel are not subject to any ethically binding oath. This cadre of personnel has on occasion been the source of breaches of confidentiality.

Pharmacies and pharmacists, too, have presented new dilemmas to medical practice in Africa. The regulation of the drug supply has been the prerogative of the ministries of health and their relevant licensing bodies. In keeping with the increased number of university-trained pharmacists, there is increased licensing of private pharmacies, especially in Zaire, Kenya, Cameroon, and Nigeria. Pharmacists regard themselves as trained "doctors" and dispense drugs without prescription, including drugs that have previously required doctors' prescriptions. Pharmacies also may dispense inactive drugs or drugs that have no relevance to the patient's illness (World Health Organization, 1992).

The Ethics of Educating and Remunerating Doctors

Medical education has had to contend with the issue of "excellence versus quantity" in the training of doctors. Most African medical schools have felt it necessary to enroll students of the highest possible scientific caliber and to train them to internationally accepted standards. (These students are chosen based on their national high school final examination results.) The result has been that very few doctors can be graduated in any given year; but much more important, in many countries the best and sometimes the only available scientific skills are channeled into medicine, depriving other socially important areas of potential contributors. This is an ethical issue of considerable importance. In the end, many of the doctors produced choose to become specialists who can practice medicine only where they find quite sophisticated support facilities and services. Frequently they serve existing hospital needs rather than those of preventive medicine. The frustration and wastefulness of this situation underscore one of the major ethical issues on the African medical scene.

Doctors' fees have been the subject of debate in many African countries. Poverty is a major socioeconomic problem in all the countries of sub-Saharan Africa. Civil wars, political instability, ethnic violence, drought, and famine have transformed millions of already poor individuals into refugees who have fled across borders. In the midst of extensive poverty, charging fees for care raises serious ethical questions. In most of these countries, physicians are employed by the government and are not supposed to charge fees for their services. However, government pay schedules have not kept up with the cost of living, and many government doctors engage in private practice to supplement their salaries. In the late 1980s, the Kenya Medical Association considered fee schedules that would charge standard amounts for various services, without waivers or reductions for the poor. Objections were raised, and the schedule was not adopted. In Ghana, attempts have been made to adjust doctors' salaries to costs of living. In general, the costs of physicians' services, drugs, and hospitalization amid such serious deprivation deserve serious ethical scrutiny.

Population, Family Planning, and Abortion

Population control as advocated in the Western world unfortunately has blurred the issues of family planning and led to a debate that should have been completely unnecessary. There are two basic concepts in family planning. The first is to regulate total family size to a level that can be comfortably maintained using the available resources. The second is to space the intervals between pregnancies in order to promote the health of both mothers and children (King). Many African countries rightly consider themselves underpopulated. Some, such as Gabon, Cameroon, and the Central African Republic, want much larger populations. All feel that they need development for the benefit of their people; but with very few exceptions, they refuse to admit that curbing population growth is relevant to the need for increased development.

Unfortunately, some doctors have failed to recognize the doctor's role in articulating relevant issues in family planning. Many doctors seem not to understand the medical importance of postponing pregnancies until a woman is biologically most prepared and of helping to stop reproduction when biological factors are no longer in a woman's favor. They also fail to recognize that spacing of births—which used to be practiced in Africa based either on sexual abstinence or on a geographic separation of husband and wife—is necessary to ensure the health of both mother and child. The excessive mortality in childbirth for women fourteen to forty-five years of age has not been fully appreciated by most of the medical profession in Africa (World Health Organization, 1975). Even where this situation is recognized, continued adherence to inappropriate laws and practices imposed from Europe often means that family-planning services are withheld from the majority of the population in need. The Catholic church, through its influence in the French-speaking countries, did much to prevent

medical leadership in family planning. French laws passed in 1920 prohibiting contraception are still on the statute books of many French-speaking African countries, despite their repeal by France and Mali in 1972 (Wolf).

In the field of contraception, the major ethical question the doctor faces is, therefore, whether he or she should encourage free provision of contraceptives by nonmedical personnel, knowing that Europe and the United States, which are the sources of these supplies, require that they be dispensed almost exclusively by doctors. The doctor must weigh the possibility of breaking outdated laws against the results of withholding such supplies from populations that have no other source.

Other serious ethical questions are raised in providing contraception to women who are not married, according to the traditional norms prevailing in their locality, or who want to practice contraception without the knowledge of their regular partner. Yet so tenuous are some of the marital relationships, so difficult is it to get some husbands into a hospital or family-planning clinic, that insistence on consent by both parties might, in the end, do an injustice to the woman. Physicians must resolve this ethical dilemma within their own national frontiers.

African societies generally do not accept abortion because they value highly the continuity of lineage; the unborn child, for example, may be a reincarnation of an ancestor. However, it would be untrue to say that abortions were not known in Africa before the arrival of white colonizers. In many African cultures, pregnancies resulting from taboo relationships or from adultery are terminated generally by women and the men are kept in the dark.

The question of abortion is now debated seriously. Many of the abortion laws in Africa are based on those of England and France, which repealed them in 1967 and 1974, respectively. However, in the majority of former British and French possessions the old laws are still on the statute books. The increasing number of illegal abortions, with their consequent mortality, morbidity, and sterility, have still not prompted the collective conscience of medical practitioners to have the laws reviewed. Zambia did review its laws and amend them in 1973, but stipulations within the new law, particularly one that the approval of two medical practitioners is required, make it unlikely to serve the majority of those in need. The Africa Regional Conference on Abortion held in Accra, Ghana, in 1973 agreed to call for a review of the laws, but little has been done.

The doctors' dilemma regarding abortion is twofold. Despite the law, increasing numbers of women risk their lives by recourse to back-street abortionists. At the same time there are so few doctors to respond to such a wide range of needs that to make abortion laws more liberal may mean increasing the load on doctors still further. Given these problems, it is difficult to understand the view of some doctors in African countries that education, information, and services for fertility regulation should be limited.

Healthcare and Research in the Era of AIDS

The acquired immunodeficiency syndrome (AIDS), first recognized in 1981, has had the most profound impact on healthcare in Africa. Major concerns in healthcare provision are related to confidentiality, informed consent, counseling, research, drug therapy, serotesting, and care of the sick.

When AIDS was first identified as a major public-health problem and a rapidly spreading epidemic in Africa, many African governments reacted with violent denials. This behavior, which was attributed in part to the claim that AIDS originated in Africa, received support from some physicians and ministries of health. The early rapid spread of AIDS in Africa was partly a result of the fact that it was not acknowledged as a major public-health problem and thus received only slow governmental response (Ndinya-Achola).

Confidentiality and counseling are two components in AIDS-control programs that have received, at best, lip service in Africa. Counseling is an extension of preventive educational campaigns. At population levels these campaigns use information, education, and communication as their basic tools, and public-health officials as their main promoters. Counseling deals directly with the individual. The personal interaction between counselor and patient enables individuals to better understand their personal risks, to make informed decisions, and to take appropriate action.

Under ideal conditions, counseling is provided on a one-to-one basis and each case is dealt with on its own merit. Counseling also involves providing facilities that respond to the physical and emotional needs of the affected individuals and their loved ones. In Africa, AIDS counselors began to be trained in 1988; the needs of the society far exceed the number of counselors available. Much of the counseling that is provided is done by individuals who have no training. In many instances it amounts to informing an individual that he or she is infected with the AIDS virus; the healthcare provider is faced with the ethical question of whether to withhold information about the illness because there are no facilities to cater to individual needs.

Even where conditions are adequate and counseling facilities are available, confidentiality is a major issue because some of the trained counselors are not ethically bound to

keep confidentiality. In particular, confidentiality is lacking in Africa for individuals diagnosed with AIDS. Counselors, however, are not the only healthcare providers ignoring confidentiality. Information regarding AIDS diagnosis often is leaked by hospital laboratory and other care staff.

Biomedical Research

Care for those with AIDS and drug therapy are two additional areas of major ethical concern. In many African settings the diagnosis of AIDS results in patient neglect because of the stigma attached to the disease. AIDS is a stigmatized disease in Africa mainly because the earliest information linked it to homosexuality, which is regarded as antisocial behavior in many parts of Africa. After it was ascertained that AIDS was being transmitted primarily by heterosexual contact, the homosexual stigma of AIDS lessened; but then AIDS became further stigmatized because of the rapid spread among heterosexuals by means of multiple sex partners and increased promiscuity. AIDS educational programs also had the inappropriate but true message that death is the final outcome. For these reasons, AIDS has had a negative impact on social interactions. Many people fear to be associated with a person with AIDS. This fear is evident even among professionals. Nurses have been a little more ethical in their approach to care of AIDS patients than physicians, perhaps because the nurses' increased contact with the patients makes them more sympathetic to the patients' plight.

During the early years of the AIDS epidemic, researchers from all over the world quickly identified populations in Africa for epidemiological studies (Van de Perre et al.; Kreiss et al.; Piot et al.). Clinical studies on drugs and vaccines are also being done. This research brings to the fore ethical questions about biomedical research in African countries that predated the AIDS epidemic: Should Western scientists do studies on populations that may never benefit from the results? Can appropriate informed consent be obtained in cultures that have different values? These questions are much debated within Africa and abroad (IJsselmuiden and Faden). Standards of research have been improved: Some medical journals, such as *East African Medical Journal,* insist that proof of informed consent be provided before articles are accepted; granting agencies in Europe and the United States require local ethical review before funding is provided; and local review boards are becoming quite strict.

One of the important contributions of biomedical research in AIDS is the development of antiretroviral drugs for treating infection caused by human immunodeficiency virus (HIV), the causative agent of AIDS. Although the available drugs do not currently offer a cure, some of them have been shown to prolong life significantly. These drugs are far too expensive for African populations. The same research groups that solicited funds for epidemiologic studies should be persuaded to do the same in order to make anti-AIDS drugs affordable for African populations. The first ten years of the AIDS epidemic has had profound social, cultural, economic, and health impacts in sub-Saharan Africa. These effects, which include loss of social structure, orphaned children, reduced productivity, and severe depletion of healthcare budgets, no doubt will significantly increase over the next decade. Even if medical care or a vaccine were made available immediately, the already large number of infected individuals will continue to burden the society. Healthcare standards will be influenced by the AIDS epidemic for a long time. The decade of the 1990s is the right time for African healthcare services to review their programs and put in place relevant practices and resources without compromising their ethics in caring for people with AIDS. It would be heartening to see African countries taking a lead in the care of people with AIDS.

Conclusion

Significant improvements are continually being made in medical training and standards of healthcare throughout sub-Saharan Africa. These improvements, however, are still not matched by proportionate improvement in medical ethics. Many African medical schools' curricula do not include ethics. Where it is included, the subject is still accorded very little time (usually a one-hour lecture). In order to sensitize doctors and other healthcare personnel on issues related to medical ethics, African medical schools and medical training colleges should be encouraged to develop curricula on ethics. It may also be necessary to sensitize populations on the subject along the same lines that disease prevention has been brought to the community level through health education.

II. SOUTH AFRICA

The histories of medicine and of medical ethics in South Africa are intimately linked to political, social, and economic aspects of that country's development, dominant components of which include racial discrimination and social segregation. A brief review of some key political events will provide an illuminating backdrop to a description of the evolution of medical services and the ethics of medical practice in this controversial country, which typifies in microcosm many of the world's diverse human problems and arguably poses the most challenging contemporary opportunity to demonstrate human ability to resolve conflict peacefully.

Political Background

During the period of the Dutch settlers (1652–1820) the indigenous Khoi-Khoi (pastoral people) and the San (hunter-gatherers) were treated with the arrogance and paternalism that for subsequent centuries epitomized European domination over blacks and exploitation through enslavement and colonial/cultural imperialism. These attitudes, together with warfare and the introduction of new diseases (e.g., smallpox in 1713), led to the decimation and destruction of the organized cultures of these indigenous peoples (Burrows; Laidler and Gelfand).

British annexation of the Cape (1795) and the arrival of British immigrants in Algoa Bay were followed by ninety years of conflict that included devastating wars between rival black tribes, the freeing of slaves (1833), the "importation" of Indians to work in the cane fields of Natal (1860), the first Anglo-Boer War (1880), several wars against the Zulus, and the bitter second Anglo-Boer War (1899–1902), during

which twenty-six thousand Afrikaner women and children died in British concentration camps.

The British Parliamentary Act of Union (1910), which gave whites the right to self-determination, and the subsequent failure of the British to exercise their veto powers to restrain the Union Parliament from enacting oppressive racial laws (Native Land Act of 1913, depriving blacks of their land, and the Native Administration Act of 1927, depriving them of their right to self-determination), set the scene for the growth of Afrikaner political and economic dominance. The rise to power of the Nationalist Party in 1948 was followed by proliferation of apartheid policies, relentlessly entrenched through legislation that oppressed and dehumanized the black people of South Africa.

Black opposition evolved from powerless peaceful protest into a politically powerful process of potentially peaceful progress. It was hampered, however, by a growing culture of individual and group violence, fueled by brutal elements within the state security forces and by internal sources of conflict that horrified the world (Schlemmer). Intensification of black resistance, more clearly articulated demands for human rights globally, and changing foreign policy agendas progressively isolated South Africa from its previous friends and from international markets. By the 1980s economic decline, rapid population growth, urbanization, destabilization in the neighboring states, and collapse of communism in eastern Europe and the Soviet retreat from regional conflicts constituted the matrix from which arose the Nationalist Party's acceptance of the need to seek, with the black opposition parties, a negotiated settlement as a step toward developing a democratic South Africa (Benatar, 1992).

Legislative changes since the "unbanning" of the black opposition movements in February 1990 have included repeal of the 1913 Native Land Act, the 1927 Native Administration Act, the 1950 Population Registration Act, and the 1950 Group Areas Act, which together formed a powerful core of statutory discriminatory policies. While the transition period abounds with ironies and ambiguities, optimism that peaceful and constructive pathways to progress could and would be found followed the December 1991 Convention for a Democratic South Africa (CODESA) Conference and the March 1992 referendum. It is against this background that the history of medicine and medical ethics in South Africa can now be briefly reviewed.

History of Medicine

The first manifestation of any formalized medical service was the erection of hospital tents following a smallpox epidemic introduced by a visiting fleet in 1713. Further episodes of smallpox (1751 and 1755) led to the construction of two rudimentary hospitals, one for poor Europeans and the other for slaves, the well-to-do being treated at home.

Medical practice developed in two directions: a private commercial venture predominantly for those who could afford to pay, and a public service for the poor, to which the mission medical service (introduced by the Missionary Society of London) made a major contribution in rural areas for well over a century. Concern for public health, stimulated by the 1918 influenza epidemic, generated decades of successful research on infections in close collaboration with the World Health Organization (WHO). Public health services of a high standard were developed through the creation of medical schools with public teaching hospitals open to all—on a segregated basis; ostensibly separate but equal.

The developing systems of medical practice and of medical education mirrored the diverse characteristics of South African society. Undisputedly high standards of medical education in the Western tradition, dedication of generations of practitioners to high standards of medical practice and patient care, considerable goodwill between doctors and patients of all races, extensive public-health facilities—including teaching centers of excellence and well-funded private medicine—reflect the successes. Privileged access to medical education; fragmentation and duplication of health services; lack of planning; wide disparities in health and in access to healthcare (predominantly on a racially discriminatory and unequal basis); focus on curative hospital-based medicine; paucity of preventive, promotive, and rehabilitative services; paternalistic attitudes to patients; and dismissive attitudes to African traditional medicine reflect the racist and oppressive aspects of a system doomed to failure through its institutionalized neglect of civil and social justice (Van Rensburg and Benatar).

Deficiencies in the healthcare system were clearly articulated in the 1940s, and the case for reform toward a unitary health service has been the subject of intense debate since the 1980s (Benatar, 1986, 1990b, 1991). Traditional African medicine continues to be practiced, particularly in rural areas. While black Africans have increasingly accepted Western medicine, they eclectically choose varying combinations of modern and traditional medical advice (Edwards).

Medical Ethics

The South African Medical and Dental Council (SAMDC), a statutory body, was established in 1929 with the primary purpose of protecting the public through maintenance of high professional (including ethical) standards of practice

and with a view to serving the interests of the medical and dental professions—insofar as these interests are compatible with high standards. The wide range of powers vested in SAMDC included the power to institute inquiries into any complaint, charge, or allegation of improper or disgraceful conduct of its members and to exercise disciplinary power over them.

As in most other Western countries in the first sixty years of the twentieth century, discussions on medical ethics in South Africa largely took place within the framework of the authoritarian, paternalistic behavior expected of professionals supposedly adhering to the Hippocratic Oath and similar codes. The first South African text on medical ethics (Elliott) was limited to discussion of ethical codes, professional secrecy, advertising, the conduct of consultations, fees and financial matters, and upholding the "traditions" of medicine, with only brief reference to abortion and sterilization, and to the ethics of investigative medicine. This text, based on Guy Elliott's experience of deliberations on ethical matters by the Medical Association of South Africa (MASA) and the SAMDC, provides a succinct outline of accepted medical ethics in South Africa (and in many Western countries) in the first half of the twentieth century.

Issues of bioethics have usually been stimulated by the widespread application of technological advances in everyday medical practice, the social changes that challenge many traditional professional values, cost considerations, uncertainty regarding the effectiveness of innovative treatments, and increasing concern for individual autonomy and shared decision making in the United States and Europe.

The pace of social change, and of change in medicine and bioethics in South Africa (a middle-income country—per capita gross national product (GNP) less than one-tenth that in the United States and falling), has been much slower. Expenditure on health has increased only marginally and, despite their high profile, modern lifesaving medical treatments are available only on a limited scale. Public and even professional debates on ethical issues in medicine have been very limited in a repressive, authoritarian society lacking a patients' rights movement and unaccustomed to public discourse on civil and political liberties (Benatar, 1988).

As in the United States, theologians have played a pioneering role in reawakening interest in bioethics; several conferences were held in South Africa (in the 1960s and 1970s) under church or theological auspices. The first, stimulated by the historic heart transplant in Cape Town (December 1967), was on the ethics of tissue transplantation (Oosthuizen). Others followed on abortion (Oosthuizen et al., 1974), euthanasia (Oosthuizen et al., 1978), professional secrecy (Oosthuizen et al., 1983), and clinical experimentation (Oosthuizen et al., 1985). These provoked little ongoing public or professional debate. In the 1980s some medical schools began developing modern bioethics education programs, but progress has been slow and the programs remain (1) in a fledgling state, (2) dependent on enthusiastic physicians who have heavy professional responsibilities and minimal formal training in philosophical ethics, and (3) without the financial and institutional support to develop formal programs with committed support from other disciplines (e.g., philosophy, law). One medical faculty has published the proceedings of four symposia on bioethics (Benatar, 1985, 1986, 1988, 1992). These have encompassed theological, philosophical, and sociological debates on death and dying; resource allocation; the doctor–patient relationship; abortion and in vitro fertilization; research on humans; principles of biomedical ethics; moral reasoning; withholding and withdrawing treatment; healthcare of detainees; hospital ethics; the right to healthcare and the structure of health services; ethical considerations in relation to acquired immunodeficiency syndrome (AIDS); and teaching medical ethics. These proceedings reflect progressive movement toward the views being popularized in bioethics debates in the United Kingdom and the United States. By retaining a degree of "cultural sensitivity" they endeavor to avoid the pitfalls both of "ethical imperialism" and of "ethical double standards."

A milestone event in the history of medical ethics in South Africa was the inadequate SAMDC and MASA responses to the unethical manner in which state-employed medical practitioners provided professional attention to prominent black activist Steve Biko prior to his death during detention without trial in 1977. Failure of SAMDC to exercise its duty to protect the public by acknowledging the unethical behavior of Biko's doctors and taking appropriate disciplinary action against them, and MASA's response to SAMDC's deficient protection of the public met with resounding criticism nationally and internationally (Nightingale et al.). The sequence of events through which the efforts of a small group of rank-and-file members of the profession led to a Supreme Court injunction against SAMDC, which resulted in a reversal of its previous decisions and the imposition of disciplinary action, is well documented. The National Medical and Dental Association (NAMDA), formed in 1982 as a result of discontent with MASA's actions following the death of Steve Biko, has received international acclaim for its outspoken advocacy against discriminatory practices. MASA, which came under considerable criticism for its inadequate reactions to the Biko affair, has, to its credit, taken some sincere steps in an attempt to rectify its previous shortcomings. Its statements

are now clearly on public record, and the challenge ahead is to ensure their further implementation in practice. Greater attention to ethical responsibilities toward prisoners, detainees, and hunger strikers has been a gratifying response to the Biko case (Benatar, 1990a; Kalk and Veriava). The public confession of guilt by the district surgeon who bore major responsibility for Biko's medical care, emphasizes the need to maintain professional independence in the face of state security and other coercive pressures.

Professional institutional responses intended to stimulate higher standards of ethical practice include the MASA and the Medical Research Council (MRC) guidelines on professional ethics and the ethics of medical research, respectively (both currently under further revision), and the publication by the College of Medicine of South Africa of its Credo. The long-standing requirement by some universities that all proposals for human and animal experimentation need approval by institutional ethics committees is spreading to other universities, and such prior approval has now become a requirement for all funding applications to the South African Medical Research Council.

Conclusion

In a period characterized by national economic attrition, real per capita expenditure on health of less than one-twentieth of what is spent in the United States, burgeoning population growth, rapid erosion of financial support for academic medicine, and political liberation with rapidly escalating human expectations, development of the discipline of bioethics in South Africa has been initiated and sustained more as a hobby by a few enthusiasts than as an integral component of medical education and practice. The need to include formal teaching of bioethics and clinical ethics in professional schools, which has gained widespread acceptance in the developed world, remains to be achieved in South Africa, as in other developing countries. Who should teach, what should be taught, how teaching of this discipline can be made most effective, and the ways in which such teaching can enrich medical and social education and practice are, as in any new discipline, matters of ongoing debate. If South Africa can learn from the developments in other countries and, with international support, use these lessons to build a national bioethics program and a better healthcare system in South Africa, this could contribute toward restructuring a new South Africa that could play a vital role in helping to rehabilitate southern Africa.

MEDICAL ETHICS, HISTORY OF THE AMERICAS

I. COLONIAL NORTH AMERICA AND NINETEENTH-CENTURY UNITED STATES

North American physicians fashioned their ethics as professionals from the dominant cultural ideals of their era, from norms hallowed through centuries of professional tradition, from rules and regulations of newly established medical institutions, and from laws and legal institutions operative in the communities in which they practiced.

Christian Practitioners

The soil of religious values grounded the quest for professional ethics. For the majority of British and French physicians who settled North America in the seventeenth and eighteenth centuries, Jesus was as real and significant as Asclepius, Hygeia, and Panaceia had been to the author of the Hippocratic Oath. An intimate causal connection existed between character and professional righteousness. The beliefs and rituals of Christian institutions formed character. The ethically acceptable physician displayed the characteristics of a Christian.

Cotton Mather, a Puritan cleric who wielded considerable power throughout New England during the early eighteenth century, was a major figure in the evolution of North American medical ethics. He believed that Christian physicians who abided by the secrecy clause of the Hippocratic Oath became special confessors who had extraordinary opportunities for offering "admonitions of piety" to their trusting and needful patients (Mather, 1966). Because sin was the ultimate cause of all diseases—spiritual, mental, and physical—Mather expected physicians to prescribe Christian beliefs as well as drugs (Mather, 1972). Though he acknowledged confusion about the variety of remedies proposed as cures for any single disease, he would not dishonor "skillful and faithful" physicians (Beall and Shryock).

Though many Bostonians objected, Mather advocated inoculation during smallpox epidemics. He believed that the ultimate success of smallpox inoculation depended on God's mercy, but the validity of inoculation required trial-and-error testing and statistical comparisons between those naturally infected and those artificially inoculated. If deaths were prevented or suffering mitigated, as had occurred in Africa and Turkey, then inoculation was a good practice for doctors in North America. Its goodness as praxis was determined by the scientific demonstrations of practical trials involving mathematical standards and utilitarian outcomes that would be the basis for the reform of medical therapeutics during the nineteenth and twentieth centuries.

Gentlemen Practitioners

North American physicians repeatedly urged students and colleagues to be both Christians and gentlemen in their interactions with each other and with patients. The principal characteristics of a gentleman included proper birth, sufficient wealth, unblemished character, adequate learning, and civic service. While the importance of birth and wealth faded

in the more egalitarian atmosphere of the New World, that of character, learning, and civic virtue grew stronger. Was a physician good because he cured many sick patients, or because he was a Christian and a gentleman? Doctors who prepared the earliest biographical dictionaries of deceased physicians in the United States and Canada judged their worth by Christian and gentleman standards, not by curative or preventive statistics (Thacher). Hallmarks of professional goodness depended on allegiance to the dominant cultural ideals.

Educated Doctors

Those who promoted higher standards for judging physicians frequently decried the immoralities of uneducated practitioners. In 1765, two years after the British assumed rule of New France (Canada) and ten years before the battles of Lexington and Concord, John Morgan proclaimed that most North American practitioners were ignorant, unsteady, irresolute, idle, negligent, and merciless. After six years as an apprentice to John Redman in Philadelphia, four years as a military surgeon, three years of medical studies in London and Edinburgh, and the luster of a European "grand tour," it was easy for Morgan to feel superior.

Wanting to improve this deplorable situation, Morgan and others established the first colonial medical school at the College of Philadelphia (1765). Samuel Bard, another Edinburgh graduate, delivered the first commencement address at King's College Medical School in New York City in 1769. Bard's judgment, no less harsh than Morgan's, was a fusion of Christian ethics, gentlemanly values, and academic ideals: "As those who have neither emulation nor honesty, who neither have abilities, or will give themselves the trouble of acquiring them, I would recommend it to such, seriously to consider the sixth commandment, 'Thou Shalt Do No Murder'" (Bard, p. 6). Morgan, Bard, and others fervently advocated formal education to produce morally acceptable doctors.

Because of the influx of practitioners from the United States and Great Britain, and because of British restrictions on degree-granting institutions in the colonies, enduring medical schools were not established in Canada until the third decade of the nineteenth century. In 1830, when the medical school at McGill University was one year old, twenty regular medical schools functioned in the United States. Graduates of these schools usually championed academic norms as measures of professional goodness: collegiate studies before medical ones, a systematic formal education in a medical school, improving medical science by careful clinical observations, development of effective teacher-pupil relationships, and continuing studies after formal education. Physicians were professionally good if they were Christians, gentlemen, and scholars.

Legal Proprieties

North American physicians were not considered wholly ethical unless they were law-abiding citizens. Throughout Canada's early history, its doctors associated professional propriety with approval by licensing authorities, established as early as 1788 when the British Parliament passed a licensure act governing the Canadian settlements (Heagerty). Two Canadian groups assumed licensing responsibilities: the College of Physicians and Surgeons of Lower Canada in 1847 and the College of Physicians and Surgeons of Ontario in 1869. The voluntary medical societies organized in Canada before 1850 were not concerned with licensing.

The situation was quite different in the United States. Legislators granted exclusive licensing rights to medical societies in some states and to separate boards of physicians in other states. Such licensing bodies had been established in most states by 1832. During the subsequent forty years, however, existing states repealed or ignored their medical licensing laws, and new states adopted none. Since possession of a medical degree was sufficient for licensing in many states, there seemed to be little need for sustaining separate powers for societies or boards. No group enforced these laws uniformly or effectively. Nor had the laws prevented the growth and development of medical quackery and sectarianism.

Legislators believed that free Americans could be trusted to discover the good physician and to sue the bad one. Even if a physician in the United States could be judged a good professional without being licensed, as was the situation between 1835 and 1875, he did not want to be accused of malpractice, much less convicted in court.

During the first half of the nineteenth century, the American culture, unlike the Canadian, experienced an outburst of religious pluralism, the populist effects of expansion to the West, an economic atmosphere of laissez-faire, and widespread opposition to centralized regulation by governmental authorities. These conditions fostered the lack of interest in licensure laws and the willingness of legislators to charter schools for homeopaths, hydropaths, and other sectarian practitioners.

These social and cultural conditions caused many practitioners to believe that standards of professional propriety were disappearing in a sea of populist relativism. If models of personal morality, such as Christian or gentleman, were so varied and even conflicting (Could Jewish doctors be good?),

and if standards of knowing were so pluralistic that legislators relinquished efforts to distinguish among them, what could be done by practitioners who still believed in the integrity and dignity of a medical profession?

Codes of Ethics

To cope with the pluralism and relativism of the modern era, physicians created codes of professional ethics. During the last decade of the eighteenth century, Thomas Percival, a general practitioner in Manchester, England, had developed a systematic view of medical ethics based on the premise that it was possible to comprehend a moral order suitable for all medical practitioners. Universal truths about good professional behavior could be learned and applied by all conscientious and respectable doctors. Percival delineated these truths within a fourfold categorization of physicians as persons, caregivers, livelihood competitors, and civil servants.

The following admonitions exemplify Percival's approach. Physicians should be Christian gentlemen: considerate, reasonable, self-critical, temperate, educated. Doctors ought to interrogate patients privately and have special regard for their feelings and prejudices. Practitioners should consult openly and respectfully with each other, searching for proper remedies and sharing responsibilities in the care of the sick. Doctors ought to honor the trust of their communities by providing medical services free to public institutions and by providing medical knowledge needed by courts and governing officials. Percival included these and numerous other exhortations in a book on medical ethics published in 1803.

This book, together with John Gregory's lectures on medical education and medical ethics published in 1772, became a handy guide for North American practitioners who wanted practical criteria for judging propriety but had little interest in theoretical formulations of moral philosophy that might bring them too close to the Catholic traditions of the medieval universities. Most of these doctors were Protestants, and many were stalwart Puritans who, like Cotton Mather, deliberately rejected the "new moral philosophy" of the seventeenth and eighteenth centuries. In their view, these modern philosophies contained too much ancient paganism and too little Christianity, and placed more reliance on observation and reason than on faith and ritual.

Despite such theoretical objections, American physicians became exemplars of the "new moral philosophy" as they created codes of professional ethics during the first half of the nineteenth century. In 1808 an association of Boston physicians adopted a code of medical ethics composed of nine sections that addressed consultations between physicians, interfering with another doctor's practice, arbitration of differences between doctors, discouraging the use of quack medicines, promoting professional respectability, fees and exemptions from fees, practicing for a sick or absent doctor, and seniority among practitioners. All of these precepts could be found in the second chapter of Percival's *Medical Ethics.* Titled "Boston Medical Police," this code became the model for codes adopted by at least thirteen medical societies in eleven states during the ensuing thirty-four years.

In 1823 the New York State Medical Society adopted a code that resurrected the broader scope of Percival's original view. The New York doctors presented ethical claims about the personal character of physicians, quackery, consultations, patient care, and public obligations. In 1832 an original code was adopted by the Medico-Chirurgical Society of Baltimore. Norms were offered about the obligations of physicians to each other, quackery, consultations, and fees. This code also included a separate section about duties of patients toward physicians, an approach that had been taken by Benjamin Rush in a lecture to students. Rush thought that citizens should employ only serious-minded, educated doctors. Patients should not burden doctors with too many details of their illnesses, and they should strictly follow their doctors' orders and pay their fees promptly.

These examples of distinctive codes from Boston, New York City, Baltimore, and Philadelphia demonstrate the extraordinary interest in codifying professional ethics among American doctors, an interest that culminated in the adoption of a national code in 1847 by the newly established American Medical Association (AMA).

The AMA doctors accepted Percival's fourfold pattern of categorizing professional ethics and many of the specific claims cherished by the British practitioner. They advocated excellence of moral character, though Christian norms were no longer identified as the exclusive grounds for this character, probably because Isaac Hays, a prominent Jewish physician in Philadelphia, was a member of the committee that drafted the code. Though the AMA doctors valued proper education, they insisted that loyalty to professional colleagues was more important than scientific attainments. Article IV explicitly forbade association or consultation with irregular practitioners, that is, physicians whose "practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession," an injunction directed primarily against homeopaths. Standards of patient care included careful attention to professional secrecy, a proper number of visits to the sick, absence of gloomy prognoses, and refusal to abandon patients who have incurable diseases.

Physicians also had excellent opportunities for influencing the personal character of patients. Section 7 of Article I of Chapter 1 of the code is quite specific: "The opportunity which a physician not unfrequently enjoys of promoting and strengthening the good resolutions of his patients, suffering under the consequences of vicious conduct, ought never to be neglected." Sustaining Cotton Mather's view of the sickroom as a stage for confession and redemption, the AMA doctors accepted professional roles as moral therapists. Since "moral" then included what would be called psychotherapy today, the AMA code also sanctioned the devotion of those physicians who had chosen careers as superintendents of institutions caring for the mentally ill.

The AMA doctors emphasized the ideal of shared obligations between physicians and patients, between the profession and the public. Copying Rush, the AMA committee codified the rights of American physicians in a long list of obligations of patients toward their physicians. In the last chapter of the code these duties of patients were expressed more generally as the obligations of the public to the profession, for example, in supporting medical schools and allowing them to acquire cadavers for anatomical dissection. In return, the profession acknowledged a relatively new dimension of professional ethics by its willingness to provide medical knowledge to the governing groups of their communities. This knowledge was needed, for example, in adjudicating civil and criminal proceedings as well as in deliberations about the proper kinds of laws and institutions needed for sanitation, quarantine, and other public health measures.

Worthington Hooker, a general practitioner who later became a professor at Yale, focused on the ideal of reciprocal obligations in *Physician and Patient* (1849), the only comprehensive view of professional ethics published in book form by a North American practitioner before 1900. Hooker's religious beliefs were almost as conservative as those of Cotton Mather, but Hooker believed that moral philosophizing was acceptable for a Christian apologist. He became a moral philosopher of medicine. Like other conscientious midcentury doctors, he knew that religious, educational, and legal institutions had failed to provide a fully acceptable set of moral standards for judging physicians. Hooker believed that doctors were obliged to discover acceptable standards of professional behavior, to publicly proclaim these standards in a format that would be comprehensible to both professionals and the public, and to determine whether such standards had been honored by individual doctors. A code of medical ethics adopted and enforced by a national organization could become the cultural and social instrument for shaping a uniform and universal moral order for American doctors. Hooker viewed his book as an extensive commentary on the AMA code.

Thus, Hooker and many others touted the advantages of the AMA code. Professional righteousness in the United States could be measured by the extent of adherence to this code. Professionally virtuous doctors maintained professional secrecy, made the proper number of visits to the sick, did not offer gloomy prognoses, cared for the incurably sick, requested consultations as needed, and abided by the numerous other precepts in this code that was adopted voluntarily by many societies. In 1855 the AMA decided that all state and local societies wishing to send delegates to its meetings had to adopt its code of ethics.

Not a few chided the AMA's officers about the absence of enforcement procedures. Some state and local societies reprimanded members for consulting with irregular practitioners and occasionally expelled members for criminal offenses, gross immorality, or the sale of secret medicines. The AMA established a judicial council in 1873, but there is no evidence that the council enforced the code regularly or extensively. Similar difficulties affected Canadian practitioners.

One year after its establishment in 1867, the Canadian Medical Association adopted a code of ethics that was almost identical with the AMA code. Minor changes had been made in wording. One clause in the article about obligations of the public to physicians had been omitted, and a new paragraph in Section 3 of Article I permitted beginning practitioners to announce the existence of their offices in the public press. Although some doctors lauded its rules and enforcement was attempted, this code was hardly the final word in matters of medical ethics for most Canadian practitioners.

The attitudes of Canadians contrasted sharply with the sentiments of many practitioners in the United States who believed that the AMA code was as important as the Bible and the Constitution. If the American government could create a bill of rights suitable for all citizens, then the American medical profession could prepare a bill of rights suitable for all reputable medical practitioners. The AMA code of 1847 was that document. In filling a moral vacuum caused by religious pluralism, unacceptable educational standards, loss of confidence in traditional remedies, and ineffective licensure laws, the AMA code became the set of sacred values voluntarily created and professed by respectable and honorable doctors. Sick patients could place their trust in practitioners who gave their allegiance to this code.

In 1880, when one editor doubted that the majority of Canadian medical practitioners had ever read the code adopted by the Canadian Medical Association ("Code of Medical Ethics," 1880a), journal editors in the United States were about to receive an onslaught of articles for and against the AMA code. The problem involved the prohibition against consultation with any practitioners other than those

exhibiting allegiance to the code. In 1882 the New York State Medical Society revised its code of ethics so that its members could consult with legally qualified practitioners regardless of their scientific or sectarian status. Seventeen state societies condemned this action, and the AMA refused to admit the New York delegates to its annual meeting. In the following year, the AMA expected all delegates to sign a pledge to obey its original code of ethics. Articles for and against the code and supporting or opposing the renegade New York physicians appeared in nearly all state medical journals. The code-loving conservatives withdrew from the New York State Medical Society and started a new organization that became larger than the original society. Conservatism was the order of the day; the code of 1847 withstood revision until 1903.

Exemplifying a practical application of the moral philosophy taught as a senior year course in most American colleges of the nineteenth century, the AMA code and its predecessors had nurtured professional unity and social respectability during the heyday of Jacksonian egalitarianism in the United States. These codified norms sustained important traditions in Western medicine, reminded all practitioners of essential duties to their patients and colleagues, and encouraged doctors to participate in those public institutions designed for the health and welfare of all.

Science Versus Codes

Those members of the New York State Medical Society who revised their code of ethics in 1882 exemplified a new breed of medical practitioner emerging in North America during the last three decades of the nineteenth century. These individuals could not accept the AMA code's claim that intraprofessional loyalty was more important than scientific truth. When Francis Delafield announced in 1886 that he and his colleagues wanted an association in which there would be no medical politics and no medical ethics, he heralded a fundamental change in the approach of North American practitioners to the perennial challenge of fashioning an acceptable set of professional ethics. Delafield and his colleagues wanted to associate with those practitioners who were able "to contribute something real to the common stock of knowledge" in medical practice (Konold, p. 39). They could no longer tolerate those practitioners who rested secure with a fundamentalist allegiance to the code of one organization whose precepts were rooted in eighteenth-century British experiences. The iconoclastic doctors of the late nineteenth and early twentieth centuries advocated a professional morality that would judge physicians in terms of their skillful application of specialized scientific knowledge in caring for the sick and the healthy. This new moral philosophy of medicine gradually became institutionalized in some medical schools and societies between 1870 and 1900.

The more progressive schools established teaching and research laboratories, and hundreds of North American practitioners journeyed to the laboratories and clinics of Europe for instruction in the basic sciences, especially microbiology and pathology, and in the clinical specialties, especially the surgical ones. Between 1864 and 1894, American physicians organized more than a dozen national societies for medical specialists (e.g., pediatrics, obstetrics, urology).

These groups did not adopt written codes of ethics. Instead they proclaimed—by word and deed—the values of a liberal premedical education and a thorough education in the medical sciences, allegiance to the experimental method as the proper approach to truths about health and disease, and a strong belief in research and continuing education.

These doctors espoused the rightness of their values as dogmatically as those who believed in the AMA code. Physicians and patients knew of numerous practitioners who did not accept the code but were reputable as persons and successful as healers. The same could not be said for doctors who ignored the bacteriological discoveries, the vaccines, the antiseptic principles, the improvements in diagnostic technology, the pharmacological therapeutics—all based on the methods of experimental science and clinical trials. Good doctors were those who competently and humanely applied this medical science.

These values led to numerous reforms in North American medical education, facilitated and sanctioned by the reestablishment of licensure policies in all of the United States by 1898. In 1902 the Medical Council of Canada became the central licensing agency for the provinces. These new licensure approaches not only sanctioned the reform measures adopted by the progressive American and Canadian medical schools but also upheld obedience to law as an important measure of professional virtuosity.

The physicians who supported these laws and schools recognized that the AMA code said nothing about the more technically proficient environments of the modern hospitals emerging after 1870. To provide competent surgical care, doctors needed instruments and assistants. By the late 1890s, scientific practitioners needed X-ray equipment and laboratory machines that could not be carried in black bags. Technically imprecise care was immoral to these doctors.

Technically adequate care, especially surgical care, required the services of trained nurses. As hospitals became cathedrals of applied science, doctors supported the training schools for nurses initiated by London's Florence Nightingale in 1860. At least fifteen of these schools existed in North America by 1880 (Rosenberg, p. 219). The ethical values

espoused by these professional nurses encompassed certain cultural ideals about women, as well as specific norms about knowledge and obedience. Women were believed to be the moral standard-bearers of Victorian society. Those who chose to become nurses were special women who sacrificed much for the glory of God and the needs of the sick. Soldiers in the fight against disease, these nurses organized militaristic training schools that prepared women, attired in starched and pressed white uniforms, to assist physicians obediently in applying scientifically derived medical knowledge.

The AMA code had said nothing about nurses or women or blacks. Physicians and patients welcomed trained nurses who were social products of a new moral philosophy of medicine that assigned special values to some women. Overcoming objections by most males, other women became doctors. Nearly 400 women physicians practiced in 21 states by 1881 (Burns, 1988). Excluded from the AMA, black physicians adapted to the segregationist culture of their era by organizing the National Medical Association in 1895. The AMA codifiers made no revisions to accommodate these scientific, professional, and social changes.

The most significant change involved the transformation of the hospital into a powerful institution that incorporated the moral values of religious charity, scientific excellence, specialized patient care, and social justice. The number of hospitals in North America grew from about 300 in the 1870s to more than 4,000 by 1910. These hospitals became arenas for moral confrontations between medical practitioners and nonprofessional administrators and other laypersons. They fostered the emergence of new healthcare workers and professionals, including laboratory technicians, nurses, occupational and physical therapists, social workers, and hospital chaplains. Each group forged its particular ethical agenda. Hospitals also supported the rapidly expanding urge for specialty differentiation among physicians. At the turn of the twentieth century, hospitals became the interpersonal crucibles that sustained and transformed the legacies of North American medical ethics.

Conclusion

Before 1900, North American physicians were morally acceptable if they cherished dominant religious ideals, behaved as gentlepersons, learned the fundamentals of medical science, revered a code of professional ethics, and abided by the laws of their communities. Professional virtuousness was measured by the extent of allegiance to the cultural and professional traditions of the West, as those traditions had been adapted to North American conditions. During the last quarter of the nineteenth century, a small group of doctors began to challenge some of the value claims for professional orthodoxy. They believed that favorable results in curing and preventing specific diseases in particular humans made possible by the technically proficient behaviors of skilled professionals applying scientifically derived knowledge were more important than the status-seeking rituals of AMA codifiers or the religious beliefs of the professionals. Yet, the conservative tendencies were so tenacious that the majority of practitioners, at the opening of the twentieth century, still believed in codification as the primary method for establishing professional ethics and still displayed loyalty to the values of one association's code even though major changes in the cultural, scientific, technological, and institutional legacies had changed the nature of the quest for professional ethics.

II. THE UNITED STATES IN THE TWENTY-FIRST CENTURY

The field now called bioethics originated in the 1960s in the United States. It has its roots in the traditional medical ethics of Anglo-American medicine, in the cultural setting of American healthcare, and in certain social, religious, and moral perceptions that had emerged in the American ethos. This entry will first delineate the background for the development of bioethics and then relate the events, issues, and concepts that stimulated its growth during the latter half of the twentieth century (Jonsen, 1998).

The Culture of U.S. Healthcare

Bioethics, in the broad sense of the study of ethical problems encountered as humans interact with the biological within themselves and in their environment, comprehends much more than medicine and medical science. Nevertheless, the development of bioethics can best be understood against the background of the development of medicine in the United States from 1900. The twentieth century saw enormous growth in American medicine—in the amount of money devoted to medical care, the number of persons with access to care, the number of personnel and specialties, the complexity of institutional systems, and the extent of scientific technology. Three principal lines of development that contribute to the interest in ethical questions are the changing role of the hospital, the predominance of science and technology, and the development of specialization (Jonsen, 1998).

Beginning in the late nineteenth century, hospitals were founded at an increasing rate and eventually became the principal sources of medical care in the United States. As medical diagnosis and treatment increasingly involved elaborate techniques and devices, it was seen as more efficient and economical to centralize care in hospitals. Physicians could allocate their time more conveniently; nurses, technicians, and medical specialists could coordinate their work more effectively. Communities desired hospitals as a matter of pride; cities needed hospitals for indigent patients. The passage in 1946 of the Hill-Burton Act, which provided federal support for local hospital construction, and the tendency of the newly popular health insurance to reimburse hospital care rather than office or home care accelerated the evolution of the hospital in the United States (Rosenberg; Stevens, 1989).

With seminal discoveries in bacteriology, pathology, and physiology during the nineteenth century, scientific medicine came into its own. But it became an integral part of medical practice in the United States only after the extensive reorganization of medical schools in the decades around 1900—a period marked by the vigorous efforts of the American Medical Association to reform medical education and to improve the standards of medical practice. Medical school reform was greatly stimulated by the Flexner Report,

Medical Education in the United States and Canada, sponsored by the Carnegie Foundation for the Advancement of Teaching. Scientific investigation, increasingly supported by the federal government, especially during and after World War II, brought research physicians into medical education and patient care. Experimentation involving human subjects, both patients and health volunteers, became more widespread as the National Institutes of Health opened and sponsored clinical research centers in the 1950s. The twentieth century brought a "new" medicine, one profoundly shaped by the biological sciences. Diagnosis and treatment took on forms dictated by the scientific knowledge generated in the laboratory, tested in clinics, and assessed by statistical methods.

The fascination of scientific knowledge and techniques drew many physicians into narrower fields of concentration. The vastly increased body of knowledge became too much for individual physicians to master. Moreover, it became possible for physicians to build careers by performing procedures focused on limited aspects of patient care. Thus, scientific medicine fostered the growth of specialties. Specialty boards, organized to test and certify competence in the particular fields of medicine, were established in a variety of specialties and subspecialties, beginning in the United States with the Board of Ophthalmology in 1917 (Stevens, 1971). The social and economic status of physicians improved significantly during the first half of the twentieth century and American physicians gradually moved from middle- to upper-class status, which distinguished them in attitudes, lifestyle, and place of residence from many of their patients (Starr).

In general, the three developments described above set the scene for the ethical concerns that began to surface in the United States in the 1960s. The concentration of specialized medical care in hospitals encouraged an impersonal, organizational approach to medical care. While social, behavioral, environmental, and personal aspects of illness were not totally neglected, scientific medicine focused on the biological and physical aspects; complaints that physicians had lost the ability to care for "the whole patient" were increasingly heard. As scientific knowledge increased, teaching in the sciences tended to crowd other concerns from the basic medical curriculum. Specialization narrowed attention to particular organ systems and diseases, and patients were shuttled between a variety of specialists rather than cared for by the family doctor. Leading medical educators felt obliged to continually stress the more comprehensive view of medicine, but educational, economic, and professional pressures constantly obscured these calls. By the 1960s, physicians, formerly close and familiar to their patients, had become "strangers at the bedside." This alienation was an important impetus for the emergence of bioethics (Rothman, 1991).

Social and Cultural Trends

In addition to these directions within medicine, cultural and social movements involved the public in the ethics of medical care to an unprecedented extent. The mass media stimulated public interest in medicine. By emphasizing new discoveries, dramatic incidents, and "human interest" stories, the media underlined growing tensions between complex medical technology and its humane use. Growing urbanization and the consequent uneven distribution of population heightened existing obstacles to healthcare. A higher standard of living and increased educational achievement for many increased the sophistication of patients. Growing support of biomedical research by the federal government during the 1950s and 1960s thrust research into the realm of public policy. The ability of persons to purchase healthcare, dramatically improved by the introduction of employment-based insurance in the 1930s and augmented for the poor and the elderly by the passage of Medicare and Medicaid in 1965, gradually began to erode. Healthcare in the United States, while technically superb, became extremely costly and, because of its cost and organization, excluded large numbers of Americans from adequate care. This situation had evolved into a social and political crisis by the late 1980s. No resolution had been found as the twenty-first century opened.

The slow but incessant influence of consumerism, from the concern about adulteration of food in the early decades of the twentieth century to the militant demands for consumers' rights in the 1970s, began to influence the healthcare system. The patients'-rights movement in the 1970s was a segment of a larger movement for civil rights. The women's movement brought attention to the care of women patients and the distribution of women professionals in healthcare. These movements heightened sensitivity to the unmet healthcare needs of women and people of color. The issues of birth control and abortion divided the public on the role of health professionals in family and population policies. Medicine began to draw practitioners from a culturally broader population, and many new allied health professions and technical specialties were added to the healthcare team, enriching and intensifying debates over values among healthcare providers. The peace movements of the 1960s and 1970s and growing ecological movements drew attention to burgeoning international health problems arising from war, environmental hazards, and pollution (McCally and Cassel; Leaf). These concerns challenged the role of medicine in maintaining the overall health and well-being of

Earth's population. Physicians for Social Responsibility was founded in 1971, on the premise that the health risks of nuclear armaments fell within the social responsibilities of physicians. Although threats to the global biological environment emerged as major research and political concerns in the 1970s, the study of ethical issues in these areas remained rather separate from the study of ethical issues in medicine and health sciences (Geiger; Jonsen and Jameton; Cassel and Jameton).

These social and cultural trends, together with the direction of the biological and medical sciences, were the background for the bioethics movement that began in the 1960s. Bioethics as it is known today had its roots in general public concerns over issues of individual rights, social justice, and environmental quality that marked American culture in that era. Before examining the bioethics movement itself, it is advisable to examine the ideas, activities, and interests that were its precursors.

Traditional Medical Ethics

The effort to establish a unified medical profession during the nineteenth century and the accompanying internecine strife among physicians of various doctrinal allegiances profoundly influenced the nature and content of medical ethics at the opening of the twentieth century. Although strains of the Hippocratic, medieval, and Enlightenment tradition were invoked, the dominant themes stressed the respectability and collegiality of the profession and detailed the etiquette of professional relationships that promoted those themes. At the beginning of the twentieth century, this goal of a unified profession was within reach. The American Medical Association (AMA), through the strenuous efforts of its chief spokesman, Joseph McCormack, represented the profession as dedicated to orthodox scientific medicine, the advancement of medical education, the elimination of quackery, and the promotion of public health, particularly through support of pure food and drug legislation (Burrow, 1977; Jonsen, 2000; Baker et al.).

One crucial mandate of professional ethics—that ethical physicians did not consult with or refer patients to unorthodox practitioners—was firmly in place in the early twentieth century. Decades before the turn of the century and for several decades afterward, many ill-trained or untrained persons practiced "medicine." A vast number of substances and devices were promoted as cures for various or all disorders. A strong public voice favored freedom of choice of practitioner, claiming that the "scientific" practitioners and drugs offered nothing better than their untutored and untested competitors. Others, particularly the more educated practitioners, set out to discredit quacks, nostrums, and patent medicines.

This concern stimulated the debate among physicians over cooperation between physicians and "irregular" practitioners. Many regular physicians refused to treat patients who had received prior treatment from irregulars; medical society codes of ethics barred irregular practitioners from society membership, hospital admitting privileges, and joint practice with regular practitioners (Gewitz). During the years before World War I, the AMA led a fight that finally persuaded state legislatures and Congress to pass legislation controlling the practice of medicine and the sale of drugs. Midwives were among the targets of the campaign against quackery, and despite better health outcomes by many midwives at the turn of the century, the campaign for "scientific" practice won public support and midwives have been largely displaced by obstetricians (Leavitt). During the era before World War I, medical ethics appeared to some as exclusively concerned with the criteria that restricted practice to "orthodox" physicians. While self-interested motives can be imputed to organized medicine, many repudiated the "freedom of choice" argument out of the sincere concern that medicine "at least do no harm" (Burrow, 1977). Still, as many commentators have noted, medical ethics, in this matter, served the ends of medical monopoly (Berlant).

A second important question about consultation and referral was vigorously debated: whether referring physicians were entitled to a fee or "kickback" for having sent a patient to a specialist or consultant. This practice was particularly common in surgery. Some surgeons solicited patients through general practitioners who, in turn, found it lucrative to refer patients who sometimes did not require surgery. The abuses of fee splitting scandalized the public and many professionals. The American College of Surgeons, founded in 1915, required its fellows to take an oath that explicitly repudiated fee splitting. Although branded by all professional organizations as unethical, this practice continued in a covert way for many years (Davis).

Perhaps the most agitated debate in traditional medical ethics during the first half of the twentieth century was over the integrity of the patient–physician relationship. Fee-for-service practice by solo practitioners who sought to develop their own followings of patients was the predominant model. However, some "contract practice," in which a physician undertook to provide unlimited service to a designated population for an agreed amount, had long existed. Plantations in the American South had used this method for the medical care of slaves. Fraternal organizations formed by immigrant populations had insured their members in this way, and in the West, the railroad and lumber industries contracted with physicians to care for their workers. Many

in the organized profession, however, objected to contract practice, condemning it as "cut-rate medicine," as inferior to private practice in the quality of care and personal relationship, and as allowing a "third party" to dictate conditions of care, to the possible detriment of the patient. The same objections met the forms of group practice that evolved from contract practice in the first half of the twentieth century. Bitter battles raged over these issues; many medical societies excluded physicians who were involved in these "schemes." A series of antitrust decisions by the U.S. Supreme Court, beginning in the 1940s and continuing into the 1970s, gradually cleared the way for the development of a variety of corporate practice forms, such as health maintenance organizations, that a few decades before would have been considered unethical forms of medical practice.

Another ethical issue was closely related: the debate over payment for medical care. The traditional ethics had required physicians to charge their patients fairly and to provide free or discounted services to those who could not pay. The emergence of free public clinics and hospitals in the late nineteenth century threatened that ethic. Many physicians claimed that even patients who could pay sought free care, draining the physicians' practices and making it impossible for them to provide charitable services, because they needed a steady income from paying patients to be able to afford to provide such services. Thus, at the turn of the century, extensive public use of free clinics was debated as an ethical question. Some argued that it was conducive to continued pauperization; others claimed that forcing poor people to pay for needed medical care was immoral. Some practitioners opposed free clinics because they viewed them as unfair competition by medical schools, which they saw as using free clinics to obtain patients for medical education. At the same time, the organized profession realized that the costs of care were beyond many persons and that physicians' incomes were low. Initial support was given to proposals emanating from organized labor for government-supported compulsory health insurance. By 1916, a broad coalition of organized medicine, labor, and social reformers had almost achieved the passage of national health insurance. World War I intervened, and the coalition was weakened: National health insurance seemed a "Germanic" proposal to many (Germany had long had such a program) and "socialistic" to others. Organized medicine, from then on, firmly opposed almost all forms of government health insurance. Again, it was proclaimed that because this would interpose government between doctor and patient, such programs would be unethical. This opposition persisted down to the passage of Medicaid and Medicare in 1965 (Marmor; Fein).

The AMA revised its 1847 Code of Ethics in 1903, 1912, 1947, 1957, and 1980. The revisions, successively more succinct, reflected an increased sense of professionalism and ideals about the scientific excellence of the practitioner. At the same time, the professional ethics expressed in official codes and in the positions taken by organized medicine on social questions reflected an interest in maintaining the status quo of the profession and the practice of medicine as it had been evolving in the late nineteenth and early twentieth centuries. With few exceptions, such as increased tolerance for group practice, the 1957 revision of the AMA Code, which consists of a condensation into ten "principles of medical ethics," bears little evidence of the major social changes that had begun to affect medical care in the United States. In 1985 the AMA Judicial Council changed its name to the Council on Ethical and Judicial Affairs; it now issues regular statements on issues of current ethical import, such as euthanasia, the obligation to care for patients with AIDS, and financial conflict of interest. Many major medical organizations, such as the American College of Physicians and the American Academy of Pediatrics, have formed ethics committees with a similar purpose. Although commentaries and informal codes on the conduct of nurses can be found as far back as the inception of the profession by Florence Nightingale (1820–1910), the American Nurses' Association did not adopt an official code of ethics for nurses until 1950.

Thus, during the first half of the twentieth century, medical ethics consisted of professionally devised propositions to enhance the unity and monopoly of the profession. Professional self-interest sometimes hid behind ethical claims that were often to the detriment of the public. At the same time, the profession, in encouraging improved medical education and advocating public health and safety measures, lived up to its more noble traditions (Jonsen, 1990).

The Influence of Theological and Philosophical Ethics

The medical profession in the United States imbibed an ethic from the Judeo-Christian culture of the nation. The ethical physician was expected to be respectful of religion and to be a "good Christian gentleman" (Burns, 1977). The dominant Protestant culture offered some admonitions about health and medicine. For example, in the nineteenth century physicians of strong Protestant faith urged the enactment of strict laws against abortion (Mohr). Nevertheless, theological ethics was relatively silent on particular issues concerning medicine and health.

Roman Catholic moral theology, however, had a long tradition of concern with moral questions in medicine. Since the seventeenth century, principles of Scholastic philosophy and theology had been applied to such issues as abortion,

sterilization, and the duties of physician and patient. Acute analyses had been made of the duty to sustain life and the circumstances under which the death of a patient could be permitted. This tradition was conveyed to students in the Catholic medical schools that were founded in the nineteenth century. Father Charles Coppens, S. J., lectured in the Medical Department of Creighton University at the turn of the century. His 1905 book, *Moral Principles and Medical Practice: The Basis of Medical Jurisprudence,* treated abortion, sexual behavior, and the duties of physicians in light of philosophical and theological principles. His work represented "the emergence of medical ethics as a medical school subject, especially at religiously affiliated schools" (Burns, 1980, p. 282). During the 1940s and 1950s, this tradition was carried on in the extensive writings of theologians Edwin Healy, Gerald Kelly, Charles McFadden, Francis Connell, and Patrick Finney. In 1949 the Catholic Hospital Association issued *Ethical and Religious Directives for Catholic Health Facilities* (revised in 1954 and 1971), which obliged all physicians and health professionals working in Catholic institutions to follow Catholic moral tenets with regard to a number of specific medical procedures (U.S. Catholic Conference).

Catholic reflection on medical moral issues continues in the *Linacre Quarterly,* published by the National Federation of Catholic Physicians' Guilds since 1932. Theologians Charles Curran, Richard McCormick, Kevin O'Rourke, Margaret Farley, and Lisa Sowle Cahill are now the principal voices of this tradition. The Catholic tradition, in its doctrine of natural law, has affirmed that moral questions can be analyzed from a philosophical viewpoint, without explicit reference to revealed theological truths. Thus, common ground can be found with those who do not share the Catholic faith. This somewhat nonsectarian approach has allowed Catholic analysis of problems to have a significant influence on the intellectual development of secular bioethics.

The Protestant denominations, while not producing a detailed analysis of medical-moral problems, had taken positions on such questions as suicide, euthanasia, abortion, and contraception. In 1950 Willard Sperry, dean of Harvard Divinity School, published lectures given at Massachusetts General Hospital and the University of Michigan Medical School under the title, *The Ethical Basis of Medical Practice.* He offered reflective, humane, literary, but unsystematic commentary on such problems as truth telling, prolongation of life, and euthanasia as the era of medical technology was opening. Four years later, Episcopal theologian Joseph Fletcher published the groundbreaking and prescient study *Morals and Medicine.* Fletcher's work was the first to emphasize the patient's rights as the center of an ethics of medicine and to argue "the ethical case for our human rights … to use contraceptives, to seek insemination anonymously from a donor, to be sterilized and to receive a merciful death from a medically competent euthanasist" (p. 25). He strongly asserted the patient's right to be told the truth about his or her diagnosis and prognosis. Fletcher's book is the pioneering work of the new medical ethics.

Sixteen years later, Methodist theologian Paul Ramsey produced the foundational work of bioethics, *Patient as Person.* Ramsey, professor of religion at Princeton University, took the unusual step of spending a year in intense dialogue with physicians, scientists, and students at Georgetown University and immersing himself in the clinical activities of the Georgetown University Hospital. *Patient as Person,* first delivered as the Beecher Lectures at Yale University in 1969, examined questions, such as organ transplantation, experimentation with human subjects, and the use of life-supporting technologies, that had not been on the agenda of previous commentators on the moral aspects of medicine. Although he spoke from a very different theological ground than did Fletcher, Ramsey also placed the freedom and rights of the patient at the center of his ethic but subsumed patients and physicians within the scope of a theologically defined covenant. Despite the theological tone and language of Ramsey's work, its cogent analyses of issues such as consent were widely influential (Ramsey, 1970b). At about the same time, James Gustafson of Yale Divinity School produced thoughtful essays on the implications of medical and scientific advances. Many Protestant theologians followed the paths laid down by these pioneers, among them Kenneth Vaux, William May, Harmon Smith, James Childress, and Stanley Hauerwas. In 1987 the Park Ridge Center for the Study of Health, Faith, and Ethics was founded under the auspices of the Lutheran Hospital Association to foster religious reflection on the issues of bioethics. The center has published a fine series of volumes describing the teachings about medicine and morality of major Christian denominations and other world religions (Marty; Vaux). The distinctive features of modern bioethics begin to appear in Fletcher and Ramsey: attention to the effects of new technologies, affirmation of the centrality of the patient as free and responsible agent, and the invocation of the concepts and method of moral analysis from the classical disciplines of theology and philosophy.

The Jewish faith has an ancient tradition of reflection upon questions of life, death, health, and medical care. Issues in medical ethics, such as allocation of scarce resources, risk–benefit evaluation, quality of life, abortion, contraception, and indications of death, are discussed in great detail in Talmudic literature. The doctoral thesis of Immanuel Jakobovits, published in 1959 as *Jewish Medical Ethics,* drew these teachings together and brought them into

contact with modern scientific advances. In so doing, Jakobovits gave a distinct identity to a field of study that had not been previously singled out in Jewish scholarship. Talmudic scholars such as Moses Tendler, David Bleich, David Feldman, Elliot Dorf, Laurie Zoloth, and the physician Fred Rosner have continued this effort. The first course in Jewish medical ethics was taught by Rabbi Tendler at Yeshiva University in 1956, and the Institute for Jewish Medical Ethics was established in San Francisco in the early 1980s.

The influence of moral philosophy came rather late to the analysis of medical-moral questions. Although the first AMA Code of Ethics was strongly influenced by the English physician Thomas Percival (1740–1804), who was affected to some extent by the philosophers of the Scottish Enlightenment, American philosophers paid scant attention to these questions. In 1927 Chauncey D. Leake noted in his edition of *Percival's Medical Ethics* that all of the classic codes represented "medical etiquette" or the tenets of professional courtesy rather than medical ethics. "It is interesting," he wrote, "that writers on medical ethics have seldom availed themselves of the philosophical analyses of the principles of ethical theory made by recognized ethical scholars" (Percival, p. 3). In words that predict the bioethics movement of the 1960s, Leake called for a medical ethics that would bring the systems of moral philosophy to bear on the problems of medical practice. He undertook to do this in a dialogue with philosopher Patrick Romanell (Leake and Romanell). Three decades later, moral philosophers were important figures in the elaboration of ethics of healthcare.

Secular academic philosophy did not find it easy to approach the practical problems posed by evolving science and medicine. In the 1950s philosophical ethics was struggling with the diverse theoretical challenges of naturalism, relativism, utilitarianism, Marxism, linguistic analysis, and positivism; hardly any attention was paid to the analysis of actual moral problems. This began to change in the 1960s as students vociferously raised questions about the moral legitimacy of the war in Southeast Asian and racial discrimination with their professors of moral philosophy. Interest in practical philosophy slowly appeared within academic philosophy. The questions of life and death raised by new technologies began to intrigue some philosophers. In 1969 Nicholas Rescher wrote an early article on the allocation of "exotic medical lifesaving therapy," such as dialysis and transplantation. Medical ethics began to be taught as an undergraduate philosophy course for which textbooks were produced (Gorovitz et al., 1973; Gorovitz et al., 1976). Daniel Callahan, trained in the analytic philosophy tradition at Harvard University, realized the ethical dimensions of the new medicine and in 1979 founded, with psychiatrist Willard Gaylin, the Institute of Society, Ethics, and the Life Sciences, later renamed the Hastings Center. Although slower to enter the field of practical ethics than the theologians, philosophers such as Baruch Brody, K. Danner Clauser, Tom Beauchamp, and Stephen Toulmin made significant contributions to the methods and substantive analysis of biomedical problems. Indeed, as Toulmin has claimed, "Medical ethics saved the life of philosophy," imparting an intellectual vitality and moral urgency to a field that had turned from the moral concerns of personal and social life to arid speculation.

Legal scholars were also prominent in the early years of bioethics. William Curran and Paul Freund of Harvard University and Jay Katz of Yale University contributed to the important symposium on experimentation with human subjects sponsored by the American Academy of Arts and Sciences in 1966; Katz subsequently published major work in this area (Freund; Katz, Capron, and Glass). John Noonan wrote perceptively on abortion and contraception. As the issues surrounding death and dying became prominent, particularly with the Karen Ann Quinlan case in 1975, lawyers became deeply involved, because law has always taken a serious interest in the determination of the causes of human death. Similarly, the evolution of the doctrine of informed consent has been strongly influenced by jurisprudence and judicial opinion. It is difficult to distinguish between the lawyer and the bioethicist in such figures as George Annas, John Robertson, Alexander Capron, and William Winslade. Indeed, one of these scholars, in a 1993 book, asserted, "American law, not philosophy or medicine, is primarily responsible for the agenda, development and current state of American bioethics" (Annas, p. 2).

Many physicians and scientists have become interested and adept in bioethics. As the field developed, however, the majority of its practitioners came from theology and philosophy; relatively few physicians have devoted themselves to scholarly productivity. Notable exceptions are Edmund Pellegrino, Mark Siegler, Howard Brody, Eric Cassell, and Christine Cassel. They bring to their contributions the sense and sensitivity of the practicing physician.

Although ethics was once taught in American colleges as the summit of the curriculum (often by the president of the college), as the twentieth century opened, ethics had retreated from that academic prominence to a refined and remote subspecialty of philosophy. Many believed that ethics was "caught" rather than taught. Medical ethics, it was said, was best conveyed to medical students by the example of prominent physicians, such as William Osler, as well as by the role models of the leading teachers in individual medical schools. Their lives and writings were common touchstones of discussion. Moreover, resolution of ethical issues tended to emphasize the need for the excellent overall character and

reputation of the physician, that is, an ethics of virtue. This emphasis on the good intentions of the physician was congruent with the model of practice then supported by the AMA—the independent practitioner in contract with the individual patient.

Medical jurisprudence, the study of the relationship between medical practice and the law, had been taught in American medical schools with some regularity during the nineteenth century. No course on medical ethics as such is known to have been offered until the late 1920s, except in the Catholic medical schools. The curriculum of the first known course in a secular medical school, offered by Park White at Washington University School of Medicine, St. Louis, in 1924, included discussion of group practice, consultations, relations with other practitioners, quackery, eugenics, euthanasia, and birth control (Burns, 1980). In 1926 the AMA recommended that medical ethics be made part of the medical curriculum. By 1931 it was reported that 43 percent of the sixty-seven American medical schools offered a course in medical ethics, most of these courses in the required curriculum. Approximately the same level was maintained through the 1950s, although course time was stretched to cover other subjects, such as medical sociology and economics, and it is unclear what topics were covered as medical ethics. During this era, Richard Cabot, who was both professor of medicine and professor of social ethics at Harvard University, was a dominant figure. He stressed the importance of personal integrity and honesty in the physician, as had the earlier professional ethics, but he placed this within the evolving framework of scientific medicine: Integrity must be manifested in clinical competence, the primary ethical obligation of the practitioner (Burns, 1977).

As the century progressed and the social and psychological sciences spread in collegiate education, discussion of the art of character development became increasingly overlaid with psychological and psychiatric analysis of the physician's character. Indeed, in the 1940s and 1950s, the Freudian model of psychological dynamics and of the doctor–patient relationship became prominent in the analyses of the virtues of physicians (Binger). Meanwhile, the increasing midcentury confidence in the social sciences tended to displace ethics terminology with concepts of "professional development," "human engineering," and so forth, sometimes even denigrating the admonitions of traditional morality as no more than "taboos." Ethics was often seen as so colored by religion that its teaching was bound to be covert indoctrination. In the secular climate of that time, any formal acknowledgment of ethics was suspect: Even the National Endowment for the Humanities, which eventually became a strong supporter of bioethics, originally excluded ethics from the list of the humanities whose study it would fund. Thus, ethics was rarely taught in higher education and even more rarely in medical education. This hiatus in the teaching of medical ethics during the 1950s may be seen as a prelude to the bioethics movement, in which neglected ethical questions forced their way back into the consciousness of the profession and the public alike.

The first national conference on the teaching of medical ethics was held in 1972 under the sponsorship of the Institute of Society, Ethics, and the Life Sciences and the Columbia University College of Physicians and Surgeons. By this time, out of 114 medical schools, only three required an ethics course and only thirty-three offered ethics as an elective (Veatch, Gaylin, and Morgan). The Society for Health and Human Values, formed in 1969, and its attendant Institute on Human Values in Medicine, encouraged medical ethics teaching. In the decade that followed, the number of schools providing organized teaching of ethics increased, and faculty members, often philosophers and theologians, were appointed. The content of the course shifted from the traditional topics, such as truth telling, confidentiality, care of the poor, care of the dying, and relations among practitioners, to the newer problems raised by technology and the social setting of modern medical care. In 1987 ninety-five American medical schools reported that they required a course in medical ethics, and the Association of American Medical Colleges strongly urged the inclusion of ethics in the curriculum (Bickel).

Nursing Ethics

Although medical students received little formal instruction in ethics, nursing schools developed a strong tradition of ethics teaching. Several major works on ethics were published by nurses at the turn of the century, notably *Nursing Ethics* by Isabel Hampton Robb (1901). Although her text is marked by a stern and self-sacrificing message to nurses, it includes sensitive discussion of many aspects of nurse–patient and nurse–physician relations. Textbooks on nursing ethics published in the first two decades of the century went through many editions before fading from popularity in the 1940s and 1950s. Notable among the authors were Charlotte Aikens and Thomas Verner Moore, whose books made extensive use of case studies. In 1931 religious educator Paul Limbert published a defense of nursing ethics courses: They were needed, he argued, to make ethical concerns explicit and to assist student nurses in interpreting their clinical experiences in such a way as to foster good professional character. As in the medical ethics of that era, the emphasis was on the character development of the nurse rather than on principle-centered or patient-centered ethics.

An important theme for nursing ethics has always been the impact of the feelings and character—the "humanness"—of the practitioner on the care and cure of the patient. As new technologies developed with increasing efficacy, practitioners felt the need to redefine the role of their personality in relationship to those technologies.

At the beginning of the twentieth century, nursing was predominantly a home-based practice; by the end of the century, it had become predominantly institution based. This redefinition of the nursing role provided a stimulus for some of the recurring issues in the nursing literature of the early part of the century. For instance, whether a nurse should do housework, such as washing diapers or tending the fire in the grate, was a significant issue until the 1950s. How the nurse should react to the errors of quacks and regular physicians continued to be a prominent issue. In all such cases, texts resolved the questions in terms of dedication to the welfare of patients. Indeed, nursing ethics took an early stand against permitting patients to be injured by other practitioners, including physicians, and nurses have taken an increasing role in institutional quality control.

Like physicians, nurses struggled with the problem of "irregular" practitioners. In the earliest part of the century, the "untrained nurse" was represented in the nursing ethics literature as ethically, as well as technically, incompetent. The emergence of the licensed practical nurse in the 1930s and the increasing number of nursing aides during the century challenged professional nursing, and the ethics of relationships with these occupations has been delicate. In the 1970s the American Nurses' Association took a stand that a bachelor's-level education was necessary for professional nursing, calling into question the standing of nurses trained in hospitals and community colleges. In the 1980s nursing was again challenged by a recommendation from the AMA, calling for the creation of a "registered care technician" to perform some of the technical functions of nurses. The ethics of the relationship of nurse to physician is still being debated in the nursing ethics literature. It is commonly asserted that power and gender relationships are central to the ethics of nursing. Original presentations of the ethics of nursing have appeared: The works of Mila Aroskar, Martin Benjamin, Joy Curtis, Anne Davis, Marsha Fowler, Sara T. Fry, Sally Gadow, Amy Haddad, Andrew Jameton, Christine Mitchell, James Myskens, and Michael Yeo are notable. Their work carries the themes of nursing ethics into the broader stream of bioethics. The bioethics movement has also touched the many other professions involved in the care of patients: dentists, occupational therapists, pharmacists, physical therapists, physician assistants, medical technicians, and social workers.

Ethical Issues in the Emerging Biomedical Technologies

In the years after World War II, the rapid advances of biomedical science were translated into clinical interventions that could save and sustain life in ways never before possible. These technological advances brought not only the benefits of improved health and prolonged life but also a range of puzzling moral questions (Jonsen, 1998). One of the first of these technologies to raise explicit ethical concerns was the 1961 invention by Belding Scribner at the University of Washington of a technique for chronic hemodialysis of persons with end-stage renal disease. Because the first artificial kidney center in Seattle, Washington had limited machines and trained personnel, it could serve only a tiny portion of the 15,000 or so persons in need of such lifesaving care. A committee consisting of seven lay members and two physician-advisers was chosen to select patients who would be admitted. Those who were not admitted would die. The committee employed social criteria, such as productive livelihood and respectable citizenship, for selecting candidates from among the many medically eligible patients. There was a strong public reaction and much severe criticism of using social values in life-and-death decisions (Fox and Swazey, 1974).

Philosophers and theologians noticed the issue and engaged in debate over it (Rescher; Childress; Ramsey, 1970b). The issue of rationing the scarce resource of dialysis was resolved in 1972 by an amendment to the Social Security Act providing payment for about 90 percent of the high cost of dialysis. This led to further discussion comparing the plight of other persons in high-cost disease categories, such as hemophilia, with that of kidney patients. In justice, the argument ran, various other groups ought to receive similar public aid. This early example of the ethical dilemmas posed by the new technology exemplified some of the themes that would become central to bioethics: the acceptance of lay opinion into decisions formerly reserved to physicians, the appearance of philosophical and theological analyses of the issue, the recognition of questions of fairness in application of medical resources, and the profound implications of life-and-death decisions. Indeed, the questions "Who should live? Who should die? Who should decide?" became the theme of bioethics.

The first heart transplantations were done in South Africa in 1968; similar operations were attempted shortly thereafter in the United States. Optimistic claims by medical innovators fostered public enthusiasm, which turned to disillusionment when, after three years, the very poor survival rate resulted in a virtual moratorium on heart transplants (Fox and Swazey, 1974). As heart and kidney transplantation became more effective, ethical issues surrounding

organ donorship arose. To encourage cadaver donorship, the Uniform Anatomical Gift Act was proposed by the U.S. National Conference of Commissioners on Uniform Laws in 1968 and subsequently adopted by all states (Katz, Capron, and Glass). Because of high costs and the scarcity of organs, transplantation forcefully raised questions of whether the gains of new technology could justify the costs. At the same time, the determination of death, traditionally done by noting the cessation of cardiorespiratory functions, began to be questioned: These criteria seemed obsolete under conditions of artificial respiratory support and did not allow for removal of organs for transplantation. A vigorous debate ensued about the ethical and legal implications of shifting to clinical criteria that would focus on cessation of brain activity. In 1968 a committee at Harvard Medical School formulated a statement defining *brain death* as a criterion for declaring death (Harvard Medical School). Brain death criteria were accepted and legalized slowly, beginning in Kansas in 1970. Still, considerable confusion required further refinement of the concept, leading eventually to the recommendation of a Uniform Statute for the Determination of Death, which has now been adopted in most jurisdictions (U.S. President's Commission for the Study of Ethical Problems in Medicine, 1981).

During this same period, artificial implants to assist or replace the heart were being developed. Denton Cooley in Houston, Texas, unsuccessfully attempted to implant an artificial heart in 1969. In anticipation of the time when such a device might be ready for use in humans, the National Heart and Lung Institute in 1971 established a panel to study the possible ethical, social, economic, legal, medical, and psychiatric consequences of its development. This was the first effort by the federal government to explore the ethical implications of new medical technologies (National Heart and Lung Institute; Jonsen, 1973). The first actual implantation of an artificial heart—in Barney Clark, at Salt Lake City in 1982—aroused considerable debate about the appropriateness of this device (Shaw).

By the mid-1960s, issues of research ethics had begun to ferment among scientists (Ladimer and Newman). The Nuremberg trials in 1947 revealed the horrors of the Nazi concentration camps, where cruel and lethal medical experiments had been performed on prisoners. Several articles on the ethics of human experimentation had appeared in the American medical literature, but the ethical issues of biomedical experimentation with human beings were not widely discussed, perhaps because many believed that nothing so horrible could happen in the United States (Alexander; Annas and Grodin). During World War II, however, the intense efforts to improve the capabilities of military medicine occasionally spurred researchers to design experiments in which persons were treated dangerously and without their consent. In the years after the war, biomedical research was fueled by large infusions of funds from the newly expanded National Institutes of Health, and research projects were sponsored in hospitals throughout the country. As the volume and intensity of research increased, questionable practices appeared and were tolerated as the price to be paid in the war against disease. Informed consent of research subjects was rarely obtained, and oversight by anyone other than the researcher was unusual. In 1962 a number of children were born with serious congenital defects due to their mothers' ingestion of thalidomide, an unapproved drug. This tragedy stimulated congressional hearings at which the ethics of human experimentation, then largely uncontrolled, was aired. Subsequently, amendments to the federal Food, Drug, and Cosmetic Act in 1964 required full and free consent of all subjects of drug trials.

In 1966 Henry Beecher, professor of anesthesia at Harvard University, brought problems in the ethics of experimentation to the attention of the medical community. He detailed twenty-two medical experiments carried on by respected investigators that he branded as unethical because of lack of consent or inappropriate assessment of risks in relation to benefits (Beecher; Rothman, 1991). In 1966 (with revisions in 1968) the U.S. Public Health Service formulated guidelines for protection of the rights and welfare of human subjects in all federally supported research. In 1971 these guidelines became regulations of the Department of Health, Education, and Welfare, requiring research institutions to set up medical and lay panels to review all federally funded experimentation to ensure that subjects are informed and freely consent to the research procedure, and to determine that the scientific benefits justify the risks of the research (Levine).

A number of scandals in research ethics brought public attention to the need for regulation. At Willowbrook State Hospital in New York, a series of studies on hepatitis were conducted from 1965 to 1971 that involved infecting mentally retarded children with hepatitis virus. At the Jewish Chronic Disease Hospital in Brooklyn in 1963, live cancer cells were injected into senile patients without their knowledge or consent. In 1971 a study begun in the 1930s at Tuskegee, Alabama, came to public attention: A number of rural black men suffering from syphilis had been left untreated in order to ascertain the "natural history" of the untreated disease (Jones). In response to these and several other scandals, the U.S. Congress established the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research (1974–1977) to make recommendations for federal policy on the broad problems of human subjects in research as well as the special problems

posed by research with fetuses, children, prisoners, and other dependent or vulnerable persons. These recommendations were codified in federal regulations and are now widely enforced in research institutions. The field of bioethics was significantly advanced by the work of this commission. Several scholars in ethics sat on the commission, and many philosophers, theologians, lawyers, and sociologists were asked to contribute to its deliberations, thereby stimulating thought about the issues and making public careful analyses of the problems and principles. The commission's *Belmont Report* (1978), stating the principles of research with human subjects, first enunciated the triad of bioethical principles: autonomy, beneficence, and justice. Federal regulations codified the commission's recommendations, and for the next several decades clinical research, scrutinized for ethical probity by institutional review boards, proceeded without incident. In the late 1990s, however, several deaths and widespread evidence of inadequate review of research led to a revival of concern. The ethics of research returned to the agenda of bioethics.

It became increasingly common during the twentieth century for people to die in a hospital, often under conditions of dehumanizing technology. This reawakened age-old discussions of death, dying, and euthanasia, now in light of the new technical potential of modern medicine. Although there had been several unsuccessful attempts to make euthanasia legal in the early years of the century, death and dying had become a taboo subject in medicine. Elisabeth Kübler-Ross's sensitive interviews with dying patients, captured in her 1969 book, *On Death and Dying,* did much to awaken interest in the psychology of dying.

In 1976 the state of California passed novel legislation about termination of life support. The Natural Death Act authorized patients to sign a legal document directing physicians to remove or to withhold life-support devices under carefully defined circumstances. Many states have followed California by enacting legal forms of "advance directives" to guide physicians in following the wishes of their dying, incompetent patients. In 1976 a New Jersey Supreme Court decision allowed the parents of Karen Ann Quinlan—a young woman not quite dead by the Harvard brain death criteria, but who could be maintained indefinitely on a respirator with no hope of recovery—to have their daughter removed from the respirator (*In the Matter of Karen Ann Quinlan,* 1976). Subsequent judicial decisions in many states and one U.S. Supreme Court decision—*Cruzan v. Director, Missouri Department of Health* (1990)—have elucidated the conditions under which life support might be forgone. Many of these decisions have been influenced by the bioethical debates over active and passive euthanasia. In the 1990s, the debate over legalization of active euthanasia was renewed, spurred by the public perpetration of euthanasia by the physician Jack Kervorkian and by the advocacy of the Hemlock Society, which promoted legislation that would authorize physicians to provide "aid in dying" at the request of terminal patients. In the 1990s several states held initiatives to legalize this practice but only in the state of Oregon did the voters approve. Since 1994 citizens of that state have been permitted to seek, under stringent conditions, the aid of a physician to end their life. This and other efforts to make euthanasia legal have prompted important judicial decisions, even in the U.S. Supreme Court (*Vacco v. Quill,* 1997; *Washington v. Glucksberg,* 1997; Hillyard and Dombrink). These questions about the nature of appropriate care for the terminally ill, as well as many other ethical questions, are made more urgent by the increase in the numbers of elderly people in the United States: Since the beginning of the twentieth century, the number of Americans over the age of sixty-five has tripled in proportion to the general population (Jecker).

In 1978 the U.S. Congress reestablished the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research as the U.S. President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research. Among the new commission's mandates were studies of brain death, genetic screening, access to healthcare, and the use of life-sustaining technologies (U.S. President's Commission, 1981, 1983a, 1983b, 1983c). Like its predecessor, it called on scholars from many disciplines to contribute to its deliberations. Its reports make up a veritable canon of bioethics. Its recommendations on the definition of death have been enacted into law in all states as the Uniform Definition of Death Act.

The ascendancy of technological medicine inspired critical study of the nature of the healthcare professions and institutions. Popular and academic works investigated the conceptions of health employed in medicine and the efficacy of medical services offered (Illich). They explored the nature and authority of the health professions and raised questions about ethical responsibilities of health professionals whose attitudes are shaped by economic and social forces (Freidson). The proper role of health professionals has been questioned in many contexts, including the right of health professionals to strike and the extent to which they bear responsibility for patients' lives, for behavioral factors affecting health, and for social and political factors causing disease. The helplessness of individuals in the face of a massive medical establishment led to a patients' rights movement. As evidence of this concern, the American Hospital Association published *A Patient's Bill of Rights* in 1973, with the suggestion that it be

adopted by all hospitals. Attempts to pass federal legislation in support of a Patient's Bill of Rights have been unsuccessful.

Reproduction and reproductive technology also fostered debate. During the first part of the century, birth control was an important issue in the feminist movement. Not until the late 1960s were restrictions on the use and teaching of birth control removed in most states. The feminist movement, especially through Margaret Sanger (1879–1966), also sponsored and encouraged research on new birth-control methods (Gordon). In the 1960s abortion became a center of debate. The discussion began with the American Law Institute's model statute permitting abortion for medical and psychological conditions as well as after rape and for fetal defect. The "responsibility for pregnancy" issue for the most part dropped from the debate as it became an issue of women's right to control their bodies, on one side, and the claim of the fetus's right to life, on the other, a claim largely, although not exclusively, urged by Catholics. The U.S. Supreme Court in *Roe v. Wade* (1973) chose a position protecting the mother's decision in the first trimester of the pregnancy, with increasing possibility for legal restrictions during the second and third trimesters. Abortion, because of its intriguing questions about personhood, stimulated considerable professional, philosophical, and theological reflection (Callahan, 1970; Grisez). That reflection has, in the 1990s and early 2000s, ceded to vigorous, even violent political activism. Whether the reflection or the activism will prevail in policy remains to be seen.

In the 1960s advances in genetics and reproductive technology caused much speculation about social consequences of such possible innovations as cloning, in vitro fertilization, and extrauterine gestation. The concern over cloning human beings, vigorously debated in the 1960s, when the question was still speculative, resumed in 1996, after the successful cloning of the sheep Dolly by two Scottish researchers (Ramsey, 1970a; MacKinnon). Interest in the potential and the dangers of genetic manipulation was heightened by the development of recombinant DNA technology in the mid-1970s. Amniocentesis (a test to diagnose certain fetal disorders during early pregnancy) and improvements in genetic history-taking made possible the development of genetic counseling as a profession in the late 1960s, with attendant ethical questions (Hilton et al.). Many questions considered speculative in the 1980s came close to realization by the early twenty-first century. The federally sponsored project to map the entire human genome has become a focus for the study of the ethical questions involved in genetic diagnosis, treatment, and social policy. Its Ethics, Legal, and Social Implications Project has sponsored a wide variety of scholarly and institutional activities in the ethics of genetics (Juengst and Watson; Cooke-Deegan).

Questions about the biological basis of personality, achievement, and social behavior continued to arise. In the early part of the twentieth century the eugenics movement fostered many state laws requiring or allowing sterilization of persons with mental retardation or illness. Debate over sterilization arose again around 1970, when protection of women and minority groups against pressure for sterilization became an issue. The role of genetics in behavior continued to be debated with the development of sociobiology and studies on IQ and heredity. There was disagreement over the goals of genetic counseling, as well as over whether genetic factors in behavior could or should be identified. Screening of populations for genetically determined conditions was much debated (U.S. President's Commission, 1983c; Holtzman).

Biology and behavior was also an issue in the treatment of mental disorders by surgical methods. Prefrontal lobotomy was widely used but much debated after its introduction in 1935. With improvements in surgical techniques in the 1960s, new types of brain surgery were attempted for treatment of violence and other indications. The use of psychosurgery on prisoners became a public issue (Valenstein). The National Commission for the Protection of Human Subjects issued a report on this practice that recommended only its strictly controlled experimental application. A related but quite different form of brain surgery involves the implantation of tissue from aborted fetuses into those suffering from certain neurological and endocrine disorders. This practice, initiated in the late 1980s, aroused great debate. Several advisory committees convened by the National Institutes of Health approved this form of research as acceptable public policy, yet the federal government refused for almost six years to fund studies (Vawter et al.). Although this precise form of therapy has yet to be proven efficacious, scientific interest in the therapeutic value of embryonic stem cells stirred up an ethical storm. On August 9, 2001, President George W. Bush told the nation that "Embryonic stem cell research is at the leading edge of a series of moral hazards." He announced that he would appoint a council to monitor stem cell research and investigate other bioethical questions. The President's Council on Bioethics was established on January 16, 2002, headed by a distinguished bioethicist, Dr. Leon Kass (U.S. President's Council, 2002; Green).

Although psychosurgery is the most physically invasive mode of treatment for behavioral problems, all levels of psychiatric treatment were subject to ethical inquiry. The warrant and nature of involuntary commitment to mental hospitals had been a source of contention for many years (Rothman, 1980). Commitment laws in many U.S. states

were modified in the 1960s to increase protection of individuals from arbitrary commitment, although at the same time, the policy of deinstitutionalization thrust many mental patients into a world for which they were unprepared. The right of hospitalized mental patients to receive treatment was established in the United States initially by the Supreme Court decision in *Wyatt v. Stickney* (1972). The use of drugs in treating psychiatric disorders became an issue after chlorpromazine and related major tranquilizers became widely available in the 1950s, reducing the need for hospitalization. The conventional medical view of behavioral problems as disease came under attack from radical psychiatrists such as Thomas Szasz (1961). Goals and values in psychotherapy came to the fore in discussions about treating patients who manifested "antisocial" behavior. The growth of behaviorism and behavior modification seemed also to challenge traditional libertarian values. Rapid evolution of the neurosciences has resuscitated ancient ethical questions about free will and responsibility and raised new ones about the limits of enhancement of cognitive and affective life. Scholars in bioethics are only beginning to study these questions.

In 1981 a previously unknown disorder of the immune system appeared, at first in men known to engage in homosexual activities. This disorder, named acquired immunodeficiency syndrome (AIDS), was quickly traced to a blood-borne retroviral infection. The resulting disease was relatively slow to appear but was, given the therapeutic possibilities available, inevitably fatal. It spread in epidemic fashion among gay men and among those who shared needles while taking drugs intravenously. Fear of the disease and widespread homophobia led to discriminatory actions against those infected. Old ethical questions about restricting freedom of persons suspected of having a communicable disease were revived. Public health needs appeared to conflict with personal rights. The duty of healthcare professionals to treat infected persons was vigorously debated, as was the right of infected care providers to practice. Bioethics, by now adept at the discussion of practical ethics, made a major contribution to these debates (Bayer).

The problem of just allocation of healthcare had been noticed in the earliest days of bioethics. At that time, however, it was largely defined in terms of selection of patients for rare and expensive technologies, such as dialysis. In the early 1980s, it was recognized that some 35 million Americans were not covered by any healthcare insurance (U.S. President's Commission, 1983b; Dougherty; Churchill). Ethical questions about the justice of such a system were raised as health-policy experts began to note the rapid inflation in healthcare costs. Lack of access to care competed with cost containment in public debate and political maneuvering. These problems became central to the concerns of many bioethicists, who began to produce acute analyses of the issues of justice in the healthcare system and its financial base. These ethicists raised and examined the politically unpalatable issue of rationing of healthcare resources (Daniels; Callahan, 1988; Menzel; Morreim).

Academic Bioethics

As the 1970s opened, a number of scholars were beginning to attempt to analyze the issues discussed above within the perspectives and methodologies of the two disciplines traditionally concerned with ethics, philosophy and theology. As these scholars began to publish and communicate, a distinct field of study called bioethics came into being. The word *bioethics* was first applied to the ethics of population and environment (Potter), and soon became the rubric for a diverse collection of considerations about the ethical issues inherent in healthcare and the biological sciences (Callahan, 1973). The term, although considered unsatisfactory even by some of those who employed it, was canonized by the inauguration of the *Encyclopedia of Bioethics* project in 1972 and by the publication of the first edition, edited by Warren T. Reich, in 1978. The scholars in this new field now come from many disciplines, such as theology, philosophy, social sciences, and law. Bioethics concentrates on a specific set of issues, such as those mentioned above, and employs a range of analytic methodologies, explained in texts such as *Principles of Biomedical Ethics* (Beauchamp and Childress) for the more theoretical questions and in *Clinical Ethics* (Jonsen, Siegler, and Winslade) for the more practical questions. It has professors, students, texts, journals, learned societies, and research centers. At the beginning of the twenty-first century, more than a dozen graduate programs offer higher degrees to students trained in the topics and methods of the field.

Bioethicists show considerable interest in the theoretical definition of the field and its methodologies. Albert Jonsen and André Hellegers published an essay in the early days of the field's existence in which they saw it as a mélange of traditional professional ethics, philosophical ethics, and theological ethics (Jonsen and Hellegers). Robert Veatch, however, was the first to attempt a full exposition of the theoretical underpinnings of bioethics. His 1981 book, *A Theory of Medical Ethics,* set the field firmly on the ethical considerations relative to autonomy of the patient. H. Tristram Engelhardt Jr. followed in 1986 with *The Foundations of Bioethics,* an even more strongly stated thesis about autonomy as the basis of the discipline. Nevertheless, some

have asserted that bioethics, while it had its origins in the strong affirmation of autonomy for patients, may have moved too far in this direction and thereby neglected other aspects of healthcare, such as benevolence, community, and social justice (Pellegrino; Daniels).

The study of bioethics, together with other fields in applied ethics, has inspired much debate about the methods appropriate to studying practical ethics in general. Many of these nascent methods have lent a richer, more detailed texture to ethical discussion than is permitted by principle- and theory-based ethics. The long-abandoned casuistry that employs rhetorical and analogical reasoning to examine cases is now being viewed with renewed and critical interest (Jonsen and Toulmin; Arras; Sugarman and Sulmasy). Mathematical decision analysis has been used to study values through systematically related cases (Smith and Wigton). Stories, real and fictional, are used as texts open to moral interpretation according to the methods of hermeneutics (Brody; Hunter), and phenomenology seeks to capture the ethical subtleties of clinical encounters (Zaner; Carson). Echoing the language of ethics from the nineteenth century, but with much greater attention to depth and detail, interest in virtue- and character-based ethics is vigorous (Drane; Shelp).

Although the early development of bioethics was dominated by male scholars, women such as Elizabeth Fee, Renée Fox, Loretta Kopelman, Karen Lebacqz, Ruth Macklin, Ruth Purtilo, and Judith Swazey have made significant contributions to theoretical and practical bioethics, and feminist ethics has begun to attract much attention. Feminist bioethics offers social criticism of the treatment of women as patients and physicians, discusses the interrelationship between gender and power, provides fresh analyses of issues of traditional concern to women (such as pregnancy, birth, and reproductive choices), and emphasizes important theoretical concepts—such as caring, community, and responsibility—neglected by male scholars (Holmes and Purdy; Sherwin).

Other authors note the ethnocentricity of U.S. bioethics; it has been charged with a failure to reflect the concerns of people of color, and new work is beginning to appear that increasingly reflects diverse viewpoints. Collections of narratives of the African-American experience with disease and healthcare have begun to appear (Secundy and Nixon; White). A Center for Bioethics was inaugurated at Tuskegee University at the time of President Bill Clinton's formal apology to African Americans for the Tuskegee syphilis experiments; this center will concentrate on ethnic issues in bioethics. Some authors have discussed the tensions between expressed philosophical ideals and systematic patterns of discrimination, such as abuses of birth control, sterilization, and selection of subjects for research (Dula; Flack and Pellegrino). U.S. bioethics is becoming more international and less ethnocentric in its concerns: American bioethicists visit many nations, and bioethicists from around the world spend time in American programs, stimulating cross-cultural comparisons and analyses (Fox and Swazey, 1984; Harding; Sagoff). American scholars are active in the International Association for Bioethics.

The tendency of ethics researchers to study clinical questions cooperatively with clinicians has inspired empirical study of ethics in healthcare. This in turn has fostered cooperation between the social sciences and normative philosophical ethics. Termed the *contextual approach* by some authors, it has begun to call attention to significant social and cultural features of life that affect ethical expression and debate (Weisz; Thomasma). Some researchers have used in-depth ethnographic techniques, such as participant observation and interviews, to study the microcontext of clinical settings; others are employing epidemiological methods to ascertain frequency of behaviors, such as resuscitation. The empirical social sciences and philosophy are beginning to converse with each other on the common ground of bioethics (Guellemin and Holmstrom; Bosk).

In the 1970s, as faculty members were appointed to teach ethics in medical schools, it became common for the ethicist to accompany physicians on teaching rounds. This led to the participation of ethicists in consultations about cases that presented particularly difficult ethical decisions. This practice came to be called clinical ethics. In 1977 ethicist John Fletcher was appointed assistant for bioethics to the director, Clinical Center, National Institutes of Heath, with responsibility for ethics consultation. Because philosophy itself provides little guidance about how to assist in actual decision making, various methods were devised to apply principles to practice. Clinical ethics spread from university hospitals to community hospitals; many individuals, physicians and philosophers alike, now act as clinical ethics consultants. The *Journal of Clinical Ethics* was initiated in 1991. As might be expected, some dispute surrounds the idea and practice of ethics consultation, because it seems to imply that some persons are "ethical experts," a notion rather foreign to a morally pluralistic culture (Fletcher, Quist, and Jonsen). The American Society for Bioethics and the Humanities published criteria for clinical-ethics consultation.

As the field of bioethics was beginning to form and as yet lacked institutional support for regular teaching and discussion, conferences and symposia were an important source for developing literature, teaching, and publicity. Some of the more important early conferences were

the Joseph P. Kennedy, Jr., Foundation's International Conference on Abortion, held in 1967 in Washington, D.C.; a New York Academy of Sciences' conference, New Dimensions in Legal and Ethical Concepts for Human Research (Ladimer and Newman); a U.S. National Academy of Sciences Institute of Medicine's conference, Health Care and Changing Values, held in 1973; a series of transdisciplinary symposia on philosophy and medicine, the first of which was held in Galveston, Texas, in 1974 (Engelhardt and Spicker); and the 1975 conference Experiments and Research with Humans: Values in Conflict, sponsored by the National Academy of Sciences. In the 1990s such conferences, on a wide variety of topics, were announced at a dizzying pace.

Several privately funded institutes are devoted primarily to the study of bioethics. The Institute of Religion, established in 1954 at the Texas Medical Center, Houston, began to devote attention to bioethical issues in the late 1960s. The Society for Health and Human Values evolved in 1969 from a smaller interdisciplinary group that had formed the Committee on Health and Human Values in 1963 with support from the ecumenical United Ministries in Higher Education. In 1998 the Society for Health and Human Values, the Society for Bioethics Consultation, and the American Association for Bioethics united to form the American Society for Bioethics and the Humanities, which by 2002 had enrolled 1,500 members, drawn from bioethics, medicine, nursing law, religion, and the social sciences. The Hastings Center, originally called the Institute of Society, Ethics, and the Life Sciences and founded in 1969 by Daniel Callahan and Willard Gaylin, investigates social, legal, and ethical aspects of the health sciences. It conducts a program for visiting fellows and associates; publishes the most widely read of the ethics journals, *Hastings Center Report* and *IRB: A Review of Human Subjects Research;* organizes study groups on special topics; and conducts courses for health professionals and others. In 2002 the Hastings Center had 109 fellows and almost 12,000 members.

For several years in the 1970s, the Joseph P. Kennedy, Jr., Foundation funded the Interfaculty Program in Medical Ethics, which joined Harvard University's Medical School, School of Public Health, and Divinity School to train scholars in this new field. In 1971 André Hellegers founded the Joseph and Rose Kennedy Institute for the Study of Human Reproduction and Bioethics, now known as the Kennedy Institute of Ethics, at Georgetown University. This program, initially financed by the Kennedy Foundation, has supported research by permanent and visiting scholars, courses and workshops in bioethics, and cooperative and consulting programs with private and governmental institutions. The Kennedy Institute has specialized in the creation of fundamental research tools in the field of bioethics. Starting in 1972, the institute sponsored Warren Reich's project for the preparation of the *Encyclopedia of Bioethics,* a landmark in U.S. bioethical studies. Its National Resource Center prepares the computer-based bibliography of bioethical literature called Bioethicsline, a part of the National Library of Medicine's Medlars network; Bioethicsline is also published in book form as *Bibliography of Bioethics* (Walters). The Kennedy Institute originated the important *Journal of Philosophy and Medicine,* which is now published independently, and currently produces the *Kennedy Institute of Ethics Journal.* In 1993 the American Association of Bioethics came into existence to promote the exchange of ideas among bioethics scholars, encourage the development of new scholars, and maintain contact with international societies in bioethics.

As bioethics flowered, many ethical issues were being debated as matters of public policy. Some bioethicists found themselves working as public employees to aid in policy formation, and others served as members of and consultants to advisory bodies such as the National Commission for the Protection of Human Subjects, the U.S. President's Commission for the Study of Ethical Problems in Medicine, the now defunct Ethics Advisory Board of the Department of Health and Human Services, and state bodies such as New York's Task Force on Life and the Law and New Jersey's Bioethics Commission. Ten of the eighty-two "special government employees" working with the 1993 Task Force on Reform of Health Care were persons identifiable as bioethicists. The National Bioethics Advisory Commission was established by an executive order of President Clinton in 1995, and during the next six years this commission produced a series of excellent reports on such issues as cloning of human beings, stem cell research, and research involving persons who have mental disabilities. Beyond these official bodies, several thousand physicians, nurses, clergy, and laypersons sit, often with bioethicists, on the hospital ethics committees that have, since the 1980s, become part of most medical centers in the United States. Grassroots bioethics activities, such as the Oregon Health Decisions Project, strive to involve laypersons in making decisions about the ethics of healthcare allocation policy. Bioethics has become, to some extent, a philosophy for the people.

The bioethics movement has demonstrated extraordinary vitality in the United States since the 1970s. Its work effected significant changes in the practices of healthcare. Its first historian, David Rothman, wrote, "The record since 1966, I believe, makes a convincing case for a fundamental transformation in the substance as well as the style of medical decision making" (Rothman, 1991, p. 251). That

transformation consists largely in the flow of lay opinion and judgment into the formerly closed world of medical decision and policy, in both clinical and research settings.

By the 1990s, bioethics was firmly established as a field of study within academic settings. This gives it a prestige and institutional base that it had previously lacked, but that may also imperil its vitality and independence. Although initially seen by some as a fad, bioethics is linked with social and personal issues deeply rooted in the culture of the United States during the twentieth century. The impact of technology on human life, the distribution of increasingly scarce health resources in an otherwise affluent society, the role of government in the pursuit of health by individuals and populations, and the voice of the consumer-patient in decisions about medical care—all these issues are central to the concerns of bioethics. Inevitably, ethical issues in the life sciences also embrace the larger social problems of environment and population. It is likely that the diffuse field of bioethics will take shape as it increasingly finds its place in the education of future health professionals, as it becomes part of the attempt by schools and consumer organizations to increase personal responsibility for health and environment, and as it attends to the formulation of public policy about social life in the biosphere.

III. CANADA

Two aspects of Canadian society are particularly determinative of the Canadian approach to bioethics: (1) the country's universally accessible, publicly funded healthcare system, and (2) the role of law. While a multitude of bioethical issues have occupied Canadians since the 1960s, there have been three major areas of bioethical activity: clinical ethics, research ethics, and ethics in public policy. The history of bioethics in Canada can be divided into two time periods: from 1800 to the 1960s, and from the 1960s to the present. During the first period, medical ethics predominated, although theological ethics and the ethics of nursing were also important. Since 1960, the field of medical ethics has been incorporated into the broader field of bioethics.

Medical Ethics: 1800–1960

In 1867, the year of Canada's formation as a nation, the Canadian Medical Association (CMA), came into being. At its first annual meeting in 1868, the CMA adopted the Code of Ethics of the Canadian Medical Association, which was closely modeled on the American Medical Association's code of ethics. Since then there have been a number of revisions to the CMA Code of Ethics, most recently in 1996. This code outlines general responsibilities, responsibilities to the patient, responsibilities to society, responsibilities to the profession, and responsibilities to oneself.

The Canadian Nurses Association (CNA) was established in 1908. However, the association did not have a code of ethics until 1954, when it adopted the one that had been prepared the previous year by the International Council of Nurses. In 1980 the CNA moved to establish its own code, which was published as *CNA Code of Ethics: An Ethical Basis for Nursing in Canada.* This code has since been revised on a regular basis (1985, 1991, 1997, and 2002) and is now entitled *Code of Ethics for Registered Nurses.* The content is structured around three themes: (1) the nature of ethics in nursing, (2) nursing values defined, and (3)nursing values and responsibility statements.

The Roman Catholic Church has played an important role in healthcare in Canada since colonial times. The Catholic Hospital Association of the United States and Canada (CHAUSC), founded in 1915, adopted a code of ethics in 1921 that dealt primarily with surgical issues in obstetrics and gynecology. This document was updated in 1935, and in 1949 it was revised and published as *Ethical and Religious Directives for Catholic Hospitals.* In 1954 the Catholic Hospital Council of Canada (established in 1942) declared its independence from CHAUSC and renamed itself the Catholic Hospital Association of Canada. It adopted its own moral code in 1955. Now known as the Catholic Health Association of Canada, this organization updated and renamed its moral code, the *Health Ethics Guide,* in 1971, 1991, and again in 2000. This document addresses issues related to social services and organizational ethics. The core focus areas for the Catholic Health Association of Canada are ethics, spirituality, values development, and social justice.

Canadian contributions to the medical ethics literature were few and far between until the 1940s. The most renowned Canadian physician of this period, Sir William Osler (1849–1919), made few references to medical ethics in his many publications. He did, however, have a great deal to say about the practice of medicine and about physician behavior. The chief virtues of the individual physician are variously referred to in his writings as equanimity (*aequanimitas*), imperturbability, and detachment. His stated ideal for the medical profession was that of "noblesse oblige" (Osler).

Not until the 1940s did a significant number of Canadian publications in medical ethics begin to appear, most of them written by Catholic theologians (e.g., LaRochelle and Fink). Some Catholic schools of medicine (e.g., the University of Ottawa) and nursing (e.g., the University of Montreal) made faculty appointments in medical ethics; and the professors who took these posts contributed to the growing body of Catholic literature in this field (e.g., Paquin,). However, comparable work by philosophers and health professionals was noticeable by its absence.

Bioethics: 1960s–2000s

Beginning in the mid-1960s, the field of medical ethics underwent a radical transformation, and by the end of the 1970s it displayed all the features of what has become known as bioethics. In Canada the major actors in the development of bioethics have been professional associations, public commissions, and academic institutions.

The major professional health associations expanded their ethics activities during this period. In the early 1980s the CMA remandated its Committee on Ethics to deal with the whole range of bioethical issues, rather than those affecting only physicians. In 1989 the CMA established a Department of Ethics and Legal Affairs. The Royal College of Physicians and Surgeons of Canada created a Biomedical Ethics Committee in 1977, and the College of Family Physicians of Canada followed suit in 1991. The Canadian Nurses Association established an ad hoc ethics committee that met regularly from 1985 to 1997 to revise its code of ethics. In the Spring of 1997 this committee was given permanent standing.

A favored way of dealing with contentious social issues in Canada is through public commissions, such as federal and provincial law reform commissions. The federal Law Reform Commission was established in 1971 to review the federal laws of Canada on a continuing basis, and to make recommendations for their improvement, modernization, and reform. Bioethical issues were dealt with in the Protection of Life Project, one of four commission projects. Between 1979 and 1992, a dozen or so study papers, working papers, and reports to Parliament were published on topics such as euthanasia and assisted suicide, experimentation on human subjects, and medically assisted procreation. In 1992 the commission was terminated by the government for budgetary reasons. Five years later, in 1997, the federal government created the Law Commission of Canada. This commission has not undertaken specific projects concerning bioethics, but it has supported work on the governance of research involving humans.

Academic institutions have experienced tremendous growth in the area of bioethics since the 1960s. Courses in this field have proliferated in philosophy and religious-studies departments, where they are often the most heavily subscribed offerings. Bioethics instruction is now offered in every Canadian medical school at the basic degree level and is rapidly expanding into residency training programs. Nursing, health administration, and dentistry programs have also

formalized ethics teaching, and in many universities instruction in the ethical aspects of animal experimentation is required for biology, zoology and psychology students.

Research in bioethics has been fostered by the creation of centers, institutes, and professional associations for practitioners in this field. The Center for Bioethics of the Clinical Research Institute of Montreal, established in 1976, was the first such organization in Canada. It was followed three years later by the Westminster Institute for Ethics and Human Values, based in London, Ontario (now defunct). By 2002 there were at least nineteen research centers and groups in Canada, most of them university based. A national association, the Canadian Bioethics Society, was formed in 1988 through a fusion of two previously established associations.

The Institutional Matrix of Bioethics

The Canadian healthcare system and Canadian law have been two of the most important forces shaping the context within which bioethics has developed in Canada. The healthcare system has also been the source of some of the most difficult bioethical issues Canadians have faced since 1971, when the country's national health insurance program was fully set in place (Taylor). Although Canadian legislation and jurisprudence have largely guided and supported work in bioethics, there have also been points on which they have clashed.

THE CANADIAN HEALTHCARE SYSTEM. The Canadian healthcare system is in reality not a single system, but rather a network of ten provincial and three territorial healthcare systems. The coherence of this network derives from the Canada Health Act (1984) and a series of accords between the federal, provincial, and territorial governments. The federal government provides funds to the provinces and territories for healthcare; the latter governments, in return, agree to incorporate the essential features of the national health insurance program into their healthcare systems. This sharing of responsibility is currently being challenged, however.

The Canadian national health insurance system, as defined in the Hospital Insurance Act (1957) and reaffirmed in the Canada Health Act (1984), is founded on a values system to which the Canadian people fiercely adhere. The principal features of this program (comprehensiveness; universality; accessibility; portability; and public administration) derive from Canadians' commitment to the principle of equality. Equality before the healthcare system, as Robert Evans has phrased it, is as strong a principle in Canada as equality before the law (Evans). The basis of this principle is that all Canadians should have access to a similar level of care, regardless of their ability to pay for it.

There have been challenges, however, to the Canadian healthcare system's principle of universal access to hospital and medical services. The practice of user fees and extra billing by doctors, which is prohibited by the Canada Health Act, represented one such challenge. Extra billing would allow doctors to bill patients for charges exceeding what the national health insurance plan paid doctors for a medical service. For a short time in the mid- to late 1980s extra billing occurred in seven provinces. In response to this violation of the Canada Health Act, the federal government stopped transfer payments to these provinces, thereby providing the provincial governments with the necessary incentive to enforce the principles of the Canada Health Act. Extra billing has not occurred since.

The way a country organizes its healthcare system as a whole is not just an issue of economics and administration. It is also an issue of public ethics and is deeply rooted in the conflict between powerful interest groups and the requirements of justice (as interpreted by a society's governing ethos. The Canadian ethos of universal access with equal terms and conditions for all is being challenged by new questions of fairness. For example, the current Canadian Medicare program pays for physician and hospital services, but not drugs (unless these are administered in a hospital). For many patients, good health depends upon access to expensive medications, and since these are not covered by the national health insurance system they are at risk of incurring significant debt or, worse, doing without their medications.

Another issue concerns waiting lists. Some individuals who do not want to wait to access needed health services and who have the resources to pay for these services argue that they should not be prohibited from purchasing what they are able to pay for. Some of these concerns are examined in the final report of the National Forum on Health, which focused on values, striking a balance, the determinants of health, and evidence-based decision making The forum paid particular attention to the need to balance resources within the health sector, and between the health sector and other sectors of the economy (National Forum on Health). The emphasis in these reports was on the core Canadian value of equal access to care irrespective of ability to pay. The National Forum on Health called on the federal government to expand public health insurance to home care and drugs.

In 2002 there was renewed debate about the future of the Canadian healthcare system with particular focus on two issues: (1) public administration (whether there should be a

single- or multi-payer system), and (2) delivery of goods and services (whether this should be public, private not-for-profit, or private for-profit). Two reports looked at the sustainability of the universally accessible, publicly funded healthcare system with particular attention to the question of whether Canada should move to a two-tier system by allowing the use of private hospitals and private insurance. The first of these reports was issued by the Senate Standing Committee on Social Affairs, Science and Technology, which undertook a study on the state of the healthcare system in Canada. The report is widely known as the Kirby Report—in reference to Senator Michael Kirby, who chaired the Committee. It endorses an increased role for private healthcare corporations.

The second report, Building On Values: The Future of Health Care in Canada, is by the Commission on the Future of Health Care in Canada (widely known as the Romanow Report, after the commission chair, Roy Romanow). The report examines four strategies for continuing to ensure access to high quality of care regardless of ability to pay: (1) more public investment (paid for by raising taxes or diverting resources from other programs), (2) more user pay (through charging fees as an incentive to deter abuse), (3) an increase in private choice (either for-profit or non-profit), or (4) a complete reorganization of the healthcare delivery system. A commitment to health care as a social good and service, not an economic commodity only available to those who can pay, informs the analysis.

BIOETHICS AND LAW IN CANADA. In Canada, the Constitution Act (1867) was amended in 1982 through the introduction of the Canadian Charter of Rights and Freedoms. This charter obliges government actors not to violate rights considered fundamental. Such rights include life, liberty, and security of the person; freedom of conscience, thought, belief, and expression; and freedom from discrimination. Democratic support for legislation that violates the charter does not compel the courts to uphold the legislation, since the charter protects fundamental freedoms and legal rights against even democratically composed majorities. This is illustrated in the 1988 Morgentaler decision of the Supreme Court of Canada, in which a law passed by a democratically elected government was struck down by the Supreme Court of Canada because it violated the charter.

Another significant case is the 1991 Ontario Court of Appeal decision in *Malette v. Shulman.* A Jehovah's Witness woman was taken to the hospital unconscious and bleeding after a car accident. The physician attending her was informed that she was carrying a signed but undated card refusing blood products, but he nonetheless gave her a transfusion in order to prevent her death from heavy loss of blood. The patient, Georgette Malette, sued him for the civil wrong of battery (unauthorized touching) and was awarded a favorable judgment, which the Ontario Court of Appeal upheld. The trial judge observed that, while the transfusion may have saved her life, the principle of respect for autonomous persons prevailed over principles of beneficence and nonmaleficence. In other words, society may not share her priority of interests, but it must respect her autonomy.

From the mid-1970s through the mid-1980s, numerous symposia, workshops, and position papers reflecting the thinking of a cross-section of Canadians supported the conclusion that contraceptive sterilization, in some circumstances, would be truly beneficial for some mentally disabled persons, as it would allow them to enjoy sexual fulfillment without the risk of bearing and rearing children. There was controversy only regarding the process that would be used to select individuals eligible for sterilization. It was not clear what conditions had to be fulfilled to protect mentally disabled persons from being sterilized for someone else's benefit. However, a 1986 decision of the Supreme Court of Canada (*Eve v. Mrs. E.*) clarified the law and dramatically affected practice. The Court declared categorically that sterilization should never be authorized for nontherapeutic purposes. In the absence of the affected person's consent, the Court believed that it can never be safely determined that such sterilization is for the benefit of that person. This decision has proved to be difficult for clinicians, parents, those with institutional responsibility for the care of mentally disabled persons, and, perhaps, for the latter themselves, for their social lives and privacy in relations with members of the opposite sex may be restricted for fear of pregnancy. This decision also serves as a focus for continuing discussions about what should be done when what is judged by some to be ethically justifiable has been declared to be illegal or unconstitutional.

Key Issues

Although Canadians have been preoccupied with many bioethics issues, the following discussion is limited to those issues that have most intensively mobilized the thought and action of Canadians in the fields of clinical ethics, research ethics, and ethics in public policy.

CLINICAL ETHICS. Several court cases in Canada illustrate the interplay between clinical ethics and jurisprudence when decisions have to be made regarding cessation of medical treatment. An ethical and legal consensus has grown in Canada since the late 1980s in support of the view that

physicians are justified in withholding or discontinuing treatments that do little more than prolong a patient's dying and suffering. However, there continues to be debate about physician-assisted suicide and euthanasia, as illustrated in the legal cases summarized below.

In 1992 the Superior Court of Quebec affirmed that the request of a competent patient to discontinue life-supporting treatment should be honored (*Nancy B. v. Hôtel-Dieu de Québec*). Nancy B., a twenty-five-year-old woman, was permanently dependent on a respirator due to Guillain-Barré syndrome. After two years, while lucid and without clinical depression, she asked that the respirator be stopped, knowing that this would lead to her death. The court held that discontinuing treatment would not constitute criminal negligence or homicide. In so ruling, it cited the Canadian Law Reform Commission's recommendation that ambiguous sections of the Criminal Code of Canada should be changed so that the criminal law of Canada could not be interpreted as obliging physicians either to treat patients against their informed and free refusal or to initiate or continue treatments that are therapeutically useless and not in patients' best interests (Law Reform Commission).

A year later, in 1993, Sue Rodriguez—a competent woman suffering from amyotrophic lateral sclerosis who wanted to commit assisted suicide—brought a challenge to the prohibition against assisted suicide found in the Criminal Code. The Supreme Court of Canada upheld the prohibition by a five-to-four margin based on their application of the Charter of Rights and Freedoms to the facts of the case. Despite this decision, Sue Rodriguez ultimately died as a result of physician-assisted suicide, and no one was prosecuted in connection with her death.

Also in 1993, Robert Latimer was charged with first-degree murder in the death of his twelve-year-old daughter, Tracy Latimer. Mr. Latimer had placed his severely handicapped daughter (a quadriplegic child with the intellectual capacity of a three-month-old) in the cab of his truck and, with the intent of alleviating her suffering, asphyxiated her with carbon monoxide. In 1994 Mr. Latimer was convicted of second-degree murder and given the mandatory sentence of life imprisonment without eligibility for parole for ten years. He successfully appealed his conviction to the Supreme Court of Canada, and a new trial was ordered. In 1997 Mr. Latimer was tried again on a charge of second-degree murder, was again convicted, but was now sentenced to two years less a day (instead of the mandatory sentence of at least ten years in prison). Mr. Latimer again appealed his conviction and the Crown appealed the sentence. The Court of Appeal dismissed Latimer's appeal, allowed the Crown's appeal, and imposed the mandatory minimum sentence. Mr. Latimer then appealed to the Supreme Court, and in 2001 the Court upheld the conviction and the life sentence with no parole for ten years.

These cases show that the courts in Canada will respect the wishes of competent patients to refuse life-sustaining treatment, reject the wishes of competent patients to actively bring about their own death through physician assisted suicide, and not tolerate deliberate actions to bring about the death of another person even when the motive is to alleviate suffering.

RESEARCH ETHICS. Canadians have been intensively occupied with elaborating the conditions for ethically acceptable research involving humans. In August 1961, Walter Halushka volunteered to be a research subject in a project to test a new anesthetic drug. Halushka suffered a cardiac arrest during the experiment, and though successfully resuscitated, he was left with some brain damage and could no longer continue his university studies. The Court of Appeal found that the physician-researchers had failed to inform Halushka that the test was of a new drug, that they had little previous knowledge about this drug, that the drug was an anesthetic, and that there was risk involved in its use. The investigators also failed to tell the subject that the test would involve putting a catheter up a vein in his arm into his heart. The Court of Appeal clarified the requirements for consent in the research setting:

> There can be no exceptions to the ordinary requirements of disclosure in the case of research as there may well be in ordinary medical practice.… The subject of medical experimentation is entitled to a full and frank disclosure of all the facts, probabilities and opinions which a reasonable man might be expected to consider before giving his consent. (*Halushka v. the University of Sasktchewan et al.*)

Though patients are rarely harmed seriously in clinical research, serious harm, and even death, can and does occur. It is particularly tragic when a research-related death occurs that might have been avoided if consent negotiations had been adequate. On October 13, 1981, Julius Weiss, a sixty-two-year-old man, died in a Montreal hospital while participating in a research project being conducted to test the efficacy of a drug (indomethacin, administered by eyedrops) designed to reduce swelling in the eye after cataract surgery. This project also required that Weiss undergo a series of radiological examinations called fluorescein angiograms to gauge the effects of the indomethacin eyedrops. Weiss had a history of heart problems and went into convulsions following a drop in blood pressure after the first injection of

fluorescein dye. His heart stopped, resuscitation attempts failed, and he died. Weiss's widow and children sued the two physicians involved in the clinical study and the hospital where the study was conducted. In his judgment on this case, rendered on February 23, 1989, Judge Louis De Blois of Quebec Superior Court found that the patient would not have agreed to be in this project had he known it carried even a small risk of cardiac arrest and death (see *Weiss v. Solomon*).

In Canada, unlike other countries, health research involving humans is governed primarily by guidelines, not legislation. The first such guidelines were promulgated by the Medical Research Council of Canada in 1978 and later revised in 1987. Some years later, in the wake of a number of research-related controversies, a Tri-Council Working Group involving all three federal research funding agencies—the Medical Research Council of Canada (MRC), the Natural Sciences and Engineering Research Council of Canada (NSERC), and the Social Sciences and Humanities Research Council of Canada (SSHRC)—was convened to develop a common set of ethics guidelines that would govern virtually all publicly funded research involving humans in Canada (an international first). In 1998 the Tri-Council Policy Statement on Research Involving Humans was adopted. These guidelines outline the expectations regarding ethics review and set out the rules for researchers and institutions that receive public funds for research.

ETHICS IN PUBLIC POLICY. Between the 1960s and the 1990s, the issue of abortion dominated the public-policy debate in bioethics. The debate was ignited in the late 1960s, when the federal government proposed changes to the Criminal Code that would relax restrictions on divorce, homosexual acts between consenting adults, the distribution of contraceptives, and abortion. The last issue was the most contentious and engendered widespread public discussion and lobbying of members of Parliament. The law in effect at the time prohibited termination of pregnancy under any circumstances, and criminal sanctions could be brought against the pregnant woman and anyone who would perform the abortion. In 1969 a new abortion law (section 251 of the Criminal Code) was adopted that retained the criminal sanctions against both the woman seeking an abortion and anyone who would perform the act, but legalized termination of pregnancy if the following conditions were met: (1) the abortion had to be performed by a qualified medical practitioner in an accredited or approved hospital; (2) it had to be approved by a therapeutic abortion committee of the hospital; and (3) the continuation of the pregnancy would, or would be likely to, endanger the life or health of the woman seeking the abortion.

Following this liberalization of the abortion law, there were many complaints of unequal access to abortion services, as well as accusations from antiabortion groups that the law was being applied too loosely. Since the federal government refused to revise the law, both proponents and opponents of abortion decided to challenge the law in the courts.

In 1970 Dr. Henry Morgentaler established an abortion clinic in Montreal, in clear opposition to the law. After his third jury acquittal, in 1976, on charges of performing an illegal abortion, the Quebec government allowed his clinic to operate, despite vigorous protests from antiabortion forces.

In 1983 Dr. Morgentaler set up an abortion clinic in Toronto and was promptly arrested and charged, along with two colleagues. A jury once again acquitted him. This decision was appealed, and in 1985 the Ontario Court of Appeal overturned the decision of the jury and ordered a new trial. Dr. Morgentaler appealed this ruling to the Supreme Court of Canada. On January 28, 1988, the Supreme Court, in a 5-to-2 decision, overturned the Court of Appeal decision and restored the original jury acquittal. The Court also declared the 1969 abortion law unconstitutional because it violated the Canadian charter of rights and freedoms.

The Supreme Court heard another abortion-related case in 1988, this one initiated by an opponent of abortion. In 1981, Joe Borowski, a former Manitoba politician and antiabortion activist, challenged the 1969 abortion law on behalf of the fetus. A Saskatchewan court heard the case in 1983, and in its judgment rejected Mr. Borowski's claim that the fetus is a person with legal rights. Mr. Borowski appealed this decision. In 1989 the Supreme Court declined to decide the case because the appeal was moot, due to the abortion law having been struck down.

Between 1988 and 1991, the federal government made several attempts to pass a new abortion law, but none were successful. A bill introduced in 1989 would have recriminalized abortion except when performed by a doctor "of the opinion that, if the abortion were not induced, the health or life of the female person would be likely to be threatened." (Bill C-43 An Act respecting abortion, 2nd Sess., 34th Parl., 1989; defeated in the Senate January 31, 1991). Health was defined as including physical, mental, and psychological well-being. The bill was approved by the House of Commons in May 1990 by a narrow margin (140–131), and it was then sent to the Senate, where it received detailed examination. In January 1991, a vote was taken, but the Senate was deadlocked. Under Canada's Senate rules, a tie is considered a defeat. As a result, Canada is in the unusual circumstance of having no criminal restrictions on abortion.

New reproductive technologies have also generated considerable public-policy activity in Canada and have been the subject of several public inquiries, including a federal Royal Commission, which received and commissioned many submissions focusing on the ethical aspects of reproductive technology. Feminist concerns (e.g., regarding commercialization in paid contractual pregnancies) have figured prominently in the Canadian discussion of these issues (Overall; Sherwin). In 1996, Bill C-47, the Human Reproductive and Genetic Technologies Act, was introduced in the House of Commons. This bill died on the Order Paper, however, when an election was called before the legislative process was complete. (Bills under consideration that have not received royal assent are on the Order Paper. When an election is called, all such bills are considered dead.) Years later, in May 2002, Bill C-56, the Assisted Human Reproduction Act, was introduced. Ironically, it too died on the Order Paper in September of the same year when Parliament was prorogued (to terminate or suspend a legislative session). Bill C-56 did not share the same fate as the earlier bill, however, in that it was reinstated as Bill C-13, which at the time of writing was continuing through the legislative process. Interestingly, much of the public debate around this bill has not been about assisted reproduction, but about whether the embryos that remain after infertility treatment can be used for human embryonic stem cell research.

The Future

Canada is a multicultural nation. For the most part, however, bioethics has been (and continues to be) monocultural, reflecting the values of the white, largely Anglo-Saxon, professional class that has dominated Canadian society, including its science and medicine. If bioethics is to be relevant to Canadian society in the future, it must develop a multicultural sensitivity and expand the range of issues it considers, the perspectives from which the issues are viewed, and even the backgrounds of individuals working in the field.

IV. LATIN AMERICA

This entry presents a historical panorama of biomedical ethics in Latin America, the name given to a linguistic and cultural community encompassing South America, Central America, Mexico, and part of the Caribbean. From political, economic, and social points of view, the Latin American nations are quite different, although at present they have underdevelopment in common.

Since bioethics as a discipline flourished first in the United States, it is useful to compare medical ethics in North America, with its predominantly Anglo and northern European culture, and in Latin America, pointing out the differences between the two traditions within the Western culture.

First, the Latin American tradition of medical ethics is described; next, the incipient bioethics movement in Latin America is considered; then the major bioethical problems of the region are noted; and finally, the challenge to Latin American bioethics is discussed.

The Latin American Tradition of Medical Ethics

When Spain and Portugal established colonies in the Americas, they brought with them the profound influence of the Roman Catholic Church, heir to that Western culture whose roots are Greek philosophy, Judaism, and Roman law. The Catholic tradition has in fact defined Latin American ethics and the Latin American ethos. First, Catholic moral theology built a system of medical ethics based on (1) natural-law theory as the basis of morality; (2) the principle of the sanctity of human life as a moral criterion; and (3) the commandment of love, or the virtue of charity, as the golden rule. Second, through their pastoral role and religious authority, priests reinforced the paternalistic medical ethos of the Hippocratic tradition. The paternalistic model of medical responsibility centered on the principle of beneficence (that benefit must be produced and harm avoided); the principle of autonomy is not taken into account. Beneficent paternalism has dominated the relationships between doctor and patient, and between medicine and society, in Latin America up to the present day.

As the cultures of northern and southern Europe evolved in the Americas, the differences between the two were accentuated. Modernity did not have the same secular, liberal, and pluralistic cast in Latin America as it did in North America. In Latin America, morality was not detached from metaphysics and religion; it did not establish a new basis in scientific and political rationalism, nor did it set itself up as critical and autonomous over against the natural and supernatural order of the medieval epoch.

Beginning in the eighteenth century, it is possible to contrast two ethics: the classical tradition of virtue, represented by the Mediterranean peoples (particularly the Italians and Spaniards), and the tradition in which principles are central, dominant in the English- and German-speaking countries (Mclntyre). In Latin America, the political paternalism of the *ancien régime* and the medical paternalism of the Hippocratic tradition go together; the result is a paternalistic model on both the individual-clinical and the social policy levels.

The ethics and ethos of Latin American medicine are expressed in professional codes of ethics and in health policy

and legislation. The forebear of all these normative institutions was the *protomédicato.* Originating in the Roman Empire, the *protomédicato* was a tribunal of royal physicians (*protomédicos*) that granted professional licenses and acted as a judicial and legislative body in health matters. In the thirteenth century, Castile was one of the first kingdoms to establish legal regulations for medical practice and public health; examples of this were found in the School of Salerno, and the laws of Frederick II in Sicily (Mainetti, 1989). The *protomédicato* was transplanted from Spain to the Americas, where it endured until the period of independence (early nineteenth century), at which point medical instruction, practice, and policy began to be modernized.

In the twentieth century, professional associations and medical colleges in various countries began to formulate their own codes of ethics, in accordance with the deontological tradition that regulates the relationships of doctors among themselves, with the public, and with the state. One of the first such codes was drawn up in 1918 by Luis Razetti, a leading Venezuelan physician who specialized in medical deontology, under the influence of the French—an influence that was at that time very perceptible in Latin American society in general and in the medical culture in particular. This same code was later adopted in Colombia (1919) and in Peru (1920); it provided a basic model for other Latin American codes, which are essentially traditional guides for professional courtesy or etiquette, the relationships of physicians among themselves, with the patient, and with the state (León).

The medical codes promulgated in many Latin American countries are influenced by a variety of factors, among them biomedical progress, malpractice legislation, and the political changes throughout the region after decades of military rule. Brazil's Federal Code of Medical Ethics (1988), for example, incorporates concern about new problems like AIDS, and reformulates the rule of medical confidentiality. The Medical College of Chile has been very active since 1984, demonstrating its sensitivity to—among other issues—the participation of Chilean physicians in torture during the years of authoritarian rule that ended in 1984 (Mainetti, 1990).

The state's responsibility for healthcare has constitutional status in Latin American countries (Pan American Health Organization, 1989). The right to healthcare is included among social and economic rights. The first nation to incorporate the right to healthcare in its constitution was Chile, in 1925, followed by Bolivia, Cuba, Guatemala, Guyana, Haiti, Honduras, Mexico, Nicaragua, Paraguay, Peru, Uruguay, and Venezuela. The responsibility of the state for health planning is legislated by many Latin American countries, which provide for universal access to essential medical services and a national healthcare system that is either free or based on co-payments, but with limited coverage. In Latin American government, health policy generally demonstrates a significant gap between principle and practice: between justice, which theoretically endorses the equal right to health care, and actual practice in societies that, owing to their social and economic development, are not able to guarantee that this and other rights will be respected.

Codes of ethics and health legislation are based on a moral view that is both dogmatic (codified and legalistic, in contrast with philosophic, analytic, and critical) and authoritarian (based on professional authority, which is partly religious and partly governmental, rather than civic or democratic). The Latin American tradition of medical ethics can be defined as naturalistic, paternalistic, dogmatic, and authoritarian. The new Latin American medical ethics, represented by bioethics, has developed in contrast with this older tradition.

The Bioethics Movement in Latin America

The bioethics revolution that has occurred in the industrialized nations has arisen both from the scientific and technological progress of biomedicine and from the liberal and pluralistic character of those nations. By contrast, in the developing Latin American countries bioethical interests correspond more to those of a low-technology society and a tradition of confessional morality (Mainetti, 1988). Bioethics, based on the principles of beneficence, autonomy, and justice, may be seen as civic morality to which the parties to an increasingly conflictual relationship—physician, patient, and society—appeal. Or bioethics may be seen as medical culture, expressed in the "introduction of the moral subject into medicine," the promotion of the rational, free agent in the therapeutic relationship. It is fair to say, however, that bioethics has barely arrived in Latin America in either guise.

Latin American bioethics evolved over a period of thirty years, in three decade-long stages, commencing in the 1970s: reception, assimilation, and re-creation. Public and academic interest in bioethical topics appeared in the 1980s with the proliferation of new medical technologies, such as those used in intensive care units, transplants, and assisted reproduction, and with the appearance of democratic governments in the region. On the one hand, legal intervention in medical cases increased, due perhaps to the distances created between the professional and the patient by specialization. Malpractice and a patient's rights movement in Latin America imitated the early history of U.S. bioethics. On the other hand, there was an academic rehabilitation of practical, moral, and political philosophy as they could be applied

to medicine. This development was in keeping with the kind of ideological pluralism and consensus formation that has characterized bioethics as a discipline in the United States.

The academic and professional development of bioethics in Latin America has been a process of incorporating the U.S. model in stages. As the twentieth century neared its end, the institutionalization of the discipline as expressed in the creation of research centers, professorships at universities, ethics committees at hospitals, and national commissions on bioethics could not be said to be significant. Nor had the three main functions of bioethical studies been carried out. These are the educational function (deontology and legal medicine still stand for ethics at medical schools); the consultative function (clinical and healthcare ethics are not practiced in hospitals and other healthcare facilities); and the political function (groups of experts have not formed to advise public institutions on biomedical norms). Bioethics is also just beginning to capture the attention of the public and the media.

Among the groups active on the Latin American bioethics scene, several deserve mention: the Instituto de Humanidades Médicas y Centro de Bioética of the Fundación Mainetti (Institute for the Medical Humanities and Center for Bioethics of the Mainetti Foundation) in La Plata, Argentina, and the Instituto Colombiano de Estudios Bioéticos (Colombian Institute for Bioethical Studies) in Bogotá, Colombia. The former, established in 1972, combines the European and Anglo-American traditions of medical humanism, serving as a model and resource center for other countries in the region, particularly through its Escuela Latinoamericana de Bioética (Latin American School of Bioethics, ELABE), directed by Juan Carlos Tealdi. The latter, founded in 1985 by Fernando Sánchez Torres, former dean of the National University of Colombia, together with the ASCOFAME (Colombian Association of Medical Faculties) with its Center for Medical Ethics, directed by Alfonso Llano Escobar, S.J., and the Colombian School of Medicine and its Health Care Ethics Committee, also lead in the process of renovating medical ethics in the region.

Other academic and professional associations have emerged in Latin American countries in recent years for the purpose of developing programs of bioethical studies: the Department of Bioethics of the Catholic University of Uruguay; the Sindicato Médico of Uruguay, a very important professional organization that appointed a bioethics commission; the Department of Bioethics of the Chilean Catholic University; and the Chilean Medical College, mentioned above. These associations work actively on deontological questions, and the Brazilian Association of Medical Ethics Teachers emphasizes bioethical issues.

The bioethics enterprise also can be evaluated by the number of people interested in the discipline; by courses, conferences, and other scientific activities; and by the publication of books and articles. The classic 1973 Latin American text on medical ethics, by Augusto León, was followed by several bioethics texts (Mainetti, 1988; Varga; Vélez Correa). According to a 1990 report issued by the Pan American Health Organization, conditions in Latin America were expected to encourage the development of programs to integrate medical ethics into the health system. This integration could occur along a broad spectrum ranging from legislation and public policies to academic curricula, and should include the revision of the ethics codes of established medical associations. To this end, the Latin American School of Bioethics has been coordinating a regional program of hospital ethics committees since 1989 (Tealdi and Mainetti). The growth of interest in bioethics justified a Latin American bioethics association to unite isolated efforts, and thus to offer a concerted response to the needs of the region. Meeting in La Plata, Argentina, in December 1991, representatives from several Latin American nations founded the Federaciòn Latinoamericana de Instituciones Bioéticas (Latin American Federatíon of Bioethics Institutions, FELAIBE).

In 1990 the Pan American Health Organization (PAHO) commissioned James Drane of the United States to produce a decisive report that reviewed the development of bioethics in Latin America and proposed several steps for the further regional development of the discipline (Drane and Fuenzalida). That same year, PAHO published a special issue on bioethics, edited by Susan Scholle Connor and Hernàn Fuenzalida-Puelma, formally introducing bioethics in Latin America. This was the first collection in which early authors in the field addressed diverse topics and set out different perspectives on the discipline. Finally, PAHO, a pioneer among international health organizations, created the Regional Program on Bioethics (1994) with headquarters in Santiago de Chile, but whose activities are decentralized in order to serve all the member countries of PAHO. This program—a comprehensive policy in bioethics and its associate disciplines—entered a new stage under the outstanding scholar Fernando Lolas Stepke's leadership (Programa Regional de Bioética, 2000).

Bioethics has become a field of new challenges in Latin America. A seeming uniformity hides a rich, heterogeneous set of activities. Not only European and Christian influences but also indigenous intellectual traditions are very important in the development of Latin American bioethics. It does not have its own philosophy, as Anglo-American bioethics is perceived to have, but it does have its own literature or

narrative. The particular historical setting, cultural ethos, and social reality of Latin America could infuse new life into the global bioethics community. In this sense, a symptom of the new times is the fact that the Second Congress of the International Association of Bioethics took place in Buenos Aires, Argentina, in 1994, and the Sixth Congress was held in Brasilia, Brazil, in 2002. A "new Brazilian bioethics" or "hard bioethics," inspired by Brazil's contradictory social reality, began to flourish at the turn of the twentieth century, and explores alternative perspectives to traditional bioethical currents (Garrafa).

Bioethics first arrived in Latin America as a foreigner, and later underwent a transcultural shaping. Transplanted to a new habitat, bioethics took on its own distinctive character and voices and has become a strong intellectual and political enterprise (Lolas Stepke, 1994; 1998).

In comparison to the North American style of bioethics, Latin American bioethics takes a more theoretical and philosophical approach. As a search for a *critical, radical* and *global* bioethics, Latin American bioethics represents a global, "post-bioethical" age (Drane, 1998; Spinsanti). Although Latin American bioethics is far from being a unified theoretical system or a single coherent perspective, it represents the *ethica spes* of the new millennium.

Major Topics in Latin American Bioethics

Latin American countries share a concern about a number of problems with implications for both law and policy. A common sociocultural and public-health situation defines the Latin American biomedical ethos. Ethnomedical ethics ought to be an essential topic, because the health and disease conceptions, practices, and values, as well as the needs, of the native (precolonial) Latin American peoples are not properly understood by academic medicine and the health policy of the dominant culture. These peoples still await the fulfillment of the World Health Organization's proclamation calling for the integration of their healing arts into modern medicine. Among the most pressing bioethical issues facing Latin America are the following.

REPRODUCTIVE ETHICS. Both the prevention of human reproduction (contraception, sterilization, and abortion) and assisted human reproduction (reproductive technologies) are central issues for Latin American population policy. This policy is clearly linked to health and to religious, secular, and geopolitical factors. Underdevelopment and overpopulation form a vicious circle that distances societies more and more from the goal of sustainable development. The Catholic Church does not tolerate what it calls "artificial" control of fertility and condemns abortion, which is legally prohibited in most Latin American countries. To date neither public debate nor legislative reform has occurred, although the widespread and frequent practice of clandestine abortion effectively expresses Latin American governments' laissez-faire policies. The ethical complexity of assisted reproduction provokes polemics about the status of the embryo without leading to a declared war between "Catholics" and "secularists, " but this area requires legal regulation.

THE ETHICS OF DEATH AND DYING. In Latin America, death is not as medicalized nor is the medical profession as tormented about it as is the case in the First World. The technological assault on dying, the new *danse macabre* in the intensive care unit, does not offer the same sort of spectacle in Latin America as it does in the United States. Nevertheless, the contemporary "art of dying" is a challenge in Latin America, too, even if living wills, do-not-resuscitate orders (DNRs), the ethical principles of critical care medicine, and the pro-euthanasia movement have yet to become major issues. Palliative medicine, the hospice movement, and campaigns for death with dignity are the modern Latin American versions of *ars moriendi.* At the beginning of life, pediatrics ethics committees are improving regulations regarding the treatment of premature and disabled newborns. At the end of life, legislation authorizing removal and transplantation of organs has advanced markedly in many Latin American countries (Fuenzalida-Puelma).

RESEARCH ETHICS. Biomedical research in Latin America lacks both a legislative framework and an effective set of controls. Much research also lacks scientific validity and, motivated more by monetary interest than by interest in knowledge, overlooks patient's rights such as consent and confidentiality. Developing countries must create the scientific and financial conditions for research itself; they must also attract projects that involve international cooperation while avoiding the risks such cooperation often brings with it, including economic and human exploitation. Oversight committees are needed so that international standards, with criteria appropriate to the cultural modalities of each community, may be applied. U.S. standards of consent, for instance, cannot be implemented easily in the social conditions of developing countries (Levine). Questions that must be considered in the future include research priorities, allocation of resources for research, and access to new, experimental drugs. This last issue, which has an especially high profile because of the global AIDS crisis, now involves not only the right of patients to protection from possible ill effects but also their right to have access to such drugs, which may prolong or save their lives.

HEALTHCARE ETHICS. Health status in Latin America must be seen within a larger picture of underdevelopment, poverty, hunger, and economic crisis aggravated by the foreign debt of the region. Two global short-term goals set by the World Health Organization have not yet been reached in Latin America: Infant mortality has not been brought below 5 percent, and life expectancy has not risen beyond sixty-five years. Healthcare expenditures in Latin America did not exceed 5 percent of the gross national product in the 1970s and 1980s, compared with 10 percent for the so-called developed countries.

Although there is a plethora of medical students and an oversupply of physicians, approximately 75 percent of the population of Latin America does not receive medical attention. This dramatizes the gap between the proclaimed right to healthcare and the conditions necessary to exercise it. Primary care—including family planning, maternal and child care, immunization, health counseling and education, campaigns against tuberculosis, and treatment of infectious diseases—should be the goal of health policy in all developing nations. Healthcare policy must be focused on health as an indicator of development, oriented to the basic needs of the majority of the population, and designed to promote medical care based on criteria of equity, integration, participation, and efficiency (Pan American Health Organization, 1989).

Between 80 and 90 percent of the resources allocated to healthcare in Latin America is spent on secondary and tertiary care. "Bioethics in the time of cholera," to paraphrase the novelist Gabriel García Márquez—medical ethics faced with plagues like cholera and AIDS—sums up the challenge to healthcare ethics in Latin America.

ENVIRONMENTAL ETHICS. The environmental problems of Latin America are in part peculiar to the region and in part similar to those in western Europe and the United States. Overpopulated cities like Mexico City, Caracas, and São Paulo are more polluted than their European counterparts, and the Latin American urban crisis ranges from street cleaning to disposing of radioactive wastes from nuclear power plants.

In agricultural areas, the indiscriminate use of biocides contaminates crops and reduces the fertility of the soil. The extinction of animal and plant species produces imbalances in the ecosystem. Of worldwide importance is the devastation of the Amazon rainforest, the largest jungle in the world. An ecological reserve with an influence on world climate, the area has been deforested by 10 percent. It faces the prospect of destruction within half a century, for reasons not unrelated to the sizable foreign debt owed by Brazil.

Governments and publics in Latin America are just beginning to become conscious of the importance of the environment to human and animal health; to national, regional, and world economies; to the preservation of nature and of life itself. Some countries have environmental protection legislation, projects to protect or preserve natural resources, and active ecology movements. Bioethics, however, has yet to raise its voice in civic and public arenas with regard to environmental ethics (that is, ecological rights), a new type of third-generation human rights, and policies of sustainable development (Pan American Health Organization, 1987).

The Challenge of Bioethics for Latin America

Because of its humanistic medical tradition and the social conditions of developing countries, Latin America can offer a distinctive bioethics perspective. There are two dimensions to this perspective. First, a discipline established along European lines of the general philosophy or theory of medicine, with three main branches (medical anthropology, epistemology, and axiology), may be better equipped to transform academic, scientific medicine into a new humanistic biomedical paradigm (Mainetti, 1988). Such an approach would guard against the accusations often lodged against bioethics in the United States and Europe: that the discourse of bioethics only appears to humanize medicine while obscuring the real dehumanization of the system. For example, the bioethical discourse on autonomy may hide the depersonalization of medical care and its risks of iatrogenesis, exploitation of the body, and alienation of health. In response to the development of biomedicine in a technological era, bioethics may be able to play a more critical role, one that is less complacent or optimistic about progress.

Second, the Latin American reality of "bioethics in the time of cholera" requires an orientation toward social ethics, with an accent on the common welfare, the good society, and justice rather than on individual rights and personal virtues (the modern and classical traditions of morality, respectively). A macroethics of health or public health may be proposed as an alternative to the Anglo-American tradition of micro or clinical ethics. Greater emphasis can be placed on the social importance of medicine; as far as medical ethics is concerned, the great need in the developing countries is fairness in the allocation of resources and the distribution of health services. Latin America has not lost hope that it might be the continent of justice.

Several decades after its birth, bioethics in the United States is moving toward new intellectual models. This

movement shows up in the revisionist-foundationalist debate within the discipline; the application of ethics to other discourses, including the political arena; the rediscovery of ethics of virtue; the return to what is experiential; and the cross-cultural and international dialogue. The bioethics revolution in North America and Europe—summarized in a high-technology *bios* and individualized ethos—must be complemented in Latin America by a humanistic *bios* and a communitarian ethos.

A promising outlook is emerging as the bioethics traditions and problematics of the two Americas move closer to one another. Perhaps in the context of the new world order and the beginning of the twenty-first century, bioethics—the bridge toward the future of humanity—will also be a bridge of inter-American cooperation and integration.

MEDICAL ETHICS, HISTORY OF AUSTRALIA AND NEW ZEALAND

• • •

Medical ethics in Australia and New Zealand (Australasia) evolved slowly until the early 1980s, when major advances in reproductive technologies prompted widespread public discussion of bioethical issues surrounding human conception.

Early History

In the early decades of the twentieth century, ethical debates centered on issues of professionalism in the delivery of medical services, such as the permissibility of advertising by individual practitioners and the setting of standard fees to avoid "undercutting" by competitors. The branches of the British Medical Association (BMA) that had been set up in the colonial Australian states were federated in 1912, when a unified code of professional ethics, dealing mainly with the regulation of advertising and etiquette toward patients, was introduced (Egan). After World War I, medical schools in Australasian universities began to include brief didactic instruction in the ethical obligations of physicians. There was also some public discussion of abortion, methods of birth control, and confidentiality in relation to patients with venereal disease.

A Labour government with a strong social welfare platform was elected in Australia in 1941. In the late 1940s this government attempted to introduce a national health service, which would have provided universal access to healthcare for the first time in Australia. However, a bitter debate developed with the BMA, the majority of whose members saw the government's plans as a threat to the autonomy of medical practitioners and as the first step toward the nationalization of medicine. After legal challenges, the plans for a national health program were defeated in 1949 (Gillespie). Under the free-market policies of subsequent Liberal governments, access to publicly funded healthcare was available only to recipients of old-age and invalid pensions. This situation persisted until 1975, when the Labour government introduced Medibank, Australia's first national healthcare program, which provided access to government-subsidized healthcare for all. While the incoming Liberal/National coalition government gradually dismantled this program during the late 1970s, it was reinstated as Medicare in 1983 by the newly elected Labour government, and has continued to operate into the twenty-first century.

Ethical issues in reproduction became a major concern in Australasia in the early 1980s, following pioneering research on *in vitro* fertilization (IVF) carried out by a joint research team led by Carl Wood and Ian Johnston at the Monash University Queen Victoria Medical Centre and the Royal Women's Hospital in Melbourne during the 1970s. In 1983 this research led to the world's first live IVF births from frozen embryos and donated eggs, and the embryo research carried out by Monash University scientists in order to improve IVF and other assisted reproduction techniques sparked worldwide interest. These developments in reproductive technology stimulated much public discussion in Australia, particularly among Roman Catholics, who constitute over a quarter of the population.

Euthanasia

Care for the terminally ill became another widely debated issue in Australia in the 1980s. Influenced by the growing public support for voluntary euthanasia, the state governments of South Australia and Victoria passed legislation (in 1983 and 1988, respectively) permitting patients to refuse medical treatment in certain circumstances, even where such treatment might prolong their lives. In 1995 the Northern Territory's single-chamber parliament passed the Rights of the Terminally Ill Act, making it the first jurisdiction in the world to legalize active voluntary euthanasia. This legislation permitted doctors to carry out voluntary euthanasia, under certain specified conditions, for terminally ill patients with unbearable suffering. The lives of several patients were lawfully ended under this act before it was overruled by the Euthanasia Laws Act, passed by the Australian federal parliament in 1997.

Ethics Centers

Australasia's first research center in bioethics, the Monash University Centre for Human Bioethics, was established by the philosophy professor Peter Singer, together with colleagues in medicine, science, and the law, in 1980. A number of smaller research centers for bioethics were set up in Australasia during the next two decades, including Melbourne's St. Vincent's Bioethics Centre, Adelaide's Southern Cross Bioethics Institute (both of which have a Christian perspective on bioethics), Sydney's John Plunkett Centre for Ethics in Health Care, the Ethics Unit at Melbourne's Murdoch Childrens Research Institute, and the University

of Otago Bioethics Research Centre in Dunedin, New Zealand. Bioethics research is also pursued by several of the large groups of philosophers appointed to the Centre for Applied Philosophy and Public Ethics, which was established by Charles Sturt University in both Canberra and Melbourne in 2000. The interdisciplinary Australasian Bioethics Association was formed in 1990, and its inaugural conference was held in Melbourne in 1991.

With Helga Kuhse and others from the Monash Centre, Peter Singer has written extensively on ethical issues arising from the new reproductive technologies and on questions surrounding the care of terminally ill adults and infants. Other noteworthy Australasian writers in bioethics include the philosophers Max Charlesworth, Julian Savulescu, and Robert Young; the feminist academics Renate Klein and Robyn Rowland; the lawyers Michael Kirby and Loane Skene; and the theologian Norman Ford. In 1989 the Monash Centre introduced Australasia's first master's program in bioethics, and this institution also publishes Australia's only peer-reviewed bioethics journal, the *Monash Bioethics Review*.

Reproductive Technologies

In 1982 advances in infertility research in Victoria led the government of that state to appoint Louis Waller, a professor of law at Monash University and an Australian law reform commissioner, to chair a committee whose mandate was to consider the social, ethical, and legal issues arising from IVF. The three reports produced by this committee supported the use of IVF under certain regulations, prompting the Victoria Parliament, in 1984, to enact the Infertility (Medical Procedures) Act, the world's first legislation to deal specifically with these new reproductive technologies (see Charlesworth 1989). Among other provisions, this legislation allowed IVF to be carried out at approved hospitals, for married couples who have already sought infertility treatment for at least twelve months prior to attempting IVF.

At the federal level, the National Bioethics Consultative Committee (NBCC) was established in 1988 as an advisory committee on issues such as access to information about their origins for children conceived through IVF; artificial insemination by donor; surrogate motherhood; and embryo experimentation. In 1990 this committee issued a report that supported surrogacy arrangements and proposed draft legislation to regulate such arrangements. In light of the heated public controversy that ensued, however, the Australian government decided against implementing its recommendations nationally. Nevertheless, most Australian states have not outlawed IVF-assisted surrogacy in cases where the surrogate mother receives no fee, and in 1994 the Australian Capital Territory enacted legislation to regulate such surrogacy arrangements. In 1991 the NBCC was subsumed under the existing National Health and Medical Research Council (NH&MRC), which merged the functions of the NBCC and the Medical Research Ethics Committee to form the Australian Health Ethics Committee.

The groundbreaking work of Australian researchers with human embryonic stem cells and biotechnology became the focus of much public discussion at the beginning of the present century. The cloning of human beings was outlawed in 2002, following the recommendations of a federal parliamentary standing committee, but research will be permitted on stem cells that had been extracted from human embryos prior to early 2001.

Human Experimentation

Australasia's first recorded institutional ethics committee to review human experimentation was set up at the Royal Victorian Eye and Ear Hospital in Melbourne in 1957 (McNeill), and at the instigation of the NH&MRC (which allocates government funding for medical research), Australian universities began, in the 1980s, to form ethics committees to oversee medical and other research carried out at those institutions. Following wide community consultation and a 1996 federal government review of the relatively brief NH&MRC guidelines on human experimentation, the detailed and remarkably broad-ranging *National Statement on Ethical Conduct in Research Involving Humans* was issued by the NH&MRC in 1999 as a guide for all human research ethics committees in Australia. The basic principles in the *National Statement* are integrity, respect for persons, beneficence, and justice, which are developed in more detail through their application to a variety of different types of research.

In New Zealand, the Medical Research Council (set up in 1937 by the government to supervise medical research) decided in 1968 that all research must adhere to the World Medical Association's Declaration of Helsinki, which stressed nonmaleficence and the need for informed consent on the part of the experimental subjects. In 1987 unprecedented public outrage followed revelations of an experiment involving clandestine selective nontreatment of women with cervical cancer, which was carried out at the National Women's Hospital in Auckland from 1966 to 1981. The New Zealand government immediately set up an inquiry into the experiment, which resulted in an amendment to the Human Rights Commission Act of 1977, that added a statement of patients' rights to proper standards of care and adequate disclosures to enable genuinely informed consent. This amendment also provided for the appointment of a national

health commissioner to encourage awareness of these rights by members of the medical profession (Campbell).

Patient's Rights

During the 1990s there was considerable discussion in Australia about patients' legal rights to treatment information, prompted by the Australian High Court decision in *Rogers v. Whitaker* (1992), which gave legal recognition to a patient-centered standard of disclosure of medical information. Following this decision, the NH&MRC issued a booklet containing guidelines on providing information to patients.

Influenced by the increasing recognition of patient's rights, Australasian medical schools have gradually woven the teaching of ethics into their curricula. For example, the University of New South Wales in Sydney and the University of Newcastle began teaching substantive courses in ethics to medical undergraduates in the 1970s, and the University of Adelaide's medical school introduced ethics into the undergraduate syllabus in the early 1980s. Following the recommendations of the National Inquiry into Medical Education—a committee of academics and health professionals set up by the federal minister for health, which heard submissions during 1987 and 1988—many other Australian medical schools have included clinical ethics as part of their undergraduate programs. These developments in bioethics education should help promote lively and informed discussions of medical ethics issues in Australasia as they arise in the future.

MEDICAL ETHICS, HISTORY OF EUROPE

I. ANCIENT AND MEDIEVAL. A. GREECE AND ROME

Ancient Greece and Rome are often treated together by scholars who seek to describe in a limited space any aspect of those two civilizations. Greek history is typically divided into the Mycenaean period (2000–1200 B.C.E.), the "dark age" (1200–750 B.C.E.), the archaic period (750–500 B.C.E.), the classical age (500–323 B.C.E.), and the Hellenistic period (323–30 B.C.E.); and Roman history into three phases: monarchy (753–509 B.C.E.), Republic (509–31 B.C.E.), and

Empire (31 B.C.E.–476 C.E.). During the archaic period the Greeks engaged in considerable colonization in the Near East and throughout the Mediterranean basin, including southern Italy. The Hellenistic period, which was immediately preceded by Alexander the Great's conquest of much of the Near East, was marked by a fusion of Greek and various Near Eastern civilizations. Roman culture was influenced by the Greeks of southern Italy and, to a much greater degree, by the various Hellenized peoples whom the Romans conquered during the last two centuries of the Republic. The culture of the first three centuries of the Empire is appropriately labeled Greco-Roman. During the last two centuries of the Empire, a gradual division between the Latin West and the Greek East culminated in the emergence of the European Middle Ages in the former and the Byzantine era in the latter.

The Ancient Medical Profession

Although some herbal medicine and primitive surgery were employed by Greeks as early as the time represented in the Homeric epics (before 750 B.C.E.), the understanding and treatment of disease were predominantly magico-religious. It was not until the late sixth or early fifth century B.C.E. that Greek philosophy provided a rational/speculative theoretical framework for understanding health and disease, and hence for the emergence of what may be called a medical profession. The development of such a framework for the practice of medicine marks the origin of the expectation that physicians are above all products of a scientific training and orientation; that is, that they deal with disease and other physical ailments both empirically and rationally, not magically, mystically, or superstitiously (Amundsen and Ferngren, 1983). Desacralized medicine was an important aspect of Greek culture that spread throughout the Mediterranean world during the Hellenistic period and was adopted and adapted by the Romans during the late Republic.

There were no institutions that granted medical degrees or certification, nor was there a licensure requirement at any time or place. All who wished could call themselves physicians and practice medicine. Nevertheless, from the fifth century B.C.E. until the end of the period under consideration, the prevailing picture is of a population that typically distinguished between physicians (*iatroi* in Greek, *medici* in Latin) and those who practiced a magico-religious healing.

THE HIPPOCRATIC OATH. Professional standards enforceable by sanctions against physicians did not exist. Those who chose to call themselves physicians and undertake the practice of medicine were not required to swear any oath or to accept and abide by any formal or informal code of ethics. Several medical oaths, however, are known from classical antiquity. The most famous is the Hippocratic Oath, though no scholar today believes it was written by the historically elusive "father of medicine." Even the date of the oath's composition is unknown; some scholars place it as early as the sixth century B.C.E. and others as late as the first century C.E. Apparently it did not evoke much attention before the Christian era; the first known reference to it was made by the physician Scribonius Largus in the first century C.E.

Some of the stipulations in the oath are not consonant either with ethical precepts prevalent elsewhere in the Hippocratic Corpus and other classical literature or with medical practice as revealed in the sources. Attempts have been made either to explain away these inconsistencies or to attribute the oath to an author or school whose views were, in other respects as well, discordant with those characteristic of classical society. Most influential has been Ludwig Edelstein's theory (1967) that the oath was a product of the Pythagorean school, whose tenets included belief in reincarnation, the practice of vegetarianism and sexual purity, and a condemnation of abortion, suicide, and the shedding of blood. Although his thesis has appealed to many scholars, few now accept it (Deichgräber; Kudlien, 1970; Lichtenthaeler; Nutton, 1993). Parallels for even the most esoteric injunctions in the oath can be found outside Pythagoreanism. Furthermore, the Greek text offers many variant readings, some of which can be translated in significantly different ways.

THE IDEAL PHYSICIAN. One constant emerges from the variegated history of ancient medical ethics. When a Greek spoke of *iatroi* or a Roman of *medici,* each was using a word charged with meaning. Unless modified by a pejorative adjective, both meant compassionate, objective, unselfish persons, dedicated to their responsibilities. By the fifth century B.C.E. *iatros* was thus employed in a simile and metaphor; the good ruler, legislator, or statesman was frequently referred to as the physician of the state, and philosophers often described themselves as physicians of the soul. Such usage was carried over to the Latin *medicus.* The popular ideal of the physician was a dedicated, unselfish, and compassionate preserver or restorer of health—and, sometimes, inflicter of health-giving pain—always committed to the good of the patient, regardless of how far short of this ideal many physicians undoubtedly fell.

Beginning in the fifth century B.C.E., a body of medical literature developed that describes the ethics of Greek physicians. These books dealt with eminently practical concerns suggested by medical practitioners for their own benefit,

such as issues of the physician–patient relationship, and obligations to the arts, to humanity, and to life itself.

General Etiquette and Deportment

Greek physicians' formulation of a standard of general etiquette and deportment provided the basis for a social expectation that has remained since that time: physicians are guided by certain basic standards of deportment or professional etiquette in dealing with patients (Amundsen and Ferngren, 1983). The physician should look healthy and be of suitable weight, "for the common crowd considers those who are not of excellent bodily condition to be unable to take care of others" (*The Physician* 1; in the Hippocratic Corpus). This is of particular significance, especially for classical Greek culture, in which health was considered by many both a virtue and an indicator of virtue. Health, the highest good, was set above beauty, wealth, and inner nobility. Health was a goal in itself, for without health, nothing else had value.

Especially in dealings with their patients, physicians should be cheerful and serene, but neither harsh nor silly. They should be reserved, speak decisively and briefly, exercise self-control, and not be excitable. Ostentation was regarded with particular distaste. Further, "It is disgraceful in any art and especially in medicine, to make a parade of much trouble, display, and talk, and then to do no good" (*On Joints* 44; in the Hippocratic Corpus). Physicians were urged to refrain from holding lectures for the purpose of drawing a crowd. Conducting one's practice with much fuss, although it might appeal to the vulgar crowd, smacked of charlatanism. Charlatans avoided consultations; good physicians, recognizing their own limitations and respecting their colleagues' knowledge, turned to other competent physicians for advice. Since consultations could lead to disputes, "Physicians who meet in consultation must never quarrel or jeer at one another" (*Precepts* 8; in the Hippocratic Corpus).

The Physician-Patient Relationship

Physicians' relationships with their patients usually commenced with an examination followed by a prognosis. Then the physician was faced with two or three ethical decisions: (1) whether to take the case if it appeared to be dangerous or hopeless; (2) what to tell the patient; and (3) what treatment to pursue.

INFORMING THE PATIENT. When determining what to tell their patients, two considerations impinged upon physicians: (1) the effect of their statement on the patient, and (2) the effect of these cases on their own reputation. There was considerable reluctance to take hopeless or doubtful cases. Some physicians, if they considered their cases hopeless, merely informed the patients that they were going to die, and left them. A treatise in the Hippocratic Corpus, probably written in the second century B.C.E., advises physicians to "conceal most things from the patient while you are attending to him … revealing nothing of the patient's future or present condition. For many patients through this cause have taken a turn for the worse" (*Decorum* 16). If the case was dangerous and the outcome uncertain but not hopeless, it was sometimes suggested that the patient's relatives or some other third party be informed, or that the patient should be told and advised to make a will. Sextus Empiricus, a physician and philosopher of the second century C.E., argued that "The physician who says something false regarding the cure of his patient, and promises to give him something but does not give it, is not lying though he says something false," since in saying it he has regard to the cure of the person he is treating (*Against the Logicians* 1, 43). The great diversity of advice and examples in both medical and other literature shows that opinions on this delicate question varied considerably then, just as they do now.

CHOICE OF TREATMENT. The question of what treatment to pursue posed an ethical problem for some ancient physicians. Therapeutics were placed in three categories: the mildest, dietetics; next, drug therapy; and the most drastic, cutting or cauterizing. Those who abided by the Hippocratic Oath swore not to "cut for stone," which some scholars interpret as a rejection of all operative surgery. Especially in the last century B.C.E. and the first century C.E., different medical sects vigorously debated whether drug therapy was unethical and whether milder therapeutics were preferable. But some, like Scribonius Largus, argued that it was even more unethical to refuse to employ drugs responsibly when their benefit to patients was so obvious (Hamilton).

THE PATIENT'S COOPERATION. The cooperation of patients was, of course, recognized as important (*Aphorisms;* in the Hippocratic Corpus), for if they did not obey their physicians' instructions, their condition might worsen or they might die, in which case their physicians would be blamed (*The Art; Decorum;* both in the Hippocratic Corpus). A brilliant prognosis, including a description of what course their illnesses had already taken, might so impress the patients that they would be inclined to obey their physicians (*Prognostics;* in the Hippocratic Corpus). Persuasion might be used; a passage in the *Laws* of Plato advances the idea that good physicians will reason with their patients and persuade them to follow the treatments prescribed (cf. *The Statesman*). Galen remarks on the importance of convincing

patients that remarkable benefit will ensue if their physicians' orders are obeyed. But it is the patients' respect and admiration for their physicians that are most desirable. Since faith in one's physician could render treatment more efficacious, Galen, for example, maintained that patients should admire their physician like a god.

CONFIDENTIALITY. Should physicians treat as confidential any information they acquired in their contact with patients? In the Hippocratic Oath, the following injunction appears: "What I may see or hear in the course of the treatment or even outside of the treatment in regard to the life of men, which on no account one must spread abroad, I will keep to myself, holding such things shameful to be spoken about." Edelstein sees in this stipulation a clear indication of Pythagorean purity, an insistence on secrecy "not as a precaution but as a duty" (p. 37). Those things that one ought not spread abroad, whether encountered within or outside of practice, are categorized as "shameful to be spoken about," or in another translation, "holy secrets." Elsewhere in the Hippocratic Corpus the physician is advised to "say only what is necessary. For … gossip may cause criticism of his treatment" (*Decorum* 7). In another treatise in the Hippocratic Corpus, the physician is urged "not only to be silent but also of a great regularity of life, since thereby his reputation will be greatly enhanced" (*The Physician* 1). While the stipulation to refrain from speaking too much may be motivated by a sense of duty to keep inviolable especially those private things physicians encounter in practice, the other two quotations belong in the context of a self-interested regard for reputation rather than a concern for the supposed "rights" of patients.

SEXUAL PROPRIETY. A very practical stipulation in the Hippocratic Oath reads, "Whatever house I may visit, I will come for the benefit of the sick, remaining free of all intentional injustice, of all mischief, and in particular of sexual relations with both female and male persons, be they free or slaves." Edelstein stresses again the Pythagorean tone of this injunction, especially the emphasis on justice, and sees in the prohibition of sexual relations with members of the patient's household evidence of Pythagorean severity in sexual morality. Whether this advice was motivated by ideals of purity or by merely pragmatic concerns, physicians who used their close contact with patients or their households to satisfy their sexual passions would earn not only disrespect and contempt but also distrust. Having a reputation as a seducer of patients and their family members simply did nothing to enhance one's medical career (see also *The Physician*).

Duty to the Art, Society, and Life

LOVE OF HUMANITY. Sometimes ancient medical literature addresses very fundamental questions of motivations for practicing medicine, physicians' role in society, and the obligations incumbent upon them in that role. One statement in the Hippocratic Corpus—"Where there is love of humanity [*philanthropia*] there is also love of the art [*philotechnia*]" (*Precepts* 6)—has often been taken to demonstrate that for Greek physicians, love of humanity and love of the art were the foundational motivations for their practicing medicine. Sir William Osler saw in it the Greek physician's "love of humanity associated with the love of his craft—*philanthropia* and *philotechnia*—the joy of working joined in each one to a true love of his brother" (Edelstein, pp. 319f.). The precept in question, however, may not be so lofty. Vivian Nutton, for example, sees it as simply a pragmatic assertion that physicians' showing love for humanity will foster in their patients a love for the medical art (1993). In any event, it is evident that for many physicians, love of one's honor, glory, and reputation provided a greater motivation than *philanthropia* (Amundsen and Ferngren, 1982).

The statement quoted from the *Precepts* in the preceding paragraph occurs in the context of a discussion about fees that is introduced by the admonition "I urge you not to be too unkind." The noun *apanthropia,* the antonym of *philanthropia*, is here translated by the adjective "unkind." In the Hippocratic Corpus *philanthropia* generally is little more than kindness and compassion. Owsei Temkin, however, emphasizes that one must take care not to trivialize their philanthropy (1991), which one may easily do by contrasting it with the nearly religious flavor that philanthropy took on during subsequent eras. A profound change occurred in late Hellenistic and Roman thought, which, affected by the influence of humanitarian and cosmopolitan ideas on both philosophical and popular ethics, began to see *philanthropia* (Latin, *humanitas*) as humane and civilized feeling toward humanity in general; that is, the principle of the common humanity of all people as expressed by the Stoic philosopher Sarapion around 100 C.E. in a poem titled "On the Ethical Duties of the Physician": "Like a savior god, let [the physician] make himself the equal of slaves and of paupers, of the rich and of rulers of men, and to all let him minister like a brother; for we are all children of the same blood" (Oliver, p. 246).

This sentiment is strongly present in Galen (second century C.E.), for whom the best physician was also a philosopher, motivated by *philanthropia* (Brain). Galen, however, conceded that many physicians were motivated not by *philanthropia* but by the pursuit of money or love of

glory (Temkin, 1973). Although a few sources, such as Scribonius Largus, held that to be truly a physician, one must be motivated by *philanthropia* (Hamilton), a majority of our sources concur with Plato that the motivation to practice any art, including medicine, has little or nothing to do with the integrity of the art itself: the practitioner must only be competent (*Republic*). Nevertheless, while few physicians or laymen may have regarded *philanthropia* as essential for the physician, most people probably regarded lack of kindness and compassion as distinctly undesirable for a physician. Ample evidence suggests that the "presence of compassion among doctors was taken for granted by authors of the first century" and that, even much earlier, physicians "could think of compassion as rooted in medical ethics" (Temkin, 1991, pp. 33, 34).

FEES. Ancient medical writers expressed much concern about fees. Physicians were acutely aware that the appearance of greed could have a detrimental effect on their reputations. Hence, in the Hippocratic Corpus physicians are urged to be more concerned with their reputation than with financial reward, sometimes to give their "services for nothing, calling to mind a previous kindness or [their] present reputation," and to avoid beginning a case by discussing fees, since it could adversely affect patients, particularly those whose condition was acute (*Precepts* 6). Physicians were admonished to consider their patients' economic situation in setting fees and to provide less expensive remedies for the poor than for the rich (*On Diet*). In spite of such sentiments, physicians do not appear to have engaged in much charitable activity from a sense of duty to humanity, to the community, or to the poor (Hands). Furthermore, the subject of medical fees in antiquity is complicated because some physicians objected to being considered "hirelings" and, especially during the Empire, some insisted that medicine was a liberal art, which entangled their remuneration with the complexities of Roman laws governing honoraria (Kudlien, 1976; Temkin, 1979).

EXPERIMENTATION. Ancient physicians strove to improve their proficiency and the efficacy of their art. The most extreme example of medical experimentation was vivisection of human subjects, a very controversial subject (Ferngren, 1982). Celsus states that Herophilus and Erasistratus in Ptolemaic Alexandria performed vivisections on condemned criminals supplied by the crown. Whether or not Celsus's statement is accurate is debated (Von Staden, 1989; Scarborough), but he presents the arguments for and against the value of vivisection, concluding that "to lay open the bodies of men while still alive is as cruel as it is superfluous … [since] actual practice will demonstrate [what can only be learned from the living] in the course of treating the wounded in a somewhat slower yet much gentler way" (pr. 74f.). There is ample evidence for the vivisection of animals either to gain new knowledge or to test new theories (Galen, *On Anatomical Procedures*).

Some physicians recognized that without attempting new procedures and remedies, medical knowledge and techniques would not advance (Michler). The author of *On Joints* in the Hippocratic Corpus, after describing the failure of a novel attempt at reducing a dislocation, writes, "I relate this for a purpose: Those things which after a trial show themselves to have failed and which show why they failed, also provide good instruction" (*On Joints* 47). The author of the same treatise urges physicians to study incurable cases. Commenting on the Hippocratic maxim "Experiment is perilous" (which can also be translated "Experience is unreliable"), Galen cautions that "In the human body, to try out what has not been tested is not without peril in case a bad experiment leads to the destruction of the whole organism" (Temkin, 1991, p. 60). Further, he asserts that in several instances he had refrained from testing some remedies when he had others whose effects he knew better, and he points out that rash experimentation presents a danger to the life of the patient (Ferngren, 1985).

Some physicians may have been deterred from experimenting on patients by a fear of being brought to court. Complaints can be found in classical sources that only the physician can commit homicide with complete impunity, but there were some very limited means for seeking redress against the negligent or incompetent physician, at least in Athenian and Roman law (Amundsen, 1973; 1977). But most physicians were probably deterred from any compelling desire to experiment primarily by concern for their reputations rather than by fear of litigation. Classical literature provides numerous examples of the worry expressed by laymen that physicians experiment at their patients' risk (Ferngren, 1982; 1985).

SHARING NEW TECHNIQUES. When new knowledge and techniques were discovered or developed, physicians were faced with the question of whether they should share this information with their colleagues—their competitors—and with the public at large. The Hippocratic Oath appears to have been composed for an exclusive sect. In it physicians swear not to impart their knowledge to those outside their sect. Similar sentiments are expressed elsewhere in the Hippocratic Corpus: "Things … that are holy are revealed only to men who are holy. The profane may not learn them until they have been initiated into the mysteries of the science" (*The Law* 5).

Apart from a few such statements, a desire to share new techniques or knowledge with other physicians pervades the

medical literature. Those who published their medical knowledge and experience obviously did not desire to keep them secret. Galen was motivated in part by the wish to help physicians after him. But many physicians undoubtedly guarded their special techniques with jealousy. Galen shows no surprise at a surgeon's intentionally concealing his operative procedures from view, but expresses disappointment that even some of his own pupils would not share their anatomical knowledge with others (*On Anatomical Procedures*). His "philanthropy is not only that of the physician, but more comprehensively that of a philosopher who subjectively delights in study and objectively labors for the good of mankind. He thinks of his work as belonging to posterity …" (Temkin, 1973, p. 50). Some physicians wrote to instruct other physicians and also to edify laymen. In their desire to share medical knowledge with contemporaries and with posterity, at least a few Greek and Roman physicians achieved the most enduring manifestation of their *philanthropia* and *philotechnia* (Temkin, 1949).

Respect for Life

How did physicians view their responsibility to nature and, more specifically, to life? Or, to put it differently, how might they have interpreted and applied the maxim frequently quoted in the Hippocratic Corpus, "to help or at least to do no harm" (*Epidemics* 1.11)? Did the Greek or Roman physician feel bound by any sense of "respect for life"?

ABORTION. The Hippocratic Oath enjoins that the physician "will not give a pessary to a woman to cause abortion" (Jones's translation [1924]; Edelstein's [1967] "I will not give to a woman an abortive remedy" appears broader in scope than the Greek). Here again we encounter a situation in the oath that runs counter to the realities of ancient medical practice. Many physicians did perform abortions, and various techniques are described in the medical literature (Carrick). Both Plato (*Republic*) and Aristotle (*Politics*) encouraged abortion as a means of population control and for eugenics. Objections to abortion were relatively rare before the beginning of the Christian era; in both Greek and Roman law, abortion was a criminal offense only if performed without the consent of the woman's husband (or father, if she was not married). By the first century C.E., some pagan physicians such as Scribonius Largus (Hamilton), influenced as much by an increasing humanitarianism as by the Hippocratic Oath per se, refused to perform abortions under any circumstances. The physician Soranus of Ephesus (late first/early second century C.E.) gives three reasons for which a woman seeks an abortion: to rid herself of the consequence of adultery, to maintain her beauty, and to preserve her health. Only for the last would he perform an abortion (*Gynaecia*). Soranus was highly critical of physicians who so strictly adhered to the injunction in the oath that they refused to perform an abortion even to save the life of the mother. It appears, then, that some physicians would perform abortions on request, some refused to do so for any reason, and others assumed a position on therapeutic abortion consonant with that of Soranus. The decision to perform or not to perform an abortion ultimately rested on the convictions of the individual physician. The opposition to abortion of the author of the Hippocratic Oath and such physicians as Scribonius Largus and Soranus was based less upon an idea of the inherent value or sanctity of life than on an abhorrence of physicians' using their art in actively terminating even fetal life.

DEFECTIVE NEWBORNS. While some voices were raised against exposure of healthy newborns, the morality of killing weak, sickly, or deformed newborns appears not to have been questioned by either nonmedical or medical authors (Amundsen, 1987). Soranus, who condemned any but therapeutic abortion, not only raised no objection to rejecting a defective newborn; he also provided criteria to be used by midwives in determining which newborns were worth rearing (*Gynaecia*).

PROLONGING LIFE AND PASSIVE EUTHANASIA. *The Art,* a treatise in the Hippocratic Corpus, defines medicine as having three roles: doing away with the sufferings of the sick, lessening the violence of their diseases, and refusing to treat those overwhelmed by their diseases, realizing that in such cases medicine was powerless. The decision whether to take on a possibly incurable case was entirely the individual physician's. Some cases in the therapeutic treatises in the Hippocratic Corpus are introduced with the advice that certain procedures should be followed if the physician chooses to attempt treatment (Amundsen, 1978). Ancient medical literature is divided on the question of whether physicians should withdraw from cases once it becomes clear that they will not be able to help. Some urged that physicians ought not to withdraw, even if by so doing they might avoid blame. Others felt that they should withdraw if they had a respectable excuse, particularly if continuing treatment might hasten the patient's death. Physicians did, however, sometimes attend cases considered incurable. In the Hippocratic Corpus many diseases that then generally ended in death are described with no mention of prognosis and with no recommendation to the physician that such cases be undertaken or rejected. For most of them, medications to be employed are named. It was recognized that it was necessary to deal with incurable conditions in order to learn how to prevent curable states from advancing to incurability, particularly in the case of wounds (Michler). Opinions varied on the

physician's responsibility to undertake treatment of hopeless or dangerous cases. In recent times it has become almost dogma to assert that the Hippocratic physician would not take on hopeless cases, but this is demonstrably false (Von Staden, 1990). Nevertheless, some laymen in antiquity held that, as Cicero wrote to his friend Atticus, "Hippocrates too forbids employing medicine in hopeless [cases]" (Temkin, 1991, p. 139).

Celsus, a medical compiler of the first century C.E., appears to represent the mainstream of medical thought: "For it is the part of a prudent man first not to touch a case he cannot save, and not to risk the appearance of having killed one whose lot is but to die; next when there is grave fear without, however, absolute despair, to point out to the patient's relatives that hope is surrounded by difficulty, for then if the art is overcome by the malady, he may not seem to have been ignorant or mistaken" (*De Medicina* 5.26.1.c). Available evidence suggests that physicians who prolonged or attempted to prolong the life of patients who could not ultimately recover their health were generally viewed as acting unethically (Amundsen, 1978).

ASSISTED SUICIDE OR ACTIVE EUTHANASIA. Would the ancient physician have thought it helping or harming to agree to assist those who for any reason wished to end their lives? To this question a majority of ancient physicians would probably have replied, "Helping, or at least not harming." The right of a free person to control his or her life as each saw fit—if not always in its living, at least in its termination—was a generally accepted view (Cooper). Suicide was, under most circumstances, outside the moral interest of the law; the exception was whether the suicide of one accused of a crime should be construed as an admission of guilt (Hooff). If a person who wished to commit suicide enlisted the aid of a second party, the latter was not legally culpable for rendering such assistance. Extralegal sources contain few objections to suicide in general, fewer still to the suicide of the hopelessly ill (Gourevitch; Hooff). Assisting in suicide was a relatively common practice for Greek and Roman physicians, and condemnations of the practice were infrequent.

One such condemnation appears in the Hippocratic Oath: "I will neither give a deadly drug to anybody, not even if asked for it, nor will I make a suggestion to this effect" (following Kudlien's translation, 1970, p. 118, n.47). This statement immediately precedes the prohibition of abortion. Both prohibitions have at least this much in common: They are inconsistent with the values expressed by the majority of sources and atypical of the realities of ancient medical practice as revealed in most medical and lay literature. Some physicians, however, may have preferred not to assist a suicide, for it could prove to be a messy business, at least from a legal point of view. Under Greek and Roman law, physicians could be charged with poisoning their patients. Indeed, physicians were sometimes charged with, or at least frequently suspected of, doing so (Kudlien, 1970; Nutton, 1985). Some physicians refused to aid anyone in committing suicide; perhaps they condemned assisting suicide under all circumstances for philosophical or religious reasons, or on the grounds that such action was inconsistent with the role of medicine (e.g., the first-century physicians Scribonius Largus [Hamilton, 1986] and Aretaeus [Amundsen, 1978]).

AT THE MOST, A LIMITED "RESPECT FOR LIFE." In light of the Hippocratic Oath and several later sources that also condemn abortion and active euthanasia, Temkin asserts that "Sufficient material has now been gathered to prove the existence of a tradition which, in its uncompromising form, did not sanction any limit to the respect for life, not even therapeutic abortion …" (1976, p. 5). This tradition appears to have been entirely negative in its emphasis: The physician would not actively terminate life by abortion or euthanasia. But it laid no stress on the positive correlate that would require the physician actively to attempt to prolong life. This negative tradition did, indeed, become stronger with the rise of Christianity and its introduction of the principle of sanctity of life: Abortion, infanticide, suicide, and euthanasia became sins. In addition, philanthropy became a virtue—the highest virtue, in fact—and the love of humanity and Christian compassion became central to the Western ideal of medical practice.

I. ANCIENT AND MEDIEVAL. B. EARLY CHRISTIANITY

Christianity arose in Palestine during the first half of the first century C.E. among the followers of Jesus of Nazareth, called the Christ, who believed him to be the Messiah and the Son of God. Although the first followers were almost exclusively Jews, this new faith spread quickly through the Mediterranean basin and soon attracted many non-Jewish converts. For its first three centuries it remained a religion of a small but steadily growing minority. Officially declared a forbidden religion by the Roman imperial government, its adherents endured spasmodic persecutions that culminated in the Great Persecution (303–311). Emperor Constantine, a convert to Christianity, pronounced it a legal religion in 313; Emperor Theodosius I (379–395) declared it the official

religion of the state and abolished the public practice of pagan religious rites.

This article covers the Christian religion from its origins to the fifth century. The sources for early Christianity are primarily literary: the New Testament, composed by followers of Jesus during the first century; and the patristic literature (the writings of early church leaders and theologians until the end of the fifth century). During this era, the beliefs and practices of the new faith were articulated and refined amid many controversies, particularly about the divinity of Christ and the nature of redemption. Gradually, a core of beliefs and a canon of literature predominated as orthodox and a church organization emerged that promoted these beliefs. By the late fifth century, orthodoxy had achieved its enduring form in doctrine and hierarchy, both of which differed in some respects between western Europe and the Byzantine culture of the East. At the same time, certain heterodox or heretical Christian groups existed peripherally. One of these, Arianism, became a powerful political and religious force.

Medical theories and practice in the varied milieu of Greek and Roman paganism were so religiously neutral that a discussion of classical medical ethics need pay relatively little attention to the subject of religion. Christianity, however, is fundamentally different in its most basic tenets and principles from the salient features of the religious pluralism in which it took root. Issues of health, sickness, healing, life, and death are so integral to Christian theology that two questions need to be addressed before anything meaningful can be said about early Christian medical ethics: (1) What was Christianity's theological understanding of illness? (2) Were the use and practice of medicine regarded as appropriate for Christians?

What was the theological understanding of illness? Patristic theology viewed physical health as a good but not an absolute good, and much less the supreme good. Physical health could even be an obstacle to the supreme good, which was spiritual health. The church fathers emphasized that the soul is infinitely more valuable than the body, and that care for the latter is not to conflict with care for the former. Yet the majority of the sources maintained that the body is to be reasonably cared for, since God has provided the means for its care. The church fathers saw health as a blessing from God, but since it was only a relative good, it could be an evil if given a higher priority than it deserved. Conversely, sickness could be a good thing. A survey of the writings of the church fathers reveals the firm conviction that Christians should rejoice in sickness as well as in health. Sickness can correct or restrain one from sin, refine, admonish, increase patience, reduce pride, cause one to be less self-reliant and more dependent upon God, and make one more mindful of eternity and one's own mortality, thus helping to wean one from the material to the spiritual, from the temporal to the eternal (Amundsen, 1982).

Sin lurked in the background of all conditions of suffering. Without sin there would be no suffering, because the fall of the first humans created by God, Adam and Eve, was the ultimate explanation for the miseries of the present. Sin, in this sense, was generic in the human race. When the church fathers identified personal sin as the cause of sickness, it was usually in the context of pastoral exhortations intended to comfort and correct rather than to foster guilt.

In the literature of the first several centuries of Christianity, three sources of disease or illness were identified: God, demons, and nature. They were not mutually exclusive. While there appears to have been a hesitancy to attribute disease directly to God, the more his sovereignty was stressed, the more he was viewed as either sending or permitting illness through demonic or natural instrumentality. The subject of disease causality in the early Christian literature is rife with confusion and interpretive problems, especially considering the perceived role of demons.

What was thought to cause disease in any given case greatly affected the choice of means of healing: spiritual/miraculous (e.g., prayer, the sacraments, exorcism, and, beginning in late antiquity, the cult of saints and relics); medical (drugs, dietetics, and surgery—typically administered by a physician); or magical (demonic or occult practices). The first two of these approaches were often combined, and sometimes magic was employed, although its use was consistently condemned in Christian literature. A Christian was to depend upon God. Sometimes the line of dependence was direct; at other times it included one or several intermediaries. The church itself (i.e., its clergy and sacraments) and the saints became variable parts of a chain of dependence to which a spiritual/miraculous healing model was essentially integral. A magical model offered an inherently incompatible, conflicting, and competing structure of dependence. A medical model was not necessarily either harmonious and compatible with the church's structure of dependence, or incompatible, conflicting, and competing with it.

Did the potential for tension between Christianity and medicine ever lead to a rejection of medicine? Some scholars have maintained that several church fathers were diametrically opposed to medicine in any form for Christians (e.g., Harnack; Frings; Schadewaldt). Most sources that have been thus interpreted have lately been shown not to be hostile to medicine per se (Amundsen, 1982; Temkin). Although more scholarly work remains to be done, it is unlikely that

any patristic source will ultimately prove to have made a blanket condemnation of medicine. Nevertheless, some church fathers maintained that only those who lacked spirituality sufficient for them to be able to rely exclusively on divine healing should use medicine (e.g., Origen [ca. 184–ca. 253], *Contra Celsum*). Others practiced an asceticism that so glorified suffering and disease that they would not avail themselves of help from any source, although they did not deny the propriety of medicine for other Christians (Harvey; Amundsen, 1982).

Even if no patristic sources totally condemned medicine, the existence of those passages that have been thus interpreted, together with numerous cautionary statements about medicine made by other church fathers, demonstrates an uneasiness and a real potential for tension. Scholars like Adolf Harnack, Hermann-Josef Frings, Hans Schadewaldt, and Vivian Nutton, have advanced two possibly complementary theories to account for the supposedly unequivocal condemnation of medicine by some church fathers and the general uneasiness about Christians' using medicine expressed by others: (1) An early, conservative hostility against medicine was gradually ameliorated by a Hellenistic, liberalizing influence; (2) Christianity's supposed emphasis on, and ostensible promise of, miraculous physical healing was a constant, major obstacle to compatibility. Both views betray a misunderstanding of the nature of the inherent, and hence enduring, tensions and compatibilities between Christianity and medicine (Amundsen, 1982), and the second compounds the error by exaggerating the importance of miraculous healing in the propagation of the Gospel and in the Christian community, especially during the second and third centuries (Ferngren, 1992). Generally the patristic sources see medicine and physicians as God's gifts. Christianity inherited from Hellenistic Judaism an appreciation of Greek medicine that defined disease naturalistically while denying neither God's sovereignty nor his prerogative to intervene in mundane affairs. Nevertheless, the church fathers regarded as both sinful and foolish the use of physicians and medicine apart from faith in God and the failure to recognize that all healing, other than magical (demonic or occult), comes from God (Amundsen, 1982; Temkin).

The Ideal Physician of Early Christianity

The tension between Christianity and medicine was overshadowed by their compatibility in one important sense: Jesus Christ was described as the great physician, the true physician, both the physician and the medication (Pease; Arbesmann; Schipperges, 1965; Temkin). Early Christian authors thus adopted and adapted a long-established tradition in classical literature that employed, in simile or metaphor, the idea of physicians as dedicated, unselfish, and compassionate preservers or restorers of health and, sometimes, inflicters of health-giving pain, always committed to the good of their patients. It was not uncommon for the term *Hippocratic art* to be used metonymously for the medical art, and Christian authors occasionally mention Hippocrates as an ethical ideal for the medical practitioner. Indeed, Christ was himself spoken of as being, "as it were, a spiritual Hippocrates" (Pease, p. 75), and it is to Hippocrates as the type of physician that Jerome (ca. 345–ca. 419), compares the Christian healer (*In Ioanem Commentarii*; cf. *Epistle* 125).

Early Christians found the "Hippocratic ideal" of decorum very appealing. Jerome wrote to a priest that it

> is part of your duty to visit the sick, to be acquainted with people's households, with matrons, and with their children, and to be entrusted with the secrets of the great. Let it therefore be your duty to keep your tongue chaste as well as your eyes. Never discuss a woman's looks, nor let one house know what is going on in another. Hippocrates, before he will instruct his pupils, makes them take an oath and compels them to swear obedience to him. That oath exacts from them silence, and prescribes for them their language, gait, dress, and manners. How much greater an obligation is laid on us who have been entrusted with the healing of souls! (*Epistle* 52.15; see Temkin, p. 182)

In a collection of letters incorrectly attributed to Clement of Alexandria (ca. 150–ca. 220), there is a passage that reads, "We are to visit the sick … without guile or covetousness or noise or talkativeness or pride or any behavior alien to piety.… [I]nstead of using elegant phrases, neatly arranged and ordered … act frankly like men who have received the gift of healing from God, to God's glory" (*De virginitate* 1, 112). This advice, which sounds as if it had been written for physicians, was intended for exorcists dealing with the demon-possessed. Every detail enunciated here, save for reference to piety and to God, is mentioned in the classical literature on medical etiquette, but one need not assume that the anonymous author of this letter was intentionally adopting principles of medical etiquette. Rather, the guidelines for conduct in both instances seem to be little more than practical etiquette for clergy as well as for physicians.

Compassion or philanthropy was the one feature of the "Hippocratic ideal" that the church fathers regarded as especially Christian. Origen writes that he followed "the method of a philanthropic physician who seeks the sick so that he may bring relief to them and strengthen them"

(*Contra Celsum* 3.74). In demonstrating the superiority of Christianity to pagan philosophy, he says that "Plato and the other wise men of Greece, with their fine sayings, are like the physicians who confine their attention to the better classes and despise the common man while the disciples of Jesus carefully study to make provision for the great mass of men" (ibid., 7.60). It was in caring for common people, especially for the destitute and the poor, that physicians evinced a Christlike compassion. Augustine (354–430) regarded his friend, the physician Gennadius, as "a man of devout mind, kind and generous heart, and untiring compassion, as shown by his care of the poor" (*Epistle* 159). He frequently mentions physicians who, motivated by charity, asked no remuneration for their services but undertook the most desperate cases among the poor with no thought of receiving any recompense (e.g., *Sermon* 175).

Eusebius of Caesarea (ca. 265–ca. 339) writes that Christ, "like some excellent physician, in order to cure the [spiritually] sick, examines what is repulsive, handles sores, and reaps pain himself for the sufferings of others" (*Ecclesiastical History* 10.4.11). And Origen paraphrases a well-known Hippocratic aphorism that a physician "who sees terrible things and touches unpleasant wounds in order to heal the sick … does not wholly avoid the possibility that he may fall into the same plight" (*Contra Celsum* 4.15; see Temkin, pp. 141ff.). Physicians, according to Augustine, should always have their patients' cure at heart (*Sermon* 9), for the practice of medicine would be cruelty if physicians were only concerned about engaging in their art (*In Psalmos*). Gregory of Nyssa (ca. 335–394) began a letter to the physician Eustathius with the statement that, "Philanthropy is the way of life [*epitedeuma,* "one's business"] for all of you who practice the medical art" (although almost certainly written by Gregory of Nyssa, it is usually printed as *Epistle* 189 of his elder brother, Basil). While philanthropy was a highly desirable attribute for many pagan physicians, it is no exaggeration to say that Christianity made it an ethical obligation for Christian physicians (Temkin). Indeed, for some it became the chief motivating factor for the practice of medicine.

Hence it is not surprising that Christians adopted and adapted the so-called Hippocratic Oath at some time before the end of the period under consideration. Several manuscripts of an "Oath of Hippocrates insofar as a Christian may swear it" are extant (Jones, pp. 54f.). The Christian Oath omits the enigmatic prohibition of cutting for stone and makes more specific and definite the antiabortion statement. Where the pagan oath reads "Into whatsoever houses I enter, I shall do so to help the sick, keeping myself free from all intentional wrongdoing and harm," The Christian Oath has "Into whatsoever houses I enter, I will do so to help the sick, keeping myself free from all wrongdoing, both intentional and unintentional, tending to death or to injury." While one should not make too much of the addition of the promise to keep oneself free from even unintentional harm, it is reasonable to suggest that this concern, although not inconsistent with pagan medical ethics, is even more consonant with an early Christian ethics of respect for life that manifested itself not only in a condemnation of such practices as infanticide and suicide (including active euthanasia) but also in a philanthropy that was regarded as owed to the destitute and the ill.

Philanthropy

There is an enormous gap between pagan and Christian concepts of philanthropy. Christian philanthropy was an outgrowth of the Jewish insistence that love, mercy, and justice were attributes of God and were essential for true worship of God (e.g., Mic. 6: 6–8). Christian philanthropy was the expression of agape, an unlimited, freely given, sacrificial love that was not dependent on the worthiness of its object, since it was the manifestation of the very nature of God, who himself is agape (1 John 4:8). It was incumbent upon all Christians to extend care to the needy, especially to the sick. By late antiquity the care of the sick had become a highly organized activity under the supervision of the local bishop (Ferngren, 1988). Institutions that with some qualification may be called hospitals, were established and maintained beginning in the fourth century. The most famous of these was the *nosokomeia* or *ptocheion* of Basil, who was the bishop of Caesarea from 370 to 379 (Miller; Temkin). These institutions, as well as orphanages and homes for the care of the elderly and destitute, first arose after the legalization of Christianity, were distinctly Christian, and were a direct outgrowth of Christian philanthropy.

During various outbreaks of plague, Christians responded with spectacular daring in their attempts to succor the ill, both Christian and pagan. One particular group, on whom we have only scant information, were known as the *parabalani* ("reckless ones") because of the risks they faced by caring for plague victims (Philipsborn). Their zeal in the face of imminent danger was motivated in part by the belief that death thus incurred ranked with martyrdom (Eusebius, *Ecclesiastical History*). Christians were so well known for their care of the destitute that Julian the Apostate (r. 361–363), the only pagan emperor after the legalization of Christianity, complained that the "impious Galileans support not only their own poor but ours as well" (*Epistle 22*). Henry Sigerist did not overstate the case when he said that Christianity introduced "the most revolutionary and decisive change in

the attitude of society toward the sick.… It became the duty of the Christian to attend to the sick and the poor of the community.… The social position of the sick man thus became fundamentally different from what it had been before. He assumed a preferential position which has been his ever since" (p. 69f.).

The Sanctity of Human Life

The Christian imperative to a practical philanthropy that extended to the poor and the sick was not solely a manifestation of Christian love but was ultimately articulated as a theology of respect for life, a principle of the sanctity of human life predicated on the concept of the *imago Dei,* the belief that every human being was formed in the image of God (Ferngren, 1987). By virtue of sharing the *imago Dei,* all human life was of value, and therefore was owed compassion and care. Specific condemnations of contraception, abortion, and infanticide, however, are not found in the New Testament. And when they first appear in Christian literature during the second century, they seem not to be predicated upon a developed concept of the *imago Dei* as the basis of human value. Rather, such condemnations appear in the context of broad and fervent denunciations of the most offensive sins to which Christians felt pagans were especially prone, such as gladiatorial shows and other exhibitions of extreme cruelty, and sexual immorality of an extravagantly imaginative variety.

The history of the treatment of contraception and abortion in the early church is rife with difficulties. First, the distinction between contraception and abortion, at least in the early stages of pregnancy, was blurred in both medical and popular perceptions (Noonan, 1966). The question of when human life begins was, and still is, hotly debated. Ancient embryology, although scientifically inaccurate, was more helpful than modern science in answering this question. Aristotle's theory of fetal succession of souls—nutritive, sensitive, rational—had a profound impact on patristic discussions of abortion. A fetus that is "fully formed" (a very imprecise concept) is "ensouled," that is, possesses a sensitive soul and is "animate" (an equally imprecise concept). One that is not "fully formed" is not "animate," in that it is not yet "ensouled" with a sensitive rather than a nutritive soul. The transition from a nutritive to a sensitive soul—that is, animation—is marked by "quickening," the first movement of the fetus, which ostensibly happens about the fortieth day with males and the ninetieth day with females.

Furthermore, Christian condemnations of contraception and abortion were based on two quite different principles. One is that contraception and abortion before "ensoulment" are essentially sexual sins but not the destruction of human life. The other is that contraception and abortion at any stage are indeed the destruction of human life. Both, of course, regarded abortion after "ensoulment" as homicide (Noonan, 1970; Connery; Gorman; Dombrowski). Some recent revisionist historians advance the argument that the early Christian community did not condemn abortion at any stage of fetal development until two factors conduced to condemning it: the desire to rely not only on evangelism to increase the Christian community but also on internal growth, and the developing contempt for women within the church that relegated them to the role of childbearers (e.g., Hoffmann). Such special pleading has little to commend it.

The Christian condemnation of infanticide, including exposure, however, was unequivocal and inclusive, counting the active or passive killing of any newborn, whether healthy, sickly, defective, or even grossly deformed, as the murder of one made in the image of God (Amundsen, 1987). Active euthanasia, except as it was condemned in the "Hippocratic oath insofar as a Christian may swear it," is not discussed in the sources, but must have been regarded as murder, especially given the early Christian community's attitude toward suicide. Although suicide was not included in the broad spectrum of sins of pagans that aroused the moral indignation of early Christians, it was condemned by numerous church fathers, beginning with Justin Martyr, who in the second century replied to the hypothetical question why Christians do not just kill themselves and save pagans the trouble, "If we do so, we shall be opposing the will of God" (2 *Apology* 4). At about the same time the anonymous *Epistle to Diognetus* states that Christians do not kill themselves because God has assigned them for an important purpose to a post that they must not abandon. Clement of Alexandria flatly states that suicide is not permitted for Christians (*Stromateis*). The anonymous *Clementine Homilies,* which reached their present form in the mid-fourth century, but were based on an original composed in the late second or early third century, assign to suicides a severe future punishment (*Homily* 12). Lactantius (ca. 240–320) condemns suicides as worse than homicides, since they not only commit violence against nature but are impious as well. Nothing, in his opinion, can be more wicked than suicide (*Divine Institutes*; *Epitome* 39). John Chrysostom (ca. 349–407) writes that all Christians justly regard suicide with horror, "for if it is base to destroy others, much more is it to destroy one's self" (*Commentary on Galatians* 1:4). His contemporaries Ambrose and Jerome also categorically condemn suicide, the former flatly stating that "Scripture forbids a Christian to lay hands on himself" (*Concerning Virgins* 3.7.32), and the latter that Christ will not receive the

soul of a suicide (*Letter* 39). Both Ambrose and Jerome make one exception to their condemnation of suicide: when it is committed to preserve one's chastity.

Augustine's rejection of this one exception led him to engage in a thorough analysis of suicide in books I and XIX of his *City of God*. His argument against the permissibility of suicide is fivefold. First, Scripture neither commands it nor expressly permits it, either as a means of attaining immortality or as a way to avoid or escape any evil. Second, the Sixth Commandment of the Mosaic law, "Thou shalt not kill," must be understood to forbid it. Third, since individuals have no right on their own authority to kill even a person who justly deserves to die, those who kill themselves are homicides. Fourth, the act of suicide allows no opportunity for repentance. And fifth, suicide violates the foundational Christian principle of patient endurance of all that the sovereign Creator permits to befall humanity (Amundsen, 1989).

While the church fathers firmly held that death was not to be sought, they proclaimed that Christians should not fear physical death, since it would furnish them entry into the ineffable delights of heaven. Hence numerous patristic sources marveled at Christians who were afraid of dying, and especially at those who desperately clung to any hope of sustaining their lives when afflicted with seemingly hopeless illness. They viewed such conduct as tantamount to blasphemy, or at least as a sad contradiction of Christian values (Amundsen, 1989).

It was bad enough to stake one's futile hope of a temporary reprieve on physicians; but to resort to magic was even more reprehensible (Amundsen and Ferngren). For example, in the late fourth or early fifth century, John Chrysostom praised a mother who chose to allow her sick child to die rather than use amulets, although her ostensibly Christian friends had urged her to do so and she herself was confident that it could save her daughter's life (*Homily 8 on Colossians*). About 150 years later, the physician Alexander of Tralles employed quite different reasoning when he argued that it was sinful not to apply any remedy that might possibly save a patient's life, even amulets and incantations (Temkin). Alexander's attitude is interesting for three reasons. First, it demonstrates that magical remedies had already obtruded themselves into medicine. Second, it graphically illustrates a conflict of priorities between the physician and the theologian. And third, it is a very early, perhaps the earliest, hint of a physician's expressing a moral, indeed a religious, obligation to prolong life, in this case based on the reasoning that the supposedly greater sin of not doing all in one's power to save a patient was justifiably avoided by the lesser sin of using magical remedies.

Christianity developed a theological basis for the sanctity of human life, condemning contraception, abortion, infanticide (even of the sickly and deformed), suicide, and (by implication) active euthanasia. Although it did not embrace any sense of obligation to attempt to prolong life (nor did it until several centuries more had elapsed), its theology of sanctity of life did conduce to the reasoning of Alexander of Tralles that is described above, an attitude that grew even stronger during the Middle Ages.

Conclusion

In early Christian literature a reasonably clear, if not exhaustive, picture emerges of ideal physicians who were "Hippocratic" in their decorum and motivated by Christian philanthropy, and who so cherished the sanctity of human life that they would neither perform abortions nor assist in suicide, yet regarded desperate attempts to forestall death as inconsistent with ultimate Christian values. Nevertheless, such a description tells us nothing directly about the ethics of early Christian physicians except insofar as individual physicians may have agreed with and attempted to conform to such an ideal.

The ideal physician had been posited in classical antiquity, and that ideal included compassion as a desirable characteristic. However, agape—Christian love, which was the basis of philanthropy—was so central a tenet of Christian theology that it was applied to the physician as not merely a desirable but as an essential characteristic. The philanthropic basis of medical practice and the principle of the sanctity of human life became the hallmarks of Western medical ethics until modern times.

I. ANCIENT AND MEDIEVAL.
C. MEDIEVAL CHRISTIAN EUROPE

The Middle Ages are typically divided into early (500–1050) and high and late (1050–1545). This survey of the history of medical ethics in medieval Europe will first examine the sparse evidence from the early Middle Ages, and then deal thematically with significant developments during the high and late Middle Ages. The Middle Ages was a period of monumental changes. There was, however, one constant—the nearly complete identification of society with the Catholic church, which became the most thoroughly integrated involuntary religious system in human history. The Catholic church, of course, evolved throughout the Middle Ages. Nevertheless, the indirect influence of the church on most—perhaps all—aspects of life, as well as the effects of its efforts to define, direct, and regulate the details of secular and religious life, provide a backdrop for much of the discussion that follows.

The Early Middle Ages

We know of the existence of a variety of medical practitioners from the early Middle Ages. Here and there in the sources are physicians who had been trained in Alexandria or in Constantinople, Jewish or Islamic physicians, and public or civic physicians in some of the surviving Roman cities of Italy and southern France. But primarily there are those who seem to have been little more than craftsmen who had learned their techniques as apprentices. The sources, nevertheless, call all these varied types *medici,* and often contrast them with *incantatores* (enchanters, magicians, witch doctors). *Medici,* although sometimes depicted negatively in the predominantly religious literature of the early Middle Ages, are presented favorably as practitioners of an art not inherently inconsistent with the teachings of the church. The *incantatores,* however, are invariably condemned in the literature, including secular and canon law, as diabolical practitioners of illicit arts inherently opposed to the church (Flint, 1989, 1991). In this sense the physicians of the early Middle Ages—indeed, throughout the Middle Ages—were regarded by those who spoke for the church as providing a theologically neutral alternative to the spiritually pernicious ministrations of the nearly ubiquitous practitioners of those healing arts that the church condemned (Amundsen, 1986).

Not only are these physicians, of whose ethics we have little or no direct evidence, contrasted with the *incantatores*; they also are distinguished from monks or other clergy who practiced medicine as part of their religious calling. Surveys of medical history typically describe the early Middle Ages as a time when medicine was practiced predominantly by monks who treated the ills not only of their fellow monks but also of the laity of the surrounding community, as an act of Christian charity. The rule of Saint Benedict, founder of the Benedictine order (early sixth century), is often cited in this regard. Chapter 36 of the rule is addressed to those who tend ill monks. Since, however, this chapter says nothing about medical care of the laity, scholars have emphasized that the rule may not be used as evidence for a policy of monastic medical care of the ill by the Benedictines (e.g., Park). But the steward, who, according to chapter 36, is largely responsible for the logistics of the care of sick monks, is admonished elsewhere in the rule to "take the greatest care of the sick, of children, of guests, and of the poor, knowing without doubt that he will have to render an account for all these on the Day of Judgment" (chap. 31). The "children, guests, and poor" in this context certainly would not be monks, nor should the "sick" here be limited to them. Still, this is far from a concise articulation of a monastic obligation to succor the ill of the lay community at large.

In the mid-sixth century, Cassiodorus wrote a rule for the members of a monastery he had founded. The section governing monk-physicians begins with praise for their performing "the functions of blessed piety for those who flee to the shrines of holy men" (*Institutiones* 1.31), which suggests his expectation that the ill would come to the monastery for medical care. The availability and quality of medical care at monasteries varied enormously during those early centuries. Only from the ninth century on can we speak with any certainty about monasteries' playing a key role in providing medical care for the sick poor (Park). Various church councils during the early Middle Ages enjoined bishops to provide accommodations for the destitute. These, originally called *xenodochia,* but soon more commonly known as *hospitia* or *hospitalia,* were attached to cathedrals or other churches (Ullmann). These *hospitalia* were not hospitals in the modern sense of that term (Miller). Often they provided only food, shelter, and some amenities; only occasionally were they staffed with medical attendants, who would then not have been monks but other clergy who devoted part of their energies to practicing medicine.

Cassiodorus wrote two documents that describe the duties of physicians. One, already cited as evidence for monastic medical care of the laity, gives inspirational guidance to those of his monks who were also physicians (*Institutiones*). The other, which he wrote as an official in the service of King Theodoric, regulated the activities of the civic physicians of Ostrogothic Rome and of the royal household (*Variae*). While in both documents Cassiodorus lauds the medical art, there is little other similarity between them. He urges the secular physicians to place their confidence in their art, while the monk-physicians are to place their hope in the Lord and not in the medical art itself. Although Cassiodorus stresses that the secular physicians are to be dedicated to their learned art and mindful of the oath by which they were consecrated, swearing "to hate iniquity and to love purity," his major concern is nevertheless with correcting negative aspects of medical practice: professional jealousies, envy, an unwillingness to share techniques with colleagues, and bedside bickering. While this secular document places a minor emphasis on the calling, motivation, or qualities of the secular physicians, the monk-physicians are to be deeply compassionate, distressed with personal sorrow at the misfortunes of others, and grieved by their suffering and peril. Motivated by compassion, they will "perform the functions of blessed piety," and their reward will be received from the Lord. Similarly, Cassiodorus' contemporary, Benedict, had charged his monk-physicians, "Before all things and above all things care must be taken of the sick, so that they may be served in very deed as Christ himself" (*Rule*, chap. 36). Their reward would come from the Lord.

While Cassiodorus' guidance to the secular physicians has no distinctly Christian flavor, the peculiar qualities of

the monk-physicians are those of the ideal physicians of earlier Christian thought and of a variety of clergy who were to devote their lives to the charitable care of the sick, especially the poor, during the high and late Middle Ages. The best-known example is the Knights Hospitallers of Saint John of Jerusalem (late eleventh to the mid-sixteenth century), an order founded to provide shelter and care for pilgrims. These Hospitallers vowed to "serve our lords, the sick" (Hume). This phrase not only is an inversion of the lord–vassal relationship but also conveys the same ideal as the injunction in the Rule of Saint Benedict that the monk-physicians should serve the sick as if the latter were "Christ himself." These highly spiritual ideals of monastic medicine merged with the secular tradition of medical ethics and etiquette in the medico-ethical literature of the seventh through the tenth century.

Numerous medical manuscripts survive from the early Middle Ages, including several that deal with medical ethics and etiquette (MacKinney). Unfortunately the authorship, intended audience, and purpose of these medico-ethical treatises remain uncertain. They may have been composed by monks or other clergy as purely literary efforts. They may have been used as part of clerical education in the liberal arts, of which medicine was typically a subdivision (Amundsen, 1979). It is most unlikely that they were intended for, or used in, the training of physicians. These treatises present a fusion of the classical tradition of medical etiquette with Christian principles of compassion and charity. The bulk of each treatise was apparently drawn from, and sometimes directly attributed to, Hippocratic writings on etiquette: The physician's aptitude and ideal character, conscientiousness and diligence in practice, bedside manner, confidentiality, sexual propriety, proper relations with colleagues, and the preservation of one's reputation, that is, decorum in the broadest sense of the word. There is nothing distinctly Christian about any of this. But intermingled with such commonsensical precepts are distinctly Christian emphases: The physician should serve the rich and the poor alike, looking for eternal rather than material rewards, making "the cases of others his own sorrow." MacKinney correctly observes that "the monastic spirit dominated … medical handbooks of the period." They were "classical as well as pious, and secular as well as ascetic" (p. 5).

We know little about the ethics of early medieval physicians except for some monks and other clergy who practiced medicine as an act of Christian charity, without thought of remuneration. We do not even know by whom, for whom, and for what purposes treatises devoted to medical ethics and etiquette were composed. Anyone could claim to be a physician and practice medicine. There were no licensure requirements and no professional organizations. Only rarely do we encounter evidence of legal efforts to regulate physicians' activities, for example, by the Visigoths (Amundsen, 1971). Nor did the church make any concerted effort, during these early centuries, to define the responsibilities and regulate the conduct of secular or monastic/clerical physicians, other than to wage vigorous warfare against the use of illicit means of healing that typically were employed not by *medici* but by *incantatores.* Much of the time, the lines blur between secular physicians and those practitioners of medicine who were monks or clergy but practiced medicine for financial gain; many physicians who appear to have been secular were in fact clergy. Nor do we have any evidence about the behavior of physicians during epidemics that affected the villages and countryside during the early Middle Ages. But all these matters were to change during the high and late Middle Ages.

The High and Late Middle Ages

MEDICAL AND SURGICAL PRACTICE BY THE CLERGY. At the beginning of the high Middle Ages most monasteries could provide medical care for their members without resorting to the services of secular physicians. Nunneries typically engaged secular physicians for serious illnesses, although nuns attended to the minor health needs of members of their communities. There were some nuns, however, who were as medically sophisticated as any monastic/clerical or secular physician. The outstanding example is Hildegard of Bingen (1098–1179). Well known to her contemporaries as a visionary and mystic, she was also famous for her scientific and medical writings. While the propriety of monks treating monks and nuns treating nuns appears not to have been questioned, the role of the clergy generally as physicians and surgeons was beginning to be subjected to close scrutiny.

In the early twelfth century, the Cistercian abbot Bernard of Clairvaux received a demand from another abbot to send back to his former monastery a monk who had fled to Clairvaux. This monk had left because his abbot "used him not as a monk but as a doctor," and compelled him "to serve not God but the world; that in order to curry favour with the princes of this world he was made to attend tyrants, robbers, and excommunicated persons" (Amundsen, 1986, p. 84), which had brought considerable financial reward to his monastery. The monk was troubled about the spiritual propriety of this. Bernard permitted him to remain. The Cistercians shortly thereafter forbade their monk-physicians to practice outside their monasteries or to treat the laity (Miller).

A general church council, Lateran II, in 1139 promulgated a regulation having the rubric "Monks and canons

regular are not to study jurisprudence and medicine for the sake of temporal gain," which condemned the avarice that motivated some clergy to pursue such studies: "[T]he care of souls being neglected … they promise health in return for detestable money and thus make themselves physicians of human bodies" (Schroeder, pp. 201–202). This law also expresses concern that clergy who practiced medicine would see "inappropriate things." But the major focus was that if financial gain were the motive for the study and practice of medicine and secular law, such pursuits were not appropriate for those who had dedicated themselves to a religious life. We should note, first, that this stipulation did not apply to most clergy but only to monks and canons regular ("regular" means living under a "rule," which did not include most clergy) and, second—and worth noting—that it was never incorporated into canon law. A regional council at Tours in 1163 enacted a law much narrower than the one of Lateran II. It simply prohibited monks and other regular clergy from leaving their religious institutions to study medicine or secular law (Amundsen, 1978). This regulation, which did not forbid the practice of medicine by clergy, became part of canon law.

In 1219 Pope Honorius III issued a rescript, also included in canon law, that extended the prohibition of the study of medicine and secular law to virtually all clergy whose major responsibility was the performance of spiritual duties. Many clergy, however, were not affected by this stipulation, whose prohibitions were significantly lessened by subsequent enactments (Amundsen, 1978). By the end of the Middle Ages, canon law still had not prohibited the clergy from practicing medicine. Surgery, however, was a somewhat different matter, since it involved much greater risk to the patient and increased the danger that a clerical practitioner might be held responsible for a patient's death and hence excluded from exercising his clerical office. In 1215, Lateran IV forbade clergy in major (holy) orders (subdeacons, deacons, and priests) to practice the part of surgery that involved cautery and cutting, in which clergy in minor orders (porters, acolytes, exorcists, and lectors) could still engage (Amundsen, 1978).

Although the practice of medicine by the clergy was permitted, the church was obviously uneasy about their motivation and the possible effects that it might have on their spiritual obligations. Many of the clergy who continued to practice medicine and surgery, at least with the tacit blessing of the church, did so predominantly for charity. For example, some clergy composed medical treatises so that their fellow clerics could treat the poor gratis. Many clergy also wrote medical handbooks to help the poor help themselves. The outstanding example is Petrus Hispanus, "who publicly taught, wrote on, and practised medicine during the early stages of a highly successful ecclesiastical career that culminated with his election as Pope John XXI in 1276" (Siraisi, p. 25). He is the probable author of the *Treasury for the Poor,* which describes herbs the poor could gather to treat themselves.

During the high Middle Ages rapid urbanization brought about widespread suffering and disease in the growing towns and cities. In the late eleventh century, Augustinian canons (who were regular clergy like monks, but unlike them in that they did not live apart from society) and various lay brotherhoods established charitable institutions that included facilities for the destitute ill (Miller). A variety of such institutions were founded by bishops, kings, feudal lords, wealthy merchants, guilds, and municipalities as endowed charitable institutions. Members of various orders, like the Knights Hospitallers of St. John of Jerusalem, sometimes staffed these hospitals. Nursing orders also arose, committed to caring for the destitute ill in such institutions. The Knights Hospitallers' phrase "to serve our lords, the sick," perfectly captures both the idealism and spiritual motivation of these orders and the very essence of their ethics. But such practitioners constituted only a small proportion of physicians and surgeons of the high and late Middle Ages. By the mid-fourteenth century, most monasteries were paying secular physicians to treat their ill monks (Park). The church's desire to decrease clerical involvement in medical practice, especially for financial gain, combined with rapidly changing social conditions that, beginning around 1050, significantly altered the practice of medicine and the nature of medical ethics.

LICENSURE, GUILDS, UNIVERSITIES, AND A RECIPROCITY OF OBLIGATIONS. Stimulated by a dynamic revival of a commercial economy, dormant since the collapse of Roman civilization, a gradual transformation of European society began around 1050, an urban revolution that created a starkly altered context for nearly all aspects of life. One of its most salient features was the corporate nature of late medieval urban society, as manifested in increasing institutional sophistication and formalized specialization of labor, regulated either internally by guilds or corporations or externally by secular or ecclesiastical authority. Both regulatory features changed the basis for the practice of most trades and professions, including medicine and surgery. No longer would the practice of medicine be a right that anyone could claim, a free enterprise constrained only by individual conscience and criminal law. The practice of medicine would now be a privilege granted, enforced, and protected by the state or the church, at the state's or church's initiative

or at the request of guilds or corporations of physicians or surgeons.

The earliest datable law instituting medical licensure is from the Kingdom of Sicily. In 1140, Roger II issued a statute specifying that those who wished to practice medicine were to appear before his officers and judges and be examined by their court. Those who practiced in defiance of this statute were to be imprisoned and their property confiscated. "… this has been arranged so that subjects in our kingdom may not be experimented on by inexperienced physicians" (Powell, p. 130; Hartung). A considerable advance over this legislation was made by Roger's grandson, Emperor Frederick II, who in his capacity as king of Sicily, in 1231 promulgated the *Liber Augustalis.* Thereafter the examination for licensure was to be conducted by the masters of the medical school at Salerno, and the license to practice would be issued by the emperor or his representative. Before the examination, the aspirant was to study logic for three years and medicine (to include surgery) for five years, and to practice for one year under the direction of an experienced physician. These revisions are introduced by the following justification: "We see a special usefulness when we provide for the common safety of our [faithful subjects]. Therefore, since we are aware of the serious expense and irrecoverable loss that can occur because of the inexperience of physicians …" (Powell, p. 131). Physicians must visit their patients twice a day and, at the request of the patient, once during the night. Fees were to be determined in part by the distance involved. The physician was required to swear to abide by the regulations fixed by the government, treat the poor gratuitously, and inform the authorities of any apothecary who prepared drugs at less than the required strength. Physicians were forbidden to make any contracts with apothecaries or to own apothecary shops (Powell; Hartung).

On the Iberian Peninsula, the first medical licensure regulation, in 1289, imposed no requirement for a course of study in a medical school; forty years later a new law established a university medical degree as a prerequisite for practice (García-Ballester et al.). The law of 1329 and subsequent legislation provided very specific regulations governing physicians' conduct and responsibilities. These regulations, which benefited both the general public and the qualified and responsible physician, evince a reciprocity of obligations between the profession and the state. Elsewhere in Europe, by contrast, artisans, merchants, surgeons, physicians, and professors were organizing into guilds, gaining charters from municipal, royal, or ecclesiastical authorities, and guaranteeing standards of quality of goods or services in exchange for the privilege of holding a monopoly in their service or commodity.

One of the most striking features of late medieval urban life was its corporative aspect, particularly its guild organization. Perhaps originally formed simply as social organizations under the auspices of a patron saint, guilds had three major interests: (1) social, manifested in both internal and external charitable efforts, and social life within the guild (banquets, etc.); (2) political, especially guilds involved in the production of economically vital commodities; and (3) commercial, involving the protection of financial and vocational interests. In respect to the last, the guilds, by obtaining charters, secured the right to exercise a monopoly on their product or service in a particular geographical area. Such a monopoly entailed the right to make and enforce standards of quality in their products or services, to control hours and working conditions, to limit competition among members, to limit entry into the craft or profession, and to ensure the proper treatment of customers. Part of the monopoly was the right to train and license new members, thus eliminating competition from outside the guild. Although one of the major aims of such measures was economic, the guilds frequently claimed that such restrictions were necessary to maintain a high level of competence and ethics in the trade or profession. Distinct from the merchant and craft guilds, the medieval universities were essentially educational guilds. Beginning in the late twelfth century, some universities gained charters and thus became corporate bodies designed to further educational interests and to protect their members. The *collegium* of teachers who examined the candidates for a degree was, at some universities, vested with the authority to grant a license or, at others, to recommend to secular or ecclesiastical authorities that a license be awarded.

Conditions were so diverse that generalities are often misleading. But usually surgeons were organized in craft guilds; physicians, at least in cities having a university, were not members of a craft guild but were part of, affiliated with, or under the supervision of the medical faculty of the university. In university cities, medical licensure requirements were generally instituted earlier than in those without a university but, from the early fourteenth century on, many cities and towns required those who wished to practice medicine within their jurisdiction to have a degree and license from an acceptable university. Physicians practicing in such places often organized themselves into *collegia* or guilds, and in some instances obtained the authority to examine and license physicians who wanted to practice within the community, regardless of the degrees held by the applicants (Siraisi).

Practitioners brought to trial for practicing without a license often accused medical and surgical guilds and faculties of self-interest (Kibre; Cosman). However, restrictions

on medical and surgical practice, whether imposed by authorities or requested by medical faculties or medical or surgical guilds, were justified in terms of the common good, especially the grave dangers to the people if charlatans and quacks were permitted to undertake medical or surgical care. For example, the medical faculty of the University of Paris initiated medical licensure provisions and, in seeking ecclesiastical and royal support to enforce these regulations, continually appealed to the "public interest." The same appeal was made in the medical faculty's attempts to establish a right to oversee the activities of surgeons, apothecaries, barbers, and herbalists, and to prosecute unlicensed practitioners in ecclesiastical or secular courts. The unlicensed practitioners often were women who were frequently "caught in the crossfire" (to use Green's phrase, 1989, p. 447) of the legal battles between licensed groups like physicians and surgeons (see also Park, for analysis; Kibre, for narrative examples). As in the early Middle Ages, there was also a concerted effort to exclude the illicit supernatural from healing procedures. Often suspected of being "witches and exorcisoresses of the devil," unlicensed women practitioners were in double jeopardy (Amundsen, 1986, pp. 93–94).

Although guilds were organized to serve their members' self-interest, guild ethics generally were beneficial to the public. In 1423, the physicians and surgeons of London petitioned the mayor and aldermen to authorize the creation of a joint *collegium* of the two crafts. George Unwin, a historian of English guilds, remarks that their petition illustrates "the best spirit of professionalism at this period of London history." He summarizes its contents as follows:

> Their rules were meant to ensure that all practitioners in both branches should be duly qualified, if possible, by a university training, and they sought to provide a hall where reading and disputation in philosophy and medicine could be regularly carried on. No physician was to receive upon himself any cure [i.e., case], "desperate or deadly," without showing it within two or three days to the Rector or one of the Surveyors in order that a professional consultation might be held, and no surgeon was to make any cutting or cauterization which might result in death or maiming without similar notice. Any sick man in need of professional help but too poor to pay for it, might have it by applying to the Rector. In other cases the physician was not to charge excessive fees, but to fix them in accordance with the power of the sick man, and "measurably after the deserving of his labour." A body composed of two physicians, two surgeons, and two apothecaries, was to search all shops for "false or sophisticated medicines," and to pour all quack remedies into the gutter. (p. 173)

The foundational principles of medieval medico-surgical guild ethics were that each guild member must: (1) be ready to help the other; (2) protect the well-being and honor of the guild; and (3) help the sick. The order of these principles is very important. The guilds were functional, inherently selfish organizations designed to promote and protect members' special interests. They were brotherhoods, companies of people united more often than not by a common economic activity. The well-being and honor of the craft depended upon the mutual cooperation of its members. If these conditions were met, then the third—the service rendered or the commodity produced—could be effectively delivered. All these, in late medieval urban life, hinged upon the freedom of the artisans, merchants, professors, physicians, or surgeons to perform their functions unmolested by those who would illicitly meddle in their affairs. Hence they sought an exclusive right to fill a particular role; in exchange, a guild would guarantee a level of expertise in the production of its commodity or in the rendering of its service, and would assume the responsibility to police and to supervise its own members, both in respect to their qualifications, that is, training (leading to licensure), and to their performance. Regulations governing the minutiae of conduct, both within the guild and in relationships with customers or the community, varied considerably from guild to guild and from city to city. But the obligation to ensure competence and quality seems to have been a constant feature.

The highest guarantee of competence to practice medicine, recognized throughout Europe in the late Middle Ages, was a degree granted by a university medical faculty. A university curriculum in medicine, a set body of literature, and the presence of instructors qualified to teach and to test demonstrate that a standard of competence existed. The reality of such a standard has important ethical implications. Luis García-Ballester goes so far as to assert that "Everything connected with the conduct of the physician—from strictly technical matters … to the question of fees or the problems of etiquette …—was derived from this strictly technical organizational scheme … what later became known as medical ethics had this technical, intellectual origin. The specific morality of the practitioner derived, therefore, from his being a healer technically trained, and was essential for his status as an expert in medicine" (pp. 44–45).

An underlying and sometimes articulated principle of medical and surgical guilds was that the guild would ensure that the ill of the community, including the poor and the hopelessly ill, would not be abandoned at the whim of individual physicians or surgeons. This was based at least in part on the conviction, which was very strong in the late Middle Ages, that one had an *officium,* that is, an office or calling, that carried with it certain duties and obligations. In

a work devoted to the responsibilities attached to kingship, Thomas Aquinas wrote, "Nor has [the king] the right to question whether or not he will so promote the peace of the community, any more than a physician has the right to question whether he will cure the sick committed to him. For no one ought to deliberate about the ends for which he must act, but only about the means to those ends" (*De regimine principum* 2). In late medieval urban (i.e., corporate) life, physicians and surgeons, by virtue of their privilege of engaging in a legitimate *officium* within the corporate structure of society, had responsibilities both to their *officium* itself, as represented by the guild, company, craft, or *collegium,* and to the community that granted them their privileges.

THE CHURCH'S EFFORTS TO DEFINE THE RESPONSIBILITIES OF PHYSICIANS. In 1215, a general church council, Lateran IV, promulgated a decree that required annual confession by all Catholics, on pain of excommunication. This decree was widely publicized and strictly enforced. In response, lengthy treatises on moral theology and numerous manuals to aid priests in interrogating penitents during confession were written by moral theologians in an effort to subject the broadest spectrum of human activities to Christian moral principles, including a wide variety of occupations. The discussion that follows is a very condensed summary of the sections of ten primary sources from the early fourteenth through the early sixteenth century that provided priests with a range of questions and moral guidance to be addressed to physicians and surgeons during their mandatory annual confession (Amundsen, 1981). Where the word *physician* appears, it should be understood to include "surgeon."

Competence and diligence. Physicians who are not competent according to accepted standards within the profession sin by practicing medicine. Simply possessing a degree in medicine does not in itself guarantee competence. Competent physicians sin if they do not conscientiously exercise diligence. Rashness, which may result from incompetence or negligence, is a sin in medical practice, especially if patients are harmed. Hence physicians should be cautious and not administer medicines about whose effects they are in doubt; patients should be left in God's hands rather than be exposed to additional danger. Generally, physicians sin if they engage in any experimentation at the patient's risk, especially if they experiment on the poor whom they treat without charge. Physicians also sin if they are so cautious that they fail to give the appropriate medicines, and especially if they do so in order to prolong the illness and thereby increase their fees.

Fees and charity. Beginning with the assumption that it is licit to receive remuneration for what one is not bound to do gratuitously, but bypassing consideration of how the scholastic principle of "just price" for services could be applied to medical practice, the moral theologians discuss a wide variety of moral aspects of medical fees. The most basic principle is that physicians should ensure that they accept only a "reasonable" fee, as determined by the quality of care; the physician's labor, diligence, and conscientiousness; the custom of the place; and the patient's means. A patient who is rich must not be exploited by exorbitant rates. More problematic is the sick pauper. Is the physician obligated to give free medical care to the poor? This, as we shall see when discussing the medico-ethical literature of the high and late Middle Ages, was a source of great frustration for physicians. Thomas Aquinas, beginning with the premise that "no man is sufficient to bestow a work of mercy on all those who need it," suggests that kindness ought first to be shown to those with whom one is united in any way. As for others, if one "stands in such a need that it is not easy to see how he can be succored otherwise, then one is bound to bestow the work of mercy on him." Hence a lawyer is not always obligated to defend the destitute, "or else he would have to put aside all other business and occupy himself entirely in defending the poor. The same holds with physicians in respect to attending the sick" (*Summa theologiae* 2–2, 71, 1). The authors of the confessional literature generally follow Aquinas and specify that physicians must treat the poor gratuitously if the patient would die without treatment.

An obligation to care (especially for hopeless cases). With the advent of medical licensure requirements and medico-surgical guild monopolies, the physicians' option of refusing to treat or of deserting hopelessly ill patients became more circumscribed. Social and religious pressures also changed. Typically the moral theologians maintain that "Desperate cases that, according to the judgments of men, are held to be fatal, sometimes the diligent physician is able to cure, but rarely … therefore, clear to the end the physician ought to do what he can to cure the patient" and should not entirely withdraw from the patient "as long as nature does not succumb." If a rich miser is unwilling to employ the services of a physician, the physician is obligated to treat him or her gratis, even to provide medicines without charge; otherwise the physician is killing such a person indirectly. If the rich miser recovers, the physician may sue for fees and expenses; if the miser dies, the heirs are obligated to pay (Amundsen, 1981).

Spiritual obligations of physicians to patients. While the theologians were quite concerned to protect the patient from physical harm and financial exploitation, they were even more determined to guard the well-being of the patient's soul. At Lateran IV in 1215, the following decree was enacted:

> Since bodily infirmity is sometimes caused by sin, the Lord saying to the sick man whom he had healed: "Go and sin no more, lest some worse thing happen to thee" [John 5: 14], we declare in the present decree and strictly command that when physicians of the body are called to the bedside of the sick, before all else they admonish them to call for the physician of souls, so that after spiritual health has been restored to them, the application of bodily medicine may be of greater benefit, for the cause being removed the effect will pass away. We publish this decree for the reason that some, when they are sick and are advised by the physician in the course of the sickness to attend to the salvation of their soul, give up all hope and yield more easily to the danger of death. If any physician shall transgress this decree after it has been published by the bishops, let him be cut off from the church till he has made suitable satisfaction for his transgression. And since the soul is far more precious than the body, we forbid under penalty of anathema that a physician advise a patient to have recourse to sinful means for the recovery of bodily health. (Schroeder, p. 236)

The stipulation that physicians must advise and persuade patients, before all else, to call a priest concerns the curative effect of confession rather than the opportunity to confess before dying. The moral theologians' discussions of this stipulation vary enormously in length, detail, and sensitivity to the problems that it posed. Several maintain that this requirement applied only to cases of extremely dangerous or mortal illnesses. Some go so far as to provide lists of applicable diseases, symptoms, or injuries, especially those demanding immediate attention. This interpretation of the decree is surprising, since it flies in the face of the specific intent that patients be made aware that the requirement to call a confessor is not to be taken as an indication that their condition is hopeless. And some of the authors of the confessional literature interpret it strictly along such lines, making no exceptions. They wrestle with the question of whether a physician is obliged to withdraw from a case if the patient refuses to call a confessor, and reach a variety of answers ranging from a strict "yes" to an unequivocal "no," some of the latter maintaining that if the physician were required to abandon the stubborn patient, "the precept of the church [would] seem against the precept of God." At the end of the Middle Ages, there was no uniformity either of practice or of interpretation of this piece of canonical legislation.

In the context of discussions of the requirement that physicians have their patients summon a confessor, some moral theologians raise the question of whether physicians are obliged to inform terminally ill patients of their condition. There is some disagreement among the moral theologians who address this issue, particularly since physicians (and here Galen is cited) typically tell patients that they will recover, even if there is little hope, since predicting a fatal outcome will likely remove all hope of recovery and hasten death. Generally the authors of the confessional literature insist, however, that unless physicians are certain that their terminally ill patients have set both their spiritual and their temporal affairs in order, they must inform them of their imminent demise, since otherwise harm may ensue to patients' souls and estates.

The second requirement of the legislation in question is for physicians to refrain from advising sinful means for the recovery of health. Several of the moral theologians simply quote that stipulation without elaboration. Others condemn specific matters, such as advising fornication, masturbation, incantations, consumption of intoxicating beverages, breaking the church's fasts, and eating meat on forbidden days.

Abortion and euthanasia. The authors of the confessional literature almost entirely ignore the subject of abortion when discussing the responsibilities and sins of physicians. While all include thorough discussions of abortion under the rubric "homicide" or "abortion" or both, only two include it in their extensive considerations of medical ethics. Apparently the rest did not think that physicians or surgeons were confronted with requests for abortions. Women who sought abortions would probably not have turned to physicians or surgeons, the overwhelming majority of whom were men during the high and late Middle Ages, but to another woman, such as a midwife or an unlicensed female practitioner.

Abortion, regarded both as a sexual sin and, under some circumstances, as homicide, was an issue fraught with interpretive problems during the Middle Ages (Noonan; Connery). The opinion of Jerome and Augustine (fourth century) that abortion is not homicide unless the fetus is "formed," that is, vivified or ensouled, was incorporated into medieval canon law, which also included a conflicting decree that applied the penalty for homicide to the induced abortion of a fetus at any stage of development. Theologians, canon lawyers, and the authors of the confessional literature were split between these two positions. The stricter interpretation generally forbade abortion at all times and under all circumstances. The more liberal interpretation, which was influenced by Aristotelian embryology, did not classify induced abortion as a mortal sin within the first forty days of pregnancy in the case of a male fetus, and eighty (or, according to some, ninety) days in the case of a female, and permitted abortion during these periods under a variety of extenuating circumstances. The conflict between the interpretations of these two camps was not resolved until long

after the Middle Ages. Both, however, clearly condemned abortion as reprehensible if performed simply to destroy the unwanted consequence of sexual intercourse.

What we call active euthanasia is a subject that the moral theologians thus far surveyed never raised when discussing the sins of physicians; it was probably regarded throughout the Middle Ages simply as homicide on the physician's part and suicide on the patient's, assuming willing involvement by the latter. Martin Azpilcueta, better known as Navarrus, a leading canon lawyer and moral theologian of the sixteenth century, wrote in 1568 that the physician sins who gives any medicine that he knows is harmful, "even if he administers it out of pity or in order to please the patient." Navarrus's statement seems clear and unambiguous: active euthanasia, whether motivated by pity or by the wish of the patient, is sinful. This must be one of the earliest articulations regarding active euthanasia in such precise terms. Navarrus gives as his authority the canon lawyer Panormitanus (early fifteenth century), who had simply given the opinion that those having custody or serving a sick person sin greatly if, motivated by "a sort of pity," they obey or indulge the "corrupted desire" of the ill. Before active euthanasia was seen as a separate moral category, the closest the authors of the confessional literature could have come to including relevant comments in their sections on physicians' sins would have been to have stated that it was a sin for physicians to kill or poison their patients intentionally.

The effects of the moral theologians' efforts. Medieval European society was, with the exception of a small number of Jews and heretics (e.g., Albigensians and Waldensians), exclusively Catholic. Guaranteed the allegiance of virtually the entire population of western Europe and the prestige of ecclesiastical institutions, the church could exercise jurisdiction over areas of life that now would be the concern of either secular authority or the individual conscience. The church promulgated laws and expected obedience. Ecclesiastical courts imposed penalties ranging from penance to imprisonment to excommunication. The extent to which the confessional influenced ethics and conduct cannot be gauged with certainty. The authors of the confessional literature strove both to educate the laity so that they might be able to identify previously unknown sins, both of commission and of omission, and to correct sinful practices. The best confession was one that led to a changed life, and a changed life should be one in as close conformity to the expectations and standards of the church as possible. The priest's authority "to loose and to bind," although ultimately of eternal consequence, applied also to this life in that it included the authority—indeed, the responsibility—to grant forgiveness and restoration only to those who satisfied the requirements of the confessional, and to impose sanctions upon those who refused. The ultimate sanction, excommunication, when imposed upon those who exercised their vocation by license, would deprive them of their livelihood. Whether such steps were ever taken against physicians during the high and late Middle Ages remains unclear. Nevertheless, the morally educating (or possibly alienating) effects of this annual interrogation, which employed the detailed scrutiny available to every priest in his confessional manual, must have been profound.

PHYSICIANS' AND SURGEONS' ADVICE ON ETHICS AND ETIQUETTE. In the extensive medical and surgical literature that has survived from the high and late Middle Ages, one occasionally encounters comments made directly on matters of medical ethics or etiquette. Surgical manuals, for example, often begin with a discussion of the moral and educational qualifications of a practitioner, bedside manner, fees, and a variety of related matters. Medical and surgical literature also contains comments that indirectly reveal aspects of the ethical standards of the author, especially in the tractates written by physicians who attempted to understand and deal with the outbreaks of plague that struck Europe during the late Middle Ages.

Loren MacKinney perceived that, by the twelfth century, a change in spirit had occurred in medical literature from monastic to secular, a "shift of emphasis from ideals to practical considerations," a "despiritualization of the medical physician," particularly in the introduction of various "tricks of the trade" and a predominant concern with fees (pp. 23ff.). He credits this change to such factors as rapid urbanization, and he is probably right to a degree. But it is important to note the different walks of life from which the authors of the sources came. While the literature from the early Middle Ages was likely composed by monks, that of the high and late Middle Ages was written mainly by secular physicians. So it is not surprising that its tone is less otherworldly than that of the earlier treatises. The later literature was written with the clear intention of providing practitioners with two types of information: (1) the ideal physician's character, preparation, and practice; and (2) very practical and sometimes questionable advice on how best to survive in the profession. Both were at least moderately informed by the teachings of the medieval Catholic church.

The first category consists of the same range of commonsensical advice as appears in Hippocratic treatises and in the medico-ethical literature of the early Middle Ages. The second appeared especially in discussions of fees. As early as the tenth century, the physician is advised: "At the outset, accept at least half of the remuneration without hesitation, for he who wishes to buy [your services] is

disposed to pay and to beg [for treatment]. Get it while he is suffering, for when the pain ceases, your services also cease" MacKinney, p. 24). Somewhat more enlightened is the suggestion by William of Saliceto (thirteenth century) that "a high salary, if demanded, imparts to the physician an air of authority, which strengthens the confidence of the patient in him … so that the sick man imagines from this that he is more skillful than others and ought therefore to be successful in curing him" (Mirfeld, p. 132).

Some of the advice that follows, written by physicians or surgeons, may appear particularly crass. It is, however, important to realize that the medical literature of the time stressed, in Luis García-Ballester's words,

> the mutual confidence that should exist between doctor and patient. Without such confidence the efficacy of the curative action would be greatly undermined …. the physician's or surgeon's confidence in his patient was demonstrated by two conditions of equal significance: the first was that the patient should carry out what had been prescribed by the healer; the second that the patient should pay the remuneration agreed upon. The fee would be for the doctor the objective and tangible expression of his relationship with the patient and that of the patient with the doctor, while, at the same time, it would be a guarantee of continuity in treatment. (p. 51)

Henry de Mondeville (fourteenth century) laments that "The chief object of the patient, and the one idea which dominates all his actions, is to get cured, and when once he is cured, he forgets his own obligations and omits to pay; the object of the surgeon, on the other hand, is to obtain his money, and he should never be satisfied with a promise or a pledge, but he should either have the money in advance or take a bond for it" (Hammond, p. 159; Welborn, p. 356). Mondeville's attitude was probably the fruit of bitter experience. Official documents from the late Middle Ages record many cases of physicians suing patients in order to collect their fees. In most cases in which the treatment had been unsuccessful, the suit went in favor of the patient. Quite unreasonable demands by patients for extensive credit, the necessity that physicians sometimes demand securities before undertaking treatment, and lucrative contractual arrangements all contribute to the complex and ethically ambiguous way in which late medieval medical and surgical practitioners made a living (Rawcliffe, for late medieval England).

One area in which physicians seemed to act against their more mercenary interests was in providing advice that would keep potential patients from needing their services. Mondeville wrestled with the problem presented by surgeons' advising their patients how to stay healthy, "because the treatment which stops the onset of a new disease is more useful to a patient than all other treatments. But this is, as one can see, useless and harmful to the surgeon because he thus stops the appearance of a disease whose treatment would be advantageous to himself" (Hammond, p. 155; Welborn, p. 355).

Neither Mondeville nor his contemporary, John Arderne, seem to have felt any embarrassment over pressing for as high a fee as possible. The former recommends that "The surgeon should pretend that he has no living nor capital except his profession, and that everything is as dear as possible, especially drugs and ointments; that the fee is nothing as compared with his services; and the wages of all other artisans, masons, for example, have doubled of late" (Hammond, p. 156). He considered it essential that the fee not be reduced too much. It would be better, then, to charge nothing.

In determining how much to charge, Mondeville recommends that the surgeon consider three things: "First, his own standing in the profession, then the [financial] condition of the patient, and, third, the seriousness of the illness" (Hammond, p. 156; Welborn, p. 356). It was the second of these that was probably the most trying. Mondeville advises the doctor not "to have too much faith in appearances. Rich people have a bad habit of appearing before him in old clothes, or if they do happen to be well dressed, they make up all sorts of excuses for demanding lower fees" (Welborn, p. 356). So strong, though, is the sense of obligation to succor the poor gratis, or at least to give the appearance of doing so, that physicians and surgeons probably were quite frequently faced with very difficult judgments.

The motivation of physicians and surgeons to extend charity to the poor was more than the advantages that might accrue to their reputation and to the honor of the profession; it was a product of enlightened self-interest, with eternal consequences, fully compatible with the theology of the time, as is succinctly expressed by Mondeville: "You, then, surgeons, if you operate conscientiously upon the rich for a sufficient fee and upon the poor for charity, you ought not to fear the ravages of fire, nor of rain nor of wind; you need not take holy orders or make pilgrimages nor undertake any work of that kind, because by your science you can save your souls alive, live without poverty, and die in your house" (Hammond, p. 156).

While some effect of the church's teaching is manifest in even Mondeville's fee policies, in other areas spiritual concerns are more evident. An anonymous twelfth-century Salernitan treatise advises: "When you reach [a patient's]

house and before you see him, ask if he has seen his confessor. If he has not done so, have him either do it or promise to do it. For if he hears mention of this after you have examined him and have considered the signs of the disease, he will begin to despair of recovery, because he will think that you despair of it too" (De Renzi, vol. 2, p. 74). This work was composed some time before Lateran IV of 1215, and thus before physicians were required "before all else to advise and persuade" their patients to call a confessor. The anonymous author of this treatise does not appear unusually devout. Indeed, were one to attach an adjective to the work, "eminently practical" would describe it better than any other. The author, of course, was a member of a society in which the belief in the necessity of confession before death was deeply ingrained. While he may not have considered it especially his own spiritual duty to look after his patients' spiritual as well as physical health, he must have considered the alternative of advising patients to confess only when in dire straits to be potentially dangerous to them.

The advice on confession, as it appears in a treatise attributed to Arnald of Villanova (late thirteenth century), is significantly different in emphasis from that in the anonymous Salernitan piece: "[W]hen you come to a house, inquire before you go to the sick whether he has confessed, and if he has not, he should immediately or promise you that he will confess immediately, and this must not be neglected because many illnesses originate on account of sin and are cured by the Supreme Physician after having been purified from squalor by the tears of contrition, according to what is said in the Gospel: 'Go, and sin no more, lest something worse happens to you'" (Sigerist, p. 141). This version, written after Lateran IV, quoting the same Scripture as the canon law, demonstrates the direct influence of a constitution of canon law on a strictly secular piece of medical literature, as does even more strongly the following passage in an anonymous plague tractate composed in 1411: "If it is certain from the symptoms that it is actually pestilence that has afflicted the patient, the physician first must advise the patient to set himself right with God by making a will and by making a confession of his sins, as is set forth according to the Decretals; since a corporal illness comes not only from a fault of the body but also from a spiritual failing as the Lord declares in the gospel and the priests also tell us" (Amundsen, 1977, p. 416). About a century earlier, similar advice had been given by Mondeville: "Do not let the patient be concerned about any business except spiritual matters only, such as confession and his will and arranging similar affairs in accordance with the rules of the Catholic faith" (Amundsen, 1986, p. 90). Whether these writings composed after Lateran IV are simply examples of lip service to ecclesiastical authority or reflect genuine approval of the underlying principle upon which the legislation was based must remain an open question.

An eleventh-century treatise advises that the physician should "never become involved knowingly with any who are about to die or who are incurable" (MacKinney, p. 23). Although from the earliest times such counsel was common, in the late Middle Ages it was becoming increasingly less so. The previously quoted anonymous Salernitan treatise from the twelfth century advises the physician, just before leaving, to "promise the patient that with the help of God you will cure him. As you go away, however, you should tell his servants that he is seriously ill, because if he recovers you will receive greater credit and praise, and if he dies, they will testify that even from the beginning you despaired of his health" (De Renzi, vol. 2, p. 75). Although this treatise may be described as eminently practical, it is not clear that this particular bit of advice is ethical.

A parallel passage in a treatise attributed to Arnald of Villanova (late thirteenth century) is nearly identical, with the significant difference that instead of promising the patient "that with the help of God you will cure him," which still leaves the matter in doubt and at least partially in God's hands, it advises more crassly that "you promise health to the patient who is hanging on your lips" (Sigerist, p. 142). This treatise appears to have been hastily thrown together from various sources, since elsewhere it flatly contradicts the advice that the physician should promise health to the patient. Later it suggests that the physician "must be … circumspect and cautious in answering questions, ambiguous in making a prognosis, just in making promises; and he should not promise health because in doing so he would assume a divine function and insult God. He should rather promise faithfulness and attentiveness …" (Sigerist, p. 141). For two such opposing pieces of advice to be found in the same treatise is unusual. Such conflicting opinions, however, are typical of medical ethics in the late Middle Ages. For example, Bernard de Gordon (thirteenth–fourteenth centuries) advised that if there was little likelihood of a patient's recovering, "One should try to escape from such cases, provided one can do so honorably" (Demaitre, p. 153). Nevertheless, he also expresses a concern to do everything possible to postpone the death of terminally ill patients.

William of Saliceto (thirteenth century) recommends that the physician should "comfort his patient, and on every occasion should promise him restoration to health, even if the physician himself shall regard the case as desperate." He justifies this on the grounds that this will greatly encourage the patient, increasing his chances of recovering. He further suggests that the physician "acquaint the friends of his patient with the truth, and discuss the case fully with them as he shall deem best, lest he incur scandal or loss of reputation

from inability to offer a satisfactory statement of the case, and lest the friends of the patient regard him with distrust: nor will he then be held responsible for having caused the death of a patient who shall die; but he will be given credit for having cured the man who lives and is restored to health" (Mirfeld, p. 122). William's reason for giving a favorable prognosis to the critically ill patient is strictly for the latter's benefit. He recommends that the physician tell the patient's friends the truth for the physician's own protection, a far different piece of advice from that in the two treatises previously discussed, which recommend that the physician, regardless of the patient's actual condition, advise those close to him or her that the case is dangerous and that the patient is not faring well.

Mondeville wrote that the surgeon "ought to promise a cure to every sick person, but he should refuse as far as possible all dangerous cases, and he should never accept desperately sick ones" (Welborn, p. 350). Physicians and surgeons were sometimes charged with the deaths of patients in the late Middle Ages, and the fear of facing blame for a patient's death still motivated some to recommend, as Mondeville did, that dangerous cases not be taken on. Mondeville, incidentally, writes at some length about how to ensure that a patient's friends or relatives can be compelled to exonerate the surgeon if a case should end in the patient's death (Welborn). Nevertheless, advice not to take on dangerous cases occurs much less often in late medieval sources than in the medical literature of ancient Greece and Rome. Instead, physicians are advised to protect themselves either by telling the relatives or friends of the patient that the situation is critical, regardless of the patient's condition, or to tell the truth in cases that actually are critical.

PLAGUE AND MEDICAL ETHICS IN THE LATE MIDDLE AGES. The devastating plague epidemics that periodically swept through Europe, beginning in 1348 and continuing well beyond the Middle Ages, tried and tested the ethics of medieval physicians far beyond conditions encountered in ordinary practice. Contemporary sources almost uniformly express the conviction that plague was extremely contagious. Merely being in the vicinity of the sick, many supposed, doomed one to become infected and die. Numerous sources describe parents deserting their dying children, children their parents, wives fleeing from their sick husbands, and husbands from their wives. All who could, fled the cities and towns to take refuge in the countryside. Not only were the sick deserted by their families; physicians would not come near them, and even priests would not meet the final spiritual needs of the dying. Such accounts are plentiful. But they must be set against abundant accounts of responsible actions by family members, magistrates, physicians, and clergy.

Some physicians undoubtedly did flee. In 1382 Venice stipulated that physicians who fled during epidemics would lose their citizenship. Barcelona and Cologne took similar action during the sixteenth century. While it is impossible to determine the extent to which physicians actually did flee from plague-ridden communities, the percentage was probably relatively small. A study of nearly three hundred plague tractates written by physicians between 1348 and the early sixteenth century found not even one allusion to physicians who fled from areas afflicted with plague (Amundsen, 1977). Medieval physicians were not at all timid in castigating their colleagues in writing. Vitriolic criticism, particularly of fellow physicians' theories and medical techniques, is found throughout the medical literature. If the flight of physicians had been extensive, then one should encounter among the plague tractates such statements as "Although many other physicians fled, I remained."

Many physicians did advise people to flee from plague-infected areas as the best form of prevention. This advice, however, was typically followed by the concession that since flight "rarely is possible for most people, I advise that, while remaining, you. …" Prevention is the primary concern of most of the plague tractates. Even if they are unanimous in urging flight, it does not follow that the physicians who wrote them intended by doing so to justify flight for themselves and their colleagues. The authors of the tractates appear simply to have assumed that their readers would be able to avail themselves of the services of physicians during plague epidemics.

Did physicians who fled, or who refused to visit and diagnose those perhaps afflicted with pestilence, or who abandoned patients actually suffering from plague, violate their responsibilities as conceived at that time? Contemporary sources make it abundantly clear that both the public at large and physicians themselves viewed those physicians who fled from plague as having acted disgracefully. In the mid-fourteenth century, Guy de Chauliac, at one time personal physician to the pope, wrote concerning his own activities during the Black Death, the earliest and most devastating of a long series of plague epidemics: "It was so contagious … that even by looking at one another people caught it …. And I, to avoid infamy, dared not absent myself but with continual fear preserved myself as best I could" (Campbell, p. 3). Faced with both extreme peril to themselves and with the knowledge of the extremely high mortality rate of plague victims, physicians found themselves in an ethical quandary. Chauliac wrote, "It was useless and shameful for the doctors, the more so as they dared not visit the sick, for fear of being infected. And when they did visit them, they did hardly anything for them, and were paid nothing" (Campbell, p. 3).

One tractate maintains that physicians "must treat the ill," and another that "they must treat or visit the ill" (Amundsen, 1977, p. 414). The difference between these two is very important. While the first holds that physicians must treat plague victims, the second asserts that physicians must treat or visit the afflicted. Physicians who fled from a plague-infected area or hid in fear obviously failed even to attempt to diagnose the condition. But if the sick were indeed afflicted with the plague (since not all who became ill during a time of plague were necessarily afflicted with the plague), did physicians have an ethical obligation to attempt treatment?

A basic feature of medieval medical and surgical guild ethics was an obligation to be available to treat the ill or injured of the community and not to abandon hopeless cases. To the moral theologians who wrote the confessional literature, the duty to treat and to stay with the patient was unequivocal, although they were considering normal conditions rather than the exigencies of plague epidemics. Physicians were ambivalent about whether to take on hopeless cases; so were authors of the plague tractates. During outbreaks of plague, some physicians viewed the disease as treatable and others as at least potentially curable. Many physicians felt compelled to investigate the various strains of plague and to seek ways both to prevent and to treat them. Many of the plague tractates discuss treatment, distinguishing among different varieties of plague and stressing their faith in the efficacy of their curative methods. Some physicians, however, considered all forms of plague to be incurable. Of course physicians had to visit the ill to determine whether they were suffering from pestilence. If the condition was diagnosed as plague, some physicians then sought to determine whether the patient was possibly curable.

A plague tractate composed in 1411 advises: "If the patient is curable, the physician will undertake treatment in God's name. If he is incurable, the physician should leave him to die, in accord with the commentary on the second of the aphorisms [probably a medieval commentary on *Aphorisms* II in the Hippocratic Corpus]. Those who are going to die must be distinguished by prognostic signs and then you should flee from them. He labors in vain who attempts to treat such as these" (Amundsen, 1977, pp. 416–417). A plague tractate written in 1406 suggests that physicians not immediately inform patients if their condition is diagnosed as hopeless. Nevertheless, the physician "should refrain from administering anything to the patient that will cause him to die quickly, for then he would be a murderer" (Amundsen, 1977, p. 417, n. 64).

Various contemporary lay accounts from the time of the Black Death accuse some physicians of hiding in their houses and refusing to visit the sick for fear of infection. The authors of many plague tractates, while advising the general public to avoid contact with those afflicted with plague, do not direct such advice to their colleagues. They recommend varied and imaginative prophylactic techniques for use when visiting plague victims. The variety and abundance of such recommended precautions show the extent to which many physicians thought they were effective; moreover, there are numerous artistic representations of physicians who employed prophylactic measures while visiting plague victims. Many tractates deal exclusively with prophylaxis because their authors feel that treatment must be left to the discretion of the physician handling the case. Those that do include a discussion of treatment generally express great confidence in the curative methods prescribed. Many introduce new methods claimed effective by physicians who say they have employed them.

Some people did recover from the plague, from some strains of the disease more than from others; and although such cases of recovery were often in spite of the treatments to which the patients had been subjected, the attending physicians would have thought that their techniques had indeed been effective. The success rate in medieval medicine was, of course, much lower than in modern medicine; hence the expectations of both physicians and the public were not nearly as high as those of the present. The efforts of physicians to combat and cure various strains of plague, as well as their attempts to educate people in prevention and treatment by writing plague tractates, graphically demonstrate a high level of ethical and professional responsibility.

Summary and Conclusions

The medico-ethical treatises of the early Middle Ages blend Hippocratic etiquette with Christian morality, particularly emphasizing compassion and charity. The high and late medieval treatises, while loyal to the traditional concerns of the genre, suggest a new pragmatism born of the realities of medical practice by secular Catholic practitioners in a society starkly different from that of the monastic ethos of the early medieval medical literature. Although no mention of guilds or universities appears in this later literature, its tone and emphasis demonstrate that its authors regarded the practice of the art of medicine as a privilege that required training and skill, and carried consequent responsibilities. While there is no direct articulation of physicians' obligations to their immediate community in this literature, the obligation to the Christian community at large—an obligation to extend medical charity to the poor and destitute—is implicit and sometimes explicit.

Treating dangerous and even desperate cases is not discouraged in the later literature nearly as often as it had

been before. Warnings against it are so infrequent, compared with advice on what to tell critically ill patients and their relatives or friends, that one may conclude there was a growing tendency to take on dangerous or even hopeless cases. But were physicians who in the late Middle Ages declined to treat patients for whom they foresaw little or no hope of recovery, still acting within the strictures of accepted ethics? This was a time during which popular attitudes toward physicians' responsibilities to the terminally ill were changing. Physicians who refused to treat patients were accused of deserting them because they thought they would not be paid for their services, while physicians who continued to treat such patients were suspected of greed for ministering to patients they know would not recover.

We see these two extremes illustrated by two sermons preached in fourteenth-century England. Lanfranc of Milan exclaimed, "O wretched physician, who for the money that you may not hope to get, desert the human body travailing in peril of death; and allow him, whom, according to the law of God, you should love and have most concern for, of all creatures under heaven, to be in jeopardy of life and limb, when you can and know how to apply a suitable remedy" (Owst, p. 351). John Bromyard, by contrast, asserted, "All craftsmen would at once refuse a job for which unsuitable materials were provided. If a carpenter were offered wages for the building of a house with planks that were too short or otherwise unsuitable, he would at once say: 'I will not take the wage or have anything to do with it, because the timber is of no use.' Similarly the physician who can see no hope of saving his patient" (Owst, p. 351).

Bromyard's sentiments were deeply rooted in tradition, but attitudes were changing. This change is very significant for the history of medical ethics. It seems to have been the product of two complementary and possibly related catalysts. The first is that the practice of medicine and surgery had been changed from a right to a privilege. A specific authority, whether royal, ecclesiastical, or municipal, granted to a select few the privilege of practicing in a specified, limited region. The authorities who granted what was essentially a monopoly also were ostensibly responsible for protecting that monopoly, and the privilege of holding a monopoly carried certain responsibilities, among them to service the sick of the community indiscriminately.

The second source of the growing tendency to take on dangerous or hopeless cases is the increasing theological insistence that physicians should do all they could to cure until the end, or nearly the end, and the church's support for their right to receive fees under such circumstances. One sees in the confessional literature the seeds of what was later to blossom into a medical duty to prolong life. The view is strongly articulated that physicians are religiously obligated to extend care to a rich miser even if he or she both resists treatment and refuses to pay. Some moral theologians also maintain that even if patients refuse to call a confessor, physicians must not desert them, since help must be given to those who are in danger, regardless of how stubborn they are. While this is still far from an imperative to prolong life, it is a significant change from earlier medical attitudes and practice.

This fundamental change in perceived responsibilities of physicians to their patients is illustrated by the acts of a late-twelfth-century and a mid-eighteenth-century pope, both of whom address the request of physicians to enter the priesthood. Clement III, in the late twelfth century, ruled that the physician in question should search his memory to ensure that he had never, even inadvertently, harmed a patient by any treatment that he had administered. In the mid-eighteenth century, Benedict XIV's ruling centered on the problem that physicians can never be entirely positive that they have consistently used every available means for patients who died under their care (Amundsen and Ferngren). The concern in the twelfth century was with harm perhaps inflicted actively on patients: "Did you ever harm patients by the treatment you gave them?" But by the eighteenth century, attention focused on harm that may have resulted from oversight: "Did you ever harm patients by failing to give them the treatment you should have given?" These two papal rulings highlight a fundamental change both in physicians' sense of responsibility to their patients and in social and religious expectations, a change that occurred primarily in the late Middle Ages.

We look nearly in vain in the medico-ethical literature of the late Middle Ages for statements on two topics of medical ethics: abortion and euthanasia. We cannot conclude from this that both theologians and physicians considered abortion and euthanasia ethical for physicians to perform. Indeed, the presumption is quite the opposite. Theologians and physicians alike took it for granted that both were sinful, so much so that their sinfulness need not be mentioned explicitly. Rather, it would seem that abortion was a procedure for which women would turn to someone other than a male physician or surgeon. Facilitating the death of a patient was undoubtedly so repugnant to medieval moral principles that to mention it as unethical for a physician to do would have been gratuitous, at least in a general treatise on medical ethics.

When the contents of the late medieval medico-ethical treatises are supplemented by guild ethics and the moral pronouncements of the theologians, as well as by the evidence of physicians' conscientious response to the outbreaks of plague, the picture that emerges is of relatively high ethical standards. Although "Hippocratic ideals" persisted throughout the Middle Ages and provided the basis for

medical etiquette, the role and responsibilities of physicians and surgeons were variously affected by Christian morality. This is particularly evident in concern for the gratuitous treatment of the poor, both by individual physicians and by professional associations. The discipline of moral theology provided distinct criteria for medical ethics from a late-medieval Catholic perspective. Secular law and medico-surgical organizations, including university faculties, established regulations and standards of competence for medical licensure, and guilds and university faculties set precise codes of conduct. Essentially, the creation of medical licensure, medical faculties, and professional organizations helped to formulate medical professionalism and ethics in a sense that is still very much present today.

II. RENAISSANCE AND ENLIGHTENMENT

Medicine in early modern Europe (from the later fifteenth century to the end of the eighteenth century) is best characterized by its diversity of practitioners, practices, and conceptual foundations. Even by the end of the eighteenth century, few places in Europe had effective regulations to restrict medical practice to people with certain kinds of certification, or to regulate their practices. University-educated practitioners differed sharply with one another about the true conceptual foundations of good and effective medical practice, while among the merely literate, or even the illiterate, practitioners, views about the constitution of good medicine varied even more.

Many medical changes occurred during the period: The number of university-educated physicians rose considerably, as did the number of other formally trained (usually apprenticed) practitioners. With the proliferation of schooling, the educational level of many ordinary practitioners rose. And while the beginning of the period was marked by the proliferation of various philosophical and medical systems, by the end of the eighteenth century most of those systems had been set aside by the educated elite in favor of varieties of a more unified "science."

Throughout the period, no formal systems of medical ethics existed per se. Yet medical practitioners took varying degrees of interest in ethical issues, issues that commonly focused on the personal character of the practitioner. The discussion of the period that follows is therefore divided into two parts: a description of the general structures of the period and the organization of medical practice; and the debates among the literate, and especially among the learned, over the foundations of good medical practice and behavior.

Social Structures of Medical Practice

European society underwent a major transformation from the fifteenth to the eighteenth century. Throughout the period, Europe remained an overwhelmingly rural region, and at times the population grew rapidly. And, because of demographic, economic, political, and intellectual changes, city life came to typify refinement. As a result, most of the great changes in medical practices and mores took place in the cities, although most of the people needing care continued to live in the countryside.

The vast majority of the people in Europe—nine in ten, or more, depending on when and where—lived in a rural environment: in small towns or villages, in hamlets, or on rural manors; a few even resided in the forests and fields. In the fifteenth century, many rural laboring people lived relatively well, since after the fourteenth-century plague (the Black Death), there was land enough for most. But during the sixteenth century, the European population increased rapidly (perhaps about 1 percent per year); it generally leveled off during the seventeenth and early eighteenth centuries; and late in the eighteenth century again began to increase rapidly. While at first, people could generally grow enough food for themselves and their landlords and a little extra, with the increasing population of the sixteenth century, the number of rural itinerant laborers and destitute began to rise rapidly (Flinn).

Ordinarily, rural people bartered with neighbors and used money only occasionally, relying on mental accounts of who owed what to whom. At local markets, though, they might purchase a few goods manufactured locally or imported from afar, and sell their own goods or labor. When they needed medical care, most ill people and those caring for them relied on practices long used: self-help; recipes for home remedies (or "kitchen physic") passed down through kin or neighbors; and other traditional practices that could be gathered from local people, which might include ritual and invocation (or what the educated sometimes called "superstitious" practices). Beyond the resources of neighbors and kin, the sick often had available to them the services of people with special knowledge or powers: clergymen, herb

wives, sorcerers or witches, and people who healed by special powers of touch. In return for medical help, payment might be in coin, but probably more commonly added a debt to the mental balance of favors, or earned the practitioner goods or services such as chickens or eggs, pasturing an animal on the patient's land, or the patient's help in doing certain chores.

In a few regions, however—mainly from northern Italy along the Mediterranean coast to southern Spain, in the Low Countries and northern France, a thin strip along the south edge of the Baltic, and in southeastern England—urban life was more common. In the fifteenth and early sixteenth centuries, people in towns and cities raised animals for slaughter, and sometimes kept a plot of ground nearby on which they grew food. But by the later sixteenth century, many towns were becoming too large and too densely settled for such practices. Much of the increasing population was drawn from the countryside into the cities or, later, pushed to the overseas colonies. Many people spent a part of their lives in a city working as laborers or servants, returning to their towns or villages after accumulating enough money to establish a family. Others migrated to the towns and cities permanently, causing a huge expansion of wealthy, middling, and poor neighborhoods. The largest city in Europe, Naples, soon had rivals in Paris and London. Just how brutal were the conditions of urban life has been vigorously debated; what is clear is that urban mortality and morbidity rates in the age before plumbing and sewerage were very high indeed.

The cities wrought important economic changes, especially a greater use of money. The demand for food among the urban populations also transformed nearby regions into centers of market agriculture where individuals or landlords produced cash crops. In some areas, such as southeastern England and the Netherlands, this agricultural revolution brought into being a free yeomanry; in other regions, such as Prussia and Russia, it brought about a reenserfment of the peasantry by great landlords. Whatever the local consequences, throughout Europe people increasingly grew used to buying and selling labor and goods, and to handling money; even rural laborers often had a few copper pennies at their disposal.

With the increasing importance of money as a means of exchanging value, more and more people supplemented their incomes by engaging in medical practice for money, or relied upon it entirely for their living. Many, undoubtedly most, such people offered their services to ordinary people, doing so in their neighborhoods or traveling to offer their services among strangers. If itinerant, they found their customers wherever gatherings occurred: markets, crossroads, taverns, inns, alehouses, coffeehouses, and even street fights. They might also gather a crowd by saying something interesting from a platform or from horseback, or by presenting an entertainment from a table, wagon, or stage: These people soon acquired the name of *quacksalver* or *quack* (a term of obscure origin), or *mountebank* (probably from climbing on benches).

With the spread of the printing press and the growth of literacy in the later sixteenth century, medical advertising could be used to heighten the practitioner's reputation or to attract more people to the shows. Medical advertising could also publicize the practice of someone who did not travel but practiced out of a shop, inn, or house. By the later seventeenth century, as the postal systems of many regions of Europe developed, advertisements could be sent to agents for posting throughout a region, and medical customers could order remedies through the mail. The medical practitioners who relied on such methods for their incomes might offer special services (like cutting for cataracts or bladder stones, or setting bones), or sell special remedies (what became known by the eighteenth century as "patent remedies") (Cook; Porter, 1989; Porter and Porter).

In the cities and a few large towns, craft guilds of medical practitioners came into being or expanded from their late medieval roots. Guilds had municipal charters allowing their members the rights and privileges of citizenship, and the group the right to act as a corporation: to stand as one person before the local courts, to own property, to pass internal rules regulating their members and organizing them by rank, and often to restrict certain practices to their own members. Throughout early modern Europe, guilds of barber-surgeons and surgeons, or groups of barber-surgeons and surgeons in other guilds, could be found. In general, guilds of barber-surgeons and surgeons restricted the use of instruments on the body to their members.

The barber-surgeons undertook barbering and minor operations, such as opening a vein to let blood, and were ordinarily among the lower-ranking members of the guild (Pelling). The surgeons, far fewer in number and generally among the higher-ranking liverymen, undertook major operations, such as amputating limbs, setting bones, repairing hernias and fistulas, extracting teeth, and tending to wounds, sores, and ulcers. Among the armies and navies of Europe, surgeons performed most of the general medical tasks, and the kinds of operations that could be successfully performed gradually increased. Consequently, the status and income of surgeons grew during the period, and they began to be increasingly trusted by monarchs to develop certain kinds of medical policies for their kingdoms or principalities (Temkin; Gelfand).

Another kind of medical craftsmen were the apothecaries, or pharmacists. Originally wholesale importers of spices,

by the early modern period many sold medicines from retail shops; some of the medicines they sold could be dangerous unless used under careful supervision. Many cities therefore had guilds of apothecaries, who were subject to rigorous municipal regulations. In the Scandinavian and Germanic lands, cities often restricted the selling of medicines to a very few official apothecaries, sometimes to just one. As their numbers increased, so did the tendency of apothecaries to give medical advice. It was from the surgeon-apothecaries that the general practitioners eventually arose (Loudon).

One other kind of medical corporation proliferated in the early modern period: that of the university-educated physicians, usually called a "college" (*collegium*) of physicians. Ordinarily, colleges of physicians had formal standing from a municipal or royal charter that gave members of the group sole right to practice "physic"—the giving of medical advice—in their city and the surrounding area. Regular members had to possess a university degree in medicine (by the sixteenth century, ordinarily Medicinae Doctor). The colleges of physicians ordinarily were not authorized to grant degrees (an important exception to this rule was the Faculty of Medicine in Paris, which had its roots in the medieval university; the professors of medicine of the university were elected from the Faculty). Independent colleges of medicine first came into being in several northern Italian cities, and by the early sixteenth century had spread to Spain, France, and England. By the seventeenth century, physicians in northern European cities like Amsterdam had established their own colleges. These colleges not only governed the physicians of a city but also, sometimes, took on other regulatory powers, such as inspecting the apothecaries' shops, examining apprentices in surgery and pharmacy, and even looking into the behavior of all local medical practitioners.

In the view of the learned physicians, a medical hierarchy should exist: the physicians at the top, governing the practices of the apothecaries and surgeons, and most other practitioners being outlawed. While this ideal could seldom be thoroughly enforced, physicians often worked to obtain its legal foundations from municipal or national governments. As an important part of their argument, they fostered the idea that physicians ought to be trusted more than other practitioners because of their learning, which not only gave them knowledge but also inculcated good character. Physicians spoke often of defending the "dignity" of their profession, and concerned themselves with cultivating the outward manners that would best exhibit their inward virtues.

A final medical institution must be mentioned, that of the city physician and, eventually, the physician or surgeon officer of state. In the later Middle Ages, on the Continent, some large cities began to revive the ancient tradition of employing a physician to see to the needs of the municipality. In return for an annual salary, the city physician treated poor citizens, advised on medical regulations (including plague orders), and often served in one or more of the municipal hospitals for the sick poor (if the city had any) (Russell). By the later sixteenth century, city physicians had become important officers of local government in many places. Moreover, as unified territorial states came into being in the seventeenth century, and sovereigns tried to impose more uniform codes of law and government, they, too, began to use medical advisers to help them govern. Given contemporary international competition, princes deeply felt the need to try to increase the general wealth and power of their countries. Part of their domestic policy therefore was concerned with bettering the health of the public and increasing the population. To do so, sovereign rulers frequently tried to co-opt existing medical corporations or to establish new ones.

In central Europe, by the later eighteenth century, medical advice had become important enough to government that the phrase "medical police" (meaning medical policy promoted and enforced through government agents) had become a common topic in discussions about the structure of state institutions (Rosen; Hannaway; Jordanova; Fischer-Homberger). But associating themselves with magistrates and government might give physicians and surgeons more authority among those who supported the government; it also might make them more subject to criticism during periods of public unease. The revolutionaries in France, for example, demolished most formal medical institutions during the mid-1790s.

With a rising population, increased urbanization, the spread of the market economy, greater literacy and formal education, and the development of nations, the significance of medical help outside networks of kin and neighbors increased. These changes had many implications for those who practiced medicine. With regard to the gender of the practitioner, for example, women seem to have dominated the practice of traditional medicine, while it was predominantly men who flourished in the commercial medical market (although not to the total exclusion of women). When it came to medical guilds, outside of Italy, memberships were generally limited to men or to the widows of members. Since virtually all European universities excluded women from receiving degrees, nearly all medical doctors were men. In the eyes of the governments, if not always in the eyes of the public, a group who recognized themselves as professional men sat at the top of the medical hierarchy: the physicians, and gradually the surgeons. They obtained many new mechanisms of medical regulation from the state (for example, the French crown established a new College of

Surgery in Paris in 1750, and a Royal Society of Medicine in 1776), and increasingly tried to regulate all other practitioners. They could not always succeed in imposing medical order on society, but their professional ideals were influential.

Debates about Medical Practice and Practitioners

Because the increasingly literate and monied public of the towns and cities had a host of medical practitioners from whom to choose, the medical professionals could not impose their ideals on others. While noble and wealthy patients often consulted physicians, they often also consulted surgeons, apothecaries, "quacks," and traditional healers. Without a single, inclusive medical profession and firm regulation to govern practitioners or establish uniform requirements for their training, patients could pick and choose the kind of medicine they preferred, as long as they could pay for it or obtain it through charity. Consequently, medical practitioners cajoled and persuaded their paying patients to do what they considered right (Jewson; Porter, 1985). (Those they helped through charity could take what was offered or go without.) As a result, the various medical groups, even the physicians, had few clear ethical codes on how to treat patients that were distinct from general sentiments. Notions of virtue and good behavior existed everywhere; concepts of "medical ethics" per se were few (Waddington).

The humanist movement of the Renaissance brought to light a plethora of ancient philosophies of nature, each with its own ethical foundations. Renewed Aristotelianism, Platonism, Stoicism, Epicureanism, Hermeticism, and Hippocratism: Among the learned, each had its medical adherents. When modern natural philosophers began to take precedence over the old, physicians of a Baconian, Cartesian, or Newtonian stripe often adopted moral notions consistent with their philosophical system. For instance, with a renewed interest in Hippocratism came a renewed interest in the Hippocratic Oath (Smith); with the spreading of Cartesianism came a hard-hearted attitude toward the use of living automata (animals) in bloody experiments (Guerrini). But none of these philosophical positions was solely medical, and so none of the ethical implications were strictly medical. The physician took no more and no less interest in the ethical implications of the natural philosophy he adopted than did any other learned person.

Moreover, it is possible to discern some of the general public's ideas of ethical medicine. One can see such general notions at work in the plague. During the first outbreaks (from the mid-fourteenth century), the best advice on avoiding the pestilence that a practitioner could give or take was to "flee fast and far." But as magistrates worked to prevent or ameliorate epidemics, in part by working with city physicians, a sense that the legally privileged physicians ought to help in times of crisis grew up alongside older notions of charity and self-sacrifice (Amundsen). By the seventeenth century, colleges of physicians suffered public embarrassment when many of their members (even those who held no public office) left town during an epidemic. In the London plague of 1665, for instance, many of the physicians' rivals, especially the chemical physicians, gained the respect of the public by staying and treating victims of the plague, showing by this disinterested public service that they ought to take precedence over the cowardly physicians. For whatever reason, the public was beginning to expect higher standards of behavior from medical practitioners than from all but a few others.

Another place where public notions of ethics in medicine can be found is in the general sense that physicians should not be overly commercial. Journals of literate sentiment, like *The Spectator* or *Gentleman's Magazine* (both of London), made fun of medical commercialism. For their part, physicians generally tried to avoid becoming personally involved in public medical disputes, frowned on advertising their practices or medicines as beneath the dignity of their calling, considered fee splitting and the taking of part of a fee in advance as "quackish," and even began to accept "honoraria" instead of fees. They also continued to treat without charge some of the poor who sought their help and, when they took up hospital posts (where they saw the sick poor inmates), received no fees for their once-a-week (or so) visits. Such general notions of good and charitable behavior, ordinarily shared between patient and practitioner, underlay the more detailed treatment of medical etiquette in the statutes of the various medical corporations.

The topics of more specific debate about moral medical behavior in the early modern period included what constituted the best medical learning; what kind of person made a good practitioner; what kinds of people ought to be prohibited from practice; and what medical practices should be encouraged and which discouraged. Debates about each of these topics could hardly be separated from the others, however, since they all surrounded what might be called the early modern equivalent of "virtue" ethics.

The two most numerous kinds of documents regarding early modern medical practice illustrate how interconnected were ideas about good practice and good character. One kind is the internal regulations of medical guilds and colleges of physicians. The statutes of the London College of Physicians, Society of Apothecaries, and Surgeons' Company, for instance, governed the behavior of the members closely but had almost nothing to say about medical practice per se. (One of the few explicit prohibitions in the College statutes

is against making prognoses from the inspection of urine alone; the practices of "urine-casters" came in for much scathing comment from physicians in the early seventeenth century.) In drafting the statutes of the College of Physicians, the officers devoted much attention to whether and in what kinds of cases members might consult nonmembers, how members should behave during consultations, what the order of precedence would be during meetings and on ceremonial occasions, how they should write prescriptions, and so on, all trying to maintain the dignity, gravity, and exclusivity of the group. The same is true of the College of Physicians in Amsterdam, and colleges elsewhere in Europe; and it is equally true for guilds. One sees the same concern with character in the record of whom the London College of Physicians tried for medical misbehavior: They rarely distinguished between illicit practice and malpractice, insisting that in their examinations for membership, applicants had to show that they were the right sort of people in character as well as in knowledge, anyone else being de facto and de jure incapable of practice.

The second major class of historical documentation discussing the foundations of good or ill medical practice is the antiquackery tracts that proliferated during the early modern period. In them, physicians and others discussed practitioners' behavior far more than their medical practices. In England, perhaps the best-known early piece of antiquackery literature is by John Cotta, who passionately condemned the multitude of nonphysicians: empirics, women practitioners, fugitives, jugglers, quacksalvers, practicing surgeons and apothecaries, practicers of spells, witches, wizards, the servants of physicians, "the methodian learned deceiver or hereticke Physition," beneficed practitioners, astrologers, urine-casters, and itinerants (Cotta).

Cotta not only condemned the ignorance and bad practices of such people, he condemned above all their undisciplined characters. He explained how even good remedies cause harm when recommended by those who do not possess the learning, and hence the virtue, of physicians (Cotta, pp. 2–8). As one of his contemporaries noted, because learning and character were so closely associated, ignorance in medical practitioners could be recognized by bad behavior: "loquaciousness," "haste" in judging diseases and promising cures before the cause had been ascertained, "forwardness" in condemning and slandering proper physicians, and "boastfulness" about their own skills (Dunk, pp. 20–21). These behaviors exhibited by empirics were not tests of their knowledge but demonstrations of their indiscipline: outward signs of an inward character. Character had so foundational a role in medical practice because, as Cotta explained, "the dignitie and worth of Physicks skill consisteth *not (as is imagined commonly) in the excellence and preheminence of remedies, but in their wise and prudent use*" (1612, p. 7; emphasis added). Wisdom and prudence could be built only on the coupling of solid learning with good character. Similar works on how the good physician alone could exhibit proper medical behavior can be noted throughout early modern Europe: Gabriele de Zerbi's *De cautelis medicorum* (1495); Laurent Joubert's *Erreurs populaires* (1578); Govanni Condronchi's *De Christiana ac tuta medendi ratione* (A Christian and Careful Manner of Healing, 1591); Rodericus à Castro's *Medicus-politicus* (The Responsible Physician, 1614); Paolo Zacchia's *Questiones medicolegales* (1621); and Friedrich Hoffman's *Medicus politicus* (1738).

In countering the links made by physicians between learning and virtue, other practitioners discussed their own notions of the sources of good character, frequently arguing that it came not from academic discipline but from an inner light. Since all knowledge ultimately stemmed from God and God's creation, they argued, their direct apprehension of things through experience and a properly prepared intuition made them the possessors of a more immediate wisdom than that of the pagan- and Islamic-influenced university physicians (as they often put it). Such arguments had been put forward forcefully by the influential chemical physician Paracelsus in the early sixteenth century; by the seventeenth century, these views had spread widely among medical chemistry's advocates (Debus; Webster).

Not only chemists but also many nonphysicians took the same view about godly practice. For instance, the Swiss Protestant surgeon Gulielmus Hildanus Fabricius wrote:

> Though godlinesse be needfull for all sorts of men, yet it is most requisite in such as practise Physick, for God Almighty doth often abate the power of the Medicines, when he which administers them, is an ungodly and blasphemous man: and contrariwise, doth give wonderfull power to things despicable and vile, when they are administered by good and godly Physitians. (Fabricius, pp. 53–54)

Given the deep and bloody struggles over religion in the early modern period, comments about character and godliness divided people. Fabricius's ideas about the personal godliness of the practitioner affecting the efficacy of his medicines is quite different from the learned physician Cotta's view that even good medicines used by the unlearned could cause harm. Different kinds of medical practitioners had very different views about the inner qualities necessary for good practice, and how those qualities could be acquired. For a good Anglican like Cotta, or for his professional colleagues in all orthodox churches, sentiments about intuition and inner light such as Fabricius's smacked of dangerous religious "enthusiasm" (the sense of being inspired directly by God); for practitioners like Fabricius, linking

virtue with higher education could only reinforce the position of the "dogmatists" (those who privileged reason over intuition and experience).

By the later seventeenth century, however, many physicians, too, had come to accept the importance of learning from experience, although they continued to believe that it had to be coupled with a disciplined and knowledgeable mind rather than based on intuitions. The scientific revolution had introduced notions that associated virtue with knowledge as much as (or even more than) dignity, and associated knowledge with experience (or, in English, "experiment") rather than learned debate (Shapin and Schaffer). The "virtuosi" of Europe launched detailed investigations into things, finding the best evidences of God not in human testimony and argument but in creation itself. Consequently, by the eighteenth century, many physicians, as well as surgeons, apothecaries, and empirics, placed great weight on furthering curative and preventive medicine through scientific trials.

The foundation for experiments such as James Lind's work on scurvy, or William Withering's on digitalis, or Lady Wortley Montague's on smallpox inoculation and Edward Jenner's on vaccination, or Antoine Mesmer's on "animal magnetism," had been "folk" custom. Ignoring what they considered the superstitious explanations of what happened, and concentrating instead on the material causes and consequences of various practices, such medical investigators throughout Europe explored new medicaments and treatments. In this enterprise, surgeons and apothecaries, and even unlicensed ordinary practitioners, could make contributions equal to those of physicians. Debates among medical practitioners still implied notions of who might be the best sort of person; but as the nineteenth century loomed, medical debates focused increasingly on what might be the best treatment rather than who might be the best treater.

Conclusion

Throughout Europe in the early modern period, one finds implicit and explicit notions about what constituted a good medical practitioner. Given prevailing public ideas about morality being linked first to character and only second to behavior, the question of *who* ought to practice *what* dominated medical debates. Oral codes and written rules governing medical etiquette proliferated, while people devoted relatively little attention to what we might consider medical ethics per se in the rules of good practice. Without a united and powerful profession, no group of medical practitioners could hope to universalize their own rules, although they often tried. Instead, they had to abide by the ordinary notions of virtue and morality held by their peers and the public. Notions of public and private virtue could be vigorously contested and undoubtedly affected the behavior of practitioners, but they were seldom strictly medical.

III. NINETEENTH CENTURY. A. EUROPE

In the course of the nineteenth century, medical ethics was profoundly transformed in European countries. Social, political, economic, professional, and scientific developments influenced the relationship of physicians to their patients, to their colleagues, and to the state. Focusing on continental Europe, this article first briefly characterizes medical ethics in the eighteenth century and then discusses its transformation after 1800, in connection with the evolution of the medical profession, public health and social medicine, and medical science. Most examples are drawn from Germany and France, where debates on ethical issues in medicine became particularly intense. The codification of medical morality was based on different models in these two countries. While in the German states (and to some extent also in Spain) medical ethics was clearly influenced by the early Anglo-American professional codes, in France national traditions of codes of honor in nineteenth-century bourgeois society appear to have shaped doctors' rules of conduct.

The Gentleman Doctor

Medical ethics in the eighteenth century was determined by the personal integrity and gentlemanly manners of the physician. His moral decisions were generally based, not on written rules of conduct of a college of physicians, nor directly on the Hippocratic code, but mainly on his medical knowledge, reasoning, and an internal code of honor. Enlightenment natural law theory, as developed by Samuel Pufendorf and Christian Thomasius, may have contributed to this approach. It encouraged a morality based upon rational reflection and individual conscience, rather than upon religious and ecclesiastical precepts (Geyer-Kordesch, 1993b). Eighteenth-century doctors usually treated only a small number of wealthy patients, leaving the majority of the population to the care of barber-surgeons (trained by apprenticeship), midwives, and diverse lay healers. Physicians, like their patients, felt bound to the traditional Platonic and Christian virtues of wisdom, moderation, courage, justice, and faith, hope, charity, as well as to bourgeois Enlightenment virtues like order, cleanliness, and industry (von Engelhardt, 1985).

In the German-speaking world of the eighteenth century, particularly in Prussia, modern professional ethics began to take shape within the academic discipline of medical jurisprudence. Physicians who were called on to give expert testimony on legal cases (e.g., consummation of marriage, paternity, infanticide, murder, poisoning, assault) were exhorted to build their statements truthfully on empirical findings, to admit uncertainty in medical evidence, and to behave with dignity (Geyer-Kordesch, 1993a, 1993b). At some universities, such as Halle and Göttingen, graduating physicians had to take vows of faithfulness to and respect for the academic institutions, careful and rational treatment of poor as well as rich patients, and medical confidentiality (Helm). Ethical demands like these helped physicians distinguish their conduct from that of quacks.

Social and Professional Change

The industrial revolution, urbanization, and pauperization shaped new forms of medical care during the late eighteenth and the first half of the nineteenth century. The migration of working people to the industrial regions led to an expansion of hospital medicine. Towns created publicly funded posts for physicians to treat the registered poor (i.e., those who were officially entitled to financial support from the municipal poor-relief fund). Accordingly, doctors were now confronted with a much broader range of patients, especially from the lower classes. At the same time, medical education began to require the acquisition of practical skills in surgery and obstetrics. Surgery was integrated as an academic discipline, and eventually the occupation of barber-surgeons was abolished.

Doctors became involved in public health through campaigns of smallpox vaccination, which was made compulsory in several European states as early as the first third of the nineteenth century, for example, in Bavaria (1807), Sweden (1816), and Württemberg (1818). Other states (e.g., France and Prussia) tried to support their national vaccination programs with a combination of encouragement (bonus paid to parents per vaccinated child, cash prizes and medals for vaccinators), constraint (refusal of welfare benefits to parents of unvaccinated children), and education (La Berge).

In France a public-health movement coalesced in the 1820s, in which "hygienists" of various professional backgrounds (physicians, pharmacist-chemists, engineers, veterinarians, and administrators) made efforts to solve common health problems by undertaking scientific investigations into their causes. Pioneering studies in occupational and industrial hygiene were carried out by the leaders of this movement, the physicians Alexandre Parent-Duchâtelet and Louis-René Villermé. Differential mortality studies by Villermé and the statistician Louis-François Benoiston de Châtauneuf further demonstrated a strong correlation between standard of living, and health and longevity. Following the model of the Paris health council (founded in 1802), *conseils de salubrité* were soon formed in other French cities and departments to advise prefects and mayors in regulating public health. Some hygienists, especially Villermé, saw themselves as moral reformers who would enable workers through better material and environmental conditions to emulate the values of the middle class (La Berge).

As the connection between bad living conditions and disease became more and more obvious—particularly after the onset of cholera epidemics in Europe beginning in the 1830s, and through the experience of the typhus epidemic in parts of Silesia in 1848—liberal physicians such as Rudolf Virchow argued for the social character of medicine and recognition of the doctor as an "advocate for the poor" (Ackerknecht).

In this period of social and professional change, physicians' concern about medical competition and secure incomes deepened. The breakdown of the so-called patronage system, in which a doctor's services were remunerated by the patient with a voluntary lump sum at the end of the year, raised debates about new models of payment that could maintain the dignity and independence of the physician and defuse competition. The concept that all practitioners should become medical officials (employees of the state)—an idea originating from reform proposals of the French Revolution—was discussed in France and Germany, and was temporarily implemented in the German duchy of Nassau (Brand). An 1823 proposal to found societies of physicians that would collect and redistribute fees, suggested by the Bonn clinician Christian Friedrich Nasse in a monograph *Von der Stellung der Ärzte im Staate* (On the Position of Physicians in the State), was apparently not realized (Nasse). Instead, Russia, Prussia, Hanover, and Bavaria instituted a policy of limiting the number of licensed physicians during the first decades of the nineteenth century. Some medical ordinances, for instance, those of Baden (1807) and of the canton of Zurich (1821), made licensing as a physician contingent on a number of ethical obligations, such as helping patients at any time irrespective of their social status, being discreet, and continuing one's medical education (Anner; Brand).

Duties and Rights

Increasingly, doctors wrote about the duties entailed by their profession, often using the expression *deontology* (science of duty), a title that is still sometimes found in European literature about medical ethics. In 1831 the Spanish physician Félix Janer published a book *Elementos de moral médica,* which dealt with the "dignity and importance" of the medical profession and examined the doctor's relations to the patient, within the profession and to other healers, and to the state and law. Being strongly influenced by the *Lectures on the Duties and Qualifications of a Physician* (1772) of the Edinburgh professor of medicine John Gregory, Janer adopted the Scotsman's demand that medical men show temperance, sobriety, firmness of character, humanity, and candor. Interestingly, he also extended these moral requirements to surgeons. These developments in Spain occurred in the context of arising competition and disputes over competence between traditional university-trained physicians (*médicos puros*) and new *médicos colegiales,* who from 1827 on began to graduate from colleges for medicine and surgery. These institutions granted the title *médico-cirujano,* which gave access to hospital positions. Janer himself was involved in teaching these future "medico-surgeons," eventually becoming director of the Barcelona College. Not surprisingly therefore, he defended the unity of medicine and surgery and pleaded for harmonious relations between the two types of medical practitioners (Ortiz Gómez et al.).

Other important examples of literature on medical deontology from the first half of the nineteenth century are Christoph Wilhelm Hufeland's "*Die Verhältnisse des Arztes*" ("The Relationships of the Physician," the last chapter of his authoritative manual of medical practice, *Enchiridion medicum,* 1836; ten editions until 1857; English, 1842) and Maximilien Armand Simon's *Déontologie médicale* (1845; Spanish, 1852). Like Janer, both these authors dealt with the relationships and ethical duties of the doctor to colleagues, to patients, and to society. Simon added a part on the moral

rights of physicians, including a right to political activity, especially in the reform of laws pertaining to public health. Here Simon differed from Hufeland, who wanted to keep physicians out of any involvement in politics, permitting them only to educate the public on rational behavior in matters of health and disease. Both Hufeland and Simon described altruism as the central moral principle of the medical profession. For Simon, Christian faith formed the undisputable basis of this altruism and of all specific duties of the physician.

Both physicians' renewed admonition to care equally for the rich and the poor reflects the larger social spectrum of patients, as compared to the eighteenth century. Simon welcomed the "now multiplied" number of hospitals and dispensaries for the sick poor, yet warned his colleagues, as did Hufeland, not to abuse this group of patients for harmful scientific experiments. On the question of euthanasia, both physicians stressed that the sufferings of the dying should be alleviated, if necessary by a liberal use of opium, but that any life-shortening measures were strictly forbidden, even if the patient demanded them. Hufeland feared dire consequences for society if the physician once transgressed the line by judging the necessity of a human being's existence; Simon advanced the religious argument that man is not the master of his life. These statements were in keeping with those of the Göttingen professor of medicine Carl Friedrich Heinrich Marx, who had discussed the topic in detail in his inaugural lecture *De euthanasia medica* (1826). They expressed a general point of view within the medical profession that remained undisputed until the end of the nineteenth century.

Contemporary problems involving competition among doctors are reflected in Hufeland's strong plea for cooperative conduct—"Disparaging a colleague means disparaging the art and oneself!" (p. 906)—and in his discussion of proper behavior during joint consultations, a topic treated in 1798 by the Hanoverian court physician Johann Stieglitz in a monograph *Über das Zusammenseyn der Ärzte am Krankenbett* (On the Meeting of Doctors at the Bedside). In cases of malpractice, however, Hufeland exhorted his profession to set greater store by the "saving" of the patient than by consideration for the colleague. Difficulties with the transition of medical practice from a gentlemanly calling to a modern, economically oriented profession are evident in Simon's energetic defense against the reproach that doctors were guided by commercial interests.

Codification and Control

For physicians in the states of the North German Confederation, and soon for those of the whole German Empire, the trade ordinance of 1869 became an important step in that transition. It defined medical practice as a trade that anyone could exercise (*Kurierfreiheit*), yet granted legal protection of the title *Arzt* (physician). It abolished the doctor's duty to help any patient in case of "urgent danger," which had been included in the Prussian penal code in 1851 and was regarded by many physicians as a coercion to provide treatment. The trade ordinance intensified the resolve of academic, state-certified physicians to distinguish themselves from lay healers by establishing professional societies.

In 1873, two years after the foundation of the German Empire, an association of German societies of physicians (*Deutscher Ärztevereinsbund*) was formed. Its main activities consisted of representing professional and economic interests. Many societies of physicians had codes of appropriate conduct, some of which were modeled directly on the code of ethics of the American Medical Association (AMA) of 1847, and thus basically on Thomas Percival's *Medical Ethics* of 1803. The disciplinary powers of those societies were limited to their own members, however.

In contrast to this, the so-called chambers of physicians (*Ärztekammern*), founded in German states beginning in the mid-1860s, formed state-controlled medical courts of honor, which were given authority to punish professional misconduct by all physicians in the respective district (except army doctors and medical officials, who were under the direct control of the state). Once created, the medical courts of honor seem to have been very active. It has been estimated that they engaged in more than 3,000 proceedings between 1904 and 1909 in Prussia, which at this time had about 15,000 physicians who were not employed by the state or the army. Most proceedings dealt with charges of misconduct in medical competition, such as unlawful advertising, underbidding other doctors, disparaging colleagues in the presence of laypeople, and unauthorized use of specialist titles (Huerkamp).

This German path toward well-organized intraprofessional self-control, authorized by the state, contrasted with developments in France. Here, the formation of medical professional organizations was hindered by postrevolutionary legislation that followed the principle of liberal individualism. The Le Chapelier law of 1791 prohibited members of the same occupation from forming organizations that would promote their common interests, and in 1810 associations of more than twenty people formed without approval of the government were forbidden. Physicians were subject to legal responsibility for malpractice: Harm to a patient was a tort, as defined by the civil code of 1803, and was also punishable as a criminal offense under some articles of the penal code of 1810 (Ramsey).

The "medical marketplace" of early-nineteenth-century France, however, led to proposals for additional disciplinary provisions. Legislation in 1803 had established the first uniform licensing system for medical practitioners in the whole of France, distinguishing "doctors of medicine" and "doctors of surgery," *officiers de santé* (health officers), and certified midwives. While the doctors were required to have studied at least four years at a medical school, health officers could qualify after three years' study but also by serving six years under a doctor or five years in a hospital. Unlike doctors, the *officiers*, destined to provide constant medical care for the rural population, were permitted to work only within the *département* that had given them license to practice. On the one hand, these legal requirements drew a sharp line between regular, licensed practitioners and irregular healers, such as itinerant quacks, sedentary empirics (vendors of special remedies), and folk healers, who could now be prosecuted for illegal medical practice. On the other hand, the institution of health officers, who represented a class of less-well-trained physicians, created fears of a lapse in standards and professional decline among doctors. Moreover, economic need caused many regular practitioners to collaborate with unqualified empirics, to promote their own proprietary medicines, or to offer special cures. In these circumstances, medical reform commissions from 1812 onward repeatedly suggested the establishment of "chambers of discipline" or "medical councils," whose jurisdiction would include both illegal practice and professional misconduct. None of these proposals was put into action, however, partly because they were linked to the controversial question of reforming the institution of health officers, and partly because many doctors did not wish any further intervention by the state. In 1892 legislation abolished the title of *officier de santé,* as well as that of "doctor of surgery" (Ramsey).

Beginning in the 1850s, the number of physicians relative to the population grew steadily in France, leading to still fiercer competition and precarious incomes. In addition, legislation between 1874 and 1905 imposed new duties on French doctors, such as treating poor patients in return for a moderate state remuneration, testifying as experts in courts, and surveying the standards of public health (e.g., quality of water supply, housing conditions). In the 1880s, in response to these developments, doctors began to form medical unions (*syndicats*) to promote their professional interests. Initially illegal but tolerated, the *syndicats* were legally recognized in 1892. The ultimate aim of their most radical members was to create an obligatory *Ordre des Médecins,* analogous to the *Ordre des Avocats* for lawyers (founded in 1810). Such an order did not emerge; Both the government and a majority within the medical profession opposed it. But in an attempt to set ethical standards for doctors, to regulate intraprofessional relationships, and to form a unified front toward the public, the medical syndicates adopted deontological statutes that were binding on their membership.

These syndical deontologies were modeled upon the male honor codes of bourgeois social and recreational societies (*cercles* or *sociétés à plaisance*), which flourished in mid-nineteenth-century France (Nye, 1993b). Like these societies, the syndicates regarded the personal honorability (*honnêteté*) of their members as essential and had a policy of solving internal conflicts *intra muros* (i.e., without recourse to the courts). Members were obliged to report cases of malpractice to the *syndicat,* which had the right to withdraw membership. In this context, the old idea of "chambers of discipline" was taken up again, for example, by the medical syndicate of the *arrondissement* of Avesnes, which prescribed the formation of such a "tribunal of honor" in its statutes of 1910 (Nye, 1993a). Generally, however, the disciplinary powers of French professional organizations remained relatively weak throughout the nineteenth century, compared to those of their counterparts in Germany, Britain, and the United States (Ramsey).

In 1900 the Paris medical syndicate organized an international congress on "professional medicine and medical deontology," at which key speakers proposed that the problems created by overcrowding and competition should be solved through "confraternity" and "the force of moral law." Many French treatises on medical deontology, published around the time of the congress, reflected the same demands. They furthermore insisted on medical confidentiality to protect not only the privacy of the patient but also the reputation of the profession. Accordingly, the medical syndicates in the 1890s resisted requirements of the public-health legislation to divulge the names of patients with contagious diseases, whereas doctors in the first half of the nineteenth century had done so freely during smallpox and cholera epidemics (Nye, 1993a).

Controversial Issues

In the second half of the nineteenth century, ethical issues arising from developments in preventive medicine, medical science, and hospital medicine became topics of intraprofessional as well as public debate in several European countries. Following the introduction of compulsory smallpox vaccination in the German Empire in 1874, the many newly established antivaccination societies agitated intensely until World War I. Refusal to have one's children vaccinated was

based mainly on reasons of conscience resulting from individual weighing of benefits and risks. In part, the reasons also reflected a protest against the restriction of personal freedom in matters of health (Maehle, 1991). This aspect had surfaced as a problem already around 1800, when Johann Peter Frank, then director general of public health of Lombardy (Cisalpine Republic), proposed universal state-controlled health care in his *System einer vollständigen medicinischen Polizey* (Haun). Antivaccinationism was basically a medical lay movement. Societies against vaccination were guided by academics and few physicians, who were influenced by ideas of natural healing (through water cures, diet, exercise, sun, and fresh air) and social hygiene. The same was true for the organized antivivisection movement (Maehle, 1993), which emerged as a result of the increasing scientific use of animals associated with the rise of experimental physiology (Claude Bernard, Carl Ludwig), pathology (Virchow), and bacteriology (Louis Pasteur, Robert Koch). Antivivisectionist activities, imported from Britain in the 1860s, were particularly strong in Tuscany, Germany, Switzerland, and Sweden (Rupke). A general antiscientific and antimaterialistic attitude was often behind the overt argument that animal experiments were useless cruelties (Maehle, 1993).

The growing importance of hospital medicine, reflected in the large clinics of Vienna and Paris in the first half of the nineteenth century, combined with the progress in medical science, brought the ethical problems of human experimentation into the foreground. In 1880 the courts of Bergen, Norway, sentenced Gerhard Armauer Hansen, the discoverer of the leprosy bacillus, for inoculating a female hospital patient suffering from a particular type of leprosy with leprous material from another patient (with a different type of the disease) without prior information or consent (Vogelsang). Albert Neisser, professor of dermatology in Breslau, was fined in 1900; hoping to induce immunity against syphilis, he had injected syphilitic blood serum into eight uninformed female hospital patients (three children and five prostitutes) in 1892. These and other cases stimulated intensive public debate, which—like the vivisection controversy—often had antiscientific and anti-Semitic undercurrents. Prevented from careers in the German civil service, Jews were strongly represented in the so-called free professions, such as medicine or law. In medical university careers, doctors of Jewish origin tended to concentrate in the experimental disciplines (physiology, pharmacology, immunology) and the new specialty of dermatology and venereology, because they could hardly find entry to the prestigious "classic" professorships in internal medicine and surgery. Anti-Semites advanced propaganda arguments that animal and human experimentation was an expression of "Jewish materialism" (Elkeles).

A concrete consequence of the debate on human experiments was a decree by the Prussian Ministry of Education in 1900 that required informed consent of the research subjects and prohibited scientific experimentation on minors and other persons who were not fully competent (Grodin).

New ethical challenges also emerged with the passage in the German Empire of the Health (1883), Accident (1884), and Retirement and Disability (1889) Insurance Acts; the scheme was soon copied by Austria (1888), Hungary (1891), Luxembourg (1901), and Switzerland (1911). The task of certifying sickness and disability placed physicians between the often conflicting interests of patients and insurance companies. Medical insurance tended to strengthen the patient's position; doctors began to complain that patients behaved as if they were their employers (Brand). On the other hand, insurance companies owned by factories could serve as a means for the social control of working-class patients (Frevert). For physicians the insurance scheme created hopes of economic improvement. In the long run, however, it heightened medical competition by drawing an increasing number of individuals into the profession.

Teaching Medical Ethics

Against this background, the proposal to include medical ethics in the curriculum for medical students was debated in Germany during the 1890s. At an 1898 conference on internal medicine at Wiesbaden, those who argued that an ethical attitude must be inculcated by the family, not at the university, and that ethics could not be subdivided according to the different professions, won the day. Yet the debate generated a spate of books that advocated the teaching of medical ethics. The Berlin medical historian Julius Pagel published a *Medicinische Deontologie* for prospective medical practitioners in 1897 (Pagel), the Wiesbaden physician Oswald Ziemssen, cousin of the renowned clinician Hugo von Ziemssen, a monograph *Die Ethik des Arztes als medicinischer Lehrgegenstand* (The doctor's ethics as a medical teaching subject) in 1899. Pagel gave a great deal of space to cooperative behavior among medical colleagues, demanded solidarity in cases of professional error, and advised doctors to act with self-confidence when seeing patients. Furthermore, the doctor should take care not to speak familiarly with members of the lower classes. Ziemssen built his book on codes of German societies of physicians and above all on Jukes de Styrap's *A Code of Medical Ethics* of 1878 (de Styrap). To some extent, he also drew on German

philosophical traditions, arguing that the ethics of the physician were based on a combination of Immanuel Kant's categorical imperative, Arthur Schopenhauer's voice of feeling, and Johann Friedrich Herbart's practical judgment.

Contemporary philosophers, such as Friedrich Paulsen and Max Dessoir, also acknowledged the importance of teaching medical ethics with books and lectures. Paulsen pointed to the growing importance of medicine for modern society (von Engelhardt, 1989). Dessoir wanted the profession to compensate for a loss of ethical values in depersonalized doctor–patient relationships that resulted from specialization and the influence of medical science. Accordingly, he suggested a teaching program that would cover not only the "profession and character of the physician" and his "relationship to colleague and to the public" but also "vivisection and human experimentation" and "ethical principles in general" (p. 382).

Dessoir also served as an adviser to the Berlin neurologist Albert Moll, who provided the most significant contribution of this period with his 650-page *Ärztliche Ethik*. Moll argued that concern for medical ethics had concentrated on the physician's duties to colleagues and the profession (i.e., on medical etiquette), rather than on duties to the patient. He therefore put particular emphasis on ethical problems of medical practice, such as the doctor's refusing and breaking off treatment, euthanasia, deceiving the patient, advising extramarital sexual intercourse (e.g., in neurasthenia due to sexual abstinence, or in impotence), cosmetic surgery, and abortion. Moll devoted much attention to the issue of human experimentation, quoting numerous examples from the scientific literature. He oriented medical ethics to the well-being of the individual patient, not to the general welfare. Explicitly renouncing any basis in theological or philosophical systems of morality, he defined the doctor–patient relationship in legal terms, as a contract. This implied the physician's duty to fulfill the contract and the patient's obligation to respond by paying the fee. With this positivist approach, Moll reflected a general intellectual tendency of his time. In its comprehensiveness, his book provides a good overview of ethical issues in late-nineteenth-century European medicine.

Summary

In the nineteenth century there was a significant shift from reliance on largely implicit and nonsystematic notions concerning the gentleman doctor to written codes of professional etiquette and to a growing body of literature and theoretical perspectives concerning specific issues in medical ethics. In this century many of the concerns and methods now employed in medical ethics were first articulated.

III. NINETEENTH CENTURY. B. GREAT BRITAIN

Questions of medical ethics acquired heightened significance in nineteenth-century Great Britain. The reform of the medical profession and the growing prominence of medicine within public policy brought ethical and medicolegal issues into sharper focus. For the first time, medical ethics assumed codified form.

The period from the early sixteenth century to the close of the eighteenth saw the founding of medical colleges and societies in Britain, among them the Royal College of Physicians. But such bodies played only a minor part in imposing ethical codes upon the profession as a whole—or even suggesting them. The Royal College of Physicians and the Royal College of Surgeons possessed jurisdiction over one city, London. There was no centralized medical regulation over most of the nation. With few exceptions, it was only in the nineteenth century that medical ethics were written down, the watershed being the publication in 1803 of Thomas Percival's *Medical Ethics; or, A Code of Institutes and Precepts Adapted to the Professional Conduct of Physicians and Surgeons.* Two circumstances provided impetus for codification, one intellectual, the other socioeconomic. Intellectually, the moral philosophy of the Scottish Enlightenment and the reawakening of religious conscience associated with Evangelicalism concentrated attention on man's (concern was almost wholly with males) duties to society. John Gregory, professor of medicine at Edinburgh, had published his *Observations on the Duties of a Physician* in 1770, and Rev. Thomas Gisborne, a friend of Percival, had included a section on obligations attending the calling of a physician in his *An Enquiry into the Duties of Men in the Higher and Middle Classes of Society in Great Britain, Resulting from their Respective Stations, Professions and Employments* (1794). Percival certainly drew on both in shaping his *Medical Ethics*, though it would be a mistake to assume that Percival was significantly concerned with academic philosophy. His handbook was first and foremost practical. It contained no discussion of any philosopher by name and did not refer to particular formal philosophical schools.

At the same time, the tremendous social transformations precipitated by the industrial revolution were posing

exacting problems for medical practitioners. Newly emergent urban communities had severe medical needs but no deep-rooted traditions of professional service. In Britain's laissez-faire, free-market economy, doctors were tempted to adopt entrepreneurial attitudes, operating according to the law of "let the buyer beware." Moreover, new medical institutions were springing up, above all charity hospitals and dispensaries for the poor. Codes of practice governing the duties of doctors attached to these distinctive establishments needed to be formulated.

Thomas Percival (born in 1740) had studied medicine at Edinburgh. He became a senior and well-respected Manchester practitioner, and a leading light in the town's Literary and Philosophical Society. When a virulent intraprofessional feud flared up at the Manchester Infirmary in 1792—a sordid fracas concerning nepotistic appointments—he had been called in as a kind of peacemaker. His *Medical Ethics* arose from his musing on that unseemly rumpus. It was thus a work that spoke directly to the needs of its times. Percival set out some precepts, of a somewhat platitudinous nature, about the general duties and responsibilities of the physician to his patients, to society, and to his calling. Above all, he addressed himself in a direct manner to the tangible difficulties facing doctors in a commercial society.

High on Percival's list of priorities was the desire to secure harmony among practitioners and between the different grades of the profession. He addressed such questions as seniority and precedence, spelling out in detail the protocols of joint consultations. Though little interested in formal professional bodies, he was adamant that "medical men" should not compete against each other; instead they should cultivate, and be seen to cultivate, a comradely esprit de corps. Professional rivalries, naked jealousies, and controversies in public conducted through the medium of pamphlets would poison intraprofessional relations and ultimately work to the disadvantage of patients. Charging lower than normal fees, for instance, would deny a living to poorer brethren, and discourage the young from investing in a thorough medical education and training. A liberal profession could not be supported, Percival insisted, except as a "lucrative one."

Sentiments such as these give support to those, like Chauncey Leake and Ivan Waddington, who argue that Percival's *Medical Ethics* was misnamed, being in truth a work of "medical etiquette," primarily designed to bolster the collective status, dignity, and monopolistic power of the profession vis-à-vis the public. Percival certainly aimed to regulate "the official conduct and mutual intercourse of the faculty"; but it should not be forgotten that he added that this was to be accomplished "by precise and acknowledged principles of urbanity and rectitude"—that is, the unwritten but generally acknowledged code of gentlemanly behavior. In other words, he was concerned not with self-serving expediency but with humanitarianism, prudence, and honorable standards of virtuous conduct as understood by a gentleman.

Some American philosophers of medical ethics are inclined to see Percival as having written a work with strong foundations in academic ethical philosophies. It has, for example, been suggested that Percival and his successors may have drawn upon utilitarianism. There is little warrant for this reading in Percival himself. The great bulk of his text was concerned with resolving practical problems among medical men.

Percival upheld the ideal of the professional pyramid. Where wealth and density of population permitted a professional division of labor, the traditional hierarchical separation between physicians, surgeons, and apothecaries was to be maintained because it stimulated specialist skills. Yet physicians were not to lord it over the lesser "gentlemen of the faculty": in small communities, the humble apothecary was often the best expert on the circumstances of patients, and so his advice should be heeded.

Percival thus required courtesy among practitioners. A compassionate man, he insisted that the fears and feelings of the sick should be respected. Ever the realist, he acquiesced in the authority deriving from social status that the gentry were accustomed to wield. Wealthy patients would exercise the right to a second or third opinion: It was up to the doctors involved to manage such delicate circumstances with tact, preventing the dangers of "divide and rule." Likewise, though nostrums were an abomination, Percival judged that the astute physician would sometimes comply when a patient insisted on a worthless, but safe, favorite proprietary remedy.

With affluent patients, the one who paid the piper would evidently call the tune. But different rules must apply, Percival observed, when practitioners gave their services without charge. Charity patients in infirmaries could not expect to pick and choose among the physicians or to negotiate over treatments. Disobedient hospital patients must face dismissal. Likewise, it was permissible to experiment with new remedies or surgical procedures upon charity patients, so long as such innovations were attempted with due caution and humanity.

Prizing the close clinical relationship between practitioner and patient, Percival believed this depended primarily upon the character of the physician. The ideal practitioner was an academically educated, liberal gentleman who would combine "tenderness with steadiness," and "condescension with authority," displaying proper composure, dignity, tact,

and courtesy. He must govern himself: be temperate, avoid intoxication, and take care to retire from practice before age eroded his powers and judgment. He must be civil to colleagues, benevolent toward patients. It was a paternalist ideal, entailing a gentlemanly noblesse oblige.

Percival's book became immensely influential in the United States, serving as the basis for the American Medical Association's (AMA) code of 1847. Though reprinted in 1849, it achieved less celebrity in Britain. This was not because it was superseded by any other more illustrious tome or rival ethical scheme. For subsequent works, like William Ogilvie Porter's *Medical Science and Ethicks: An Introductory Lecture* (1837) and Abraham Banks's *Medical Etiquette* (1839), largely echoed Percival's platitudes; and as late as 1878, Jukes de Styrap was still lifting phrases out of Percival in *A Code of Medical Ethics.* Rather, in contrast to that in the United States, the medical profession in nineteenth-century Britain seems to have felt little need for explicit ethical codifications.

The contrast is readily explained. In early-nineteenth-century America, no standard, universal, and accredited licensing procedures unambiguously demarcated orthodox practitioners from quacks and irregulars. Hence, when regulars banded together into state medical societies to enhance their prestige, the adoption of a code of ethics was of immense significance as a conspicuous shibboleth. In Britain, by contrast, licensing was already well entrenched; since 1815, the Apothecaries Act had stipulated nationwide minimum qualifications for practice as an apothecary or general practitioner. Thus, in Britain, regular doctors did not need written codes of ethics to prove their standing in relation to irregulars. In Britain regulars were already adequately defined in contrast with quacks.

Nor did regulars need codes of medical ethics to affirm their personal bona fides. British practitioners were confident that they were, first and foremost, *gentlemen*. Gentility came from birth and breeding, education, wealth, contacts, manners, mien, and so forth—or at least from the capacity to create a show of such attributes. (Needless to say, most medical practitioners were not, in the literal sense, the sons of gentlemen; rather, they aspired to genteel status.) Gentlemanly behavior depended heavily upon notions of personal honor rather than upon formal ethical or religious principles. A written ethical code might have seemed to impugn a gentleman's honor, rather as the British prided themselves politically upon not having a formal written constitution. It is thus no surprise that the British medical profession was indifferent to collections of medical ethics. Neither the Royal College of Physicians nor the Royal College of Surgeons drew up an ethical code for its members.

From professors of forensic medicine, students learned a little about the rules governing evidence to be given in court. The Manchester Medical Ethical Association was formed in 1847, aiming to bind its members to a slate of regulations outlawing the marketing of nostrums and the giving of testimonials for patent medicines. And the British Medical Association—the newly formed society of general practitioners and family doctors—set up its own medical ethics committee in 1853. Over the next fifteen years, however, it signally failed actually to draw up a corpus of medical ethics. Despite such token activities, no comprehensive manifesto of ethical principles was codified in Britain that was binding upon the profession as a whole.

Yet this is not to say that the profession was indifferent to ethics. As was vehemently argued in Thomas Beddoes's *A Letter to the Right Honourable Sir Joseph Banks … on the Causes and Removal of the Prevailing Discontents, Imperfections, and Abuses, in Medicine* (1808) and in countless subsequent works, it was at bottom ethical commitments that distinguished honorable practice from quackery (although, Beddoes implied, all too often eminent regulars disgraced their vocation by unprincipled practices). And, of course, ethical dilemmas often arose that urgently needed resolution. A formal mechanism for upholding ethical standards was constituted in 1858 as a consequence of the establishment of the Medical Register, a public roll of all duly licensed practitioners. The body appointed to act as guardian of the register was the General Council of Medical Education and Registration of the United Kingdom, commonly known as the General Medical Council (GMC). The GMC was to admit properly qualified practitioners to the register, and to delete those whose conduct was professionally inadmissible—for example, those who had been convicted of a crime or who had been judged guilty of infamous professional conduct (such as adultery with a patient or vilification of colleagues). Sitting in camera, the GMC thus served as a sort of moral inquisition for the profession.

But what constituted "unprofessional conduct"? For most of the Victorian age, practitioners were held to less taxing standards than have generally been enforced in twentieth-century Britain. Considerable leeway was still permitted to engage in commercial and entrepreneurial activities. It was not unknown for eminent Victorian physicians to puff proprietary preparations with impunity, or to lend their names to extravagant publicity for spas, clinics, and balneological establishments. Such respectable medical organs as the *British Medical Journal* and *Lancet* published advertisements every week for nostrums, health foods, and medical institutions of doubtful probity (for example, so-called nursing homes that probably served as abortion clinics).

Nevertheless, the profession grew increasingly mindful of the fact that, in an age priding itself upon public probity, respectability, and heightened moral sensibilities, doctors had to be seen as above scandal. Trying situations easily occurred. For example, from the 1840s, thanks in part to the development of anesthetics, the scope for surgical intervention rapidly grew. Enterprising gynecologists and surgeons newly claimed to be able to treat a wide range of women's ailments, physical and psychosexual, through hysterectomy, ovariotomy, and similar operations upon the reproductive system. In the first flush of enthusiasm, some practitioners leapt in before the ethical implications had been adequately debated and resolved: Was proper informed consent being obtained for such operations? In the case of the removal of a womb, was it desirable to obtain the consent of the husband as well as of the patient? In the absence of diseased organs, was it permissible to perform operations for purely preventive or psychological reasons? Anxiety that the good name of the profession was being jeopardized by overenthusiastic intervention led to the expulsion, in the 1860s, of Isaac Baker Brown, a prominent advocate of clitoridectomy and similar surgery, from the Obstetrical Society (though he was disciplined not for the operations he performed but for the self-seeking manner in which he publicized them). Greater caution was subsequently exercised.

Whenever possible, the medical profession aimed to police its operations discreetly, retaining in its own hands the right to set moral standards. Thus, in ethically sensitive areas such as abortion, it was contended that termination of pregnancy was essentially a matter of clinical judgment in the individual case; in the last resort, only the personal physician was in a position to decide. Likewise, when legislation was proposed to control the sale of dangerous drugs, the profession was successful in safeguarding the right to supply narcotics on prescription.

In other medical spheres, however, ethical controversies arose that could not be kept within the circuit of professional discretion. This was because the Victorian age witnessed an unprecedented expansion of doctors' involvement in implementing state policy. For example, by 1900 new lunacy laws resulted in the compulsory confinement of nearly 100,000 mental patients. All had to be certified by due medical authorization. This created ethical predicaments for doctors that could not be resolved within Percival's notion of a tacit contract between physician and patient. Certain doctors, like the distinguished early Victorian psychiatrist John Conolly, warned of what a later generation was to call "psychiatric abuse": Some patients, Conolly feared, were being stripped of their rights and liberty not because they were sick but because they were nuisances or were merely eccentric.

It was in public health that the greatest ethical dilemmas arose. Before 1800, Great Britain had lacked the apparatus of medical police controls already in place on the Continent. This changed. The success of Jenner's variolation techniques (giving a dose of cowpox to create immunity against smallpox) led Parliament to make smallpox vaccination compulsory in 1853. Poor Law doctors—doctors appointed under the New Poor Law (1834) to tend to the parish poor, particularly those confined to workhouses—were to act as state agents in enforcing the legislation. Resistance and protests grew common during the next half-century, condemning compulsory vaccination as an iniquitous annulment of natural liberties and condemning doctors for serving as the lackeys of a coercive state.

A similar crisis arose in 1864 with the Contagious Diseases Acts. These sanctioned, under certain circumstances, medical inspection for signs of venereal disease of women detained by the police under suspicion of prostitution. Once again, opponents accused medical men of prostituting their art in the service of a corrupt state, and feminists argued that the acts were designed to provide disease-free vice for men. Around the same time, antivivisection agitators began accusing medical experimenters and scientists of inflicting cruelty upon dumb and defenseless experimental animals. The widening circle of medicine began to raise medical-ethical issues never dreamed of in the innocent days of Percival's *Medical Ethics.* Just before World War I these dilemmas came to a head when convicted suffragettes (militant feminists) went on a hunger strike, and prison doctors were instructed to administer forced feeding. Did their duty lie to society or to the prisoner (hardly a patient in the normal sense of the term, one who voluntarily seeks medical aid)?

In a characteristically British manner, professional bodies judged that the decision must be left to the doctor's scruples. The ingrained habits of individuality, specific to English liberal politics, and the cult of the gentleman that formed the unspoken code of male elites in all contemporary European societies meant that in professional eyes and, to a large degree, equally in the public mind the ethical dilemmas raised by medicine were best handled not by the law courts, jurists, academic philosophers, or Parliament but by the integrity of private practitioners following clinical judgment and their own consciences. These precepts, for better or worse, left a potent legacy to twentieth-century Britain. They certainly offered great latitude to the medical profession while placing heavy burdens upon its shoulders. Radical critics of the professions and their ideologies have contended, surely correctly, that the formulation of medical ethics enhanced the status and exalted the independence of

the nineteenth-century doctors. How far this process helped to protect the public is more difficult to judge.

MEDICAL ETHICS, HISTORY OF EUROPE: CONTEMPORARY PERIOD

• • •

I. INTRODUCTION

Bioethics was flourishing in most of the countries of late-twentieth-century Europe. However, as a field of ethical reflection and an instrument of public policy, bioethics is hardly uniform across the continent. The development of medical science and technology, as in many countries throughout the world, has stimulated an interest in the attendant

ethical issues. Yet the ways various countries have experienced that development differ, as have their ethical responses. Although influenced by social and political events, and by philosophical, literary, religious, and cultural ideas common to the European milieu, various countries and cultures have contributed in unique ways to the formulation of bioethical ideas. There is now a European Association of Bioethics, and in its deliberations, the commonalities of European bioethics can be found, as well as the distinct accents of the various national participants. This introduction will state some of the common themes; the articles that follow will emphasize national and regional distinctions.

Role of Medical Science and Technology

An important prerequisite to twentieth-century discussions and positions was the establishment in the nineteenth century of a natural scientific basis of medicine. Impressive progress in diagnosis and treatment, coupled with this development, led to new ethical problems. Concurrent with this process was an anthropological reduction—a loss of humanistic dimensions in the natural sciences and medicine leading to various attempts at balance and correction in the early twentieth century.

Philosophical Influences

Anthropological medicine and philosophical or existential psychiatry are important twentieth-century reactions to the one-sided natural scientific orientation of medicine. Various philosophical directions, associated with the names of Edmund Husserl, Martin Heidegger, Karl Jaspers, Jean-Paul Sartre, Maurice Merleau-Ponty, Gabriel Marcel, and José Xavier Zubiri, have influenced medicine. Theology has also made important contributions. An independent, intramedical discussion of methods and theory, beginning in the late nineteenth century, and the integration of psychology and sociology into medicine in the last few decades, have also affected contemporary European bioethics.

The situation of medical history in the medical faculties of the universities of Europe presents a different picture. The grand tradition of the presentation of history and theory, including the study of medical ethics, as part of the formal education required of medical students during the preclinical and clinical years was abandoned in the empirical, scientific nineteenth century. Only in Germany was it possible to establish a chair for medical history in almost every medical faculty.

These impulses and initiatives sought to bridge the separation between the natural sciences and humanities. The history of the patient was considered to be as important as the history of the illness. The ethical dimension was recognized anew in the understanding of disease, the concept of treatment, and the physician–patient relationship.

After 1900, discussions of the concept of cause led to a new appreciation of the anthropological dimensions of medicine. The concept of monocausality has been countered by that of multiconditionalism: Disease cannot be explained by one cause but by several causes. Constitution and disposition (i.e., the physical conditions of the individual) supplement the principle of exogenous infection; cause (*causa efficiens*) and aim (*causa finalis*) should not mutually exclude one another. Physical as well as mental illness can fulfill a purpose or meaning, can represent freedom in unfreedom, in the type of coping with these damages.

Literary Influence

The arts—in particular literary texts—also proffer important influences and models. Medical ethics has profited and will continue to profit from a unification with medical humanities. Novels and stories describe the attitudes and behavior of the patient as well as the physician in detail, drawing the reader into the context of the hospital as well as the wider social environment. Such literary depictions and interpretations, in providing examples, can play an important role in medical training. The scientific pleas for euthanasia at the beginning of the twentieth century find their supplementation or preparation in the literature of the nineteenth century. The texts of Guy de Maupassant, Henrik Ibsen, Theodor Storm, Anton Chekhov, and Hjalmar Söderberg describe conflicts in which the killing of a suffering and dying person is suggested; at the same time, there are warnings against active euthanasia. Normative opinions that equate health with the positive and illness with the negative are relativized or even reversed in the works of Marcel Proust, Thomas Mann, Robert Musil, Virginia Woolf, and many other writers. Health should also be understood as the ability to live with illnesses and disabilities, which may harbor opportunity and challenge. The patient has rights and duties, as does the physician; both can exhibit virtues. Their relationship manifests both asymmetry and symmetry such as differences in medical knowledge and experiences of pain and disease.

Political Influences

Ethical discussions of medical issues took place in all European countries even before World War II. Numerous essays and monographs were published on the ethics of the physician, ethics in research, and the ethics of patients, as well as the ethics of the family and of society. In 1901, the first

Congrès International de Médecine Professionelle et de Dèontologie Médicale took place in Paris. Many conventions on the subject of forensic medicine had already taken place. Bioethics in Europe is not uniform; different accents can be found in theory and practice. The differences are based on each country's respective artistic traditions as well as on the respective political and economic situations and legal regulations.

Undoubtedly, World War II and, after its end, the Nuremberg Code were turning points in bioethics. On the one hand, an increased tendency toward international uniformity in bioethics was reflected in such international declarations as, for example, Helsinki (1964) and Tokyo (1975), and in the introduction of ethics committees. On the other hand, the multitude of differing orientations retains its validity, even gaining a new weight through the presence of foreign labor and long-term migration in the European countries. Radical political changes in Eastern Europe and Germany through the collapse of communism made manifest the continuity of ethical opinions and social conditions that had been thought to be relics of the past; these hold new meaning for bioethics in the future.

Problems in bioethics must be solved on many levels, particularly in the Eastern European countries. At the center stands the task of finding a convincing ethical or humanistic solution for the vacuum of ideals left by the collapse of communism and the pressure of technical-scientific progress. Here, as is generally the case in the realization of ethical principles, the applicable legal regulations are of decisive importance. When moral principles are weak, laws can offer protection.

Medical Ethics and Bioethics

Because of the plurality of traditions that make up contemporary European bioethics, it is not possible to isolate a single path of development. The word *bioethics* itself denotes many things. Bioethics has been used to propose norms in the practices of modern biomedicine, norms of a religious-ethical nature, and norms of legal or philosophical ethics. Sometimes, under the new label *bioethics,* the method and arguments of already consolidated disciplines (moral theology, law, ethical guidelines for health professionals, moral philosophy) are easily recognizable, enriched only by the content of new problems.

In the different European cultural contexts, bioethics has had to confront a strong tradition of medical ethics that was developed and defended by physicians as their exclusive property. The proprietary claims of health professionals on medical ethics have produced ambivalent results. The independence of medical ethics has sometimes been able to protect the profession from the pressures that totalitarian ideology exerts on physicians to conform their behavior to the values imposed by the regime. Under the fascist and Nazi regimes (Italy and Germany) and in countries ruled by communism, medical ethics was denied an independent status in order to subordinate it to particular ideological visions (including racism, eugenics, the class struggle, and the dictatorship of the proletariat). In such situations, medical ethics' independence from the values that regulate the society created space for an ethics tied to philanthropic and universalistic ideals.

Nevertheless, the medical ethics elaborated by professional physicians can also obstruct the rise of formulations better adapted to the changing cultural situation. This is evident in many European countries by the many physicians who turn to traditional medical ethics, inspired by the ideals of Hippocratic medicine and strongly anchored in a paternalistic attitude toward the sick person, in order to oppose the medical models that are centered on the value of individual autonomy and the practice of informed consent.

The thrust toward bioethics is characterized, if compared with the strong tradition of an ethics developed by the medical profession itself, by the need for a civil ethics or an ethic of ordinary life elaborated in many voices. Bioethics is differentiated from medical ethics in being a consensual reformulation of rights and obligations in the context of medical practice and healthcare. This includes the professional obligations of physicians, but does not derive only from these. A further characteristic trait of bioethics in regard to civil or general ethics is the minimal ethical consensus, which obliges all citizens, in contrast to the maximal ethical consensus, which focuses on individual preferences.

A second issue that bioethics in Europe must face is its relationship with religious ethics. The weight of religious ethics relative to the moral problems posed by the corporality of man (sexuality, procreation, disease, health, death) and healthcare varies according to cultural context and type of religious communities in the society. In societies in which a single religion dominates, especially of the Catholic tradition (Ireland, Poland, Italy, Spain), religious ethics tends to superimpose itself onto bioethics, shaping it to its own norms. In countries in which a tradition of pluralism prevails, the two normative contexts—religious ethical and bioethical—are more clearly distinct.

Where religious ethics is seen as antithetical to secular ethics, a clear polarization can appear in the society; possible examples are Ireland, Poland, or Portugal, with their Catholic tradition. Justification of ethical judgment then consists

of making reference exclusively to one set of values instead of another. This happens, for example, when clinical decisions are evaluated exclusively in terms of values considered to be absolute: sacredness of life versus quality of life, benefit of the medical act versus self-determination of the patient, and so on.

A third issue in the contemporary development of bioethics in Europe relates to the challenge of universalism. Developments in the ethics of medicine and biological sciences reveal two opposing challenges for bioethics: the need to be rooted in the particular, with respect to the cultures, traditions, and local communities of belonging, and the need to refer itself to universal values. Universalism is an intrinsic dimension of ethical rationalism. At the same time, universalism is necessary to ensure normative rules and moral obligations. The directives, for example, of "Good Clinical Practice for Trials on Medical Products in European Community" (1991) have had the aim of producing one practice of experimentation in this field. In Europe, in fact, the crowded national frontiers would easily create "enclaves" where biomedical practices prohibited beyond these frontiers would be legitimate. An international consensus has to be created to prevent a "tourism" in medical research.

The various bioethics developing in Europe face the challenge of particularism as much as that of universalism. The best forms of European bioethics are clearly those that are trying to respond to both these challenges.

Recommendations of the Council of Europe

The most relevant innovation for the history of bioethics in Europe is the approval of a "Convention for the Protection of Human Rights and Dignity of Human Being with regard to the Application of Biology and Medicine" by the Council of Europe. After almost five years of work and lively discussions, the steering Committee on bioethics of the Council of Europe (CDBI) presented a text which was approved by the Council of ministers in Oviedo (Spain), on April 4, 1997. The Convention is therefore known as the Oviedo Convention or "Convention on human rights and bio-medicine." Its main purpose is to reinforce the idea that, since Europe is becoming more and more integrated from a cultural point of view as well as economically and politically, it is necessary to find a common orientation also on the subject of bioethics.

Eighteen out of the forty countries of the Council of Europe have signed the Convention. The parliaments of the signatory States are now called upon to ratify this Convention, thus agreeing to bring national legislation into line with the principles enunciated in the agreement. Indeed, unlike "Recommendations" of the Council of Europe and "Treaties," which are a mere expression of principles, the instrument of the Convention is particularly effective because it is binding on those states that ratify it, obliging them to apply its standards within their individual sets of laws. This means that the Convention is not an "exhortation," to the individual states, but has a normative value. As of September 2002, thirteen countries have also ratified the Convention they signed.

The choice made with the Convention was to focus on principles and rules that can help create a consistent set of laws, real European common rights in the bioethics area: the prevalence of human beings over science, respect for individual independence, protection of integrity and dignity, confidentiality of medical and genetic information, noncommercialization of the human body. In the Convention no position has been taken on widely debated topics, including medically assisted procreation, the cloning of embryos, or genetic engineering. The most controversial aspects of bioethics are expanded upon in additional protocols. Two of them have been drawn up so far: on the Prohibition of Cloning Human Beings (January 12, 1998) and on Transplantation of Organs and Tissues of Human Origin (January 24, 2002).

The essential elements of the Convention are: the primacy of the human being (article 2: "The interest and welfare of the human being shall prevail over the sole interest of society or science"); equitable access to healthcare (article 3: "Parties taking into account health needs and available resources, shall take appropriate measures with a view to providing, within their jurisdiction, equitable access to healthcare of appropriate quality"); the central role of information and consent (article 5: "An intervention in the health field may only be carried out after the person concerned has given free and informed consent to it. This person shall beforehand be given appropriate information as to the purpose and nature of the intervention as well as on its consequences and risks").

DIETRICH VON ENGELHARDT
SANDRO SPINSANTI (1995)
REVISED BY AUTHORS

II. SOUTHERN EUROPE

The term *southern European countries* includes all the occidental European countries in the Mediterranean area (Spain, France, Italy, Greece, Malta, and Cyprus), plus an Atlantic country closely related to them (Portugal). In addition to

geographical and climatological affinities, these seven countries have for many centuries shared a common history centered on the Mediterranean Sea. Although they maintain local peculiarities and differences, the nations of southern Europe can be said to have a common identity.

This common identity is particularly evident in ethical issues (Gracia, 1993). Occidental ethics had its origin in the Mediterranean Greco-Latin culture, and since the days of the Greek philosophers, this ethics has centered on the concepts of virtue and vice. Only with the Enlightenment did a new ethical tradition, with right and duty as its main concepts, begin to take shape in central Europe. Since then the two approaches have widely been considered opposites, although they are in fact complementary. The ethics of virtue has persisted in those countries in which the Enlightenment had less influence, such as the Catholic or Orthodox southern European nations (Savignano), while the ethics of duty has prevailed in the Protestant central European and Anglo-Saxon countries (MacIntyre).

Today the occidental world harbors three palpably different ethical traditions, each with its own characteristics: the Anglo-Saxon, the central European, and the Mediterranean. Because modern bioethics is a product of the Anglo-American culture, Mediterranean countries have not attempted simply to import or "translate" bioethics but, rather, to re-create or remake the discipline according to their own cultural and ethical traditions (Gracia, 1990).

A "Latin Model" of Bioethics

If traditional Anglo-American philosophy is generally classified as empiricist, European philosophy has been more influenced by rationalism. Anglo-American ethics is generally more teleological and consequentialist, and European ethics more deontological. This explains why, for instance, the term *autonomy* has acquired a different meaning in the United States than in Europe. According to North American ethics, autonomy is the capacity to act intentionally, with understanding, and without controlling influences. On the other hand, European ethicists often interpret the principle of autonomy in a Kantian sense, as the capacity of human reason to impose absolute moral laws upon itself. The latter is a metaphysical assumption, while the former is only the lack of constraints. To European ethicists, acting autonomously means that the human reason is capable of freely establishing absolute and compulsory moral laws (freedom to). In the Anglo-American, on the contrary, freedom is understood only negatively, as the capacity to act without constraints (freedom from). The first is a maximal concept of autonomy, and the second a minimal one. These two meanings are so disparate that an autonomous person, according to the European point of view, may not act autonomously from the Anglo-American perspective because of constraints such as ignorance or coercion. Moreover, it is also possible to deny the capacity of reason to impose on itself absolute moral laws, and to accept the concept of autonomous choice as the absence of external constraints.

The rational foundation of ethics is closely linked to the discussion of whether the principle of autonomy is relative or absolute. In Europe, the Anglo-American propensity to base ethical analysis on several theories, such as utilitarianism and contractualism, and on a few principles, such as autonomy and beneficence, is usually considered insufficient or less adequate. Europeans generally search for more universal or transcendental ethical foundations. The meaning of the concept of *transcendental* differs in central and southern Europe. Central European ethics often attempts to reach the transcendental dimension through an intersubjective procedure, such as the universalization of personal interests. According to many Mediterranean ethicists, the transcendental universality of ethical norms is reached in a more objective way, based on metaphysical concepts like *reality, human nature,* or *personhood* (Russo). The latter is, of course, the most classical position in occidental philosophy. It is no coincidence that this classical concept of metaphysics was born on the Mediterranean coast.

Modern northern European ethics, based on the concepts of right and duty, has been the matrix of ethical minimalism (or the ethics of duty), while the traditional Mediterranean ethics, based on virtue, has tended more toward ethical maximalism (or the ethics of happiness). While minimalistic ethics looks for the basic rights and duties of every human being and society, maximalistic ethics is concerned with life projects and ideals of perfection and happiness (in Greek, *eudaimonia*). During the sixteenth century, Mediterranean countries adopted anti-Protestant, and therefore antimodern, attitudes; they considered certain aspects of modernity to be fundamentally hostile to their cultural traditions: their medieval political, ethical, and religious ideals. These attitudes may explain why many Mediterranean nations belatedly and with difficulty adopted the doctrines of human rights and parliamentary democracy, the greatest achievements of the Anglo-American world. This may also explain the relative weakness of democratic practices in these countries in comparison with other areas. This antimodern stance enables one to understand the history of southern Europe since the nineteenth century, particularly the potency of antidemocratic movements and authoritarianism during the first half of the twentieth century. And while western European countries definitively

adopted democracy and liberal systems following World War II, some of the Mediterranean countries maintained a markedly different identity.

All these elements help clarify why southern European countries have tried to elaborate a "Latin" model of bioethics (Leone). While the Anglo-American model is structured around the four classical principles of autonomy, nonmaleficence, beneficence, and justice, Salvino Leone, following Elio Sgreccia, bases the so-called Latin model on the four principles of the fundamental value of life; liberty and responsibility; totality (or therapeutic wholeness); and social subsidiarity (the idea that smaller units are always preferred to larger ones when it comes to addressing social problems) (Sgreccia; Palazzani). This search for distinctiveness also led Mediterranean ethicists to seek to establish their own terminology. The French expression *éthique biomédicale,* "meaning the desire to promote a new style of questioning in the field of biomedical sciences, both theoretical and educational" (Moulin, p. 280), has been adopted as an alternative term to the Anglo-American bioethics not only in French but also in other Mediterranean languages, such as Italian (Spinsanti, 1987) and Spanish. The reason for this terminological change is that for many authors, the word *bioethics* seems overly biologistic and suggests that ethical behavior is biologically determined. The alternative expression *biomedical ethics* was coined to avoid this danger. It situates the term *ethics* as the noun, with *biology* and *medicine* in secondary adjectival position. Of course, the term *bioethics* is also frequently used in Mediterranean countries, just as North American literature occasionally uses the expression *biomedical ethics* (Beauchamp and Childress).

The Ethics of Virtue and the Doctor–Patient Relationship

Mediterranean countries have created a realistic and personalist model of biomedical ethics, based on the classical Aristotelian-Scholastic philosophy and complemented with more modern European philosophical traditions such as phenomenology, axiology, and hermeneutics (Viafora, 1990). In this model, the idea of virtue acquires much more significance than in any other occidental tradition, a fact that has important consequences in the medical field. For example, trustworthiness is considered more crucial than the right to information (Dalla-Vorgia et al., 1992). Patients in southern European nations are generally less concerned with receiving detailed information or having their autonomy respected than with finding a doctor in whom they can place their full confidence (Gordon; Spinsanti, 1992; Fletcher; Loewy).

One virtue is particularly important in establishing a satisfactory doctor–patient relationship: friendship. The Spanish physician and humanist Pedro Laín Entralgo has written extensively on this topic, especially in his book *The Doctor–Patient Relationship* (Laín Entralgo, 1983 [1969]). This relationship must be based on what Laín Entralgo calls "medical friendship," composed of benevolence, beneficence, and confidence. His studies have had a substantial but not exclusive impact in Mediterranean and Latin American medicine; as a result, the idea of friendship as the cornerstone of the relationship between doctor and patient has gradually acquired importance in bioethics. The influence of his studies is also visible in North American bioethical literature (Siegler, 1979, 1981; Pellegrino and Thomasma; U.S. President's Commission; Cassell; Drane).

Friendship includes trust and confidence, which is why we talk about intimate friends; friendship is the ambit of trust. The three theological virtues (faith, hope, and love) are common between friends. The core of this relation is hope, understood as trust: we trust friends, we have faith in them, and we trust them because we love them. Friendship is more than ethics; it is almost a religion. Charity, or agape, is considered the most important virtue in the Judeo-Christian tradition. But, according to Laín Entralgo, agape can be considered perfect only when benevolence and beneficence, its main components, join friendship's trust and confidence (Laín Entralgo, 1985 [1972]). The result is, as Edmund Pellegrino and Warren T. Reich, two U.S. authors influenced by Laín Entralgo, have written, "com-passion," the act of putting oneself in the place of another in order to understand his or her experiences (Pellegrino, 1986, 1988, 1989; Reich, 1989, 1991). Compassion is not pity but, rather, the human relationship based on devotion, constancy, personal respect, and responsibility. As Reich says, it is the relation with the other, based on love, benevolence, comprehension, and friendship. Mediterranean bioethics has emphasized the study of the friendship aspect of the physician–patient relation, and the Spanish contribution has been important (Gracia, 1989).

Ethics and Law

The relationship between ethics and law is peculiar in the Mediterranean. In its origins, Roman law was substantially influenced by Stoicism, a school of thought that assimilated law and morality. Stoics considered nature the source of both law and morality; natural law could be known rationally, and thus formulated deontologically and axiomatically into a legal code. Because law expresses what is morally correct, ethics and law converged. Ethical goodness, the intention with which an act is performed, only added to the

legal rightness of the act and to the virtue of the person involved.

Christian thinkers adopted this relationship between ethics and law without substantial changes, and it has been a latent presence both in canon law and in the moral theology of the Roman Catholic church. Thus, in Catholic nations such as those of southern Europe, law and morality are difficult to distinguish conceptually.

One of the problematic outgrowths of this tradition is legalism, the tendency to believe that every human act can be legally prefigured, that laws precede facts, making it possible to regulate beforehand every real or possible situation. Thus, in these countries court rulings are considered nothing more than the concrete application of statutory law. This law is prior to individual rulings, quite the opposite of the Anglo-Saxon common-law system. The traditions also diverge in that the Roman model is largely centralized and state-oriented and places less importance on social dynamics. The prevalence of state over society explains why Mediterranean countries have fostered more authoritarian and less democratic political practices than Anglo-Saxon ones.

Health Systems

That the state must, in southern European countries, take responsibility for what in other countries is considered the realm of private enterprise, illuminates another distinctive characteristic of Mediterranean bioethics: its overwhelming concern with healthcare justice. In fact, the health systems of these countries are mainly state-run. Justice plays the decisive role in European biomedical ethics that autonomy plays in North American bioethics (Thomasma).

France, Italy, Greece, Portugal, and Spain have similar national health insurance systems. Their common origins date back to the German Krankenkassen (patients' fund) system, designed by Otto von Bismarck in the final decades of the nineteenth century as a means of assuring medical assistance for workers. In distinction to the socialist European countries, where all the population was covered by an insurance system financed by public funds, Mediterranean countries, following the German model, began insuring only workers, and financing the system with the economic support of both workers and employers. Coverage was later extended by public funding, and today nearly the entire population of each country is protected. This process of generalization of the health insurance system took place during the zenith years of the welfare state, between the end of World War II and the economic crisis of 1973. In the mid-1970s, health insurance as well as the entire social security system, and perhaps the welfare state itself, experienced a crisis, mainly because of the costs explosion that made it impossible to satisfy the population's health expectations. To find solutions for this complex problem, most countries set up reform commissions aimed at proposing measures to make health insurance viable in the future.

In Spain, compulsory health insurance for all workers was enacted in 1942 and implemented in 1943. Over the next three decades, coverage was gradually extended. In 1986 it became a national health system very similar to those in Britain and Italy, covering the healthcare of most of the country's population (Gracia, 1987). This satisfied one of the people's greatest wishes but at the same time gave birth to a new problem, which became more and more acute as time went by: the scarcity of economic resources and the subsequent need to limit free health services. In order to analyze and evaluate the needs of the national health system, in 1990 the Spanish parliament set up a commission, known as the Comisión Abril Martorell. The commission's main report, published in July 1991, asserted the importance of the national health system in maintaining the level of health and well-being in Spain, and proposed certain amendments to increase efficiency without altering the basic system. One such modification would require every user of healthcare services to pay a percentage of the total cost, in an attempt to make everyone shoulder the burden of the constant increases in health expenses.

Patients' Rights

The way patients' rights were established marks another differentiating factor of Mediterranean countries. In the United States these rights, particularly the right to informed consent, took shape in the field of common law, while in Mediterranean countries their entry was directly through statutory laws and codes (Council of Europe, 1976; Gracia, 1989). In these countries, protecting patients' rights is a duty of the state more than the duty of individuals. In Spain, patients' rights were first established legally in Article 10 of the Health Law of 1986, and then socially.

In all Mediterranean countries the respect for patients' autonomy and their right to make decisions about their own bodies has grown remarkably in the last decades (Cattorini and Reichlin). This has produced profound changes in the role of healthcare professionals, as well as more litigation against physicians and other healthcare workers. The old juridical terms *professional incompetence* and *negligence* that referred to faulty medical procedures have come to be overshadowed by new complaints about health workers' lack of skill or their negligence in giving information, or about battery, for handling the patient's body without consent.

The patients' rights movement of the 1970s provoked wide-ranging legislative changes (Council of Europe, 1976).

For example, the large antipsychiatry movement in 1978, led in the Mediterranean area by Italy, prompted some countries to modify laws on the compulsory restraint of the mentally ill by passing new legislation more respectful of these patients' human rights and providing greater protection against possible abuse by family members or health professionals. In 1997, the Council of Europe introduced the "Convention on Human Rights and Medicine"; the fifth article of this document states that "an intervention in the health field may only be carried out after the person concerned has given free and informed consent to it. This person shall beforehand be given appropriate information as to the purpose and nature of the intervention as well as on its consequences and risks. The person concerned may freely withdraw consent at any time" (Council of Europe, 1997) The convention has been signed by all the Mediterranean countries, and has influenced national legislation about the rights of patients and informed consent.

Additional consequences of this new respect for patients' rights are the strict regulation of biomedical experimentation and the creation of institutional review boards to monitor every clinical trial and research project protocol, analyzing not only technical and methodological but also ethical aspects. On November 24, 1986, the Council of the European Community approved a directive on the protection of the animals used in research and other scientific projects (European Union). Every country of the European Community adopted its own legislation in the following years, and by the end of the twentieth century, research with animals was strictly controlled (Illera).

In an attempt to promote organ transplants while avoiding any kind of commerce and abuse in the donation process, all Mediterranean countries have introduced legislative criteria for brain death and have elaborated laws regulating transplants. The legal regulation of medical care to the dying has encountered greater obstacles, and has provoked heated debates over euthanasia (Gracia, 1987, 1988; Lefevre; Dracopolou and Doxiadis; Bompiani).

Issues related to the origin of life, especially abortion and new techniques for human reproduction, have been the subject of the most intense debates. Mediterranean countries have adopted conservative positions in these debates. In these nations the U.S. Supreme Court decision *Roe v. Wade* (1973), based on the right to privacy and restricting the right of states to legislate on abortion in terms of viability and trimesters, is not easily understood. In Mediterranean countries, abortion is held to be a public rather than a private issue and therefore a matter of justice and not of autonomy, since the life of a human being is believed to be at stake. Hence, in these countries, laws governing the interruption of pregnancy are based on exceptional circumstances or indications rather than on periods of time or terms of pregnancy. These laws allow abortion in three exceptional indications: great danger to the mother's health or life; important defects of the fetus; and rape. Only a few countries, such as Italy and Cyprus, have included a fourth indication: socioeconomic incapacity, valid during the first trimester of gestation. The Veil Act (1975) in France established that any pregnant woman can undergo an abortion during the first ten weeks of pregnancy if gestation is a source of anguish (*détresse*) for her, an indication that, in practice, is analogous to a law of terms (a period of time in which abortion is permitted without any indication). Since 1986 Greece has had a law of terms: Abortion is permitted in the first twelve weeks of pregnancy. After this period, gestation can be interrupted only with an ethical (nineteen weeks), eugenic (twenty-four weeks), or therapeutic indication (Glendon).

The problems presented by new techniques of human reproduction are so various and complex that every southern European country has established a specific commission for their study. The Comisión Palacios of Spain and the Commissione Santosuosso of Italy are examples. Both bodies have elaborated reports for legislative enactment, which has been achieved in both countries (Gracia, 1988; Fagot-Largeault; Mori; Walters; Bompiani). More important, these commissions highlighted the need for national committees on bioethics, which were firmly established in the Mediterranean area by the end of the century. This same process has taken place in Europe as a whole, where the Council of Europe in 1983 established the Ad Hoc Committee on Ethical and Legal Problems Related to Genetic Engineering, which a few years later became the Ad Hoc Committee of Experts on Bioethics and was later called the Steering Committee of Bioethics.

National Committees of Bioethics

National committees of bioethics have been set up because of the increasing complexity of biomedical research and to avoid dangerous research like that which made possible the construction of nuclear weapons during the 1940s and 1950s and the experiments carried out in Nazi concentration camps. The main aim of these committees is to help those involved in biomedical research by offering prudent criteria for conduct. On February 23, 1983, French President François Mitterrand created the first national bioethics commission in a European country, the Comité Consultatif National d'Éthique pour les Sciences de la Vie et de la Santé (CCNE). Its purpose is mainly to elaborate recommendations on ethical problems stemming from scientific research in biology, medicine, and other health professions (Isambert,

1989). It deals not with healthcare problems but with ethical questions raised by biomedical research. The CCNE is composed of thirty-six members plus a chairman who is appointed by the president of the republic. The departments of Education, Research, Industry, Health, Justice, Family, and Communication appoint sixteen members with proven competence and interest in ethical issues. Fifteen posts are filled by researchers and representatives of universities and the National Institutes of Health and Research. Five members, named by the president of the republic, are drawn from the "spiritual and philosophical" fields. Committee members are divided into working teams to prepare reports and recommendations. The documents so far produced have dealt with the use of fetal and embryonic tissues for diagnostic, therapeutic, or research purposes; techniques of artificial procreation; prenatal and perinatal diagnosis; the use of the abortion-causing drug RU-486; and the noncommercialization of the human body, among other topics. Every year, the committee organizes meetings of study and debate called the Journées Annuelles d'Éthique, in order to release the year's work to the public.

The French commission's work has stimulated bioethics studies in the Mediterranean area, much as the National and President's Commissions have done in the United States. Of the two possible methodologies identified by the Belgian philosopher of medicine Jean-François Malherbe—that of the lowest common denominator (the search for a formula everybody agrees with, even if it is ambiguous and makes room for very different interpretations) and that of the highest common denominator (requiring much more work, reflection, and dialogue)—the Comité Consultatif National opted for the second. This decision had an evident impact on the text of a report the committee issued, "Biomedical Research and Respect for the Human Being" (CCNE). French bioethics is coming to be, as Malherbe noted, "an active center of public morality in the life of people" (Malherbe, p. 227). The French ethics of the highest common denominator is similar to some of the most creative ideas from Jürgen Habermas and Karl O. Apels's "ethics of communication," which is based on the idea that in the context of a pluralistic society, ethics will flourish only if it takes into account the interests of every person actually or virtually involved in the conflict. The French committee has integrated German dialogic ethics with French personalism, widespread among French philosophers of the last century, and firmly established in certain Catholic (Maurice Nédoncelle), Protestant (Paul Ricoeur), and Jewish (Emmanuel Lévinas) phenomenological thinkers. According to Lucien Séve, these ideas have proved fundamental for the elaboration of a working procedure based on rational consensus and not on a merely strategic consensus.

The French committee has had great success, and hence this model has spread throughout Europe, including the Mediterranean countries. Malta instituted its Health Ethics Consultative Committee in 1989 (Le Bris). In March 1990 the Italian government approved the creation of the Comitato Nazionale per la Bioetica, directly responsible to the prime minister. The body is composed of forty members and, like the French group, is aimed at controlling research involving human beings. It has published documents on gene therapy, definition of human death, ethics of the use of seminal fluid for diagnostic purposes, biotechnological security, bioethical learning in the clinical setting, healthcare and terminally ill patients, organ donation, and ethics committees.

Portugal, following the French pattern, established the National Ethical Council for Life Sciences in June 1990 (Martinho da Silva). The body started functioning January 1, 1991, and in its three first years published three reports: on organ donation and transplantation (1991), on the use of human corpses in research and teaching (1991), and on new reproductive technologies (1993).

In 1984 Spain created a special committee known as the Comité Palacios to study problems related to new techniques of assisted reproduction (artificial insemination, in vitro fertilization, and so forth). In July 1992 the Department of Health published a legal order creating a health advisory committee whose main goal was assessing and informing the secretary of the department on scientific, ethical, professional, and social questions. This committee deals not only with problems of biomedical research but also with those raised by healthcare. This innovative feature distinguishes it from others in the region.

In southern Europe, institutional ethics committees were rare until the 1990s, in part due to the prevalence of socialized medicine and in part because Mediterraneans are not completely conscious of patients' rights. In Spain, for instance, such committees only became standard in hospitals late in the 1990s, following the General Health Law of 1986 that specifically mandates the protection of patients' rights.

Goals and Challenges for the Future

In the last decade of the twentieth century, new problems emerged; two of the most important were population ethics and ecology. Ecology is of increasing importance in all Mediterranean countries, and is beginning to be not only an ethical and intellectual issue but also a political force (Gafo; Poli and Timmerman). Latin European countries are neighbors of the underdeveloped nations situated on the southern Mediterranean coast, and they therefore understand very well that only a sustainable development can correct the unsustainable development of the First World and the

underdevelopment of the Third World. Ecology in these countries will be not only an ethical compromise but also a political project, prompted by the left-wing parties. With the death of the Marxist ideology, ecology assumes the place once held by economic theory.

Due to the increasing importance of bioethics in the life of these countries, research and teaching are growing quickly. The teaching of bioethics has been introduced not only in schools directly related to healthcare, such as medicine, pharmacy, and biology, but also in theology, philosophy, and humanities (Comitato Nazionale per la Bioetica; Gracia, 1992). Literature is being published, and universities are supporting new research centers (Viafora, 1993). All of the research centers have been integrated into the European Association of Centers of Medical Ethics. Since 1990 the Milazzo Group has published *International Journal of Bioethics.*

III. THE BENELUX COUNTRIES

The Benelux countries—Belgium (population 10 million), the Netherlands (population 15 million), and Luxembourg (population 400,000)—with three languages (Dutch, spoken by 20 million; French, by 5 million; and German, by 500,000), and two Christian religions (Roman Catholicism and Protestantism)—have been leaders in European bioethics. Institutes for bioethics were founded in these countries in the early 1980s, the region's universities developed a full curriculum for medical ethics, and European bioethics

associations of both organizations and individuals were founded in the Benelux nations.

Of the three possible approaches to medical ethics—the deontological, the forensic, and the philosophical–theological approach—the third one, particularly since the 1960s in Belgium and in the Netherlands, has produced a considerable amount of literature in both religious and lay ethics.

During the 1960s, early warning signals were issued by physicians and philosophers. Prominent among them was Jan H. van den Berg (1961; 1969), who warned against inevitable medical failures once patients become objects of medical science instead of persons and subjects of care.

The real boom in bioethics, however, did not come until the mid-1970s and 1980s, when bioethics gained institutional status. From then on, not only doctors and a few ethicists but also ordinary people, among them patients and politicians, became interested in bioethical issues. In 1974 a famous case of active euthanasia in the Netherlands, in which a physician terminated the life of her terminally ill mother at the latter's request, marked the beginning of a debate that would last several decades.

The institutionalization of bioethics is apparent in the existence of three centers for bioethics in Belgium (two in Brussels, one in Leuven) and six centers in the Netherlands (Amsterdam, Ede, Groningen, Maastricht, Nijmegen, Utrecht), as well as in a number of interfaculty working groups. In Luxembourg a national consultative ethics commission for the life sciences and health has existed since 1988 by government decree.

Belgium

In 1993 Belgium underwent a major constitutional change. Belgium became a federal state made up of three communities (French, Flemish, and German-speaking) and of various regions. Bioethics has been impacted because issues are always compounded by the institutional complexities of multiple governments, parliamentary assemblies, and powers. The Belgian approach to AIDS provides an example: preventive measures are taken by the communities, healthcare is provided by the federal state, and the hospital infrastructure is established by the regions (Binamé). Religiously speaking, the country was almost entirely Roman Catholic, though in matters of medical ethics—for example, contraception—a group of postwar Catholic doctors and moral theologians of the personalist tradition had taken a rather liberal stance. The Roman Catholic Church still plays an influential, albeit no longer a decisive role in Belgian bioethics in the twenty-first century. Academically, its bioethical message is carried by the universities of Leuven-Louvain, Namur and Antwerp. However, during the last decades of the twentieth century strong lay trends entered bioethics. The universities of Brussels, Ghent, and Liège established centers or study groups for bioethics. In 1973 the Belgian Society for Ethics and Medical Ethics was founded. Since 1990, this association has had a Flemish-language section. Other important societies are: The Belgian Academy of Medicine and the National Foundation of Medical Research.

Medical ethics at universities was usually taught by faculty from either theology or philosophy departments. Rare exceptions where physicians taught medical ethics, such as Marcel Renaer at Leuven, proved the rule. In 1980 Leuven University created a chair of medical ethics that was held by Paul Schotsmans in 2002. The Leuven (Flemish-language) center and the Louvain (French-language) center, under the direction of Jean-François Malherbe and his successor Michel Dupuis, developed teaching programs for medical ethics at the graduate level and for members of ethics committees. The annual conventions on health law at Ghent University, started in the 1960s, bring together health lawyers and bioethicists from around the world.

LEGISLATION. The federal government took several initiatives in encouraging the development of bioethics. In 1987, the Ministry of Public Health organized a national convention in order to explore the key bioethical issues of the future. The congress was expected to generate significant policy recommendations. In fact, only a general proposal resulted: that vehicles for ongoing debate should be created and that medical practice ought to be protected against wild growth and carelessness in the new fields of biotechnology. In 1993 the National Consultative Bioethics Committee was created with thirty-five members. Its major task is twofold: to provide advice in the field of biomedical ethics, be it on request or on its own initiative; and to provide information to the public at large. Belgian legislation at the federal level covers the following bioethical areas: blood (1961, 1971) and issues of the contaminated blood (1994); organ transplants (1986); artificial insemination (1987); abortion (1990); human genetics (1992); euthanasia (2002); and patients' rights (2002). At the level of the French community, an agency for the prevention of AIDS was created in 1991.

ETHICS COMMITTEES. Strictly speaking, Belgium had no law on human experimentation as of 2002. In 1999 the Hospital Act (1964) was amended by an article that made the presence of an independent review board compulsory, thereby providing these boards with a legal basis. In fact, ever since the early 1980s, ethical guidance and control over biomedical experimentation emanated from the Order of

Physicians. Their National Council had already developed a set of ethical rules and guidelines in what was called a "code of deontology" by 1975, to be respected by all physicians. Then, in 1976, the National Foundation for Medical Research charged an ethics committee with as a prime task, the review of research at university centers. In the 1980s, several academic institutions insisted that medical research be done under proper ethical conditions. University hospitals and major centers quickly established institutional review boards (Delfosse). In 1984 the National Council ruled that research ethics committees had to give their approval before research could be initiated in any hospital. At the beginning of the new millennium, close to two hundred ethics committees were in place. Gradually many of these ethics committees have expanded their mandate: the original research ethics committees also became hospital ethics committees, thus covering clinical cases and healthcare policy. In principle these committees are advisory. It is fair to say that during the 1990s efforts were made to create greater consistency, if not uniformity, in the normative as well as the procedural working methods of ethics committees.

The Netherlands

Medical ethics in the Netherlands has, over the years, gained a solid basis and infrastructure. Most universities have medical faculties or working groups where medical ethics is taught. Research and training institutes provide medical ethics information for healthcare institutions and for policymakers, and, joined by professional organizations, they offer systematic ethical training for healthcare workers. In the world of healthcare, numerous ethics committees are in place, and at the public level, the media and politics play an important role. During the 1960s Christian traditions lost their grip on social life, leaving a gap that was gradually filled by, among other things, the new (medical) ethics. The debates in the Netherlands on contraception, on abortion, on euthanasia, as well as all other debates on bioethics, were characterized by lively public participation, including patients and their organizations, as well as the movements for autonomy and self-determination. Dutch society, known for its tradition of tolerance, has displayed an increasing moral permissiveness in problems of biomedical ethics (Moor). In the immediate post–World War II period, a number of theologians as well as physicians were active in the field. Many bioethicists, even into the twenty-first century, have a religious if not a theological background, although a profound change has occurred in their interaction with society. Having gone through secularization, many of them have acknowledged the *humanum* as a basic norm that carries common agreement in this pluralistic society.

INSTITUTIONALIZED BIOETHICS. Institutionalization of bioethics in the Netherlands is best illustrated in the area of ethics committees for both research and hospital ethics. The number of independent review boards (IRBs), which began to be established in the early 1970s, grew rapidly after 1984; hospital ethics committees (HECs) seem to have grown more slowly, mainly after the mid-1980s. IRBs needed several years of adjustment after the introduction of a European Directive for "Good Clinical Practice" (1993) (Berghmans et al., 1996). Finally, in 1999, the law on Medical Scientific Research was introduced. Since then, a tendency toward the legalization of ethical issues seems to have taken over (Dupuis).

A number of professional organizations (of physicians, nurses, and hospitals) have their own study services for ethics that help them to research and develop policies in healthcare. The six established centers for bioethics as well as medical schools run teaching programs, services to clinics and physicians, and research projects in bioethics.

Dutch society, particularly Dutch political society, has at its disposal five major advisory organs to assist in making healthcare decisions: the Health Council, the National Council for Public Health, the Sickness Fund Council, the Central Organism for Fees, and the College of Hospital Provisions. All these organizations may offer advice without being asked. The Netherlands Organization for Technology Assessment monitors the ethical aspects of applied medical technology.

Dutch universities played an important role in the development of medical ethics. In the 1970s the universities of Maastricht (Paul Sporken), Nijmegen (Theo Beemer, Maurice de Wachter), and Leiden (Heleen Dupuis) were leaders in curriculum development. During the 1980s several other teaching units were established throughout the country.

MAJOR TOPICS. During the 1960s discussion of bioethics in the Netherlands focused on contraception and abortion; since then, the new reproductive technologies have attracted increasing interest. Euthanasia has been a key issue since the 1970s, and scarce resources and distributive justice, since the 1980s. A few issues that otherwise might not have been considered of importance have become so due to their link with scarcity of resources; for example, reproductive technologies, organ transplantation, the issue of insurance in the context of clinical genetics, and access to healthcare, especially waiting lists. Pervading all of these major topics is the recognition that patients' autonomy is quasi-absolute. A patient's choice is often considered to constitute the value of medical service. This is particularly true for decisions at the beginning and the end of life.

DECISIONS CONCERNING THE END OF LIFE. Euthanasia remained, in principle and for many years, punishable under criminal law although it became legal under certain conditions, such as voluntary request, hopeless suffering, and a second opinion provided by a colleague physician. Furthermore, a lenient jurisprudence was favorable to the medical practice of euthanasia and assisted suicide during the decades after 1974. Despite the publication of well-documented national surveys (van der Maas et al.; van der Wal et al.), stating that only 2,300 cases of requested euthanasia and 400 cases of assisted suicide occurred, as well as 1,000 cases of active termination of the patient's life without request, some estimates still range between 2,000 and 20,000 cases of euthanasia per year. Another critical point of discussion was the low instance of notification by physicians to the forensic doctor about their practicing euthanasia. By 1995, 6 out of 10 cases of euthanasia still remained unreported. In 1998 five regional evaluation committees started evaluating all notified cases and would then report back to the Attorney General and Health Inspection. In January 2001 a law codified what already existed: carefully performed euthanasia and assisted suicide, followed by notification, would exclude physicians from being prosecuted. Dutch euthanasia practice and legislation is perceived as exemplary in several countries, including Belgium, although the legislation is strongly opposed by others (Keown). It is fair to describe the Dutch euthanasia development over the decades as a transition from a moral debate, carried out on a large public scale during the 1970s and early 1980s, to discussions during the 1990s about careful implementation of policies, procedures, and guidelines, bringing about a clearer perception of the real practice.

HEALTHCARE SYSTEM AND REALLOCATION ISSUES. The Dutch healthcare system is based on principles of egalitarianism and solidarity. The latter principle is characteristic of the financial organization of healthcare in the Netherlands. In the modern welfare state, the moral principle is not primarily to feel individually responsible for others in need but to be held communally responsible for helping those in need. In a sense society imposes the duty to contribute financially in order to succor the needy in society. Individuals agree with this principle out of well-understood self-interest (Government Committee). At the same time, in the actual system of healthcare distribution, regulatory and marketing strategies are not necessarily contradictory (Wachter). While the population does not like cuts in healthcare or increased premiums for healthcare insurance, there is general agreement that healthcare is for all, and that the cost of individual preferences of patients beyond the basic package should be paid by the individual. The list of items excluded from the basic package around the turn of the millennium included only dental care for adults. But critics also lobbied to privatize cosmetic surgery, nursing luxury, homeopathy, physiotherapy beyond nine sessions, and alternative medicine. The government has legislated on hospital provisions (1973), on fees (1980), and on budgeting in hospitals (1983), but some problems, for example the waiting lists, remain. During the 1990s, a reform system based on the following principles was introduced: (1) private initiative is possible, and government controls only quality of care, access, and cost; (2) hospitals may plan according to local needs; and (3) insurers are free to market care.

REPRODUCTIVE TECHNOLOGIES. During the 1980s the emphasis on reproductive technologies was prominent. In 1981 abortion was legalized, offering women in distress the possibility to be treated in officially licensed clinics. A conscience clause warrants the right of healthcare workers to refuse to participate. Meanwhile, artificial procreation had become the issue of the day. Commercial surrogacy remains prohibited; artificial insemination by donor is increasingly available in all kinds of relationships. Follow-up studies have shown that no serious problems have arisen in either the physical or the psychological development of children conceived through in vitro fertilization (IVF) (van Balen).

ORGAN TRANSPLANTATION. The Organ Donation Act (1998) was meant to increase donations, to provide for the just distribution of organs, and to fight commercialization. In fact, it appears that there are fewer donations every year. The main reason for this failure is the opting-in system, where only the individual can decide to donate. But then, only one-third of the adult population returned the request to the Central Organ Donor Registry.

CLINICAL GENETICS. Several commissions have studied issues of genetic counseling, registration, access, screening and testing, as well as therapy. During 1990 the government took a position on various issues. For instance, the government agreed with the intention of the private insurers to exempt applicants from the obligation to disclose data resulting from a previous genetic diagnosis. In the case of life insurance, for example, the exemption applies to a limit of 250,000 florins, meaning that for insurance below that amount the insurer will not ask for genetic information. The insurers have shown readiness to try this policy for five years, and have repeatedly renewed this agreement. They also will not ask for additional genetic investigation. Based on principles of privacy, confidentiality, and solidarity, this position finds broad support among ethicists. Also in the context of clinical genetics, the government asked in early 1993 that the research community end all embryo research of its own

volition. Moreover, several governments intended to prohibit by law numerous types of embryo research, such as research on embryos older than fourteen days and the creation of embryos for the sole purpose of research. Although it had been suggested that the use of fertilized eggs as a source of stem cells in therapeutic research be accepted (Evers), the Embryos Act of 2002 prohibits, for a period of at the most five years, the creation of embryos—be it by IVF or by somatic cell nuclear transfer—for the sole purpose of research.

Luxembourg

The smallness of the territory of Luxembourg and the closeness of contacts intensify mutual knowledge and exchange of information. Within medical circles there is a remarkable amount of self-regulation under the guidance of the "collège médical," approved by the Minister of Health. In 1991 this body laid down an official compendium of laws, the "Mèmorial." Doctors and hospitals are still accepted as decision makers in healthcare. Public debate on issues such as euthanasia has rather been scant (Gillen). Having no medical school of its own, Luxembourg sends its medical students to neighboring countries, where they study in Belgian, French, or German universities.

In 1988 the government established the National Consultative Committee on Ethics in the life sciences and health care. As an advisory group it is supposed to study problems in a pluralistic perspective and to suggest solutions. The commission is also expected to develop programs of public information in bioethics. Reports thus far have covered patenting genetically modified organisms, reproductive technologies, youth protection, genetic research, and anonymity.

Ethics committees in hospitals and research centers are being developed in the early twenty-first century.

IV. UNITED KINGDOM

This entry surveys the development of medical ethics in Britain in the twentieth and early twenty-first centuries and some substantive medical ethical issues arising in these periods. It describes the involvement of important organizations concerned with medical ethics, the development of academic courses in the subject, and the establishment of a largely charitably sponsored independent nongovernmental national bioethics committee and of national forums for teachers and students of bioethics. It suggests that a typically

British antitheoretical, commonsense, and situational approach to medical ethics is gradually modifying so as to include at least some theoretical issues in the teaching and study of medical ethics.

Medical Ethics at the Beginning of the Twentieth Century

Respect for the professions and for the churches—especially, in England, the established Anglican church—were well-entrenched characteristics of British society at the beginning of the twentieth century, and medical ethics conformed to these cultural realities. Thus the normative standards of medical ethics were left almost entirely to the profession itself to establish and maintain. It did so largely in conformity with Hippocratic medical tradition, the ethical norms of the British protestant churches (including prohibition of active euthanasia and of abortion except to save the life of the pregnant woman), and a reliance on selecting "gentlemen" of good and honorable character to join the profession. The Medical Act of 1858 had, at the instigation of the newly established British Medical Association, established the General Medical Council to protect the public by controlling admission to the medical register on the basis of explicit medical educational standards, including ethical standards, both to exclude "quacks" (unqualified practitioners claiming to be doctors) from practicing medicine and to ensure that only those orthodox practitioners who had attained the prescribed standards were admitted to the register of medical practitioners.

Moreover, qualified medical practitioners who fell below the prescribed standards were liable to disciplinary action, including removal from the register (and thus loss of their professional livelihood) if they were found guilty of "infamous conduct in a professional respect." Among the infamous activities that could result in removal were the carrying out of abortion or active euthanasia, and having a sexual relationship with a patient. Other matters of considerable ethical concern to the General Medical Council included abuse of alcohol and drugs, fee splitting, "covering" for medical practice carried out by unregistered persons, convictions in the courts that would bring dishonor on the medical profession, abuse of the financial opportunities afforded by medical practice, improper denigration of professional colleagues, advertising for the doctor's own financial advantage, and canvassing for patients. Thus, at the beginning of the twentieth century, British medical ethics was almost entirely the prerogative of the medical profession and was concerned with protection of patients and of the public health, and with maintenance of its own honor and dignity.

Social Justice and Healthcare: 1911, 1946, and Beyond

If concerns about more equitable distribution of healthcare were not part of the medical profession's medical ethics agenda at the beginning of the twentieth century, they undoubtedly were a concern for the reforming liberal government elected with a large parliamentary majority in 1906. By 1911 David Lloyd George, then chancellor of the exchequer and later prime minister, achieved passage of his National Insurance Act; this provided working people (not their families) with medical and unemployment insurance, which was funded by compulsory contributions from workers, employers, and government (Braithwaite; Fox). The medical profession, though not opposed to the principle of such general provision of healthcare, fought the government on grounds of inadequate fees and inadequate protection for patients' choice of doctor; more than 27,000 doctors threatened to withhold their services. By 1913, however, after compromising with the doctors, Lloyd George had won the day (Lloyd; Lawrence).

The extension of medical care to the general population remained a popular political objective in Britain, and a 1942 report by Sir William Beveridge led, via the 1946 National Health Service Act, to the Labour government's establishment of the National Health Service (NHS) in 1948. This offered preventive as well as curative medical care to every member of the British public; it was provided in response to need, free at the time of that need, and financed by taxes (Bruce; Klein; Webster). While the objectives and provisions of the NHS remain widely accepted, early expectations that widespread healthcare would produce a healthier nation with reduced requirements for healthcare have never been achieved. On the contrary, concerns about increasing, yet inadequate, health expenditure multiplied, especially from the 1970s (Maxwell); a government committee chaired by Sir Douglas Black produced a 1980 report showing vast inequalities of health status in the population correlating with economic and other social disadvantages. Conservative government policy in the 1980s was more concerned to reduce costs than to remedy such discrepancies, but the New Labour governments of the 1990s and early 2000s was explicitly committed to reducing health inequalities and committed considerable additional funding to the National Health Service for this purpose.

Voluntary Euthanasia: 1936 and Beyond

A quite different issue of healthcare ethics—voluntary euthanasia—has been of public concern in Britain for almost as long as the issue of justice in the provision of healthcare. Medical proposals for its legislation had appeared early in

the twentieth century; and in 1936, following the creation of the Voluntary Euthanasia Society, the House of Lords debated and rejected a proposal to legalize voluntary euthanasia, which would have provided the legal right to request and be given medical assistance to die when suffering from incurable and fatal illness. Despite the admission by Lord Dawson, an eminent doctor, that euthanasia was carried out by many doctors (Dawson), he and another medical peer, Lord Horder, opposed the bill on the grounds that its proposals involved too many legal formalities and that, in any case, euthanasia was a matter best left to the discretion of doctors. (Many years later state archives were opened and revealed that Lord Dawson had deliberately accelerated the death of the dying King George VI, allegedly in order to enable the quality morning newspapers to report it first rather than risk the death being announced by a less-suitable evening newspaper.)

Euthanasia remains an intermittently burning public issue. Further proposals to legalize it were rejected by the British Parliament in 1969 and 1990; and in 1988 the British Medical Association (BMA) declared that, while allowing patients to die was properly a matter of medical discretion, active killing, even if requested by the patient in circumstances of severe and incurable suffering and disease, was always unacceptable and should remain illegal (BMA, 1988a). In 1992 a British doctor was convicted of attempted murder for administering undiluted potassium chloride to a long-standing patient of his who, in intractable pain, had repeatedly requested him to end her life (Brahams). His sentence of one year's imprisonment, however, was suspended, and the General Medical Council, while admonishing him, permitted him to continue practicing ("Decision on Dr. Cox," 1992). After the verdict a *British Medical Journal* editorial called for a royal commission to study active and passive euthanasia (the editorial's subtitle was "The Tide Seems to Be Running for Euthanasia" [Smith], and a *Lancet* editorial criticized the BMA's "unsympathetic public line" on euthanasia ["Final Autonomy," 1992]).

Nevertheless, the British debate about such cases and about the legalization of euthanasia in the Netherlands (e.g., Keown; Otlowski) did not result in any relaxation of British law. Two cases from 2002 clearly demonstrate the legal situation in the United Kingdom. On the one hand, refusal of life-prolonging treatment was undoubtedly a legal right: The High Court had admonished doctors for ignoring the instructions of a Ms. B. to cease treating her with artificial ventilation; after the doctors complied, she died. On the other hand, neither euthanasia nor assisting suicide was a legal right: On the same day that Ms. B. died, a Mrs. Pretty lost her case before the European Court of Human Rights to be helped to commit suicide (Boyd, 2002; JME, 2002). The distinction between killing and assisting suicide (legally forbidden) and withdrawing life-sustaining treatment at a patient's instruction (legally required) had once again been reaffirmed.

Experimentation on Human Subjects: 1947 and Beyond

Medical ethics in Britain—as in all parts of the civilized world—was given a shocking impetus after World War II by the revelations at the Nuremberg trials of Nazi medical war crimes, and the 1947 Nuremberg Code on Human Experimentation was as readily accepted within Britain as elsewhere (see Doyal and Tobias). In the early 1960s, however, Maurice H. Pappworth, an English physician, claimed that many orthodox medical research investigations were unethical, and in a book first published in 1967 he enraged the British medical establishment by likening examples of British medical research to the research of the notorious Nazi doctors. Whether cause and effect or coincidence, in the same year the Royal College of Physicians (RCP) published a recommendation that all clinical research proposals should be subject to ethical review; this advice was widely circulated by the British government's Department of Health and Social Security. Over the next few years "ethical committees," or research ethics committees (RECs), were established in the majority of hospitals and other institutions conducting medical research.

Nonetheless, development and practice of these committees was recognized to be variable, and in 1984 the RCP published guidelines for RECs, updated in 1990 (RCP, 1990a), as well as reports titled *Research Involving Patients* (1990b) and *Research on Healthy Volunteers* (1986). In 1991 the Department of Health published the first of its own guidelines for RECs. In both sets of guidelines the advice is detailed; it is designed, in the words of the RCP document, "to maintain ethical standards of practice in research, to protect subjects of research from possible harm, to preserve their rights, and to provide reassurance to the public that this is being done. In achieving these objectives ethics committees should remember that research benefits society and that they should take care not to hinder it without good cause. Ethics committees also protect research workers from unjustified criticism." (RCP, 1990a, p. 3). While the RCP guidelines were widely accepted in Britain as the national standard for ethics committees, and while research on human subjects must be submitted to RECs, there was and remains considerable doubt about what proportion of British ethics committees actually implement them (Nicholson; Gilbert, Fulford, and Parker; Neuberger).

In a 1997 government technology assessment review, Richard Ashcroft and colleagues expressed concern about the need to take careful account of the cultural and religious backgrounds of research participants. Revised guidelines on research were issued by the Department of Health in 2001, and new European legislation in the form of a "Clinical Trials Directive" was expected to take effect across the entire European Union in 2004. When this is incorporated into U.K. law, it is likely to include a statutory role for RECs for the first time; human research will thus catch up with animal research, which has been legally regulated in the United Kingdom since 1876.

Abortion: 1938 and Beyond

Another major medico-moral issue of British concern has been abortion. Under the Offences Against the Person Act of 1861, procuring an abortion was a felony punishable by life imprisonment. In 1938 an English obstetrician-gynecologist, Alec Bourne, challenged the law by reporting himself to the police after carrying out a therapeutic abortion on a girl who had been the victim of multiple rape. He was found not guilty on the grounds that the patient's life, in the sense of her mental well-being, was at risk if the pregnancy continued; just as "child destruction" (as the act calls it) to preserve the life of the mother was legally permissible under the Infant Life Preservation Act of 1929, so abortion for the mother's well-being might be lawful (see Mason, McCall Smith, and Laurie). In the 1967 abortion act the law was liberalized to permit abortion in cases in which two doctors certify that the continuation of the pregnancy would be a greater risk to the life or health of the pregnant woman, or her existing children, than a termination; or that termination would prevent grave permanent injury to the physical or mental health of the pregnant woman; or that there is a substantial risk that the child would suffer serious physical or mental disability.

In practice many British doctors, accepting that during the first three months of any pregnancy the risk of continuing to normal birth is greater than the risk of therapeutic abortion, agree to abortion for any woman who after deliberation continues to request it. The upper limit of gestation at which abortion is permitted was reduced by the Human Fertilisation and Embryology Act of 1990 from twenty-eight weeks to twenty-four weeks. No upper limit applies in cases in which the mother's life is seriously threatened and in cases in which the child, if born, would probably be seriously disabled. Significant, though minority, opposition to abortion persists both within the medical profession and among the public. In Northern Ireland, a part of the United Kingdom, opposition to abortion among the Protestant as well as the Roman Catholic population is sufficiently widespread for the Abortion Act not to apply there.

"Official" British medical ethics, as represented in this context by the General Medical Council, the British Medical Association, and the Royal College of Obstetricians and Gynaecologists, accepts abortion when carried out according to the law while recognizing any doctor's or nurse's right of conscientious objection. Such practitioners are expected to inform their patients of their moral objections to abortion, to advise them that they may seek assistance elsewhere, and to give information about sources of such assistance if requested (BMA, 1988b).

Reproductive Technology: 1978 and Beyond

In July 1978 the pioneering work of Patrick Steptoe and Robert Edwards led to the birth of the world's first "test-tube baby"—and to a paradigm shift in bioethical thinking about human reproduction and genetics. From 1982, when the British government appointed a Committee of Inquiry into Human Fertilisation and Embryology (Warnock), until the passing of the Human Fertilisation and Embryology Act in 1990, the British public and the British medical profession were gripped by a vigorous debate about the moral issues associated with in vitro fertilization (Snowden, Mitchell, and Snowden; Council for Science and Society; Bock and O'Connor; Bromham, Dalton, and Jackson). As with abortion, the central moral issue was seen by many to be the moral status of the embryo/fetus, though other issues included possible adverse physical and psychological effects on children conceived artificially and also on the women involved with such techniques, especially in the case of surrogacy. Feminist concerns included the continuing debate about access by single heterosexual women and lesbian women to reproductive technology (Hanscombe and Forster; Chadwick).

The issues were resolved in an extensive government bill that, unusually, offered alternative clauses on the most contentious issue of all: research on, followed by destruction of, the human embryo. Members of Parliament (MPs) were given a free vote (i.e., without any party pressure to vote in one way rather than another) and asked to choose between allowing such research for up to fourteen days of embryo development, as recommended by the Warnock Committee majority report, or forbidding all such research on human embryos except when done therapeutically—that is, to facilitate transfer of the embryo into the uterus of a woman. (The latter is the position of the Roman Catholic church, though it is worth noting that the eminent Jesuit theologian John Mahoney had argued in 1984 that the early embryo is "unlikely to be possessed of a soul and personhood in its

existence at the simple cell-multiplication stage prior to diversification" [p. 85]). After cliff-hanging public, professional, and parliamentary debate, the MPs accepted research for up to fourteen days of embryonic development and established the national Human Fertilisation and Embryology Authority to monitor and control all such activities.

Informed Consent: 1985 and Beyond

Of the many other medico-moral issues that have exercised both healthcare professionals and the public in Britain, two legal cases are particularly notable: the Sidaway case on informed consent to treatment and the Gillick case on treatment of minors without parental consent. In the Sidaway case, finally determined by the House of Lords in 1985, the plaintiff complained that her surgeon had been negligent in not warning her of the small risk of spinal nerve root damage, which had occurred. Their lordships decided by a majority to uphold the existing English legal doctrine according to which a doctor is not negligent if acting in a way supported by a body of reasonable medical opinion (the "Bolam test"). Nevertheless, by indicating what reasonable doctors could be expected to do in certain circumstances (for example, answer their patients' questions and warn them of any substantial risks!), the judges brought English law "edging toward" the American "reasonable patient standard" whereby the requirements of a reasonable person in the patient's situation would determine what information was required (Kennedy and Grubb)—though not all legal commentators agreed that even this modest degree of change was achieved in the case (Brazier).

In the Gillick case a mother asked the court to rule that doctors should not be allowed to give medication (birth-control pills) to her children under the age of sixteen without obtaining parental consent. Once again the case went to the House of Lords, which in 1986 rejected Mrs. Gillick's claim; it ruled that a doctor ought to try to persuade the minor to involve the parents in the consultation, but if the patient refused—provided the doctor had good reason to assess the minor as having sufficient maturity and understanding—treatment could be prescribed without involving the parents (Kennedy and Grubb).

In the early 2000s increased emphasis on the need for doctors to obtain informed and explicit consent from patients in relation to use of and retention of tissues after surgery or postmortem became more stringent in response to two NHS scandals. Thus the reports of two inquiries, one into defects in pediatric cardiac surgery at a Bristol hospital (Bristol) and the other into storage of pediatric pathology specimens at a Liverpool hospital (*Royal Liverpool,* 2001), recommended (among a host of improvements) explicit informed-consent procedures for the retention of all tissues and organs (for research or teaching) removed for therapeutic or diagnostic purposes. These recommendation were put forth despite professional concerns that such explicit procedures would often cause unnecessary additional distress to recently bereaved families or to parents whose children were about to have surgery. The general trend in the early 2000s was to explicit and "fully informed" consent for all interventions (see, e.g., Doyal and Tobias), despite professional and philosophical concerns that such moves toward ever-greater "accountability" were excessively undermining trust in medical and other professionals, which though "old-fashioned" was nonetheless ultimately in the public interest (O'Neill 2002a, 2002b).

The Organization of Medical Ethics in Britain

At the beginning of the twentieth century, the final arbiter of medical ethics was the General Medical Council (GMC), a regulatory body largely composed of doctors. In the early twenty-first century, while the GMC's role remained pivotal, it was in the process of becoming a smaller organization with a larger representation of nondoctors and an organization far more open to influence from outside the ranks of the medical profession than ever before. In 2003 the GMC was reduced from 104 members to 35, of whom 19 were elected and 2 appointed by the medical profession, while 14 were nonmedical ("lay") (and thus comprising 40 % of the GMC in contrast to the previous 25 %). The lay members continue to be appointed by the Privy Council (a group of the United Kingdom's "great and good" appointed by the monarch and relatively independent of the government of the day, though many will have been appointed by virtue of their high office in current or previous governments). The GMC, as it notes itself on its web site, is "not here to protect the medical profession—their interests are protected by others. Our job is to protect patients."

The GMC licenses doctors to practice, and it can withdraw or put conditions on a doctor's license if a complaint is upheld. It is responsible for standards of medical education, including education in medical ethics, for quasi-judicial assessment of complaints against doctors, and for provision of advice on ethical standards and professional conduct. This advice used to come in a very slender volume, "the little blue book" (e.g., GMC, 1992), but more recently the GMC has provided a broader range of advisory booklets with more extensive "guidance on good practice," of which the core is covered in *Good Medical Practice* (GMC,

2001). This advice is sent to every registered medical practitioner and is also available to everyone on the GMC web site.

Although it has no official authority in matters of medical ethics, the British Medical Association, which is the doctors' professional association and trade union, provides considerable guidance on these issues to its members, to the government, and to the public. It has a multidisciplinary Medical Ethics Committee and an ever more impressive Medical Ethics Department of permanent staff. It provides individual advice and analysis to its members as requested, provides analysis and advice to government and official bodies, and publishes books relevant to medical ethics (e.g., BMA, 1993, 2001a, 2001b). (The BMA even experimented with what may have been one of the world's first computer programs offering doctors medico-moral advice [Sieghart and Dawson]).

Other professional influences on medical ethics are exerted during medical education by individual teachers, themselves influenced not only by the GMC and (often) the BMA but also by the Medical Research Council (a government run organization that funds and or carries out much of the UK's medical research program) and specialty organizations; the latter include the Royal Colleges of Physicians, Surgeons, Obstetricians and Gynaecologists, General Practitioners, Psychiatrists, and so on, all of which offer advice and guidance on medical ethics relevant to their specialties. So, too, do the medical malpractice organizations, such as the Medical Defence Union and the Medical Protection Society. In addition the employment contracts of most doctors in Britain exert some legally binding ethical pressure on their behavior. For example, general practitioners, though they are independent contractors, are required by their contracts with the NHS to provide emergency care in their vicinity whether or not those needing such care are registered with them; and they are also required by their contracts to accept "difficult to place patients" for a minimum of three months, when required by the NHS to do so. And surgeons in NHS hospitals, according to their contract of service, must, under normal circumstances, obtain written consent from their patients prior to operating. In addition there is a strong tradition in British medicine of consultation, especially with more experienced colleagues, about any difficult medical problem, including difficult medico-moral problems. A noteworthy if embryonic development at the end of the twentieth century was the creation of clinical ethics committees at some hospitals, set up to provide analysis and advice about particular ethical problems arising in clinical practice (not in research), to advise on ethical aspects of hospital policy matters, and to have at least some educational function (see, e.g., "Clinical Ethics Committees Supplement," 2001).

Nonmedical influences on British medical ethics include the range of forces typical of a modern Western democracy. The most important is undoubtedly the law, which, as noted above, has a major role in defining the arenas within which the medical profession may make its own choices about medico-moral issues. Nurses have undergone a metamorphosis from doctors' handmaidens to independent health professionals and have become increasingly influential in British healthcare ethics, especially through the activities and pronouncements of their disciplinary body, the (United Kingdom) Nursing and Midwifery Council or NMC (e.g., NMC), and of their professional association and trade union, the Royal College of Nursing or RCN (e.g., RCN 1991, 2001).

Many public pressure groups, patient groups, and special medical interest groups exist to try to influence the profession, the media, Parliament, and the public on such matters as healthcare ethics issues. Important examples include the Patients Association, the College of Health, the Consumers Association, MIND (which promotes the interests of the mentally ill), MENCAP (which promotes the interests of the mentally disabled or impaired), CERES (Consumers for Ethics in Research), GeneWatch (which is concerned with the ethics and risks of genetic engineering), and the local community-health councils and their successor organizations, the Patient Advocacy and Liaison Services (PALS), which protect patients' interests. Also important are several "right-to-life" activist groups such as the Pro-Life Alliance, LIFE, and The Society for the Protection of the Unborn Child, and "on the other side," the Voluntary Euthanasia Society and the Abortion Law Reform Association. And the media constantly, often daily, publish and broadcast on medical ethics issues.

From a plethora of possible examples, one media event is particularly worth noting: the prestigious BBC Radio Reith Lectures, given in 1980 by Ian Kennedy, then a lecturer in academic law (later to become a professor of medical law and ethics and a knight of the realm). Published in 1981 under the profession-provoking title *The Unmasking of Medicine,* the lectures brought into the arena of intelligent public discussion many of the standard themes of medical ethics, and argued forcefully that while doctors had special training and expertise in technical medical matters, they had no such training and expertise in moral matters. Even if they had had such training (which Kennedy advocated), they had no right to assume that moral decisions in medical practice were solely for doctors to make, in the way that technical decisions in medical practice might be. The resulting public and professional debate did much to achieve Kennedy's objective of bringing medical ethics "out of the

hushed halls of Academe into the noisy market place of ideas" (Kennedy, 1981, p. xi).

The study and development of medical ethics in Britain has also been promoted by the Institute of Medical Ethics (IME). Originally named the Society for the Study of Medical Ethics, it was founded in the early 1960s by a Church of England priest, the Rev. (later Dean) Edward Shotter, who at the time had pastoral responsibility for medical students in London. Shotter soon recruited two other Protestant clerics, both from Scotland, who were to become influential in British medical ethics: Kenneth Boyd (Boyd, 1979, 1992; Boyd, Callaghan, and Shotter; Smith and Boyd; Gallagher and Boyd) and Alastair Campbell, founding editor of the IME's *Journal of Medical Ethics* from 1975 to 1980 and one of the earliest British contributors to the academic medical ethics literature (Campbell, 1972, 1978, 1984; Campbell and Higgs) and a Jesuit and psychologist Brendan Callaghan. Also recruited by Shotter was a secular Jewish doctor-philosopher, Raanan Gillon, who served as editor of the *Journal of Medical Ethics* from 1981 to 2001. Among the IME's activities have been the establishment of multidisciplinary ethics study groups within most of the British medical schools, various research projects, and the founding of two publications, the aforementioned *Journal of Medical Ethics* (1975) (by the end of the century the most highly cited journal in its field) and the *Bulletin of Medical Ethics* (1985; shortly afterward, the latter became independent of the IME, and it continues to be edited by its owner-editor, another Shotter medical recruit, Richard Nicholson).

Other organizations stimulating the early development of healthcare ethics in the United Kingdom were the medical ethics and or medical law centers at some of the universities. Pioneer centers in Britain included those at King's College, London; the University of Wales at Swansea; the University of Manchester; and the Universities of Birmingham, Hull, Oxford, St. Andrews, Leeds, and Warwick; the University of Wales at Cardiff; and the Universities of Glasgow and Bristol. Since the 1990s there has been considerable further expansion in the number of universities providing healthcare ethics, or law and ethics, teaching and research in the United Kingdom, and these have been joined by a few centers offering courses in medical humanities. In addition, the Society for Applied Philosophy is concerned with philosophical illumination of "areas of practical concern" that often include issues of healthcare ethics; it publishes the *Journal of Applied Philosophy*.

Of the various academic disciplines with an interest in medical ethics that has stimulated its development, and apart from law and theology as already mentioned, health economics has been particularly important in relation to resource allocation. Alan J. Williams (1985, 1996), Alan Maynard (1986; Maynard and Bloor), and Anthony J. Culyer (1992, 2001), from the Centre of Health Economics at York University, and Gavin Mooney and Alistair McGuire (1988) have been especially influential, particularly Williams, with his advocacy of the maximization of quality-adjusted life years (QALYS) as the centrally relevant criterion for health-service resource allocation.

Academic Courses, Degrees, and Chairs

The first British academic course in medical ethics seems to have been started by the ancient City of London guild, the Worshipful Society of Apothecaries (still a medical licensing body), when it instituted a diploma course in the philosophy of medicine in 1978, first taught by the Oxford philosopher Michael Lockwood. An annual one-week "intensive course in medical ethics for medical and nursing teachers" was started in 1983 at Imperial College, London, in cooperation with the IME, and in 1984 the Centre of Medical Law and Ethics at King's College, London, initiated a one-year postgraduate diploma in medical law and ethics, upgraded in 1987 to a master's degree. In 1985 the University of Wales introduced a highly popular part-time M.A. in healthcare ethics, and in 1987 the University of Manchester offered a multidisciplinary M.A. in healthcare ethics, administered by its Centre for Social Ethics and Policy. Since then various other British universities and colleges have developed a wide variety of courses in healthcare ethics.

British medical schools were slow to introduce the formal study of medical ethics; the Scots led the way at Edinburgh University and Glasgow University, with King's College Hospital in London being the vanguard in England under the leadership of the doctor-ethicist Roger Higgs. Full-time philosophers were appointed to teach the subject at medical schools at Liverpool and at the London Hospital; and St. Mary's Hospital Medical School London was the first to appoint a (part-time visiting) professor of medical ethics. Birmingham University Medical School appointed a veterinarian, David Morton, to the joint chair of biomedical science and ethics.

Although medical schools were stimulated into some activity by the report of an IME working group (Boyd, 1987) urging that they introduce the critical study of medical ethics, such teaching became widespread only after the GMC told medical schools that medical ethics and law should be part of the core medical curriculum and therefore compulsory for all medical students (GMC, 1993). In 1998 most of the teachers of medical ethics in U.K. medical

schools, and others, published a consensus statement on the contents of a core curriculum in medical ethics and law in medical schools (Teachers of Medical Ethics).

By the early 2000s, however, although there were several professors of medical ethics holding personal chairs, and while many medical schools had at least one full-time teacher of medical ethics, the only established chair of medical ethics in a U.K. medical school had been established in 1996 at the University of Bristol Medical School, with Alastair Campbell holding the position until his retirement in 2003. While female let alone feminist influences cannot be said to characterise British medical schools, influential exceptions in the realm of medical ethics included Ruth Chadwick, Jenifer Jackson, Janet Radcliffe Richards, Donna Dickenson, Bobbie Farsides, Heather Draper, and Ann Sommerville, along with leading medical law and ethics specialists Margaret Brazier and Sheila Mclean.

Three National Groups Formed in the 1990s

At the beginning of the 1990s three national groups concerned with medical ethics were established. The first, the U.K. Forum for Health Care Ethics and Law, was designed to bring together the increasingly numerous and various academic and other organizations, teachers, and students in Britain concerned with healthcare ethics. The second was the Nuffield Council on Bioethics, a national independent and nongovernmental multidisciplinary committee established by the private philanthropic Nuffield Foundation, to review the ethical issues raised by medical research, starting with those involving genetic manipulation, The third was the Association for Healthcare and Medical Ethics Teachers, founded for medical ethics teachers in British medical and nursing schools.

The Nuffield Council on Bioethics has flourished, becoming as near to a national committee on bioethics as the United Kingdom seems likely to have. While it remains self-appointed and unofficial this enables it to be independent of government, and its funding seems secure now that the government's Medical Research Council and the Wellcome Trust have joined the Nuffield Foundation in supporting it. Helping to account for the high respect with which it is held are its independence and multidisciplinarity, as well as the high caliber of its reports and discussion documents, on subjects including ethical aspects of genetic screening, xenotransplantation, stem cell therapy, health research in developing countries, the patenting of DNA, genetics, and human behavior (all available through the organization's web site). Also likely to be relevant to the development of medical ethics in the UK is the creation in 2002 of the Association for Medical Humanities.

Continental Influences

Three continental European influences on the British approach to medical ethics are also important to note. The Council of Europe has an international bioethics committee and has produced a Convention on Human Rights and Biomedicine, which is legally binding on signatory states (Council of Europe) and is in effect an extension of its European Convention on Human Rights. A protocol to the convention banning human reproductive cloning is in effect, and protocols on organ transplantation, medical research, and the embryo and genetics are being developed. The United Kingdom has not signed on to the convention, in part because it forbids a form of scientific research that is accepted in the United Kingdom: the production of human embryos for the purpose of research.

The European Union also has an international bioethics committee, but more importantly for U.K. bioethics it has distributed significant funding for bioethics research projects if these involve cooperation between member nations. This has resulted in several U.K.–led projects involving such areas as education in bioethics, ethical aspects of HIV/AIDS, stem cell research, virtue ethics and chronic illness, and neonatal research. The United Nations Educational, Scientific and Cultural Organization (UNESCO) also has an international bioethics committee and has produced a (nonbinding) Universal Declaration on the Human Genome and Human Rights, which was adopted by the United Nations. Academic bioethics in the United Kingdom is also influenced from continental Europe through participation in the European Association of Centres of Medical Ethics and the European Society for Philosophy of Medicine and Health Care.

Religious Influences on Medical Ethics

Religious organizations are influential in medical ethics in Britain, both at a personal level, affecting the decisions of patients, healthcare workers, and others concerning medicomoral issues, and as a result of institutional activities. Relevant institutions include the Church of England Board for Social Responsibility (see, e.g., Dunstan, 1987; Dunstan and Seller); the (Roman) Catholic Bishops' Joint Committee on Bioethical Issues (see, e.g., Catholic Bishops' Joint Committee); the (Roman Catholic) Linacre Centre (see, e.g., Linacre Centre); the (evangelical Protestant) Christian Medical Fellowship (which holds regular meetings and publishes the *Journal of the Christian Medical Fellowship*); and the Jewish Chief Rabbinate (one of whose members, Lord Immanuel Jakobovits, obtained the first doctorate devoted to Jewish medical ethics; see Jakobovits).

The National "Flavor" of Medical Ethics in Britain

While it is always risky to generalize, a pragmatic, situationist, commonsense, antitheoretical, and antiregulatory approach tends to characterize the British approach to medical ethics (as to do many other aspects of British life—though resistance to regulation may be being increasingly overridden). Despite this national reluctance to theorize, however, it is gradually being acknowledged that some theoretical underpinning is needed even for commonsense ethical decisions. In the context of medical ethics, a distinction is increasingly recognized between two medical ethical concepts ("Two Concepts," 1985). The first is traditional medical ethics, in the sense of promulgating and enforcing within the medical profession certain medico-moral norms—what Gordon R. Dunstan called "the obligations of a moral nature which govern the practice of medicine" (1981, pp. xxviii–xxxi). This sort of medical ethics has characterized medical education and practice since Hippocratic times. The second, more recent sort—philosophical or critical medical ethics—sets out to examine rigorously, and in the light of argument, justification, and counterargument, the issues of medical ethics, including the claims of traditional medical ethics.

Prompted from without as well as from within, the British medical profession has, since the mid-1970s, increasingly accepted the latter medical ethical concept as a proper part of medical thinking and education. Evidence for this includes the General Medical Council's greatly increased interest in medical ethics since it held a conference on medical ethics teaching in 1984; publication by the *British Medical Journal* in 1985–1986 of a series of twenty-six articles under the title "Philosophical Medical Ethics" (Gillon, 1985–1986); publication of *The Pond Report* on medical ethics teaching (Boyd, 1987), recommending such teaching in medical schools; the GMC's requirement that medical ethics and law should be part of the core medical curriculum (GMC, 1993); publication of the consensus proposals for the core curriculum (Teachers of Medical Ethics); the increasing teaching of critical or philosophical medical ethics in medical schools; and the increased attention paid to critical medical ethics by the British Medical Association.

But virtually all involved in the British medical ethics scene agree on one issue: the central importance of real cases, manifesting real medico-moral problems, in their real human context, for any adequate critical study, teaching, or understanding of the "humanized version of ethics" called for by the moral philosopher Jonathan Glover (1999).

V. REPUBLIC OF IRELAND

"Ireland" here refers to that part of the island of Ireland (twenty-six of the thirty-two counties) that achieved independence from British rule in 1921 and was declared a republic in 1949.

Ireland's moral traditions and its history in ethics are inextricably linked with centuries of religious history that are primarily rooted in the nineteenth-century Roman Catholic Church. After experiencing religious persecution under British rule, the government of the new Irish State reinforced the traditional religious ethos in its laws and institutions, particularly education and healthcare. The Irish Constitution of 1937 recognized the "special position" of the Holy Roman church as guardian of the faith of the great majority of Irish people. This constitutional recognition was deleted in 1972 when Ireland was preparing for membership in the European Economic Community; the deletion signaled recognition for a religiously pluralist state.

In what follows, bioethics in the Republic of Ireland is discussed in two time periods: 1922–1982 and 1983–forward. The period division marks a development of appeals to legal resolution to negotiate ethical diversity. Four areas of national development frame the discussion: reproductive ethics, research and ethics committees, obligations to prolong life, and establishment of the Irish Council for Bioethics.

Between 1922 and the early 1980s, a religious homogeneity of tradition and practice largely prevailed. While cultural changes are never abrupt, a change in Irish political and social conditions was initiated on January 1, 1973, when Ireland became a member of the European Economic Community (now known as the European Union). Ireland increasingly interacted with other countries whose philosophies of life were based on secular viewpoints. Moral questioning in the society, in politics, education, and healthcare practice became more sustained, open and tolerated.

Reproductive Ethics

In the early 1970s, women's groups actively protested a prevailing legal ban on contraceptives and the complete ban on elective abortion even in cases where women were victims of rape or incest. Women who could afford private healthcare could get contraceptives and abortion advice. Women who sought prenatal genetic testing generally could not be accommodated within the hospitals of the Republic of Ireland. The concern was that some test results might contribute to pro-abortion decisions. But private patients were often accommodated by referral outside the country. The justice of a two-tier health system came under moral and political scrutiny. A private citizen, Mrs. McGee, challenged the Irish government's long-standing prohibition of the sale and importation of contraceptives. Her efforts led to the Health (Family Planning) Act of 1979, in which the Irish state allowed restricted access to contraceptives. Outsiders may be incredulous at Ireland's preoccupation with reproductive ethics. However, this area of morality is central in Irish traditional religious teachings, which have consistently reaffirmed the primacy of women's procreative capacity and fetal life.

Until the 1980s, the topic of abortion was largely a closed moral and legal issue. Ireland had never rescinded the complete ban on abortion specified under the British Offences Against the Person Act of 1861. In practice, termination was permitted under the principle of double effect in exceptional cases, such as ectopic pregnancy. Yet Irish women did (and do) procure abortions. On average, six thousand Irish women a year go to England to have abortions under the provisions of the 1969 British abortion legislation. Irish women gradually became more politicized and organized public demonstrations, claiming their rights to control fertility. Serious polarization of views developed as other groups in society feared that elective abortion might be legalized in Ireland. A national campaign began to guarantee protection of embryonic life by means of constitutional amendment.

In 1983, the eighth amendment to the Irish Constitution gave "the unborn" the same rights to life as other citizens. Since then, this amendment has generated a complex series of political, legal, and moral challenges, leading to a Supreme Court judgment of 1992, *Attorney General v. X and Others,* which argues that abortions may lawfully be carried out in Ireland where continuance of the pregnancy constitutes a real and substantial risk to the life of the pregnant woman. A threat of suicide was specified as such a risk. Following the Supreme Court Judgment of 1992, it remains for the Irish government to provide legislation to specify the conditions under which it is lawful to have abortions in Ireland.

Moral concerns to protect fetal life also influenced the development of guidelines for in vitro fertilization (IVF) issued by the Institute of Obstetricians and Gynecologists. The guidelines specified that IVF should be offered to married couples who have been appropriately counseled and have given informed consent. Only sperm and ova from the consenting couple may be used, and all resulting fertilized ova should be placed in the potential mother's uterus. However, with the Government's establishment of a Commission on Assisted Human Reproduction in 2000, existing IVF guidelines and policies on all forms of assisted procreation began being researched and ethically assessed. Submissions from the public, service providers, and consumers were invited. The Commission consists of four working groups studying topics from the status of the embryo to gamete donation, anonymity or disclosure, access to assisted reproduction, and embryo research. The working groups draw on the expertise of fertility experts, lawyers, ethicists, geneticists, social theorists, and theologians. The debates on the Commission are evidence of the growing diversity of ethical and legal views on reproductive matters. The Commission's report is expected to form the basis for legal decisions on the status of the pre-implanted embryo, and implementation of policy recommendations or regulatory mechanisms for all forms of assisted reproduction and embryo research.

Research and Ethics Committees

For years, medical research and clinical trials in Ireland were assessed by Institutional Review Boards whose composition and procedures lacked any nationally agreed-upon guidelines. The ethical norms from the Declaration of Helsinki were applied. The death of a male participant in a nontherapeutic drug trial in Ireland resulted in the government's issuing of the Control of Clinical Trials and Drugs Act 1990. The principal features of this legislation are that, with certain exceptions, the minister for health must authorize all proposed clinical medical trials and members of the ethics committees examining protocols must be approved by the minister. Ethics committees have the responsibility for ensuring that participants in any trial give their informed consent personally or by proxy. The latter provisions allow for clinical trials with psychiatric patients who might not be considered competent to consent. To avoid a conflict of interest, investigators involved in any clinical trial are not allowed to give proxy consent.

Ethics committees in Irish public hospitals traditionally were given the job of adjudicating requests from doctors for female sterilizations. Women's groups and gynecologists are now rejecting this role for ethics committees, and criticize what is judged to be unwarranted religious influence on decisions of ethics committees in public hospitals. While doctors are increasingly trying to minimize intrusions into the privacy of the doctor–patient relationship, ethics committees are still established throughout the state for educational purposes and for consultation by patients, families, and healthcare practitioners.

Irish patients are now requiring more communication about diagnoses and prognoses, and also expect increased participation in medical decision making. The value of respect for patients and the importance of securing consent is a corollary of expectations for a role in decision making. In efforts to reinforce the values of respect for personal autonomy and informed consent, in 2001 the Irish government set up an inquiry into policies and practices surrounding post-mortems in the state since 1970, particularly with regard to the removal and retention of organs by hospitals. The stimulus for the inquiry came from parents of children who had died in hospital and whose organs had been removed and retained by hospitals for research without the consent of parents. The public, parents, hospital management, and scientific institutions recognize that the value of trust can be readily undermined if ethical guidelines are not in place to reassure relatives that consent will be sought for

post-mortem tissue or organ procurement. While parents do not dispute the need for research, they argue that the issue is the informed consent of relatives and accountability of institutions in receipt of public money.

Since the 1980s, doctors in Ireland have experienced increasing lawsuits for alleged malpractice or negligence. Further analysis is required to determine the multiple causes for such an increase, but the Medical Defence Union, an indemnity insurer for doctors, continues to urge doctors to reflect on the quality of their relationships with patients and to work to improve levels of communication. The previously dominant model of strong paternalism characterizing the doctor–patient relationship and more general practices of healthcare institutions are under challenge due to changing educational experiences of doctors and nurses and a more questioning Irish population. Courses in ethics are taught in Irish medical schools, where almost 30 percent of students are now non-Irish. In their required university work, nurses are encouraged to reflect on reasons for their moral views and to consider the possible validity of diverse ethical positions. Religious orthodoxy is no longer taken for granted. Such courses are usually required of medical students and nurses, and vary in length from several weeks to a full year.

Obligations to Sustain Human Life

Public debate about moral obligations to prolong human life came to the fore in 1995. The family of a woman who was in a persistent vegetative state (PVS) for over twenty years appealed to the Irish courts to have a gastrostomy tube removed and to allow her to die naturally. The patient was made a ward of court because the healthcare institution responsible for her care had, many years earlier, differed ethically with the family concerning what life support measures were morally justified. In 1995, in *Re a Ward of Court,* the High Court and, on appeal, the Supreme Court judged that in the best interests of the woman, it would be legal to remove the feeding tube. Following the Supreme Court judgment, the Irish Medical Council and the Nursing Board issued statements for members, in effect disagreeing with the ethical basis of the Supreme Court decision and claiming that access to nutrition and hydration is one of the basic needs of human beings. The *Re a Ward of Court* case raised difficult questions about active and passive euthanasia, withholding and withdrawing life support systems. Who should be involved in life and death decisions is a concern with arguments to the effect that decisions about withholding life-support systems for the terminally ill are areas of medical decision making where patients and family members ought to have more voice. In trying to determine moral boundaries in the prolongation of life, the Roman Catholic tradition distinguishing obligatory and nonobligatory treatment (ordinary and extraordinary) may be justly recognized as a well-argued basis for granting patients considerable voice in their treatment decisions.

The Irish Council for Bioethics

In 2002, concerns about ethical questions in modern biotechnology and genetic engineering prompted the Irish government to establish the first Irish Council for Bioethics. Members are invited by virtue of their personal expertise and not as representatives of particular bodies or professions. The members range in specialty areas from genetics, molecular biology, nursing, fertility, theology, law, and ethics. The Council operates under the aegis of the Royal Irish Academy but is an independent body. The aims of the Council are to identify and interpret ethical questions raised by biological and medical research and to examine and report on a range of questions with a view to promoting public discussion and understanding. Where appropriate, the work will contribute to the formulation of new guidelines in areas such as genetically modified products, stem cell research, biological samples, Ethics Community and human genetic research.

As Ireland continues to be more actively integrated into the European Union, ethical pluralism is being acknowledged as a reality requiring open debate. The hope is that such efforts at public discussion will yield a stronger, because more consensual, public morality that will signal respect for the now undeniable differences of ethical viewpoints among Irish people. In the years ahead, the work currently under way should yield policy developments in assisted reproduction, research protocols, biotechnology, and debates about advance directives and obligations to prolong human life.

VI. GERMAN-SPEAKING COUNTRIES AND SWITZERLAND

Interest in bioethics in the German-speaking countries (Germany, Austria, and Switzerland) originated, as it did elsewhere, with medical-ethics questions related to both modern biotechnological potential and a growing ethical pluralism. These factors not only induced physicians to debate these issues, they were part of the reason for a "rehabilitation of practical philosophy" among a number of German academic philosophers and theologians that included a renewed interest in moral, social, and political problems.

In several respects, bioethics in Germany, Switzerland, and Austria differs from that in the United States or other European countries. First, as a major, collective, and socially visible effort, it developed relatively late—in the 1980s. Some explanations for this are the lack of civil rights movements that would have endorsed issues of patients' rights; a widespread and deeply rooted medical paternalism; good, uniform access to medical care (and thus little need for allocation debates); a different philosophical tradition; and, in Germany, a severely disturbed moral self-assurance due to the relatively recent experiences of Nazi Germany's indescribable immoralities.

Second, there are many theological voices in German bioethics. In the German world, theology is given a legitimate academic presence within universities, where it enjoys the same juridical status as all other disciplines. It also possesses relative independence from religious institutions. Third, German law is solely statutory in nature and is not linked to case law, as it is in the American judicial system. Hence, going to court is a far less common way to trigger public discussion on difficult bioethics cases. In Switzerland, plebiscites (direct voting by the population on an issue) are an instrument of legislative decision making. In addition, legal authority resides partly with the Bund (federation) and partly with the 26 different cantons (states), which show remarkable legal differences in handling some bioethics problems.

Fourth, Germans place great importance on the study of the history of medicine and medical anthropology, the philosophical clarification of fundamental medical categories. Fifth, Germany labors under the historical weight of the Nazi regime's deadly medical experimentation, eugenics, and euthanasia—and of the concomitant moral degradation of many physicians. Thus, public mistrust of bioethics "experts" seems to be comparatively deep and widespread.

Not only does the Nazi specter affect the discussion of bioethics in Germany, but it is seen by many to have a direct connection to a number of issues discussed in contemporary bioethics. Concern is heightened by the fact that Nazi experimentation occurred despite the existence of guidelines for therapeutic and scientific research on human subjects that prohibited such treatment. These guidelines, thought to be the first of their kind, were originally published as a Circular of the Reich Minister of the Interior on February 28, 1931, and remained in force until 1945 (Sass, 1993). Several groups and movements have taken the position that preimplantation diagnosis, selective abortion, euthanasia, and gene therapy are not only immoral, but represent a continuation of Nazi ideology.

Philosophical Bioethics in Germany

The philosophical clarification of medicine's role, and of its fundamental categories (e.g., pathology, illness, healing) in Germany still has an influential intramedical tradition as

medical anthropology (Weizsäcker). German medicine has long cultivated historical study, and the many institutes devoted to medical history increasingly view part of their work as preparatory to or incorporating moral reflection on medicine. Whereas medical ethics has traditionally focused primarily on aspects of the physician–patient relationship (e.g., truth-telling, confidentiality, humaneness), its spectrum has long since been broadened to cover all issues addressed by Anglo-American "bioethics." The latter, however, is opposed by many—be it merely as a label, as the writing of those who call themselves bioethicists, or as a discipline in general. Thus (in contrast to medical ethics), "bioethics" has frequently been understood as an ideological and uncritical defense of biotechnological progress or profit—or at least with a suspected (i.e., "analytical") style of philosophy.

German philosophers have thus been late to join the contemporary Anglo-American debate on any issue in applied ethics. Analytical philosophers had to leave the country under the Nazi regime—and continental philosophers of the period were rarely attracted by either utilitarianism or pragmatism, which are among the dominant theories in contemporary Anglo-Saxon ethics debates. Immanuel Kant (1724–1804), with his rejection of material ethical values and his predominant interest in a metaphysico-rational justification of ethics, has certainly been the major influence for those opposed to these theories.

At the beginning of the twenty-first century, this gap seems to have closed. Meanwhile, quite a number of philosophers consider bioethics a serious aspect of their own academic work. In 2003 the German book market still lacked a basic comprehensive textbook covering both in-depth theory and the whole spectrum of ethical problems in healthcare, which are covered by a number of influential Anglo-American examples. However, introductory anthologies (e.g., Wiesing; Düwell and Steigleder) and shorter monographs (e.g., Höffe; Schramme) have enriched the debate and provided educational material. Comparable to the Anglo-American context, bioethics has—not undisputedy—also become part of many public discussions and debates, with philosophers increasingly serving on ethics committees and presenting their views in newspapers and on talk shows. Simultaneously, this "expertise" (and its limits and dangers) has itself become subject of critical methodological reflection (Gesang; Ach and Runtenberg), again paralleling developments elswhere.

Institutions and Teaching

Paralleling the belated onset of bioethical debates in German-speaking countries, the development of institutions focused on the study of bioethics has also been comparatively slow. However, a number of chairs, institutes, and centers devoted to this field have been established, most of them university based. Many of them offer optional courses, but forthcoming revisons of federal regulations require medical ethics to be part of the medical curriculum. They are also involved, to various degrees, in consultation and research, with some publishing their own series on specific issues in bioethics and some drawing fellows and postgraduate students from different disciplines into collaboration and common discourse on ethical aspects of medicine, science, and the law. Since the 1980s, a pioneering role can be attributed to the *Institut für Geschichte der Medizin* (Institute for History of Medicine) at the University of Freiburg in Breisgau—now part of the *Zentrum für Ethik und Recht in der Medizin* (Center for Ethics and Law in Medicine); the *Zentrum für Ethik in den Wissenschaften* (Center for Ethics in the Sciences and Humanities) at the University of Tübingen; and the university-based *Zentrum für Medizinische Ethik Bochum* (Bochum Institute for Medical Ethics). Since the 1980s the *Forschungsinstitut für Philosophie* (Research Institute for Philosophy) in Hannover, founded with financing from—and under the auspices of—the Roman Catholic Church, has focused on issues at the intersection of religion and philosophy in the Catholic tradition of philosophical thought, offering a broad spectrum of activities in ethical research and education.

Among the more or less recently founded or reorganized bioethics institutions are the *Institut für Wissenschaft und Ethik* at the University of Bonn, the *Interdisziplinäres Zentrum für Ethik* at the University of Frankfurt/Oder; the *Ethikzentrum* at the University of Jena; the independent *Institut Mensch, Ethik und Wissenschaft* in Berlin (founded by various institutions that advocate for the rights of the disabled); and the *Institute für Ethik, Geschichte (und Theorie) der Medizin* at the Universities of Erlangen, Münster, and Göttingen. The institute in Göttingen is, moreover, linked to office of the interdisciplinary *Akademie für Ethik in der Medizin* (see below) as well as to the Information and Documentation Center for Medical Ethics (IDEM), which is part of Euroethics, a European database, and provides a database for German literature in the field. The institute in Bonn is in charge of the German Reference Center for Bioethics Literature (DRZE), which is a repository for both national and international literature.

In Switzerland, several institutes are active in the study and teaching of bioethics: most notably the *Institut für Sozialethik* and the *Arbeits- und Forschungsstelle für Ethik* (founded in 1989), both at the University of Zurich; the *Interdisziplinäres Institut für Ethik und Menschenrechte* at the University of Fribourg; the *Centre Lémanique d' Ethique* in Lausanne/GENF; as well as the *Institut für Angewandte*

Ethik und Medizinethik (IAEME; founded in 2000) and the unit of ethics in biosciences both at the University of Basel.

In Austria, the university-based centers in the field are the *Dokumentationsstelle für Ethik* in Vienna; the *Institut für Medizinische, Anthropologie, und Bioethik,* also in Vienna; and the *Koordinationsstelle für Grund- und Grenzfragen der Medizin* in Salzburg, In addition, the *Wissenschaftliche Landesakademie für Niederösterreich* (Scientific State's Academy for Lower Austria) has established an institute for the research, teaching, and study of bioethics. But, as in Germany and Switzerland, bioethics has become an expanding discipline, and is by no means restricted to established centers, but pursued by a growing number of academics in various disciplines and settings.

The first German-language journal for medical ethics, *Arzt und Christ* (*Physician and Christian*), was founded in Austria in 1955. Since 1993 the journal has been called *Zeitschrift für medizinische Ethik* (*Journal of Medical Ethics*) and is published in Bonn, Germany.

Professional and Government-Appointed Bodies

Common to all German-speaking countries is the existence of a governing body regulating the contact of healthcare professionals and possibly administering sanctions against those who disobey to their rules. Characteristically, these institutions focus on determining professional ethics and they have widely recognized authority in judging new medical practices.

In Switzerland, the *Schweizerische Akademie der medizinischen Wissenschaften* (Swiss Academy of Medical Sciences) is a foundation comprised of all Swiss medical schools and physicians' associations. Its Central Ethics Commission prepares guidelines on specific issues of medical or research practice that are considered ethically problematic, such as policies for new reproductive technologies for withdrawing life-supporting treatment. In addition, the fourteen-member commission serves as a permanent ethics counseling body for physicians and the public.

Similarly, in Germany, the Federal Chamber of Physicians (*Bundesärtzekammer,* membership in which is obligatory for German physicians) has established an Ethics Advisory Board to its Scientific Council to issue ethics guidelines for intraprofessional self-regulation and to serve as a counseling body. In areas of conduct that lack legal regulation, this type of binding professional self-legislation functions somewhat as a legal substitute for such regulations. Other important bodies are known as *Gesellschaften* or *Akademien* (societies of experts). They aim at promoting scientific debates and research among their members and the public. The body for medical ethics in Germany is the *Akademie für Ethik in der Medizin* (Academy for Medical Ethics). Founded in 1986, it has in 2003 an interdisciplinary membership of approximately 450 members, most of whom are German. The *Akademie* receives a mix of public and private funding and provides a forum for research (working groups on specific topics), for expert and public debate, and for teaching medical ethics. Since 1989 it has published the second German language journal on medical ethics, *Ethik in der Medizin,* and in 1993 it established the first German bioethics literature database, IDEM. Another professional body (of both law and medicine) worth mentioning is the *Deutsche Gesellschaft für Medizinrecht* (German Society for Medical Law), which formulated recommendations on the treatment of severely disabled newborns (the Einbecker Recommendations). In Switzerland, the most important professional body is the *Schweizerische Gesellschaft für biomedizinische Ethik* (Swiss Society for Biomedical Ethics).

Finally, governments or parliaments in these countries have increasingly appointed working groups or expert commissions to issue advisory reports on a variety of bioethical and legal issues. The first to be published in Germany (by the *Bundesminister für Forschung und Technologie*) was the 1985 report of the Benda Commission on assisted fertilization, genome analysis, and gene therapy. In Switzerland, the *Expertenkommission Humangenetik und Reproduktionsmedizin* issued the Amstad Report, dealing with the same subjects, in 1988. These initial efforts were followed by number of similar working groups and expert commissions dealing with a variety of topics. They contributed to the increasing gain in public attention to problems in bioethic, although the ethical analyses contained in their reports are certainly less in-depth, and also less balanced, than, for example, the reports of the various President's Commissions in the United States. Participants with a background in philosophy served on these bodies only in rare instances.

The three German-speaking countries created national ethics councils later then almost any other European country. In 2001 each of them established such a body: in Germany the *Nationale Ethikrat* was established (in fruitful competition with the nonpermanent Commission for Law and Ethics of modern medicine); in Switzerland, which already had a national ethics commission for questions of nonhuman genetic technology, the Bundesrat appointed a *Nationale Ethikkommission im Bereich der Humanmedizin* (Swiss National Advisory Commission on Bioethical Ethics); and in Austria, the 18-member *Bioethik-Kommission* was established at the Federal Chancellery. All three bodies exercise an independent advisory function and are supposed to stimulate public debates in matters of bioethics.

They have already come up with a couple of published recommendations.

Ethics Committees for Human Experimentation

Local *Ethikkommissionen* (ethics committees), functioning almost exclusively as review boards for medical experiments on human subjects, exist in Austria, Germany, and Switzerland. Only in very few hospitals, committees have also been established to consider different ethics questions such as treatment decisions for individual patients or the development of institutional ethics guidelines. As in other Western countries, the institutionalization of review boards for medical research on humans occurred in response to the Nuremberg Trials of Nazi physicians, in accord with the 1964 Declaration of Helsinki and its subsequent revisions.

In Switzerland, the pioneering 1970 guidelines on research involving human subjects (revised in 1989 and 1997) issued by the Swiss Academy of Medical Sciences (*Schweizerische Akademie der Wissenschaften,* or SAMW) required the establishment of ethics committees at hospitals and research institutes to make certain that proposed projects were important, well designed, and of acceptable risk—and that subjects were insured and had given informed consent. The participation of nurses on these committees was required, leaving other details to institutional discretion. Since 1993 experimentation on human subjects is covered by federal law. The Federal Act on drugs and medical products (in force since 2000) requires all research on human subjects—be it publicly or privately funded—to get prior (ethical) approval by a research committee. The about 25 existing such cantonal committees are to have members of both sexes, among them nurses, lay persons, and at least three nonmedical members with experience in social, ethical, or juridical matters.

In Germany (see Toellner; Wiesing, 2002), the introduction of ethics committees was not generally recommended until 1979, when it was endorsed by both the German Federal Chamber of Physicians (*Bundesarztekammer*) for the chambers on state and federal levels and by the Federal Association of Medical Schools for the medical schools. In 1983 the Working group of Medical Ethics Committees (*Arbeitskreis Medizinischer Ethik-Kommissionen*) was founded. It is comprised of all ethics committees at the state physicians' chambers and the medical faculties. The workgroup meets annually to share experiences, promote standardization, and revise its procedural principles.

In 1985 the *Bundesärztekammer* turned the requests for ethics-committee review into an obligatory standard of professional practice. And finally, the German Drug Law ACT (*Arzneimittelgesetz,*) of 1995—and under revision in 2003—is making it obligatory for any research on human subjects, their tissues or person-related data, to get approval from an ethics committee. For publicly funded research in 2003, there were 17 committees at the state chambers of physicians (*Landesärztekammern*), and 38 at the university-based departments of medicine. Most committees have between seven and nine members (plus substitutes) of a—legally required—interdisciplinary background. Local bodies possess some discretional freedom on how to interpret this requirement; only a minority of them include nurses or lay persons. Both public and professional trust and acceptance in those commissions' work seems to increase steadily, although a number of crucial issues are yet unsolved, for instance, regarding the missing evaluation and quality assessment procedures of the committees' work; or the lack of oversight, particularly of commercial or "free" (not institution-affiliated) committees. Other issues under debate are the coordination of different ethics committees in multicenter research, or possibilities to monitor ongoing research compliance to ethical standards.

In Austria, research ethics committees have been legally required since 1988 for the medical faculties and research hospitals. These prescriptions were revised in detail in 1993, and now require that the states issue legal regulations, according to which every ethics committee must include: (1) women; (2) at least one independent person and one physician with particular expertise in the research at stake; (3) at least one representative of the hospital's chaplain (or somebody else with ethical expertise related to patients, staff, and legal services; and (4) a pharmacist.

Specific Ethical Issues

EUTHANASIA. The *Guidelines on Assistance in Dying* of the Swiss Academy of Medical Sciences (issued in 1976, revised in 1981 and 1995) emphasize a patient's right to turn down any medical treatment. They further permit withholding treatment for irreversibly terminal patients, as well as for patients with a loss of consciousness considered irreversible. Dispensable "treatment" in such cases may explicitly include respiration and artificial nutrition. Decisions must include substituted judgments made with the help of the patient's next of kin, and they must consider the patient's best interests. As of 1995, living wills must be followed. Active voluntary euthanasia, however, is illegal under the Swiss Penal Code. Assistance in patient suicide, though not illegal, is not considered a proper activity for physicians. However, it is not explicitly and strictly said to be unacceptable under every circumstance. Assistance in suicide for competent terminally ill patients is provided by two Swiss societies, Exit

and Dignitas, the latter being open also for non-Swiss patients. A highly controversial "suicide tourism" has thus developed, with 55 instances of assisted suicide by non-Swiss individuals in 2002.

The German Federal Chamber of Physicians modeled its 1979 guidelines on "assistance in dying" almost verbatim on the Swiss guidelines (Baumann). Remarkably, however, two points were left out: the explicit permission to withhold or withdraw respiration and artificial nutrition in the irreversibly dying patient, and the explicit permission to forgo treatment in patients with an irreversible loss of consciousness. Moreover, these early German guidelines consider living wills to be merely a nonbinding piece of evidence. In a 1993 update of these guidelines, this last point was explicitly reaffirmed. The 1999 revision of the guidelines, however, exhibit substantial changes. Advance directives (which have since become subject to separate guidelines) are granted a binding status, as long as they are precise and relevant. Furthermore, artificial nutrition, though part of the commonly indispensable basic support, can legitimately be withdrawn from an irreversibly terminal patient, as long as he or she is kept comfortable and neither hungry nor thirsty. Indispensibility of basic care and treatment, with the explicit inclusion of artificial nutrition, is, however, reconfirmed for patients with an irreversible loss of consciousness. Also reconfirmed is the impermissibility of active voluntary euthanasia.

The German Roman Catholic Conference of Bishops and the Protestant Church have repeatedly and strongly argued against active euthanasia, while emphasizing the need—and Christian obligation—to care in a humane and Christian way for the suffering and dying. A hospice movement that provides palliative care for the dying is seen by many as an appropriate way both to fulfill the obligation to care for the terminally ill and to eliminate the very reasons patients ask for voluntary euthanasia. In addition, any use of the term *euthanasia* in Germany conjures up vivid images of the use of the term by the Nazis as they carried out their goal of exterminating millions of fellow human beings who were deemed to be of "inferior" quality. The deeply emotional nature of this historical association explains current objections by many Germans to any discussion of euthanasia. The media and public culture are so aware of Nazi cruelties that lectures by Peter Singer and Helga Kuhse—Australian bioethicists who support both voluntary euthanasia and the permissibility of passive as well as active euthanasia (withholding treatment as well as directly killing) for severely disabled neonates on parental request—have been prohibited or protested in Germany and Austria (Schöne-Seifert). In the aftermath of this "Singer affair" (starting in 1989), organizations of disabled people and other political and interest groups have vehemently argued that those in favor of euthanasia for severely disabled newborns are making an indirect judgment about the worth of a life and are in danger of creating a climate in which elimination of the unfit or discrimination toward the sick, feeble, and disabled will again be accepted. These objections have also been raised in debates about selective abortion, creating a rather widespread antibioethics climate in both Germany and Austria.

In Switzerland, withdrawing treatment for most severely disabled newborns is considered morally permissible and is narrowly specified as such in the Swiss guidelines. The German Society for Medical Law had issued rather similar recommendations (the so-called *Einbecker Empfehlungen* [Recommendations of Einbeck]) in 1986. At the time, the Society considered it morally permissible to let newborns die when they either suffer from most severe mental disabilities or can only be kept alive by permanent intensive care. After the Singer affair, these recommendations were revised (in 1992), and forgoing treatment is now restricted to newborns with irreversible medical problems that will lead to death within a short period of time.

Legalized active euthanasia at the request of terminally ill patients has been advocated by some German voices. For example, the *Deutsche Gesellschaft für Humanes Sterben* (German Society for Humanely Dying, or DGHS), founded in 1980, advocates for respect for the dying patient's autonomy. This lay organization, which does not enjoy much support in the medical or legal communities, also provides its members with forms for living wills, and in the past it has provided assistance in suicide (because suicide is not a criminal offense, assisting it is not illegal either). Physicians, however, are seen by law to stand under specific professional obligations (*Garantenpflichten*), which some courts—in contrast to the view dominant in the legal literature—have interpreted to include suicide intervention. Hence, there is an unresolved legal tension that makes jurisdiction on physicians' assistance (and consequent nonintervention) in suicide unpredictable. The credibility of DGHS was severely shaken in early 1993 when its founder and president, H. H. Atrott, was arrested for selling cyanide capsules—moreover at inflated prices.

In 1986, the *Alternativentwurf eines Gesetzes über Sterbehilfe* (Alternative Draft of a Law for Assistance in Dying) was published by a number of reputable experts in medicine and law (Baumann). Among its suggestions was one to waive prosecution of euthanasia (though illegal) when it is persistently requested, and if the euthanized patient was competent and suffering from terminal illness. However, the draft never succeeded, due to lack of sympathy for it from

the Federal Chamber of Physicians and the German Legal Association.

Advance directives (see Meran et al.), be they in the form of living wills or of durable powers of attorney, have slowly started to play a role in medical decision making in all three German-speaking countries. Although the 1992 Care ACT (*Betreuungsgesetz*) in Germany in principle provides for both instruments, and although various forms for living wills are publicly available, the legal status of advance directives is disputed and considered uncertain. This situation discourages both its acceptance by the medical profession and wider use by patients. In 2003 a critically debated Supreme Court decision upheld a ruling that decisions to stop life-saving treatment cannot be validly made by a patient's advocate without confirmation of the courts. Critics consider this position both nonrealizable and contrary to a patient's right to self-determination. In the same decision, however, advance directives, at least for the terminal phase of disease, were acknowledged as expressions of a patient's autonomy in former days and as legally binding.

In Austria, the overall situation is very similar to that in Switzerland and Germany: Active euthanasia is illegal under the national Penal Code; withdrawing treatment is not, by either law or policies, regulated in any detail; and advance directives seem to be slowly gaining in use and impact.

ABORTION. With the 1990 reunification of the German nation, most laws and regulations of the former Federal Republic of Germany (West Germany) were applied to the citizens of the former German Democratic Republic (East Germany). However, there were very different models of legal abortion in the penal codes of the two Germanys, which resulted in a heated debate. In the West, a 1974 law permitted pregnant women to choose abortion until the end of the first trimester. Based on a charge of nonprotection of the rights of the unborn, the constitutionality of this law was challenged in 1975. The resulting interpretation of the constitution (*Grundgesetz*) by the Federal Constitutional Court (*Bundesverfassungsgericht*) held that human dignity (*Menschenwürde*)—a conceptually loose term that is used by both sides of the abortion debate to support their position—is constitutionally protected from the moment of conception. It enforced an *indication model,* permitting legal abortion until the end of the first trimester only if a physician certified that certain social or medical indications were present. Under this model, the physician was the ultimate moral agent and an acknowledged right to life of the unborn was to be balanced against medical or social hardship. Generous interpretation of these criteria often led to a de facto policy of abortion on demand in the first trimester, but with different standards and variability in enforcement in the various states of the Federal Republic. In the German Democratic Republic, a *term model* for legal abortions operated since 1972, wherein abortion was allowed until the end of the first trimester and was cost-free.

In the new Germany, a heated public debate (though involving little philosophical analysis) took place on the underlying theological, moral, and political positions motivating the clashing views on abortion. In 1992 the federal parliament approved a compromise law under which abortion would be legal in the first trimester (and paid for by health insurance) as long as the woman had a consultation session prior to abortion. Mandatory counseling and education were intended as an additional step to strengthen fetal protection (a goal that was emphasized almost unanimously) and include informing a pregnant woman about existing supportive social, welfare, and employment programs, as well as kindergarten settings for the child, that might enable her to choose to continue her pregnancy.

However, conservative parliamentarians and the Roman Catholic Church petitioned the *Bundesverfassungsgericht* to declare the law unconstitutional. The German Supreme Court did just that in May 1993, stating that the counseling sessions did not go far enough in protecting fetal human life, as required by the (formerly West) German Constitution. The Court argued that the constitutional rights of a woman (to physical integrity, human dignity, right of personality) do not go so far as to allow her to claim a fundamentally protected legal right to kill an unborn child by means of abortion; that abortions at any point during a pregnancy are fundamentally wrong, and thus illegal; and that the state's duty to protect the unborn also includes maintaining and raising the public's consciousness of the unborn child's legal right of protection. However, the Court held that a future abortion law would be considered constitutional even if it abstained from prosecution of illegal first-trimester abortions that were performed at the pregnant woman's request, as long as she has undergone prior mandatory and explicit pro-life counseling. A new abortion law, which came into force in 1995, includes this requirement.

Both public and expert reactions to this legal reform are heavily split. Where some emphasize its being a socially integrative compromise, conservative critics deplore what they consider a violation of the embryo's human dignity, while others object to both the Supreme Court's and the legislation's blatant inconsistencies. For them, accrediting a full-blown right to life and dignity to the early embryo is incompatible with de facto permission of first trimester abortion on demand and the state's court-mandated provision of abortion facilities (Merkel). The required pro-life counseling is seen as a violation of women's right and

competency to self-determination (Kuhlmann), and the preemption of prosecution for illegal abortions is considered to undermine the public's trust in the law.

In Switzerland (where women first began to acquire the political right to vote only in 1971), abortions had been permitted only for serious medical indications or in case of grave emergency (commonly interpreted to include rape and embryopathy). In the 1970s, opinion polls suggested that a majority of the Swiss people would opt for a liberalization of abortion law. However, a plebiscite in 1977 went narrowly against abortion on demand in the first trimester of pregnancy (with a majority of French-speaking and predominantly Protestant cantons [states] in favor of liberalization, and German-speaking and predominantly Catholic cantons against). A repetition of the plebiscite in June of 2002, however, saw 72 percent of the votes being in favor of first trimester abortions on demand, and they are now allowed, with only a prior comprehensive consultation with the physician who is going to perform the intervention.

In predominantly (85%) Roman Catholic Austria, first-trimester abortion on demand has nevertheless been legally permitted since 1975. Costs of medically indicated abortions are covered by insurance, while those resulting from abortions performed for nonmedical reasons must be paid for by the women themselves. A pro-life referendum initiated the year before the introduction of this law won only 18 percent of the vote, and none of the three major political parties supported the initiative.

NEW REPRODUCTIVE TECHNOLOGIES AND EMBRYO TESTING. A great deal of the public debate in German, Austrian, and Swiss bioethics continues to focus on reproductive issues. All three countries criminalize egg donation for reproductive purposes (and thus surrogate motherhood), the fertilization of more (3 eggs maximum) than are to be transferred (thereby theoretically preventing the existence of "spare" embryos), as well as any research on or manipulation of an embryo not in its own therapeutic intererest. Genetic manipulation on the germline cells (those from which gametes are derived) is prohibited.

In Germany, the Benda Report of 1985 recommended that a future reproduction law ban: (1) all forms of surrogate motherhood; (2) heterologous (with sperm other than a woman's spouse) in vitro fertilization (IVF) and assisted insemination by donor (AID), at least for single women; (3) research on embryos other than those that are purposefully left over from IVF; and (4) any genetic manipulation of germline cells. These measures were considered necessary to prevent violations of "human dignity." The first regulations, issued in 1985 by the Federal Chamber of Physicians, had the status of intraprofessional self-regulation. They were revised in 1988 and 1994, and now permit only homologous (using only the spouses' egg and sperm) IVF and GIFT (gamete-intra-fallopian-tube transfer), and only in married couples. Only somatic infertility is explicitly accepted as an indication for IVF, for example, and the restriction to homologity and marriage are justified by the well-being of the child-to-be. In accordance with the 1991 Embryo Protection Act, embryo donation and all forms of surrogate motherhood are prohibited (though, theoretically, unpaid-for donor sperm may be used in rare cases). However, no cases of AID have occurred since 1985, and issues of access to (heterologous) IVF—and its ramifications for family law—still await a long-planned reproductive medicine law.

In a second set of guidelines issued in 1985, the chamber prohibited the production of embryos for research and restricted embryo research to important questions of infertility treatment or embryo development—and to spare embryos less than 14 days old—after approval of the central commission. After heated public debates on the relevant meaning of human dignity and of reproductive autonomy, and on the permissibility of research even on spare embryos, the German Embryo Protection Act (*Embryonenschutzgesetz*) was introduced in 1991, setting unprecedented standards in terms of restrictivity. In summary, the law prohibits: (1) artificial insemination of an oocyte for any purpose other than a nonsurrogate pregnancy of the "possessing" woman, and (2) any kind of nontherapeutic manipulation or research on the embryo, even in case of spare embryos (whose occurrence is made unlikely by the first prohibition). In addition, (3) any single totipotent cell (an early embryonic cell from which a whole organism could still develop) is given the legal status of an embryo. Further restrictions rule out (4) reproductive egg donation and any form of surrogate motherhood, as well as (5) cloning or the creation of chimeras (organisms with a combination of human and animal genes). Violating these regulations can result in lengthy prison terms and monetary fines, but punishment applies only to third parties (i.e., physicians, researchers, and agencies), not to biological, gestational, or social mothers-to-be.

This law has been controversial, particularly in the light of the more recent options of "using" embryos for stem-cell research, which is clearly prohibited by this law. It has been praised by its proponents for its strict embryo protection, while critics claim it interferes with self-determination, responsible parenthood, and reproductive choice.

Preimplantation diagnosis (PID) is currently not practiced in Germany, but it is increasingly demanded by various people and groups. Initially, most legal experts considered PID implicitly prohibited by the Embryo Protection Act, though this view has been challenged by a growing number

of experts. There is a broad consensus, however, that regulation of the issue is required before PID can be practiced. As can be witnessed in other countries, those strongly opposed to PID (and the involved selection of embryos) make several arguments. They consider the procedure to be: (1) a violation of the early embryo's dignity and right to life; (2) a form of, or at least an invitation to, unacceptable eugenics; and (3) discriminatory toward, or hurtful of, those disabled individuals who have been born with one of those diseases PID would select against. Those in favor of PID most commonly want it offered very restrictively to couples with a family history of severe hereditary disease. Not only do they question the plausibility of the above arguments, but they criticize what they consider an ethical double standard; that is, forbidding preimplantation diagnosis, while at the same time allowing elective abortion after prenatal diagnosis of the very same severe hereditary diseases (and even less severe ones) in significantly later stages of pregnancy.

Austria's Reproductive Medicine Act (*Fortpflanzungsmedizingesetz*) regulates both the use of new reproductive technologies and embryo protection. It was introduced in 1992 after long and heated debates, and it represents a political compromise between the Roman Catholic opposition to reproductive technologies on theological grounds and more liberal approaches that emphasize the benefits of new reproductive technologies to support individual reproductive freedom and choice. Both homologous and heterologous IVF or GIFT are permitted as infertility treatments for married couples or those in stable relationships, but embryo donation and all forms of surrogate motherhood are forbidden. Only freely donated sperm from living donors may be used, and, based on the concept of human dignity, a child conceived from donor sperm is permitted to know the identity of the biological father once he or she reaches maturity (records must be kept for thirty years). Issues of inheritance and other matters affecting IVF offspring are regulated elsewhere in the law. Preimplantation diagnostics, though not expressly mentioned, are considered forbidden and currently not practiced in Austria.

In Switzerland, the Swiss Academy for Medical Sciences (SAMW) issued guidelines on the use of new reproductive technologies in 1990. Homologous IVF in married or quasi-married couples, as well as IVF using anonymously donated sperm or eggs in married couples, are permitted as either infertility treatment or as a means to prevent transmission of a genetic disease. Embryo donation, all forms of surrogate motherhood, preimplantative sex selection, germline manipulation, and any research on embryos are all prohibited.

In 1992 the Swiss implemented Article 24, a constitutional amendment requiring federal regulation of embryo protection and of reproductive technologies according to the following restrictions: The manipulation of germline cells and embryos, the creation of chimeras, and the production of spare embryos are illegal; homologous and heterologous IVF are legal as an infertility treatment (allowing—like German and Austrian law, and in contrast to the SAMW guidelines—for later access to information about one's biological parent) or as a means to prevent transmission of a genetic disease; embryo donation and all forms of surrogate motherhood are illegal; but research on (the few available, see above) spare embryos is not explicitly ruled out. Since 2001 the federal Reproductive Medicine Act has been in force, prohibiting egg and embryo donation, the creation of surplus embryos, and the performance of PID. As in Austria and Germany, public opinion on these matters are heavily split.

EMBRYO RESEARCH AND CLONING. Since the late 1990s, embryo research is no longer an abstract ethical issue, but is being discussed with regard to stem-cell research with its promises of future therapeutic breakthroughs. In all three German-speaking countries, the creation of embryonic stem cells is prohibited by the above described laws. In 2001, both in Germany (by the *Deutsche Forschungsgemeinschaft*) and in Switzerland (by the Swiss National Fonds) the scientific communities questioned these prohibitions publicly and suggested that embryonic stem cells be imported from abroad, thus legally providing scientists with the tools to participate in the promising new research. Simultaneously, they and many others urged public debates and legal reforms that would allow Swiss and German scientists to use (deep-frozen) surplus embryos, the existence of which cannot completely be prevented even by the restrictive current laws.

In Switzerland, a research project on imported embryos began in 2001, while the issues were still subject to controversial public debates. In 2003 the country was awaiting a stem-cell research law, which will most probably permit the creation of stem cells from surplus embryos. The more general issues of embryo research will be handled in an additional future law regulating overall issues of research on human subjects.

In Germany, scientists have also started to work on imported stem-cell lines. Here, however, they waited for a clear legal basis, provided by a new stem-cell law implemented in the summer of 2002. While strictly prohibiting the destruction of early embryos, even for highly promising medical purposes, it nevertheless permits, under a number of restrictions, the importation of existing stem-cell lines. A majority of parliament members viewed this legislation as an acceptable compromise, whereas critics consider it to be another instance of ethical hypocrisy.

In Austria, no attempts have yet been made to legalize the importation of embryonic stem cells, and the whole matter of destructive embryo research is under debate.

Cloning, both for reproduction and for biomedical research, is one of the most recent bioethical issues dealt with in all three countries.Reproductive cloning by any method will certainly be ruled out by laws to come. Cloning for biomedical research purposes, on the other hand, has been rejected by a majority of experts and the public—though not unequivocally. Again, the moral status of (artificial) embryos, the moral claims of future patients, slippery-slope arguments, and the difficulties in handling the bioethical pluralism of modern societies will be prominent arguments in these discourses.

HUMAN GENETICS. The use of genetic testing techniques in Germany, Switzerland, and Austria is regulated quite strictly. Each of these countries has regulations regarding the use of genetic testing, the need for informed consent of the individuals involved, and the need to integrate genetic testing into a larger process of genetic counseling. The memory of eugenics experiments during the Third Reich inevitably generates negative emotions, especially in Germany, toward any medical intervention concerned with the prevention of hereditary disease. German reflection seems particularly concerned with the question of how far society and parents should go in accepting disabilities that can easily be discovered using prenatal diagnosis, while at the same time protecting the woman's right to decide whether or not to use prenatal diagnosis. Another major issue discussed in all three countries is the appropriate balance between people's autonomy (to know about a carrier status or genetic disease in themselves or their embryo, and to draw consequences they consider appropriate) and the protection of the same people from unwelcome or unbearable information, from unreasonable risk assessment, or from external sanctions upon their genetic status. There seems to be a strong public consensus for a ban on germline manipulation, whereas somatic gene therapy, although met with a much public suspicion, was applied for the first time in 1994 on somatic cells (cells other than those from eggs and sperm). The Federal Chamber of Physicians is currently at work on guidelines on somatic gene therapy.

The German Gene Technology Law of 1990 (revised in 1993) does not address questions of genetic testing or engineering in humans. Three commissions, one at the level of the federal parliament, and two composed of executives from state and federal governments have already issued recommendations for a law that would specifically regulate issues of genetic counseling and testing in embryos, neonates, carriers, high-risk persons, or at the workplace. For the time being, these issues are partly regulated intraprofessionally. Guidelines issued in 1991 by the German Federal Chamber of Physicians urge that genetic testing always be integrated with genetic counseling, that such counseling be provided by nonmedical personnel under medical supervision, and that consent be required for testing. The Commission of the German Society for Human Genetics also supports genetic testing only within nondirective genetic counseling. This commission also holds that screening for nonmedical information, such as the sex of the fetus, should be prohibited, and that information obtained by genetic testing is to be strictly confidential.

The Federation of Swiss Physicians asserted in 1991 that genetic analysis for occupational health or insurance issues must always be rejected, even if consent is given and the information is to be confidential. The Swiss Academy of Medical Sciences guidelines of 1993 assert that genetic testing must be part of a larger counseling relationship. The academy supports voluntary testing for (1) diagnosis of hereditary diseases, (2) carrier testing and genetic counseling for family or career planning, and (3) presymptomatic testing whenever medical intervention or changes in lifestyle may reduce or postpone disease. Counseling and education prior to testing are obligatory. Article 24 of the Swiss Constitution states that "the genetic endowment of a person cannot be analyzed, registered or revealed without that person's consent or a legal prescription." Probably still in 2003, a new federal act on human genetics will be enacted, regulating genetic testing in humans and providing safeguards against genetic discrimination.

In Austria a Gene Law was introduced in July 1994, regulating genetic counseling, diagnostics, and manipulation both inside and outside human beings. It prohibits any release of genetic information to third parties, notably insurance companies and employers.

ORGAN TRANSPLANTATION. Germany's long awaited Transplantation Act came into force in 1997. Basically, it confirms what had been the current policy regarding posthumous organ retrieval, namely the requirement of explicit prior consent by the donor, or substitute consent by his or her proxy. In addition, it restricts live donation, rules out any commercialization, and legally acknowledges the whole-brain definition of death (according to which a complete cessation of brain functioning indicates a person's death).

Various drafts for a transplantation law were debated over several years. The most likely legal regulation had once been a policy requiring that donation be requested of the deceased potential donor's proxy, consent of the patient

being presumed if he or she had not objected to organ donation. Protests were raised against these suggestions, however, on the grounds that they disregard the right to self-determination and represent an uncritical protransplantation ideology. Among the protestors were a number of Protestant theologians, despite the fact that both the Protestant and the Catholic churches had officially praised organ donation.

The whole-brain definition of death was at the center of much debate and protest. German physicians officially adopted this definition in 1982, but this position has been a matter of intraprofessional policy, rather than legal statute. Rising concerns about the definition's underlying, allegedly reductionist concept of human life (spurred by recent cases involving attempted continuation of pregnancy in brain-dead women by maintaining them for weeks on life support, and by rumors that authorities of the former East Germany sold organs, sometimes prior to fulfillment of death criteria) had fueled public suspicion and professional objections, and had even raised the possibility of revision of the brain-death formula (Hoff and In der Schmitten).

In Austria, the 1982 *Krankenanstaltengesetz* presumes consent to organ procurement if the donor or his or her proxy do not oppose it—without, however, explicitly requiring that the proxy be informed about his or her right to oppose.

In Switzerland, the cantons (states) have different legal requirements for organ transplantation, with a majority having a presumed-consent policy. Efforts are being made to issue a federal transplantation law, which will likely be enacted in 2004.

Germany is a member of the Netherlands-based Eurotransplant Center, which computerizes the distribution of available organs, primarily according to tissue compatibility, among a network of European transplantation units. Organ information and distribution centers in Switzerland and Austria are more loosely affiliated with Eurotransplant.

RESOURCE ALLOCATION. Social-welfare systems in each of these countries provide almost universal coverage for health-related costs, as well as allowances for certain conditions (e.g., maternity, disability, old age, work-related injuries, dependent children). Overall health conditions, healthcare, and access to physicians are very good in each of these countries.

However, the steadily increasing costs of modern medical care have begun to endanger the unlimited approval of the underlying "solidarity principle" by which the rich and healthy pay for the care of the sick and needy. Moreover, various cost-containment policies that claim to increase cost-effectiveness without decreasing the quality of care have slowly increased public awareness of the underlying ethical questions of distributive justice and permissible rationing criteria. The debates on a decent maximum of generally accessible healthcare have only started. Again, public concern about a renaissance of Nazi spirit is raised by the prospect of rationing treatment, which might discriminate against the disabled and elderly.

ANIMAL EXPERIMENTATION. Strong concern exists throughout Europe for the ethical use and protection of animals in research. Swiss guidelines, inspired by animal-rights activists, have served as the basis for regulations in other countries. In the late 1970s, Switzerland became the first European country to include animal protection into its constitution, and in 1992 an amendment granted constitutional protection to the "dignity of creation." Germany's 1986 Animal Protection Act (*Tierschutzgesetz*) was revised in 1998 and contains detailed regulations concerning the type of experiments permissible, selection criteria for animals, supervision by qualified veterinarians, and standards for the treatment of animals in agriculture and as pets. Notice must be given to qualified animal-welfare commissioners. Animal-welfare committees exist in all states, with membership based on nomination by animal-welfare groups and academic training and professional experience. This legislation is supplemented by public education and information campaigns designed to bring about more humane treatment of animals in all spheres. The 1998 revision made it obligatory for any institution experimenting with vertebrates to appoint a qualified person to be officially responsible for animal protection. Experiments on dogs, cats, and apes require their being bred for research. Animal experiments for developing any kind of cosmetic product are prohibited.

In 2002 Germany finally—after more then ten years of debates, and through the addition of two words—incorporated animal welfare into its constitution. Article 20a of the German Constitution now reads "The state takes responsibility for protecting the natural foundations of life *and animals* in the interests of future generations." This amendment will not have any immediate effect, but it will influence the way in which future German legislation is drawn up and current laws are interpreted.

Austria passed its Animal Research Act (*Tierversuchsgesetz*) in 1989, which provides for criminal penalties if research is not reviewed or performed ethically or responsibly and according to current scientific standards. The law also calls for a reduction in the number of experiments performed and the number of animals affected. Attempts for a federal animal protection law unifying existing legislation

in individual countries have so far been as unsuccessful as those for including animal welfare in the Austrian Constitution.

Conclusion

Despite a comparatively delayed academic and public interest in modern biothics in the three German-speaking countries, and despite some tendencies to avoid debates on certain issues regarding human life because of past atrocities, the field and its substantial and methodological problems have become widely acknowledged as important.

VII. NORDIC COUNTRIES

This entry provides a brief overview of the modern development of medical ethics in the Nordic countries: Denmark, Finland, Iceland, Norway, and Sweden. The focus is primarily on the period after the beginning of the 1960s. The entry begins by giving an account of the establishment of ethics review committees and other medical ethics bodies and organizations. Then changes in the educational and research situation are described, along with the establishment of special institutions for medical ethics. Finally, attention is given to some essential features of the debate on a few principal issues.

Codes, Ethics Bodies, and Organizations

The attempt formally to regulate physicians' duties toward their patients and colleagues began early in the history of medicine. Ethics codes in the Nordic countries can be traced to the early practice of physicians taking an oath of office and allegiance. For example, in seventeenth-century Sweden, when physicians still received doctoral degrees abroad, usually in Holland, permission to practice medicine required the taking of an examination given by the Swedish association of physicians, the Collegium Medicorum, which was founded in 1663. When passing the examination the physician had to take a special oath. The taking of an oath was an obligatory part of the examination of physicians in Sweden until the late nineteenth century and still is required in Denmark, Finland, and Iceland.

It was only after World War II, however, that the making of ethics codes in the Nordic countries came to encompass areas outside clinical practice and to include professional categories other than physicians. The current ethical guidelines for physicians' clinical work were adopted in their original forms by the Danish Medical Association in 1976, by the Finnish in 1956, by the Icelandic in 1918, by the Norwegian in 1961, and by the Swedish in 1951. During the 1950s and 1960s other health professional groups, such as nurses and physical therapists, began to develop their current ethical codes. The 1964 adoption of the Helsinki Declaration by the World Medical Association extended the codification to the explicit inclusion of ethics in research. To facilitate its implementation the Nordic countries created a system of ethics review committees.

Those committees are organized somewhat differently in the different countries. Denmark and Norway have regional committees, whereas Finland and Iceland have local hospital committees and Sweden has both regional and local committees. The Danish system, which was established in 1978, consists of seven regional committees and a central scientific-ethical committee. The committees in Norway are organized in a similar way. In 1985 regional committees were set up in each of Norway's five national service regions. To establish a coordinating and advisory body for those regional committees, the Norwegian Medical Research Council's Committee for Medical Research Ethics, which was formed in 1978, became the National Committee for Medical Research Ethics in 1990. In Finland the first ethics committee was set up at Helsinki University in 1972; since 1977 all medical faculties have had ethics committees. In Iceland the two national university hospitals have had ethics committees since 1976. In Sweden an advisory council was formed at the Karolinska Hospital in Stockholm in 1965. That council was superseded the next year by the first medical-faculty ethics committee, which was established at the Karolinska Institute. By 1967 similar committees were in place at all medical faculties in that country.

Since those committees were established, the call for assessment of the ethical implications of new technologies and other advances in medicine has increased. To respond to growing pressures on political decision makers an additional type of national ethics body was created. Its principal task is twofold: to provide expert knowledge to the government, the parliament, and the health-service authorities and to contribute generally to a continuous exchange of information and opinions on medical ethics issues among researchers, politicians, and the public. To that end the Danish Council of Ethics was established by the parliament in 1987; the National Research Ethics Committee, by the Finnish Parliament in 1991; the National Biotechnology Advisory Board, by the Norwegian government in 1991; and the National Council of Medical Ethics, by the Swedish government in 1985. Iceland still lacks a national body of this kind. (For further information about the origin, composition, and activities of these national bodies and of the review committees see Council of Europe; Solbakk.) In 1988 the Nordic Committee for Ethics in Biotechnology was created by the Nordic Council of Ministers. Like some of the national bodies, this committee deals with bioethical issues in the broad sense of the term. Besides issues in medicine, the Nordic Committee addresses ethical questions in, for example, stockbreeding and agriculture.

Several other bodies and organizations play an important role in the analysis and debate of issues in medical ethics. For example, ethics committees were set up within the medical associations of Denmark (1969), Finland (1975),

Norway (1962), and Sweden (1979), as well as within the National Finnish Board of Health (1988), the National Swedish Board of Health and Welfare (1984), and the Ministry of Health and Social Affairs in Norway (1988). In 1989 the Council of Ethics was established at the Office of the Director General of Health in Iceland. There are also a number of medical societies: the Delegation for Medical Ethics, established in 1969 within the Swedish Society of Medicine (earlier called the Swedish Society of Medical Sciences); the Society for Medical Law and Ethics, founded in Finland in 1980; the Danish Society for Medical Philosophy, Ethics, and Methodology, founded in 1988; and the Swedish Society for Medical Ethics, founded in 1989. In 1988 a section for medical ethics in the Nordic countries was established within the European Society for Philosophy of Medicine and Health Care.

Education and Research

Since the beginning of the 1970s medical ethics has been taught at medical faculties and nursing schools in all the Nordic countries. However, there are no uniform requirements regarding the scope and content of this teaching in any of the Nordic countries. At a meeting in Reykjavik, Iceland, in 1991, the medical associations of the Nordic countries agreed to work toward making medical ethics a compulsory subject at all medical faculties in those countries and creating teaching positions in the subject (Oldinger).

Textbooks have been written in most of the Nordic countries. For a long time *Medicinsk etik* (1971), a doctoral dissertation by Clarence Blomquist, a pioneer in Swedish medical ethics, was the only general introduction; it dealt with both metaethics and normative ethics and covered most of the principal issues in medical ethics at that time. Subsequently, a number of textbooks have appeared, including some broad general introductions (Fagerberg et al.; Andersen et al; Tranøy, 1991; Wretmark et al.), some more philosophically oriented works (Malmgren; Tännsjö, 1998), and some texts dealing not only with ethics but also with other philosophical issues in medicine (Bjarnason; Tranøy, 1978; Wulff et al).

The philosophical rather than the medical faculties have been responsible for most postgraduate education in medical ethics. Blomquist's *Medicinsk etik,* the first doctoral dissertation, was defended at the Department of Philosophy at Uppsala University in 1973. Since that time philosophy departments have produced dissertations on specific medical ethics issues such as suicide, paternalism, and abortion as well as on the nature and scope of philosophical medical ethics in general. Partly empirical doctoral dissertations that focus primarily on issues in medical ethics have been written within the fields of sociology, nursing research, and medicine.

The establishment of two special institutions for medical ethics, one in Norway and the other in Sweden, as well as the foundation of a unit for the philosophy of medicine in a broader sense in Denmark, has improved the opportunities at medical faculties for both graduate and postgraduate education in medical ethics. The Center for Medical Ethics at the University of Oslo was founded in 1989. A chair in medical ethics was created at the University of Oslo Medical Faculty in 1992. Lund University in Sweden established the Department of Medical Ethics in 1991. The department came into existence through the creation of a chair in medical ethics at the Swedish Medical Research Council in 1990. In 1988 the University of Copenhagen established the Unit of Medical Philosophy and Clinical Theory at the Panum Institute.

Those institutions have strengthened the position of medical ethics as an independent research field at medical faculties. Research in medical ethics otherwise is carried on normally only in the form of time-limited projects and mainly outside medical faculties in philosophy departments and departments of theology. Some institutions focus on medical ethics as a principal area of research. For example, the Department of Health and Society at Linköping University in Sweden has had a chair for the philosophy of medicine since 1987. Two institutes have been established: one in Iceland in 1989, the Ethics Institute at the University of Iceland, and the other in Sweden in 1988, the Ersta Institute for Health Care Ethics in Stockholm. In Finland the Center for Bioethics was founded in 1991 at the University of Turku.

Principal Issues

ARTIFICIAL INSEMINATION AND IN VITRO FERTILIZATION. Among the Nordic countries only Norway and Sweden have laws that specifically regulate the use of noncoital reproductive technologies to achieve pregnancy. The use of human sperm, ova, zygotes, and early embryonic forms (blastemas) for research purposes also is restricted in the Nordic countries.

The ethical and legal debate in the Nordic countries over the use of noncoital reproductive technologies has focused mainly on artificial insemination by donor semen (AID), in vitro fertilization (IVF), and ovum donation. The closely related issues of artificial insemination by the husband's semen (AIH) and gestational surrogacy (surrogate motherhood) have attracted less attention. Except among

certain religious minorities the use of AIH has generally been accepted.

To a large extent the 1987 Norwegian legislation on artificial insemination and IVF corresponds to the 1985 Swedish legislation. One point on which the Norwegian and Swedish laws differ is of particular ethical interest: the issue of whether it should be possible for a child to obtain information about the identity of his or her natural father. Sweden legislated in favor of the child's right to this information, and Norway legislated against it.

According to the Swedish legislation, (1) only women married or cohabiting with a man in circumstances of marital character should be allowed to receive insemination treatment; (2) insemination requires written consent by the husband or cohabitant, who will by virtue of that act be regarded as the legal father of a child born as a result of the treatment; (3) AID should be undertaken only in general hospitals under the supervision of a physician who specializes in obstetrics and gynecology, and the sperm donor should be chosen by the physician; (4) information about the sperm donor should be kept in a special hospital record for at least seventy years; (5) when a child conceived by donor insemination is mature enough, he or she has a right to obtain information about the identity of the natural father; and (6) when requested, the public welfare committee is obligated to assist the child in retrieving that information. (For literature on the debate and official reports preceding this law see Lindahl, 1985, 1988; U.S. Congress.)

The most controversial issue has been the right to obtain information about a child's father. The main point of departure for the Swedish legislation was the needs and interests of the child. In this respect the legislators decided to follow the general direction of modern legislation toward a gradual strengthening of children's judicial standing and the movement in society toward greater openness in family relations rather than the traditional patient-oriented perspective of clinical medical ethics. These two contrasting perspectives have dominated much of the debate.

PRENATAL DIAGNOSTICS AND ABORTION. The laws on abortion vary among the Nordic countries. In Denmark women have a legal right to abortion regardless of the reason before the twelfth week (law of 1973, in force the same year); in Norway, until the end of the twelfth week (law of 1975, in force from 1979); and in Sweden, before the end of the twelfth week or, after special consultation with a social worker, up to the end of the eighteenth week (law of 1974, in force from 1975). In Finland (law of 1970, in force the same year) and Iceland (law of 1975, in force the same year) abortion is permissible before the twelfth week, but only on certain indications (see below).

The situation in Sweden illustrates the way in which the legal status of the fetus and the understanding of its relationship to the mother changed during the twentieth century. Until the abortion act of 1974 a fetus was viewed as a separate individual, even during the first three months, and thus was legally protected. According to the earliest legislation, in the eighteenth century, abortion carried a penalty of death because it was equated with infanticide. As late as the 1920s the penalty for abortion was one year's to six years' imprisonment at hard labor. However, exceptions were made if abortion was necessary to preserve the health or life of the woman. This practice was ratified by law in 1938. From 1939 abortion was permissible up to the end of the twentieth week on any of the following three indications: medical (i.e., when, because of disease, physical defect, or weakness, childbirth would cause serious danger to the life or health of the woman), humanitarian (e.g., pregnancy after rape or incest or in minors), and eugenic (when there was reason to believe that the expected child would inherit mental disease, mental deficiency, or serious physical disease). After the twentieth week abortion was permissible only on medical grounds. Two additional indications were introduced before the abortion act of 1974: in 1946, sociomedical (i.e., when, considering the living conditions and other circumstances, it might be assumed that childbirth or care of the child would reduce the woman's physical or emotional strength seriously) and in 1963 teratogenetic (i.e., when there was reason to believe that the expected child, as a result of injury during the fetal stage, would suffer from a serious disease or defect). All these indications, somewhat differently formulated, are still used in Finland and Iceland.

In the debate surrounding the 1974 law on abortion the fetus often was no longer viewed as a separate individual but as a part of the woman's body. Abortion therefore became, according to this view, not a matter of weighing the value of one individual's life against the value of another's but a question of a woman's right to make decisions about her own body. The only legal limit to that right is the point in time at which the fetus has become viable, that is, able to survive outside the uterus. In Sweden the operation still may be performed at that time, but only if the woman suffers from a disease or physical defect and continued pregnancy therefore constitutes a serious threat to her life or health. Unless the operation cannot be postponed without danger to the woman, permission from the National Board of Health and Welfare is always required after the eighteenth week of pregnancy.

That exception has been questioned in an official Swedish investigation of the abortion law (Justitiedepartementet, 1989). The investigation points out that because abortion, according to the common medical definition,

amounts to the expulsion of a nonviable fetus, this exception must mean that the operation is performed in such a way that the fetus is dead at delivery. The investigation found that unacceptable and required that instead efforts be made to save the life of both the woman and the fetus at that stage of pregnancy.

The investigation calls attention to the reevaluation of the legal status of the fetus that was undertaken after the abortion law was instituted. During the 1980s recurrent demands were made that an unborn child be protected from the risk of injury resulting from the mother's abuse of alcohol or narcotics. That request led to the conclusion that the woman and the prospective child no longer can be viewed as a single individual.

EUTHANASIA AND THE CONCEPT OF DEATH. Until the 1990s the dominant view on euthanasia in the medical profession in the Nordic countries was virtually that expressed in the mid-1800s by the Finnish physician Immanuel Ilmoni in his book on medical ethics *Om läkarens yrke och pligter* (1847). Ilmoni called euthanasia one of the most important special disciplines of the art of medicine. At the same time he made it clear that a physician may not in any circumstances deliberately contribute to shortening the patient's life even in cases in which the patient is "incurably ill, tormented beyond description, [and] fervently desires and demands death" (pp. 45–46).

In the late 1960s and during the 1970s, when the debate on euthanasia was most intensive in the Nordic countries, it would have been hard to imagine the medical profession supporting legislation that allowed physicians to comply with a terminally ill patient's wish to die. Among the earliest and most thorough contributions to the debate was Clarence Blomquist's book on euthanasia, *Livet, döden och läkaren* (1964). In that book Blomquist discusses the five principal definitions of euthanasia that were used in the debate: (1) the original meaning: medical care in the terminal phase of life, for example, the mitigation or relief of pain and discomfort of the dying; (2) causing death as a predicted but not intended side effect of treatment; (3) the acceleration of death; (4) passive euthanasia: discontinuing treatment or refraining from initiating treatment; and (5) active euthanasia: intentional killing in accordance with the patient's explicit or implicit wish to die or irrespective of the patient's will. Obviously, these different forms of euthanasia may overlap.

A fundamental issue in the debate has been where to draw the line between life and death. Brain-related criteria of death were introduced by law in Finland in 1971, in Norway in 1977, in Sweden in 1988, in Denmark in 1990, and in Iceland in 1991. The introduction of those criteria eliminated a minor but important part of the problem.

Throughout the 1970s even euthanasia as part of medical care in the terminal phase of life was disputed. The administration of painkillers was restricted to prevent terminally ill patients from becoming addicted to those drugs. In Sweden, for example, that restriction was not lifted until 1979. There was also concern that a more liberal administration of painkillers and tranquilizers might shorten a patient's life. Blomquist was among those who found this unintentional form of euthanasia, as well as the passive form, morally justifiable but did not support active euthanasia. Others, such as the Swedish professor of practical philosophy Ingemar Hedenius, advocated active euthanasia.

In 1992 Denmark became the first Nordic country to break with the traditional legal view on medical care in the terminal phase of life, passing a law according to which, unless there is particularly good authority for acting differently, a physician may not initiate or continue life-sustaining treatment of a terminally ill patient against wishes expressed in the patient's "living will." The law further provides that in the absence of a living will the physician may discontinue or refrain from initiating treatment that may prolong the life of a terminally ill patient. The physician also may administer painkillers, tranquilizers, and similar substances necessary for easing a terminally ill patient's suffering even when that may shorten the patient's life.

Three organizations for terminal care have been formed: in Sweden in 1973, the national organization Right to Our Death; in Norway in 1977, the national association My Living Will—the Right to a Death in Dignity; and in Finland in 1993, EXITUS. In 1985 a special organization for active euthanasia, EXIT, was founded in Sweden.

Concluding Remarks

Among other areas that have attracted special attention in the Nordic countries are ethical problems in medical research, for example, questions of integrity and the difficulty of meeting the requirements of informed consent in epidemiological and healthcare research. The frequent use of personal numbers in computerized official registers provides unique potential opportunities for population studies. At the same time it creates special ethical problems (Hermerén). Another field of increasing importance is the ethical consequences of technological and scientific developments in human genetics (for an overview see Berg and Tranøy 1989; Bischofberger et al.; Therkelsen et al; Nordisk Ministerråd, 1992, 1994). Finally, the ethical questions of health economics and setting priorities in healthcare have been debated. In 1987 in Norway a government-appointed commission

produced a report on guidelines for priorities in public healthcare (Sosialdepartementet).

From the early 1960s to the end of the 1990s medical ethics underwent a sweeping transformation in the Nordic countries. From being viewed primarily as a concern only between the patient and the physician and only between colleagues, medical ethics has evolved into a field of systematic studies and extensive interdisciplinary and public debate. The scope has broadened from discussions of normative ethical issues to include metaethical analyses of the norms, values, and basic concepts of medicine. General awareness of the conflicts of interest and the incompatibility of the goals inherent in medical decision making and research has increased considerably, a development that benefits both patients and medical professionals.

VIII. CENTRAL AND EASTERN EUROPE

This entry covers Poland, the Baltic states, Hungary, Romania, the Czech and Slovak republics, the former Yugoslavia, Bulgaria, Albania, and Cyprus. In these nations to the east and southeast of the Elbe River, the doctor–patient relationship and biomedicine itself have been characterized by the paternalism and dominance of a powerful elite within the medical establishment. Furthermore, a number of factors have profoundly influenced the status of healthcare as well as bioethics in this region. Among the most important are: (1) a relatively small percentage (around 5 percent) of the gross national product spent on healthcare, biomedical research, and environmental protection; (2) Prussian-like feudalistic attitudes (e.g., a rigid hierarchical system with a small and arrogant elite at the top and a large number of disempowered people below) preserved within universities and medical colleges. For physicians the idea of being the "captain of the ship" is still self-evident, and many believe that the behavior of older doctors provides the right ethical model for future ones.

In Hungary, Poland, Romania, the former Yugoslavia and Czechoslovakia, the Baltic republics, Bulgaria, and Albania, another determining factor that shaped medicine, healthcare, and bioethics was the form of Marxism that became the official ideology after the end of World War II. The hard ideology of Stalinist Marxism prevailed in Albania much longer than anywhere else in eastern and central Europe. These ideologies instructed morals and morality, so that only behaviors that brought people closer to communism were considered morally correct. Only infallible and omniscient party leaders knew exactly what these behaviors were.

Before World War II

In central and eastern Europe a feudal-capitalistic system existed prior to World War II. Agriculture was so dominant that in most of these countries the peasantry, unskilled agricultural toilers employed by owners of huge tracts of land, made up more than half of the population. These peasant workers were not able to rise from serfdom to free citizenry. This situation existed in large part because there had never been any genuine democracy in this region. The high degree of illiteracy, and the struggle for survival within the context of wars and ethnic strife, had a great impact on the people's health as well as on medical ethics.

A significant majority of people (normally peasants and poor urban dwellers) had no health insurance, and thus no access to professional care. Infant mortality, tuberculosis, and high overall death rates due to lack of treatment were very common. It was quite natural, for example, to view patients, usually those who were unable to pay, as teaching objects in university clinics and teaching hospitals. Healthcare was basically private, a profit-oriented endeavor that brought high earnings and social prestige to physicians—who carefully controlled their own numbers, especially the number of specialists. There existed a unified medical profession and a system of professional and ethical control. Within the profession certain basic norms concerning referrals, regulation of payments (neither overcharging nor undercharging), and advertisements were generally honored, and violators were punished.

Some dedicated individuals in these countries, usually physicians, kept the Hippocratic ethics alive by writing books and articles that, for generations, exerted a strong influence over the practice of doctors: for example, in Hungary, Jozsef Imre's *Orvosi Ethika* (Physicians' ethics), 1925; in Poland, Wiadislav Bieganski's *Mysli i aforyzmy o etyce lekarskiej* (Thoughts and aphorisms on medical ethics), 1899. These authors concentrated almost as much on the duties of the patient as on those of the physician. In addition to the Hippocratic works as a source of ethical standards, Polish physicians relied heavily on Catholic moral theology in the development of bioethics, especially concerning such issues as abortion, birth control, genetics, and euthanasia.

After World War II

As a result of the Yalta agreement dividing Europe into spheres of interest, a large part of central and eastern Europe came under the dominance of the Soviet Union. The communist leaders launched a massive industrialization program in most countries of the region. This resulted in an unprecedented mobilization of people that contributed to significant changes in class structures (e.g., millions of peasants became industrial workers), disintegration of large family units, and increased migration to urban areas. All these changes occurred just after World War II.

These countries became monolithic states soon after the war. Moral pluralism existed only underground. Marxism shaped by Soviet communism or distorted forms of materialistic socialism provided the basis for the dominant philosophy and ethics. Moral rules were dictated by party leaders who claimed infallibility and ruled coercively, resulting in a monopolistic moral climate. Behind these rules there stood an irrefutable state power and an excessive bureaucratization of power, with extreme centralization of decision making.

Political theoreticians presented a future-oriented ethics in which every desirable human goal was placed in the future state of communism. At the same time they denied the right of existence to any autonomous professional ethics, believing that their form of Marxist ethics was adequate to answer all questions raised in any area of human endeavor. Ironically, the principal slogan in all these states was "The highest value in socialism is the human being."

However, as soon as a little freedom of speech was allowed beginning in the 1980s, it became obvious that the morals of socialism were in ruins, as was the socialist economy. Despite claims that the socialist healthcare system was of high quality, free, and accessible to everyone, it became evident that this was not so. Sociological surveys in these countries showed a very poor general state of health in the populations, high mortality rates, and severely reduced life expectancies. For example, in 1994 Hungary had one of the highest cardiovascular mortality rates in Europe for people below age sixty-five, and for all ages it placed fourth, after Romania, Bulgaria, and the former Soviet Union. This situation has not changed much into the twenty-first century. The percent of women in Hungary dying from cervical cancer is twice as high as the regional average; the suicide rate is the highest in Europe and about three times the regional average; the mortality rate from malignant neoplasm is also the highest in Europe, accounting for 21 percent of all deaths. Hungary and the former Czechoslovakia have the highest mortality rates for ischemic heart disease among countries in the region. There is a difference of almost five years in life expectancy between central/eastern and western Europe.

In addition, the crime, divorce, and suicide rates in the region rank among the highest in the world. Central and eastern European countries have placed a low priority on the prevention of accidents and illnesses and to occupational diseases. They have justified their notorious environmental pollution and destruction through the repeated use of slogans regarding the need to subdue nature for the sake of human progress.

The Soviet type of healthcare system was introduced in all these central and eastern European countries. Some of the features of the Soviet system, besides those already mentioned, included: little if any freedom for patients to choose their doctors; bribes and corruption, manifested mainly in the practice of patients' tipping physicians for services; injustices in distributing limited resources; prejudice against the elderly; mechanistic patient care; and a clash between heavy demand and very limited resources. There was also, incidentally, a predominance of women in the medical profession.

For decades the problems in Soviet-style healthcare could be hidden because fact-finding studies were regarded as "top secret" and revealing them was a serious political offense. Writers on the sociology or ethics of medicine were mostly either Communist party hacks or individuals afraid of writing the truth lest they lose their jobs. Consequently, it is little wonder that people in Western countries did not understand the decay and injustice that characterized the socialist healthcare systems of the region. Only after the political and economic collapse of these once-praised systems did they come under fierce criticism. The health laws of these countries seldom mentioned patient rights, and nothing at all was said about such principles as patient autonomy. In practice, physicians and healthcare institutions had no freedom in choosing patients, nor had patients any freedom in choosing doctors. Nevertheless, people could have access to healthcare that was theoretically free and officially had a high quality level. There is no doubt that many millions of people who, before World War II, might have died due to an inability to pay for medical care, could get essential treatments under the socialist system. This, in itself, was a great achievement.

Since state and party officials accepted no professional ethics beyond an exclusive Marxist version, teaching ethics meant teaching Marxist ethics. Its main features were the unrelenting struggle against the enemies of the working class and the constant urging of people to work and produce more. Ethics was taught in colleges and universities only by the departments (or institutes) of Marxism-Leninism. These institutes occasionally smuggled issues pertaining to medical ethics into medical universities, alongside the officially allowed themes of the Hippocratic Oath and the moral ills of private medical practice. Noticing the great interest of students in ethical issues in medicine, some teachers began to deal with euthanasia, transplantation, and confidentiality. But nowhere in these countries was the teaching of medical ethics/bioethics formally established or officially supported during the Marxist-Leninist era.

The pioneers who introduced a more contemporary medical ethics in health colleges and medical universities were quite often physicians. In Hungary, the first textbook on the subject was written by psychiatrist Janos Szilard in 1972; the second comprehensive textbook, written by Bela Blasszauer, a medical ethicist with a background in law and philosophy, appeared eighteen years later in 1990. In Poland, a popular collection of essays written by doctors was recommended for teaching medical ethics at medical universities (Kielanowski). These broadly based works on bioethics contained a number of previously undiscussed issues, including patient rights, informed consent, reproductive medicine, and refusal of treatment.

Since the end of the 1980s, and continuing into the twenty-first century, in Poland and Hungary more than six thousand hours are devoted to the six-year medical curriculum, and only thirty or less of these are assigned to the teaching of medical ethics. In certain medical schools there are no seminars, only lectures, depriving students of moral debates, discussions, and analysis of cases. In several countries seminar hours consist of surveying standard medical codes and existing health laws. Even in the early twenty-first century, a distinction was hardly ever made between laws and morals, laws and ethics. In Hungary, almost all the issues of bioethics were incorporated in the curriculum, especially such topics as informed consent, euthanasia, human experimentation, and patient rights.

Only a few countries at the turn of the twenty-first century, some years after the radical political changes throughout central and eastern Europe, encourage the teaching of bioethics, allowing bioethics to begin achieving a prominent place in the medical school curriculum. Whereas all Hungarian medical universities and health colleges teach thirty hours of bioethics, usually in the third year, in the Czech and Slovak republics bioethics is taught in ten medical schools; in Slovenia thirty hours of bioethics are given to medical students and fifteen hours to dental students. In Romania bioethics is on the medical school curriculum in Bucharest and Temesvar; in Estonia, one priority is to train bioethicists and to begin teaching in this area.

The war in the former Yugoslavia gave Croatia an impetus for developing medical ethics. Until the war, medical ethics was not taught as a separate subject in medical faculties but was a part of the history of medicine, social medicine, or forensic medicine. The same was true in Bulgaria and other Balkan countries. Since 1982, Croatia's capital Zagreb has been the seat of the Croatian Center for Medical Ethics and Quality of Life. In 1992, the medical faculty of Rijeka introduced medical ethics as an independent subject. It is the ambition of the Department of Social Studies at Rijeka to establish an international center of medical ethics for the neighboring countries.

Main Areas of Ethical Concern

Several issues are of universal and particular interest and are widely discussed in the media and are in the forefront of medical ethics education.

TIPPING. Sometimes referred to as *parasolventia,* gratuity, or even bribery, tipping was one of the most hotly debated medical ethics issues in many of these countries in the later years of the twentieth century (see, for example, Adam, 1986; Page; Szawarski, 1987; and Bologa). Outside of the healthcare system, tipping has long been a common practice in many of these societies. Where there is a real or artificially created scarcity, and a tradition of some occupations with obligatory tips (e.g., waiters, barbers, concierges), the spreading of the practice to medicine may not be so surprising. The practice of slipping envelopes containing money into physicians' pockets for the treatment that was provided was not only unlawful but a violation of the basic idea of free healthcare, an idea that was supposed to make socialism superior to capitalism. In Hungary from the 1950s until the 1980s, the Communist party and the government waged a campaign against tipping. It was doomed to failure at the very beginning. So far every such attempt to eliminate or at least curb tipping has been absolutely ineffective.

Still, in the few articles on medical ethics or medical deontology that did appear in these countries, only the most courageous or the most trusted authors dared to write about tipping. Generally, they would have been prosecuted for damaging the reputation of the socialist healthcare system. Moreover, though it was (and is) a well-known phenomenon, it is very difficult to prove who took such money, how much, when, and why. In Hungary, the irony is that tipping is illegal, but nevertheless it is taxed. In Poland, since tipping makes healthcare unregulated and uncontrolled, the Code of Medical Ethics forbids accepting tips (Extraordinary Congress of Physicians). The Hungarian Code of Medical Ethics, on the other hand, only forbids accepting tips if they are given before treatment or given by colleagues working in the healthcare system (MOK).

In undergraduate medical education, ethics classes were devoted to this phenomenon. Ethics teachers were expected to educate future doctors to uphold socialist morality, which condemns taking money or any other form of bribe or gift from patients. Tipping has penetrated the whole system of medical care and hinders radical reforms in the system. Whether the cause is low professional salary, lack of public resources, the patient's feeling of gratitude, or simply a general moral decay, widespread tipping has morally eroded the system of healthcare. Some experts believe that the system would collapse without this extra income, which in some cases is many times greater than the state-paid salary. Other experts claim that no reform can be successful as long as the practice of tipping exists.

To a much smaller degree, health professionals other than physicians supplement their wages with occasional tips. A common feature of central and eastern European state healthcare systems is the very low salaries of doctors and other health workers. Still, some of these professions remain attractive because financial rewards can be hoped for as long as the system of gratuities persists. One can expect that debates will continue to probe the causes of this practice that

has been causing major problems in the physician–patient relationship and also greatly distorts the relationship between physicians and nurses, as well as nurses and patients.

EUTHANASIA OF ADULTS AND INFANTS. Although discussion of euthanasia was long considered taboo in central and eastern Europe, it surfaced from time to time and aroused tremendous public interest. While laws in these countries forbid both active and passive euthanasia regardless of the status and prognosis of the patient (thus making no distinction between the active and the passive forms)—the latter is widely accepted and practiced. In Poland, euthanasia debates have been rare because the Auschwitz, Birkenau, Stuthof, Gross-Rosen, Treblinka, and Majdanek concentration camps were the sites of Nazi doctors' criminal practices and experiments. The memories of crimes against humanity and the moral teachings of the Catholic Church have made the Polish people very hostile to any argument favoring either form of euthanasia (Szawarski, 1987, 1988). In Romania, even under the communist dictatorship of Nicolae Ceausescu, there were scholars who openly advocated passive euthanasia: Erno Kiraly and Karoly Daniel introduced and endorsed the use of the living will in that country in the 1980s. In Romania it was not even possible to talk about bioethics until 1989; now there are hospital ethics committees for special care issues. In Czechoslovakia, physician Pavel Lukl advanced the idea of passive euthanasia in 1970. In Slovenia the practice of passive euthanasia is openly accepted, while active euthanasia, as everywhere else, is rejected (Straziscar and Milcinskij).

The Hungarian euthanasia debate dates back to the early 1920s, when a crusade to legalize active euthanasia, led by Karl Binding and Alfred Hoche (a German lawyer and physician, respectively), was rejected. In the 1970s the debate was renewed, and several articles and a book appeared (Boldizsar; Blasszauer, 1984; Czeizel, 1982). Those sympathetic to euthanasia were accused of deviating from the socialist norms and advocating discrimination among people on the basis of social worth (Horvath; Monory). The former Hungarian Health Act of 1972 states, without mentioning the word "euthanasia," that the physician's duty is to do the utmost until the very end for all patients, even those who suffer from incurable conditions. There is no mention of consulting the patient about his or her wishes. Nor is there discussion of what is to be done when legally mandated heroic efforts require respirators, dialysis machines, or other lifesaving devices that are in short supply.

In the case of seriously ill newborns, those who argued for the need to select infants to receive life-sustaining treatment were harshly condemned and even accused of behaving like the notorious Nazi doctor of Auschwitz, Josef Mengele (Mestyan). Because of Hungary's low birthrate, obstetricians were rewarded with promotions or premiums for infants who survived at least to the age of one. Therefore, up to the age of one the statistics are closely monitored, while beyond that age there is no incentive to provide high-quality healthcare. The decision to extend treatment to seriously ill infants belongs exclusively to physicians; in most cases the parents are not consulted. At the turn of the twenty-first century, however, some universities and county hospitals established infant-care ethics committees.

Only after the radical political changes of the late 1980s and early 1990s could such topics be discussed openly without accusations and reprisal. In Hungary a survey asked physicians, "Do you believe, in all circumstances, every possible effort should be made to sustain life?" Seventy-nine percent of responding physicians who worked in neonatal intensive-care units answered no (Schultz).

INFORMED CONSENT AND TRUTH-TELLING. Until the end of the twentieth century, in harmony with the existing paternalism, patients in central and eastern Europe usually received little, if any, information about their conditions. Physicians' unwillingness to discuss diagnosis, prognosis, and intended therapy with the patient was due to their training, their limited knowledge of contemporary bioethics, and their characteristically negative judgment regarding their patients' medical knowledge and ability to make rational medical decisions. Since the physician is the "captain of the ship," it was taken for granted that the patient's duty is to follow his or her orders. Hungarian sociologist Agnes Losonczi described the situation well when she stated that a sick person does not have as many rights as someone who seeks to have a washing machine repaired.

Generally, relatives of the patient were given medical information and left to decide whether to reveal that knowledge to the patient. Disclosure is still not common in cases of incurable disease; silence is believed to be justified by fear of patient suicide. This claim is simplistic and unsupported by fact, but despite arguments against deceiving patients, the dominant principle was expressed by prominent internist Imre Magyar: "One must never tell a hopeless prognosis, instead one must always give hope" (1978, p. 2). As long as a high court judge writes that an incurably ill patient must not be informed that a planned surgical intervention will bring only temporary relief, there is little hope that lawyers will fight for patients' autonomy (Toro). Silence still remains a practice in many places, despite the fact that after the collapse of communism, new laws in most countries require health professionals to honor the principle of informed consent.

Considering the prevalence of this practice of silence in central and eastern Europe, little can be said about the principle of informed consent. Although the law requires it, in reality the principle is not always honored. The Hungarian Health Act of 1997, for example, explicitly states that informed consent must be obtained before any medical intervention. Patients have seen some progress in regard to the right to access to medical documents, and many healthcare institutions provide documents to patients on request, without court intervention. The failure to obtain the consent of the patient drives most contemporary malpractice suits.

HUMAN EXPERIMENTATION, REPRODUCTIVE MEDICINE, AND GENETIC SCREENING. Because high technology is still far from being widespread in central and eastern Europe, research is primarily related to pharmaceuticals. The Helsinki Declaration of 1975 is accepted everywhere as a guideline for ethical research using human subjects, and in some of these countries (e.g., Hungary and Romania) the guidelines have been incorporated into laws regulating biomedical research. Prisoners are excluded from any experimental or research protocol, and nontherapeutic research uses volunteers, usually students. The Polish Code of Medical Ethics (1991) makes no distinction between therapeutic and scientific research. In practice in central and eastern Europe, however, research ethical guidelines are often violated, and the region is infamous for its loose approach to honoring ethical principles.

In a few clinics and hospitals, artificial insemination, in vitro fertilization, and GIFT (gamate intra fallopian tube transfer) programs proceed under vague and inadequate legal and ethical norms.

Genetic screening is done in most central and eastern European countries, but in some of them (e.g., Hungary and Poland) it meets with opposition from the Catholic Church. In Cyprus, President Archbishop Makarios introduced compulsory screening for thalassemia, a hereditary blood disease. The screening has considerably decreased the occurrence of this disease.

CONFIDENTIALITY. Throughout this region confidentiality is highly valued. Cases of its violation, however, hardly ever come before the courts because the laws in these countries allow many exceptions (the interest of the state, divorce cases, etc.). In practice, the violation of medical confidence is very common and goes hand in hand with the frequent violation of privacy. In the Marxist-Leninist era, the state had exclusive access to all patient records—patients were not even allowed to see them. In certain countries, like Hungary, the laws overregulated confidentiality; thus everything was viewed as a secret, which led to nothing being honored as a secret.

ABORTION. In most of the former communist countries abortion was considered a hard-won right for women. Laws were lenient, allowing abortion for simple social reasons. In Hungary, for example, 4.5 million abortions were performed between 1956 and 1990. Some view this as a national tragedy, but the antiabortion movement has only been vocal since the Communist party's demise. Abortion was (and is) a major method of birth control: In the former Czechoslovakia there were ninety-four abortions for each 100 live births in 1988 (Albert).

In Romania, however, abortion was forbidden; as a result of illegal abortions, at least ten thousand women died from complications during the Ceausescu era. In Poland, a heated debate accompanies the attempt, strongly urged by the Catholic Church, to reverse liberal abortion laws. The 1991 Polish Code of Medical Ethics allows abortion under two special circumstances: if the mother's life and health are at risk, or if conception was the result of rape. In Lithuania, opposition to abortion is increasing, and the law that allows abortion on demand in the first trimester is considered by the antiabortion group in that country to be a crime against humanity. The debate is especially intense and interesting in the former East Germany, where abortion laws were far more liberal than in West Germany (Breese).

TRANSPLANTATION. The policy of presumed consent for the donation of organs, tissues, or other biological material is universal in central and eastern Europe and provides an almost unlimited possibility for procurement of such materials for research, transplantation, and drug production. Lawmakers influenced by prominent members of the medical establishment were instrumental in enacting presumed-consent legislation that made organ procurement quite easy and opened the way to organ transplantation.

In these countries, transplantation has so far been largely limited to kidneys. In spite of the policy of presumed consent for donation, organs are as scarce as everywhere else and demand is high. The problem of organ procurement cannot be blamed on individuals' lack of willingness to donate their organs, but on the indifference of many health professionals. Their lack of motivation leaves many available kidneys unreported: In the early 1990s it was estimated that only 10 percent of potential donors in Hungary are made available to transplant centers. Age is one of the main criteria for transplant recipients, and in the 1980s and 1990s no "new" kidney was available for persons over the age of fifty. Heart and liver transplants have also taken place (e.g., in Hungary) and have received tremendous media coverage.

Consequently, the problem of obtaining organs has drawn great public interest and has become an important ethical issue for discussion. In these countries, where the medical establishments are strong and have significant political influence, the consent by the spouse or relatives of the dead person to use organs in most places is not necessary and their refusal is seldom honored.

MALPRACTICE. Charges of malpractice are very rare in central and eastern Europe, and successful lawsuits are even rarer. The most likely reason is not the superior professional skills of physicians working in these countries but the lack of patient rights, and the very powerful medical establishment that displays a high level of solidarity at critical times. The laws are worded in such a way that carelessness, negligence, or incompetence is difficult to prove as causally connected with the patient's state of health. Despite the fervent opposition of the medical profession, however, with the process of democratization and the planned reform of healthcare, and especially with the introduction of market conditions, malpractice is finding its way slowly into the patient–physician encounter. Insurance against malpractice had appeared in several of these countries by the beginning of the twenty-first century.

Western Help: Promising Changes

In central and eastern Europe the transition from a one-party system to political pluralism has opened the way to democracy with free elections, public control, and constitutional guarantees. These countries have begun to reform healthcare, allowing free choice of doctors; encouraging health insurance; providing mechanisms to finance health provision; overseeing the constant separation and reunification of healthcare and social services; allowing the extension of private practice; and encouraging reimbursement in accordance with the type of disease and number of patients.

The changes have brought a divergence of opinions on bioethical issues to the surface. Such world organizations as the World Health Organization (WHO), United Nations Educational, Scientific, and Cultural Organization (UNESCO), and the Council of Europe promise to bring help to the region. These organizations hold meetings, work out guidelines, keep data banks on bioethical activities, and encourage such endeavors. The Hastings Center in the United States has played a key role in helping to bring together the central and eastern European bioethicists and their western counterparts. It has provided books, journals, forums, and scholarships to a number of bioethicists in this region. The Centre for Philosophy and Health Care of Swansea, Wales, joined the Hastings Center's Eastern European Program in the late 1980s. In the early 1990s it obtained support from the Nuffield Foundation, which has been quite generous in giving scholarships, libraries, and journals to many of these countries. The European Society for Philosophy of Medicine and Health Care, the European Association of Centers of Medical Ethics, the Jefferson Medical College of Philadelphia, the Inter-University Centre of Dubrovnik, the Center of Medical Ethics of Oslo, and the International Association of Bioethics have helped move bioethics out of the underground. Without such international help, bioethics in the region would be still back in Hippocratic times and would be poorer both intellectually and materially. In 1999 the Central and Eastern European Association of Bioethics was established with the participation of nineteen countries to promote dialogue among the former Soviet satellite countries and help each other to (re)humanize the healthcare systems.

IX. RUSSIA

The history and state of medical ethics in Russia in the twentieth century has been defined by the influence of the communist regime. Communism, its evolution, and its deterioration, exercised and will exercise for a long time to come, a pervasive influence on the most diverse spheres of social life, including the area of medicine and health care.

Prerevolutionary Period

The ascendancy of the Bolsheviks in 1917 sharply interrupted the stormy development of Russian healthcare, whose beginnings coincided with the great reforms of 1861, which eliminated serfdom for a peasant population that comprised the overwhelming majority of the country. Prior to those reforms, peasants could turn only to the village folk doctor (practitioner of popular medicine) or, in certain cases, healers from among the Russian Orthodox monks. For the most part, the healthcare of serfs had been the responsibility of their owners.

One of the most important of the mid-nineteenth-century reforms was the creation of elected local self-governments: the *zemstvos,* which received some autonomy from the central authority. The organs of local self-government levied taxes that were used for general needs, including building and equipping hospitals, ambulances, homes for orphans and for the elderly, and other needs. *Zemstvos* also hired and paid doctors, doctors' assistants, nurses, and other medical personnel.

In 1864, 530 medical centers were opened in Russia. Each center served an average area of 4,860 square *versts* (one *versta* equals two-thirds of a mile) and a population of about 100,000 people. After fifty years, in 1914, there were 2,800 such centers, each of which served an area of 880 square *versts* and 27,000 people. Expenditures for *zemstvos* healthcare grew from 2.5 million rubles in 1870 to 57.7 million rubles in 1912. Before 1861, the country had 519 hospitals; by 1914, it had 1,715 (Solov'ev). The local doctor's ideals formed the ethos of Russian medicine. The ordinary *zemsky* (hired and paid by the *zemstvos*) physician had a modest social standing and a very modest income. He earned about as much as a factory worker. *Zemsky* physicians represented one of the largest groups within the Russian intelligentsia, along with *zemsky* teachers. Service to the people (i.e., the peasants) was a defining characteristic of the intelligentsia.

The ignorance and poverty of the peasants, whose work fed the whole country, evoked among the intelligentsia that considered itself dependent on the peasant class not only sympathy, but a guilt that moved them to active work on behalf of the peasants. Many of the intelligentsia, neglecting their own material well-being, saw as the highest meaning of their lives the unselfish service to the people. Thus was born the movement called the *narodniki,* that is, representatives of the intelligentsia who saw that their responsibility was to "go to the people," to work selflessly in the most far-away places in Russia. "Every comfort of life I have," wrote one of the most committed leaders of the *narodniki* movement, the philosopher and sociologist Petr Lavrov, "… is purchased with the blood, sufferings, and work of the millions.… I will discharge my responsibility for the cost in blood of my development, if I use my development to lessen evil now and in the future" (Solov'ev, p. 43).

Along with the more radically disposed social-democratic intelligentsia, the mass of *zemsky* physicians were very dissatisfied with the actual state of affairs, but they preferred the path of reform and the laborious work of education to the revolutionary path of violence. The first obstacles of the path of reform were the deep prejudices and lack of confidence of the peasants, their resistance to change from traditional lifestyles, including acceptance of medical aid or elementary hygienic recommendations.

The *zemstvos* system permitted physicians to achieve an unprecedented degree of professional autonomy; the government, however, constantly strove to curtail this autonomy. During these years, periodic meetings of local physicians were held to discuss current problems within the profession. In the *zemstvos*, physicians, together with representatives of the administration, participated in the formulation of local policies for healthcare. In 1883, the newly formed Society of Russian Doctors to the Memory of N. E. Pirogov assembled physicians of all specialties. The society, named in honor of the outstanding Russian surgeon Nikolai Pirogov (1810–1881), was the first independent organization of physicians. The Pirogov Society significantly influenced the formulation of ideas and policies about healthcare. It fought actively for improvements in the working conditions of peasants and factory workers, and mostly because of its efforts, in 1903 a law was adopted regarding the liability of owners for accidents in the workplace. The society strove to improve the health education of the people and battled for increases in budgets for medicine and healthcare. In 1910, the society blocked efforts of the authorities to unify the healthcare system and impose upon it strict government control. The society monitored physicians with regard to the norms of medical ethics, and fostered discussions about medical practice that touched on moral and ethical problems.

Medical ethics in Russia evolved, for the most part, in the light of European traditions, even though the specifics of Russian medicine left a noticeable mark. General practitioner and hygienist Matvei Mudrov (1776–1831), one of the first in Russia to concern himself with problems of medical ethics, believed that the Hippocratic Oath could be the foundation of a code of conduct for Russian physicians. Nikolai Pirogov, whose ideas attracted particular attention to the problem of medical mistakes, and Vjacheslav Manassein (1841–1901), general practitioner and organizer of state and local medicine as well as editor of the journal *Vrach* (Physician; 1880–1901), which devoted significant attention to discussions of medical ethics, developed their ideas along the same lines. Among the characteristics of Russian medical ethics of the prerevolutionary period, the marked paternalism connected with the long-standing tradition of subjugation of the personality to the state or to the peasant community stands out. Typical patients were illiterate and ignorant peasants who were considered unable to make reasonable decisions in their own best interests and, therefore, required direction from others.

The other significant characteristic was the peculiar understanding of social justice, which generated a feeling of eternal indebtedness to the most impoverished and unfortunate people in society. Not by accident, a physician of German origin, Fyodor Gaaz (1780–1853), who settled in Moscow and devoted himself to the medical care of prisoners in jails and their children, enjoyed great moral authority both during and after his life. Unselfish and self-sacrificing service was demanded of physicians who understood their duty, including the willingness to work at any time of the day or night, to venture into any weather at the first call to reach the bedside of a sick person as quickly as possible, and to spend as much time at his or her bedside as necessary. To appreciate this high idealism, one should bear in mind the vast expanses of Russia, which were (and are) far from being fully connected by roads.

These ideals were also reflected in the literary works of doctors who became famous writers: Anton Chekhov (1860–1904), Vikentii Veresa'ev (1867–1945), and Mikhail Bulgakov (1891–1940). Writers in Russia were traditionally leaders of public opinion and exerted great moral influence, so the works of Chekhov and Veresa'ev that were dedicated to *zemsky* physicians deeply influenced the education of the intelligentsia. In his *Physician's Notes* (first published in 1901), Veresa'ev sharply criticized violations of ethics in medical practice and research. For many years this book was at the center of significant discussions in Russian as well as western European literature. The ideal of the *zemsky* doctor was so deeply ingrained that it even survived the Bolshevik regime.

Communist Period

The communist regime came to power on the crest of a world war that was especially terrible and destructive for Russia. Immediately, the new government had to confront serious problems inherited from previous governments. Social collapse, hunger, and poor sanitary conditions caused huge epidemics of cholera, typhoid, and smallpox, so that the new government mounted a fierce fight against contagion (mass vaccinations, disinfections, isolation of infected, sanitary measures, and so on). Measures were taken to coordinate healthcare activities, resulting in extreme centralization. In July 1918, the Peoples' Commissariat for Health Care in the Russian Republic was founded.

This commissariat was the first national ministry for healthcare in the world, created a year before the British Ministry (Kazer). Under the leadership of the first Soviet People's Health Care Commissar, Nicholas Semashko (1874–1949), a doctor close to Lenin, all the departments of the government having anything to do with medical services were united under one ministry (Knaus). In subsequent years, however, organizations that were autonomous from this commissariat gradually appeared, though healthcare services for the railroads, the army, and other kinds of special services remained centralized. Healthcare services were supported financially by the state and were free to the people. These measures of the new authorities provoked severe criticism from members of the Pirogov Society who complained that the introduction by Soviet authorities of free healthcare would deprive physicians of their independence and initiative, both of which had been fought for during the earlier reforms. The regime, however, was not inclined to compromise with critics, especially with any type of organized opposition. The all-Russian Federation of Medical Workers (*Medsantrud*) was created in opposition to the Pirogov Society. The Pirogov Society was liquidated by 1922.

Medsantrud attempted to conserve the remains of democratic self-management of the ranks of medical workers, and this brought upon it the wrath of the authorities. For example, one of the principal organizers of Soviet healthcare, the People's Deputy Commissar for Health Care, Zinovii Solov'ev (1876–1928), wrote in 1923: "What is this 'public' and what in general can 'public' mean in the conditions of the Soviet government? Two different answers to these questions are not possible. Our public is to work on all aspects of Soviet life on the basis of the independent revolutionary class, the bearer of the proletarian dictatorship, the proletariat and its ally, the impoverished and the middle peasant class" (p. 54).

In this way the regime essentially redefined the social role of the physician. The physician was now considered a representative of the hostile bourgeois class, tolerated only as a specialist and permitted to work only under the strict control of the proletariat. In essence, however, that control was exercised by government and Party bureaucrats.

Meanwhile, the 1917 revolution and the ensuing civil war led to a serious decrease in the number of physicians in the country. In the first years after the revolution, about eight thousand physicians left Russia. Many doctors died from hunger and disease. Between November 1917 and August 1920, 46 percent of all physicians in Petrograd died (Knaus). In response, the authorities attempted the rapid training of new physicians. People were admitted into medical schools without even a secondary education and, at times, without even being able to read or write; final exams were eliminated. A system of "brigade education" was introduced whereby the knowledge of the group of students was evaluated on the basis of an oral exam of one of the students, on the grounds that the better prepared students would help the unprepared students in their training. There was, then, a rapid increase in the number of physicians, although, of course, at the cost of serious decline in professional standards.

Such reliance on collectivism was anything but accidental. Medicine, like everything else, was viewed from the class perspective. Individualistic bourgeois medicine was countered by collectivist proletarian medicine. The aim of the new medicine became the following: "The conservation of the life forces of the proletariat and the building of socialism in and of itself, of course, must be for us the main compass with respect to which a question regarding the tasks of our contemporary medical practice will be posed" (Solov'ev, p. 187). Consequently, the entire area of medical practice had to be reconsidered: "Characteristic of today's clinics is the fact that they were formed and exist today as the products of a discipline that is strictly individualistic. Contemporary capitalist society leaves its mark on medicine in the area of theory as well as particularly in the area of practice. The individualistic demand for care of a single person and not of a human collective creates corresponding methods of thought and practice" (p. 175). Key to the problem of shaping the approach and content of medical practice, according to Solov'ev, was the answer to the question of how "it is possible to strengthen the health of the human collective and restore [its] health once it has been destroyed" (p. 171).

These words affirmed the traditional approach of Russia regarding the importance of prevention in healthcare. This approach was implemented by making the work conditions and living conditions of people healthier, as well as by considering the social and ecological causes of many illnesses. At the same time, these comments by one of the

leaders of Soviet medicine in its formative stages show clearly Bolshevism's negation of the self-worth of the individual, the reduction of human individuals to the role of cogs in a system of production, and the subjection of the individual to social expediency.

In the view of the Bolsheviks, considerations of class expediency defined the areas of morals and ethics. For example,

> The much celebrated theoretician of petty bourgeois morals, Immanuel Kant, advanced in his time a moral demand: "Never look on another person as a means to an end but always as an end in itself.…" Can you imagine how far the proletariat would have advanced in its revolution if it had allowed itself to be guided by such a demand and not by the completely contrary demand of class interests.… The highest wisdom of the proletarian struggle consists not in that everyone claims his own rights, but in that everyone must selflessly, almost spontaneously, without phrases of superfluous gestures, without demanding anything for himself, pour all of his energy and enthusiasm into the common stream, and work for the goal, with the entire class, perhaps be the first to fall on the road. (Preobrazhenskii, 1923, pp. 72–73)

A systematic elaboration of medical ethics that could have corresponded to the ideological purposes of the new regime and the new system of healthcare was, with rare exceptions, not attempted. To the extent that the physician was considered as only an auxiliary, rather than as an independent professional, the idea of posing questions of specific medical ethics was deemed superfluous. Even though some problems had a distinctly moral-ethical content and as such were quite controversial (for example, abortion, confidentiality, and medical mistakes), they were not viewed as problems specific to medical ethics. In general, medical ethics or, as it was usually referred to, "physicians' ethics" was understood as the affirmation of a corporate morality opposed to the class interest of the proletariat. The viewpoint was rather widespread that Soviet people, regardless of their sex and profession, should be guided solely by the norms of communist morality, and that any specific norms of professional morality would only limit the scope of and adherence to the general norms.

With respect to medical education, systematic courses in medical ethics did not exist in prerevolutionary Russia nor were they created by the new regime. After the revolution, in fact, the initiation of new physicians by means of a professional oath, a revision of the Hippocratic oath, was eliminated, even though that practice had been obligatory since the beginning of the twentieth century. The social humanitarian preparation of medical students was limited to a course in Marxism-Leninism.

Against this background of ethical relativism and nihilism characteristic of the Bolshevik scorn for traditional moral values and principles, the earlier traditions of medical ethics could still be found. Among those who received medical education, many were inspired by the ideals of disinterested and self-sacrificing service that had characterized the ethos of *zemstvos* healthcare. The medical profession attracted intellectuals drawn to that sphere because it was not under the sway of particularly severe ideological control. The norms and values of medical ethics were transmitted under these conditions by means of informal communication and daily contact between professors and students and between experienced physicians and new colleagues.

STABILIZATION OF THE REGIME. From the end of the 1920s to the beginning of the 1930s, the communist regime consolidated itself; its radical revolutionary policies were gradually transformed into pragmatism. This pragmatism, of course, was specifically Soviet, oriented to the resolution of problems of building a communist state. All aspects of civil life began to be affected by organs of administrative and bureaucratic planning and management. Healthcare also fell under the planning system: The number of physicians in various specialties and the number of hospital beds, hospitals, and polyclinics in cities and villages, the direction and topics of medical research, the development of facilities in sanitoriums and health resorts—all were centrally planned.

Planning presupposes qualitative evaluations and measurements, and from this perspective Soviet medicine obtained impressive results. The number of doctors had long since passed one million (about 1.2 million in 1983), and a single doctor had about half as many patients as his or her counterpart in the United States. Many infectious diseases were practically eliminated, the frequency of infant mortality was significantly lowered, and the average life expectancy was increased. By these and certain other indicators the country approached the level of more developed countries or became equal to them. The results of the Soviet organization of healthcare attracted much attention outside the Soviet Union, particularly among Third World countries.

Policy in the area of healthcare, however, was always viewed as subordinate to policy in the economic sphere. Thus, when the Communist Party began to emphasize the industrialization of the country in 1929, the central task of the healthcare system was designated as the improvement of medical services to workers in the industrial centers, especially in the mining and metallurgic centers.

The system of healthcare that developed and remained relatively stable for many years was quite original in several respects. The physician became a civil servant, a kind of clerk, whose activities, regulated by numerous bureaucratic rules, consisted largely of writing reports that reflected his or her implementation of these rules. Any appearance of personal initiative was dangerous, especially because the physician's mistake could easily be interpreted as intentional, the act of a class enemy.

In relations with patients, the physician was a representative of state authority rather than an autonomous actor. Lack of autonomy, in its turn, made less urgent the problems of personal choice and responsibility. Low salaries of ordinary physicians as well as their low social prestige were among the reasons for the large number of female physicians in the country (about 80 percent). It was thought that physician's work was not so difficult, did not demand essential physical force, and therefore was well suited for women.

The social interaction of the physician and the patient was paradoxically characterized by two mutually exclusive elements. On the one hand, the long-reigning paternalism became even more entrenched, to the point where the individual regarded his or her health as a kind of state property—and therefore no one's—which could be squandered. On the other hand, health was viewed as the highest and ideal value, so high in fact that it was simply indecent to measure it by any sort of material equivalent, such as money. So, it was presupposed that self-sacrifice and unselfishness on the part of a physician was a kind of moral norm. The combination of these alternative, conflicting attitudes permitted the rather modest financing of medicine and healthcare, at a level that would ensure only the replacement of the labor force. Another characteristic of Soviet medicine was that patients were not permitted to choose their physicians.

Medical Deontology

In 1939, the famous surgeon and oncologist Nikolai Petrov (1876–1964) published an article, "Questions of Surgical Deontology," in the *Bulletin of Surgery.* In 1945, he published a small book by the same title. These publications were the first steps in the rehabilitation of medical ethics. Petrov justified the use of the term "medical deontology" by arguing that the concept of "physicians' ethics" had a narrower meaning. The latter, Petrov maintained, referred only to a corporate morality, reflecting the scientific and professional career interests of doctors (Petrov). This may have been a subterfuge designed to circumvent the ideological taboo on the problems of medical ethics. It is noteworthy that such an attempt was made by a doctor who received his training and education before the 1917 revolution.

Wide discussion of the problems of deontology did not begin until the middle and at the end of the 1960s when writings on this topic by medical practitioners and philosophers began to appear. The 1969 First All-Union Conference on the Problems of Medical Deontology in Moscow played an important role in this development. In 1971, state authorities approved the text of a document called "The Oath of the Physician of the Soviet Union." The oath was required for all graduates of medical institutes who intended to enter into professional activities. The text of the oath demanded that physicians be governed by the norms of communist morals and spoke more of their responsibility to the people and to the Soviet government than to the patient.

At the same time, medical deontology was introduced into the curricula of the medical institutes. However, notwithstanding reports to the contrary in a number of Western sources, courses on deontology and medical ethics appeared only in the beginning of the 1990s. In most medical schools the subject of deontology appeared to be spread out in separate courses in medical specialties, and philosophers had not been drawn into its teaching.

After 1971, the stream of literature in the area of deontology increased sharply. The contents of these publications, however, were often one-dimensional, moralizing reflections: criticism of the anti-humanist Western medical system coupled with a confirmation of the indisputable moral superiority of Soviet free medicine and the disinterested Soviet doctor. Attention to concrete cases, mainly from the personal practices of the authors, was frequent. Authors, however, avoided discussion of truly difficult cases that presented moral or ethical conflicts. Apart from the fact that this literature signaled the presence of ethical problems in medicine, its real interest lay in its increasing references to the moral authority of prerevolutionary Russian medicine and its attempt to present Soviet medicine as a direct and uninterrupted continuation of the best traditions of the past.

Crisis and Breakdown of State Medicine

The government-supported awakening of interest in medical deontology coincided with the first signs of crisis in Soviet medicine. Starting in the 1970s, but primarily in the 1980s, the authorities and a small circle of specialists, and then finally the public at large, became aware of the high rates of infant mortality and the consequent reduction of life expectancy. The press began to write more often about failures in the medical field and about the callousness, greed,

and low level of competence of physicians and other medical personnel. Notwithstanding the state's propaganda efforts, the people, who were losing confidence in physicians and in official medicine, turned more often to practitioners of alternative medicine.

These failures, as well as many others, revealed that the centrally planned and managed free medical system had used up all its own resources, among them the moral resource that had enabled the authorities to make do with "cheap" medicine for so long. It was clear that the communist modernization was accompanied by an erosion of traditional values, which was particularly noticeable as the medical profession became so large and more and more specialized. The turn to deontology was in some sense dictated by the efforts to mobilize the neglected moral factor in the face of growing medical crises. This attempt, to the extent that it appealed to values from the past, however glorious it might have been, could not succeed.

The attempt made during *perestroika* in 1987 to reform the system of healthcare without changing anything essential turned out to be unproductive. In 1991 the Russian parliament adopted a law providing for medical insurance for Russian citizens: This was an admission of the failure of state medicine. The stability during the last decades of the state system of healthcare was assured, even though the principles of free medicine and equal access to healthcare for all, in practice, deteriorated. The bribes that had to be given to physicians by patients and their families to some extent compensated for the pitiful financial circumstances surrounding healthcare. The availability of a special medical-care system for party members and other members of the *nomenklatura,* people given leading positions in various fields by the Communist party, made them less inclined to pursue radical reforms.

Previous stability itself made the process of thoroughgoing reform particularly painful for the people. The deeply rooted tradition of paternalism hindered the acceptance of personal responsibility for one's own health. In addition, social justice often was viewed as a pure leveling of differences. Finally, most people could not accept the idea that healthcare could be paid for, even though "free medicine" proved very inefficient.

Acute economic, ecological, sociopsychological problems during the period of reforms led to serious worsening of health of the population. For the first time since the beginning of the nineteenth century, mortality in Russia exceeded birth rate; morbidity, including infectious diseases, grew rapidly. These factors along with barely controlled commercialization of healthcare, limitation in access to medical services for most people, expense, and shortage of many crucial drugs generated on the part of many Russians a nostalgia about the free healthcare system of the past.

Specific Areas of Ethical Debate and Decisions

This section provides an overview of only those problems of medical ethics that have been treated in Russia in a rather original fashion.

ABORTION. Abortions in prerevolutionary Russia were considered criminal acts. In 1920, the Soviet government became the first in the world to legalize the artificial termination of a pregnancy at the request of the woman. Then, in 1936, in seeking means to improve the demographics, abortions were once again criminalized; in 1955, with some liberalization of the regime, they were again legalized to lessen the negative social consequences of widespread illegal abortions. The passage of legislation in 1993 permitted abortion at the request of the woman up to twelve weeks of pregnancy for any reason, and up to twenty-two weeks with consent of the woman for medical reasons. Abortion became a common means of birth control. The use of abortion for birth control may have resulted from a lack of contraceptive alternatives, as well as inadequate public knowledge and education about these matters.

Although abortions have been considered morally reprehensible, the attitude of people in concrete situations has been rather liberal. For many years the Russian Orthodox Church, the most influential confession in Russia, was prohibited from taking positions on any question of social significance. Even after the persecution of religion ceased, the church had not shown itself ready to express an opinion on most matters of biomedical ethics. One exception was the stance the church took on abortion. In 1990, the Patriarch of the Russian Orthodox Church confirmed the church's unequivocal censure of abortion; yet on a practical level priests tended to be more tolerant because of the hard economic situations of many women. In 1992, the Right to Life Society was formed to oppose abortions and was supported by the Russian Orthodox Church.

CONFIDENTIALITY. Controversial discussions occurred in the 1920s concerning the problem of physicians' secrets. The People's Commissar for Health Care, N. Semashko, announced "the abolition of physicians' secrets," which were understood as holdovers of bourgeois medicine. This position was based on the notion that an illness was not a

disgrace but, rather, a misfortune. Full abolition of physicians' secrets would occur, it was thought, when that concept was accepted by the population. Until that time the necessity of maintaining physicians' secrets was linked to the fear that eliminating them would create an obstacle for people seeking doctors' advice and help.

Even though Semashko himself, no longer a people's commissar but a practitioner, spoke out in favor of physicians' secrets in 1945, his earlier viewpoint turned out to be more influential, for many healthcare workers did not understand the need for confidentiality. The requirement of confidentiality gained a legal basis only in 1970. Up to 1993, however, a patient who returned to work after illness was obliged to bring a sick-leave certificate from a physician. This certificate containing the patient's diagnosis was available to many people. New legislation changed this norm: A diagnosis would be filled in only with the consent of a patient; without consent only general reasons (disease, trauma, etc.) could be indicated.

DISCLOSURE TO PATIENTS. The subject of disclosure to patients has been marked by strong paternalistic tendencies. The overwhelming majority of those writing on the subject considered it unacceptable to inform a terminally ill patient of his or her diagnosis and prognosis. The practice of informing patients was not generally regulated, so concrete decisions were left to the discretion of the treating physician.

However, Russian laws on psychiatric treatment and on transplantation of human organs and tissues, which were adopted in 1992, contained norms of informed consent for patients and donors. Included in the legislation were norms governing the protection of the health of citizens, granting the patient the right to know his or her diagnosis and prognosis as well as the right to refuse this information.

The law also established specific rules regarding receipt and documentation of informed consent of patients undergoing biomedical experiments. The advent of *glasnost* (openness) in 1985 permitted public disclosure of the terrifying information about fatal biomedical experiments (such as testing of nuclear or chemical weapons, new drugs, etc.) carried out on soldiers of the Soviet Army and on prisoners under Joseph Stalin (1879–1953) and Lavrenti Pavlovich Beria (1899–1953) and even later. Some steps were undertaken for ethical control of biomedical experiments, but as of 1994 most researchers were not aware of internationally accepted norms of experimentation.

EUTHANASIA. As early as prerevolutionary times the well-known Russian jurist Anatoly Koni (1844–1927), opposing the dominant view, defended the admissibility of euthanasia under certain exceptional circumstances: (1) conscious and insistent requests of the patient; (2) the impossibility of lessening the suffering with known methods; (3) agreement by a commission of doctors on the impossibility of saving the life; and (4) preliminary notice of the decision to the prosecutors. A law permitting mercy killing of a patient was adopted in the criminal code of 1922, but in subsequent legislation it vanished. It was practically inoperative and little is known about its utilization.

Sociological studies conducted among physicians in Moscow indicated that about 40 percent of them viewed euthanasia as permissible if the patient wishes it or in exceptional cases. However, many respondents did not seem to know what the word *euthanasia* meant (Bykova et al.). The public's attitude toward euthanasia appeared more tolerant: According to the findings of one public opinion poll, 55 percent of the respondents approved and 19 percent opposed the mercy killing by a physician of a terminally ill patient who wishes to die.

The majority of specialists in medical ethics, including physicians, jurists, and philosophers, have with rare exceptions adopted a sharply negative opinion of active euthanasia. The prohibition of active euthanasia, understood as acceding to a patient's request to hasten his or her death by medical means, was included in a law for "the protection of the health of citizens of the Russian Federation." Nonetheless, such forms of passive euthanasia as the refusal by the patient of treatment or the withdrawal of life-sustaining treatment from a hopeless patient were considered acceptable. The public's attitude toward euthanasia remained rather tolerant.

EUGENICS AND MEDICAL GENETICS. In the first decades of the twentieth century, Russia was among the world's leaders in the development of genetics. This interest in genetics generated a rather strong eugenics movement, which flowered in the 1920s. To some extent this interest may be explained by the consonance of eugenics with the central communist ideology of the creation of a "new man" who would be free of the "birthmarks" of capitalism. One of the leaders of Russian genetics, Nikolai Kol'tsov (1892–1940), following Francis Galton, spoke of eugenics as the religion of the future that still awaited its prophets. It was the powerful ruler of nature and the creator of life that would permit the creation of a perfect type of human being (Adams). In the 1920s, when ideological control was not yet particularly strong, the possibilities for forming a new human being were suggested by psychoanalysts as well as by those in other areas of scientific research.

The paths of communist ideology and eugenics diverged rather quickly, however. The principal criticism of

eugenics was that the new human being should be formed by social, and not by biological, methods. Eugenic projects in Russia, because of such criticism, were interrupted long before they had achieved any practical realization. Inasmuch as Russian eugenics at that time was a form of medical genetics, the blow to eugenics also impeded research in human genetics. This setback was only the first of many caused in the Soviet Union by the reigning ideology associated with Trofim Lysenko, who taught the thesis of inheritance of acquired characteristics, which lasted until Khrushchev fell from power in 1964. Even afterward the development of medical genetics ran up against ideological obstacles, since many associated it with the eugenics that served as a basis for the murderous racism of the German Nazis. Since the beginning of *glasnost* and the end of ideological censorship, some far-reaching proposals with possible eugenic interventions in the Russian population have been published, among them, killing newborns with serious defects and forced sterilization of alcoholics and drug abusers. Genetecists, however, have been rather passive in relation to public discussions of these topics. Despite the growing public concern about the genetic effects of radiation and environmental pollution and despite rather intensive research in the field of medical genetics, Russia now has only limited capacity for genetic screening and counseling except in a few large cities. In 1994, the Russian human genome project started to study possible ethical implications of recent developments in human genetics.

REPRESSIVE PSYCHIATRY. The practice of using psychiatry as a weapon in the struggle against political dissidents began under the regime of Nikita Khrushchev. The first victim was Zhores Medvedev, who was punished for wanting to publish a book on the crushing of genetics in 1948. Medvedev was diagnosed by state psychiatrists as mentally deranged and was committed for treatment. The widespread use of psychiatry in this manner did not occur until later, during the regime of Leonid Brezhnev. Hundreds of victims, without any judicial proceedings and often without even being physically present, were sentenced for indeterminate lengths of time to special psychiatric hospitals under the jurisdiction not of the Ministry of Health but of the Ministry of Internal Affairs. "Treatment" ranged from "wall therapy"—merely keeping patients inside four walls—to forcible psychotropic injections. The practice came to be used even against ordinary citizens who had conflicts with local authorities. The Soviet psychiatrist Andrei Snezhnevsky (1904–1987) worked out the basis for this method of repression, using the concept of "creeping schizophrenia" with symptoms such as the "spreading of slander," "exaggerated religiosity," and "excessive appreciation for the West." The center for expert studies and diagnoses of such afflictions was the V. Serbsky Institute for Forensic Psychiatry in Moscow.

Many cases of psychiatric repression became well known in the West. This caused the breach in 1983 in relations between the World Psychiatric Association (WPA) and the Soviet All-Union Society of Psychiatrists and Narcologists. The membership of the society in the association was renewed only in 1989. That same year, the Independent Psychiatric Association, founded in the Soviet Union in 1988 and actively involved in exposing psychiatric abuses, gained unconditional membership in the WPA.

A 1989 fact-finding mission of U.S. psychiatrists to Soviet psychiatric hospitals discovered that the malice of psychiatrists or of repressive state bodies was not the only cause of the abuse of psychiatry. Other factors included the poor training of medical personnel, the absence of adequate judicial mechanisms for the protection of the rights of patients, and the low level of ethical standards for hospital personnel. The aim of a 1992 law was the improvement of psychiatric treatment. According to this law, involuntary hospitalization in a psychiatric hospital was permissible only on the basis of a court's decision. The position of supervisor, to protect the rights of patients, was to be established in every psychiatric hospital. In 1993 the Russian Society of Psychiatrists—the most influential psychiatric association—adopted the Code of Professional Ethics of the Psychiatrist.

TRANSPLANTATION. The adoption in 1992 of a "law on the transplantation of human organs and tissues" provided an example of the direction of the reforms in Russian healthcare. Before adoption of this law, questions such as the determination of brain death, the rights of donors and recipients, and the permission for the removal of organs and tissues from cadavers were decided on by internal instructions of the Ministry of Health, instructions that were unknown to the population. On the one hand, this situation impeded the practice of organ and tissue transplants and, on the other hand, facilitated abuses, such as commercial use of human organs or the too-hasty declaration of brain death. The law on transplantation at last provided a legal basis for this area of medicine, and more important, became one of the first laws relating to healthcare using principles and practices accepted in the world community.

Perspectives for Russian Bioethics

Interest in the problems of bioethics grew as Russia emerged from isolation. Such interest evolved mainly through the

efforts of a small group of enthusiasts. Neither the leadership of the healthcare system nor the government bureaucracy nor the public itself grasped the critical importance of problems in bioethics. Democratic reforms, to the extent that they will continue, will change this situation. As reforms develop, healthcare will become one of the most important priorities of social legislation and public interest. The reform of medicine and healthcare will make both physicians and patients much more independent and, consequently, responsible parties in social interactions.

Foundations of Legislation of Russian Federation on the Protection of the Health of Citizens, adopted in 1993, as well as other laws filled in many gaps in healthcare and legal regulations. The law opened the door for the creation of ethical committees (commissions) at federal (similar to France), regional, and local levels as well as in hospitals and biomedical research institutes to defend human rights in healthcare areas.

In 1992 the Russian National Committee on Bioethics (RNCB) was established under the aegis of the Russian Academy of Sciences. The main activities of the RNCB include the development of ethical guidelines for scientific research, proposal of legislation in healthcare and biomedicine, promotion of bioethical training and education, preparation of textbooks and methodical materials, stimulation of discussions on bioethical issues in the mass media, and encouragement of bioethics in Russian regions as well as in countries of the Commonwealth of Independent States. The RNCB prepared documents on such acute problems as mass vaccination and protection of human rights, ethical aspects of transplantation of organs, ethical regulation of new reproductive technologies, ethical control of biomedical experiments, and so forth.

"Free medicine" has not been a social priority, and whoever leads the government can find more critical need for expenditures than healthcare. But the failure of free medicine, however painful for the population, will provide the basis to hope for a better future. Already the harsh reality has caused people to realize that the government or the Ministry of Health is not alone responsible, nor will either pay for the people's health; people themselves must do so. People are also beginning to realize that medicine and healthcare are areas in which the fundamental rights and vital interests of people are realized (or not realized) and, consequently, this area requires moral and ethical consideration as well as legal regulation.

MEDICAL ETHICS, HISTORY OF THE NEAR AND MIDDLE EAST

I. ANCIENT NEAR EAST

In its conventional sense the term *ancient Near East* includes a diverse range of cultures. This article limits its coverage to Mesopotamia from the Sumerian period (beginning ca. 3100 B.C.E.) through the Babylonian period (ending with the Persian conquest in 539 B.C.E.), Egypt from about 3100 B.C.E. to its conquest by Alexander the Great (332 B.C.E.), and Israel from the Exodus (variously dated from 1446 B.C.E. to 1280 B.C.E.) to the destruction of Jerusalem by the Romans in 70 C.E.

In both Mesopotamia and Egypt thriving medical professions existed throughout the period under consideration. In Israel a distinct medical profession appears to have developed very late (second century B.C.E.). If anything that could be called medical literature was produced in Israel, it was at the very end of our period. By contrast a large body of medical literature, some of which has survived, existed in both Mesopotamia and Egypt.

Conceptual Observations

No writer in the ancient Near East appears to have addressed what we call medical ethics as an area of specific discussion. No one seems to have written even on that weak precursor of medical ethics known as medical etiquette. Nevertheless, medical ethics existed as much in the ancient Near East as in any other culture. The medical ethics of any society is generally congruous with that society's moral perceptions. As a subset of its ethical values, medical ethics will be as simple or as complex as any culture is monolithic or pluralistic. An ethical framework exists for the practice of medicine wherever those who treat disease, even in a magico-religious form, administer healing. In seeking to reconstruct the medical ethics of any society, one must understand the broad cultural framework within which healers function in order to appreciate the ethical considerations that directly or indirectly govern the practice of their art. This picture may be supplemented by the incidental illumination of relevant aspects of medical practice gleaned from medical and other literature, as well as by evidence of legal constraints upon the activities of practitioners of the healing arts.

J. V. Kinnier Wilson remarks that "Medically, as in other respects, Egypt, Mesopotamia, and Palestine were three quite different worlds. Each developed along independent lines of thought and was of its own kind" (p. 337). While this statement is essentially correct, Mesopotamia and Egypt are sufficiently similar when contrasted with Israel that they may be considered together, while Israel, because of its unique religious and moral outlook, merits separate treatment.

Mesopotamia and Egypt

THE UNDERSTANDING OF DISEASE AND THE ROLE OF PHYSICIANS. In Egypt and Mesopotamia all aspects of life were molded by religions that were naturalistic and polytheistic, based on the worship of cosmic forces, and steeped in magic. Health and physical wholeness were perceived as being present so long as life remained in harmony with the forces of deified nature, while illness reflected a dissonance between the individual and his or her total environment. It was imperative to identify the cause of sickness in order that the appropriate treatment might be given for the restoration of health. Edwin Yamauchi isolates four main sources of illness, which were not mutually exclusive: (1) a divine source which sent illness as a punishment for sin; (2) a demonic source which indwelt or tormented the individual; (3) a magical source sent from a sorcerer or practitioner of black magic; and (4) a natural source as discerned by experience. The modes of treatment would include: (1) prayer, sacrifice and repentance; (2) the exorcism of demons; (3) counter-magic; and (4) empirical applications of medicine, drugs, or surgery. Quite frequently different kinds of treatment were combined. (p. 99)

In both Mesopotamia and Egypt the treatment of disease attributed to divine, demonic, or magical sources fell within the purview of a class of healers different from those who treated disease attributed to natural causes. In Mesopotamia the latter class (the *azu* or *asû*) appears to have emerged much earlier than the former (the *āšipu*). According to Kinnier Wilson, "In Sumerian times—as it would seem—the *azu* was the only doctor who was prominent in society. It is only at a later period, in Babylonia, that one meets the *āšipu,* a specialist in incantations and a kind of medical 'diviner,' capable of reading the 'signs' of suffering or of divine punishment" (p. 349). The two professions were

functionally and ideologically distinct, and only the *āšipu* was a priest. Similarly, in Egypt, the *seynu* (or *swnw*), like the Mesopotamian *asû,* was concerned with the treatment of physical conditions, whether sicknesses or injuries, for which a proximate, natural causality was evident; the *heri-ha'ab,* the equivalent of the Mesopotamian *āšipu,* was essentially a magician or exorcist (Kinnier Wilson). In a third category was the *wabw,* the priest of Sekhmet, lion-headed goddess of war, who both caused and cured epidemics. The *wabw* often combined features of both the *seynu* and the *heri-ha'ab.* Although each constituted a distinct profession, any two or even all three might be combined in the same practitioner.

MEDICAL ETHICS. The ethics of healers reflected an environment in which the understanding and explanation of reality were thoroughly religious: All aspects of life, including sickness and healing, received their meaning from religion (see Amundsen and Ferngren). The therapeutics employed by the *asû* and the *seynu* in dealing with acute diseases and injuries seem rational when compared with the predominantly magico-religious techniques of the *āšipu* and the *heri-ha'ab.* But the words of Owsei Temkin are cogent here:

> To be historically comprehensive, medicine cannot be defined as a science or the application of any science or sciences. Medicine is healing (and prevention) based on such knowledge as is deemed requisite. Such knowledge may be theological, magic, empirical, rationally speculative, or scientific. The fact that medicine in our days is largely based on science does not make other forms less medical—though it may convince us that they are less effective. (1977, p. 16)

Those ancient Near Eastern practitioners who seem to have been more rational than their magico-religious colleagues were not more ethical. Theirs were complementary, not competitive, professions. We do not have here a case of medical rationalism vying with superstition. Within their cultures neither approach was more or less rational than the other. Both perceived the causality of disease within an epistemological context in which spiritual, magical, and natural categories were not clearly distinguished. Hence, in this environment, the ethical obligations of healers must be appreciated in terms of their role as interpreters of sickness and healing within the broader cosmological realities and social values of their community. Within this general framework we can glean from the primary sources some specific, although fragmentary, aspects of medical ethics of the ancient Near East.

TO TREAT OR NOT TO TREAT. The Egyptian physician, as revealed by the medical papyri, made a prognosis before undertaking treatment. If the prognosis was favorable, the physician's comment was "an ailment that I shall treat"; if it was uncertain, "an ailment that I shall combat"; and if the prognosis was unfavorable, "an ailment not to be treated." The Edwin Smith Papyrus (a sixteenth-century B.C.E. copy of an earlier text that was probably written between 3000 and 2500 B.C.E.) contains the record of fifty-eight examinations, each followed by either treatment or a decision not to treat (Breasted). The author recommends treatment in forty-two cases and leaves sixteen untreated. In three of the hopeless cases (6, 8a, and 20), some alleviating treatment is indicated. In the Papyrus Ebers (Ebbell), which dates from roughly the same period, a small number of cases are regarded as untreatable (e.g., cols. 108–110), and in one hopeless case there is an attempt to relieve the patient. That specific alleviatory instructions are given only in a minority of hopeless cases does not necessarily indicate a lack of compassion. Incidental remarks in these papyri suggest that physicians carefully and gently treated their patients and showed kindness to the ill, injured, and maimed.

In Mesopotamia *āšipus* were prognosticators whose medical repertoire consisted mostly of incantations and charms, occasionally supplemented by ointments and purgatives. They did not hesitate to withdraw from cases that they regarded as hopeless. Their colleagues, the *asûs,* who administered medicines, performed some surgery, and seldom used incantations, seem only rarely to have refrained from treating hopeless cases, but continued with treatment to the end. This difference may be due in part to the fact that the *āšipu* treated primarily chronic illnesses, while the *asû* usually dealt with acute diseases and injuries (Ritter).

EUTHANASIA AND ABORTION. There is no direct evidence pro or contra regarding the ethics of euthanasia. It appears that in both Mesopotamia and Egypt those who committed suicide were regarded as having cut themselves off from the gods. A touching dialogue between a man contemplating suicide and his *ba* (soul), survives from Egypt, dating from the end of the third millennium B.C.E. (Pritchard). Although the man is not considering suicide owing to illness, the psychological struggle portrayed reveals a culture in which suicide was not accepted simply as a personal option without moral and religious compunctions, although the text suggests that it was not uncommon. Whether physicians assisted in suicide or viewed active euthanasia as opprobrious is unknown.

Prescriptions for induced abortion are found in the Egyptian medical papyri, but its legality remains unclear. In Mesopotamia, Middle Assyrian laws (fifteenth century B.C.E.?; Pritchard, 1969) stipulate that if a woman has an abortion by her own act, whether or not she survives the ordeal, she is

to be impaled on a stake and left unburied. The purpose here (as in much other ancient law prohibiting abortion) is not to protect the fetus but to protect the husband's right to have the child he fathered. There is no mention of the involvement of physicians in abortion.

REGULATION OF THE MEDICAL PROFESSIONS AND LEGAL PROTECTION OF PATIENTS. The first recorded attempt to protect the patient from the incompetent physician is from Babylonia, in the Code of Hammurabi (ca. 1750 B.C.E.; Pritchard). There it is specified that if a physician performs a major operation with a bronze lancet on a member of the nobility that results in the patient's death, or an operation with a bronze lancet on his or her eye that results in its loss, the physician's hand will be cut off. If an operation with a bronze lancet results in the death of a commoner's slave, or if the operation causes the loss of the slave's eye, the physician is to pay half the slave's value in silver. No punitive regulations are extant governing medical procedures other than surgery. This is understandable, particularly in a culture permeated by magical beliefs. The unsuccessful use of incantations or sympathetic magic (the administration of medicinal herbs may be included in this category), in which the healing role of the practitioner is nearly passive because of the supernatural agents at play, stands in marked contrast to the active immediacy of the physician in surgery. The Code of Hammurabi also establishes fees for surgery. The amount is determined by the social status of the patient, indicating the intention of the legislator to peg medical fees to the patient's economic means.

Little is known about the regulation of healers in Egypt. Although there appears to have been no system of medical licensure, medical procedure became rigidly prescribed over the centuries. A Greek historian, Diodorus Siculus (first century B.C.E.), whose material on Egypt was derived from the sixth-century-B.C.E. Greek geographer Hecataeus, writes that Egyptian physicians gave treatment in accordance with ancient written procedures. If their patients died, the physicians were absolved from any charge. If they deviated from traditional methods in any way, they were subject to the death penalty, on the assumption that few physicians could be wiser than the physicians of old. In the *Politics,* Aristotle describes a slightly more flexible situation in Egypt, in which physicians could alter their prescriptions after four days; if they altered them earlier, they did so at their own risk.

Little evidence exists from the ancient Near East regarding experimentation with novel procedures. In a letter to the Assyrian king (seventh century B.C.E.?), a physician suggests that a particular prescription be tested on members of the domestic staff before being administered to a member of the royal family. While cesarean section is known to have been performed in Mesopotamia in the second millennium B.C.E. as a last resort to save the infants of dying women, the evidence suggests that the procedure was used only on slaves. These examples suggest the fear of risk involved in novel procedures. But there were other hindrances to therapeutic experimentation: the tendency of empirical physicians to rely on traditional procedures; the existence of a written tradition of medical knowledge and procedures in both Mesopotamia and Egypt; and the fact that medicine was often allied ideologically with religion. These factors are likely to have inhibited innovation that deviated from accepted practice even in late Egyptian medicine. Although evidence is lacking for Mesopotamian attitudes to novel procedures, they are not likely to have been more positive.

Ancient Israel

The basic difference between the worldview of the Hebrews (ca. 1300 B.C.E.—70 C.E.) and that of their ancient Near Eastern neighbors was one of religious outlook. Israel's religion was monotheistic, while that of its neighbors was polytheistic, focused on the worship of natural forces, particularly those associated with fertility. In the Hebrew Scriptures, the cosmos is perceived as being under Yahweh's direction. Although there is a personal force of evil (Satan), he is subordinate to Yahweh and poses no significant challenge to his authority. While polytheism imposed no absolute moral standards, the ethical beliefs of Israel were grounded in the character of Yahweh, who was regarded as the transcendent creator and sustainer of the world. Religion and ethics were inseparable, since both were derived from Yahweh, who was holy and required holiness of his people. Yahweh's absolute character gave authority to his revelation to Israel, and his holiness provided the ethical basis of Israel's laws. The law of Israel, the Torah, grew out of Yahweh's covenant with the Hebrews, which made them his special people. As a requirement of maintaining the covenant, Israel was to reflect the moral character of Yahweh in its national life.

THE HEBREW UNDERSTANDING OF DISEASE AND HEALING. In the Hebrew scriptures illness is viewed in its moral and spiritual dimensions rather than as a merely physical phenomenon. A close relationship between sin and illness was believed to exist at two levels: (1) Physical evil, including illness, entered the world as a consequence of sin; and (2) illness was sometimes visited upon both individuals and nations because of their sin. Hence disease and injury were a consequence of sin, but they were also within the realm of God's control. Yahweh says, "I kill and I make alive; I wound and I heal" (Deut. 32: 39). Disease, as a manifestation of God's wrath against sin, could be seen on both an

individual (e.g., Num. 12: 9–12; 2 Kings 5: 25–27; 2 Chron. 21: 11–18) and a national level (e.g., 1 Sam. 5: 6–12). Yahweh promises health and prosperity to his covenant people if they are faithful to him, and disease and other suffering if they spurn his love (e.g., Exod. 15: 26; Lev. 26: 14–16; Deut. 28: 21–22, 27–28, 59–61; Ezek. 14: 21; Hos. 6: 1).

Passages often considered messianic offer the hope of healing, physical as well as spiritual (e.g., Isa. 53: 4–5; Mal. 4: 2). When the Messiah comes, "No one in Jerusalem will say 'I am sick'; the people who dwell there will be forgiven their iniquity" (Isa. 33: 24). The mental and physical anguish that accompanies the guilt of a person smitten and disciplined by Yahweh for sin is spoken of repeatedly in the Psalms (e.g., Ps. 38: 3, 5, 8), while to acknowledge and repent of sin is said to bring healing (Ps. 32: 3–5). Forgiveness and consequent healing were not viewed as the result of appeasing a hostile deity through ritual and offerings (see, e.g., Ps. 51: 16–17). Suffering in general, and sickness in particular, represented Yahweh's chastisement of his people, which was corrective rather than retributive. This theodicy, however, did not make suffering easier to endure for those who searched their hearts but could find no specific sin to be confessed (e.g., Ps. 88; Job, passim). The righteous sufferer must acknowledge God's inscrutable ways and ultimate goodness (e.g., Ps. 94: 12; Prov. 3: 11–12).

PHYSICIANS AND MEDICINE. The judgment upon King Ahaziah for consulting the god of Ekron concerning his illness (2 Kings 1: 2–4) resulted from the same kind of sin for which Asa, king of Judah, was condemned. Asa was seriously ill, "yet even in his disease he did not seek the Lord, but sought help from physicians. And Asa slept with his fathers" (2 Chron. 16: 12–13). Asa is not condemned for resorting to secular medicine as such but, rather, for consulting physicians who were probably Mesopotamian or, less likely, Egyptian. The procedures practiced by these physicians, even if empirical, would have been magico-religious. There is no evidence that priests functioned as physicians or surgeons in Israel. Their only involvement in matters pertaining to health was in the enforcement of a highly developed code of personal and social hygiene (Lev. 12, 13, 15, 21). Were there healers in Judah whom Asa could have consulted, whose practices would not have violated Jewish religious scruples? This question cannot be answered with certainty since there is no evidence in the Hebrew scriptures of the existence of a distinct medical profession.

The Hebrew word for healer or physician is the participle of the verb *rapha,* the original meaning of which appears to be "one who sews together" or "one who repairs." Its first participial occurrence is found in Gen. 50: 2, where Egyptian physicians are said to have embalmed Jacob. The verb itself is often used literally in the sense of healing from disease or injury (e.g., Gen. 20: 17; Num. 12: 13; 2 Kings 20: 5–8). When Jeremiah (ca. 645–ca. 575 B.C.E.) writes, "Is there no balm in Gilead? Is there no physician there?" (Jer. 8: 22), although he is speaking metaphorically, he attests the existence of both balm, as a therapeutic substance, and some kind of healers. The Israelites, of course, had knowledge of the rudimentary treatment of wounds and of herbs that could be used to treat various ailments traceable to natural causes. The Torah stipulates that if a person injures another in a quarrel and the injured party survives, the assailant is to be held financially liable "for the loss of his time, and shall have him thoroughly healed" (Exod. 21: 18–19). This passage implies that the expense both for medicines and for healers to dispense or apply them was to be borne by the guilty party. Several incidental references suggest the existence of binders of wounds (Isa. 3: 7), knowledge of the setting of fractures (Ezek. 30: 21), and the use of various therapeutic substances (Isa. 1: 6; Jer. 51: 8).

Although the Hebrew scriptures represent Yahweh as the only healer (e.g., Exod. 15: 26) and command Israelites to refrain from resorting to magical or pagan healing practices (see, e.g., Ezek. 13: 17–23), the use of natural or medicinal means is not discouraged, but is resorted to even in ostensibly miraculous healings (e.g., 2 Kings 20: 7). Medical knowledge may have been limited to folk remedies, however, and there probably were no systematized therapeutics, much less medical practitioners who were distinctively Hebrew. Not until the second century B.C.E. is there evidence of a Jewish medical profession. Contact with Greek civilization in the Hellenistic age provided Jews with something that neither Mesopotamia nor Egypt could contribute: a religiously neutral theoretical framework for a rational understanding of disease and healing that allowed the coexistence of both divine explanations of ultimate causality and natural processes of proximate causality within Yahweh's created order.

The earliest mention of a Jewish medical profession is in the Wisdom of Jesus Ben Sira (also known as Ecclesiasticus), composed in Palestine early in the second century B.C.E. Ben Sira urges his readers to honor the physician as a servant of God, who gives him his skill. Dependence upon God is essential for the patient, because it is God who heals. The physician, too, must depend upon God, "for also he supplicates God that he may make his diagnosis successful and his treatment to save your life" (38: 1–15, Noorda's translation [1979]). In spite of an occasional critic like Philo Judaeus (an Alexandrian Jew of the early first century C.E.), who scathingly condemned fellow Jews who trusted in medicine

without reference to God and turned to him only as a last resort (Temkin, 1991), Hellenistic Jews accepted rational medicine based on the Greek model as fully compatible with their faith. Apart from the available medical resources, which were limited, healing could come only from Yahweh by confession of sin, supplication, and prayer (e.g., Job 33: 19–30).

MEDICAL ETHICS. Central to understanding Hebrew and Jewish medical ethics is the concept of the image of God (*imago Dei*). In the Genesis account of creation, Yahweh is depicted as having created man and woman in his image (Gen. 1: 26–27). Endowed with rationality, self-consciousness, and volition, the human personality in Hebrew thought was represented as mirroring Yahweh's image. Persons are spiritual beings, created to have communion with God, and responsible for their own moral actions. The concept of the *imago Dei* had implications for the protection of human life, which was believed to possess intrinsic value, and hence to be sacred. Even human beings with physical defects are said to bear God's image. Yahweh asks Moses, "Who has made man's mouth? Who makes him dumb, or deaf, or seeing, or blind? Is it not I, the Lord?" (Exod. 4: 11).

As a result of the Hebrew view of humanity as possessing intrinsic worth, the Torah exhibits a greater humaneness than other codes of the ancient Near East (e.g., the Code of Hammurabi). There are, for example, provisions that protect the rights of the blind and the deaf (e.g., Lev. 19: 14). The fetus was regarded as having been created by Yahweh and designed for a specific purpose (Ps. 139: 13–16; Jer. 1: 5; Isa. 49: 1). Yet abortion was not explicitly forbidden by either the Torah or later rabbinic Judaism. In fact, in the Talmud it was permitted in some circumstances. Whether the practice was acceptable in the pre-Christian era is disputed. The accidental destruction of the fetus was not a capital offense, but required monetary compensation (Exod. 21: 22–25). The newborn child, however, was regarded as fully human and deserving of the same protection as an adult. Infanticide, a common practice in the surrounding Canaanite culture, was expressly prohibited (Lev. 18: 21, 20: 2), and the exposure of newborn children was also condemned (see Exod. 1: 17–21; Ezek. 16: 5). Castration, sometimes practiced by Canaanites for religious purposes, was also forbidden, and eunuchs were excluded from Hebrew religious life (Deut. 23: 1).

The Hebrew scriptures provide no information regarding the behavior expected of Jewish physicians. Mesopotamian and Egyptian physicians had an enormously varied repertoire of religious and magical techniques of propitiation and manipulation, as well as of natural therapeutics, from which to choose. They also had the freedom to be imaginative, active participants in processes in which the lines between what we call the natural and the supernatural were blurred. By contrast, Jewish physicians, working with and through natural means and processes, and eschewing any techniques involving magic or the demonic, were, along with their patients, to depend upon the Creator, from whom alone all true and licit healing came (Deut. 32: 39). Given the emphasis in the Hebrew scriptures on the compassionate nature of the God who heals, and the importance that Ben Sira assigns to the physician as an agent of God, it would be surprising if Jewish physicians were not encouraged to emulate the divine compassion in their treatment of the ill. This attitude would be especially compatible with the new emphasis on the meritorious nature of charity that is found in the Apocrypha (Jewish religious writings dating from third century B.C.E. to about 100 C.E. that were not included in the Hebrew scriptures). It is in the postexilic period (after 605–582 B.C.E.), too, that one begins to see a tradition of caring for the ill that makes the sick person no longer an object of stigmatization (e.g., Job 19, esp. 13–20; Ps. 42: 4–10), but a person deserving of special care, like widows and orphans (e.g., Sirach 7: 35; 2 Macc. 8: 28). This specific concern for the sick within the community of Israel is a theme that is extended and developed in the Talmud.

II. IRAN

Iran, a vast country in Southwest Asia, was long called Persia by Europeans until, in 1935, its government requested that the common indigenous name, Iran, identifying the nation as the "land of the Aryan people," be used internationally. The extensive Iranian Plateau and surrounding lands have been the site of many powerful political regimes during its long history, beginning with the empire of Cyrus the Great, the first Achaemenid emperor, in 549 B.C.E.. Located along a highway for the movement of people and ideas from the prehistoric period on, its indigenous Aryan culture has been an important link between Hellenic, Indic, and Semitic intellectual and religious traditions. Within the limits of this article, the history of Persian medicine cannot be traced; only the ethics characteristic of that history will be treated.

Prehistoric Period

Little is known about the healing practices or beliefs of the earliest inhabitants of Iran. An epic poem, *Shāhnāmah* (Book of Kings), written in the tenth century C.E., relates ancient myths, legends, and stories that may reveal something of the ancient past. Surgery is mentioned in the tales of the superhuman exploits of the heros Rustam and Isfandyar. Rustam himself is said to have been delivered by an operation much like that now known as a cesarean section, while his mother was anesthetized with wine. Abortifacients were known. The Elamite civilization, centered around Susa in southern Iran from the third to the first millennium, had cultural contact (and often political enmity) with Babylon, and it is likely that the medicine of the Mesopotamian world was known by the Elamites (Sigerist). The Code of Hammurabi, ruler of Babylon (ca. 1750 B.C.E..), which contains strict injunctions and penalties regarding surgical practice and malpractice, is known primarily from a stela found at Susa in 1902.

The Aryan Period (Ninth–fourth Century B.C.E.)

The nomadic Aryan peoples migrated from Central Asia, north and east of the Caspian Sea, to the Iranian Plateau around the seventeenth century B.C.E. By the ninth century, they dominated the region, and in 549 B.C.E., Cyrus consolidated rule over its inhabitants and established the Achaemenid dynasty, the first Persian empire. He and his successors, Cambyses, Darius, and Xerxes, extended the boundaries of Persian rule from the Ionian Sea in the west to the Indus River in the south. During this period, Persian medicine was undoubtedly in contact with Greek medicine. A story related in ancient texts tells of an invitation from Persian King Artaxerxes to Hippocrates, on the advice of a Persian physician, to become physician to the Persian army during a plague; Hippocrates refused, saying, "I have no right to share the wealth of the Persians or to liberate from disease

barbarians who are enemies of the Greeks" (Pseudepigrapha 3; see Temkin).

In the seventh century, the mysterious religious figure Zoroaster appeared in eastern Persia. Very little is known of his life, and the writings attributed to him are brief. However, by the first century B.C.E., a defined cosmogony and theology attributed to his influence had been collected in the vast literature called *Avesta,* of which his own *Gathas,* or hymns, are a small part. The doctrine is basically constructed around a cosmic duel between good and evil, of which light and darkness, life and death are the material symbols. The powerful spirit of good and light, Ahura Mazda, the wise and greatest god, battles Ahriman (or Angra Mainyu), spirit of evil and darkness, and the world is the battlefield. Humans participate in the battle through their free choices. As individuals, humans are to maintain purity of life through moral goodness, pursuit of truth and physical cleanliness, and avoidance of pollution by the dead and unclean substances. As members of society, humans are to assure justice between social classes.

The *Avesta* also contains the elements of a theory of health and disease. Diseases, created by Ahriman, come from dirt, stench, cold, heat, hunger, thirst, and anxiety, although magical causes are also recognized. Medicinal plants are the creation of Ahura Mazda. Rules of healthful living are prescribed; cupping and bleeding are recommended to reduce hot blood. The destruction of life is prohibited for theological reasons; it would contribute to the victory of Ahriman over Ahura Mazda. Thus, abortion is forbidden, and both men and women are punished as willful murderers. Special rules are laid down for the care of pregnant females (both human and animal). Surgery is recognized and strictly regulated; one ancient law requires that a surgeon have three successful cases before being licensed to practice.

Three kinds of healers are mentioned: healers with herbs, with knives, and with holy words (the latter, one text notes, being the most efficacious). There were also persons (*durustpat,* masters of health) trained to remove the causes of disease by purifying earth, air, water, and food. These physicians were often drawn from the noble and priestly classes. A modern Parsi (the contemporary Zoroastrians of India) scholar describes what he believes would have been the ideals of the Avestan physicians of ancient times:

> The first indispensable qualification of a physician was that he should have studied well the science of medicine. He should hear the case of his patient with calmness. He should be sweet-tongued, gentle, friendly, zealous of honour of his profession, averse to protracting illness out of greed and God fearing. An ideal healer heals for the sake of healing.… He should carefully watch the effect of medicine that he prescribes … visit the invalid daily at a fixed hour, labour zealously to cure him, and combat the disease of the patient, as it were his own enemy (Elgood, 1951, p. 13).

Hellenistic Period (330 B.C.E.–224 C.E.)

In 330 B.C.E. Alexander of Macedon brought down the Achaemenid empire. For the next five centuries, the Greek culture that had long flourished on the Ionian frontier of the Persian empire dominated Persian ideas and institutions. Although the historical record is meager, it may be assumed that Greek medicine and Hippocratic ethics were included in this general influx of Hellenic culture. The Zoroastrian faith languished during that era, but it would not be unlikely that Avestan ideals that had permeated the culture survived.

Sassanid Period (224–632)

The Sassanid dynasty, after victories over Roman and Parthian armies in the mid-third century, ruled Persia for four centuries, restoring the traditions, law, and culture of ancient Iran and, above all, reforming and fostering the Zoroastrian faith. In the earliest years of the Sassanid era, an event of great importance for the history of medicine occurred. In the mid-250s, King Shāpūr I, son of the founder of the dynasty, defeated the Roman emperor Valerian and sacked the city of Antioch. The king invited many of the Antiochean scholars, including physicians, to a new city, Gondishapur, that he established in 260. His son enlarged the city and founded a university that in time became the center of scholarly work in Persia.

To Gondishapur in the late fifth century came a group of Persian Christians of a denomination called Nestorian. These Christians had originally dwelt in and around the Persian city of Nisibis, then moved to the Byzantine city of Edessa, where in 363 they established a school of theology. After certain of their theological beliefs were repudiated and their leader, the patriarch Nestorius, excommunicated by the Catholic church at the Council of Ephesus (431), the Persian Christians accepted an offer of asylum at Gondishapur from the Persian king Qubād. They brought with them not only works of theology but also an extraordinary library including Syriac translations of the Hippocratic corpus and of Galen.

Another scholarly migration entered Gondishapur in 529 when the Sassanid king Anūshīrvān the Just welcomed the Neoplatonists exiled from Athens, at the urging of his chief minister Buzurgmehr, who according to legend was himself a physician and philosopher. He is quoted as having

said, "I read in medical books that the best physician is one who gives himself over to his profession.… I exerted myself in the treatment of patients, those whom I could not cure I tried to make their suffering more bearable.… From no one whom I treated did I demand any sort of fee or reward" (Elgood, 1951, p. 52).

The king also sent missions to India to procure the arts and sciences of Hindu culture, including the works of Ayurvedic medicine. By his order, a massive work on poisons was compiled, and many Greek and Indian books were translated into Pahlavi (ancient Persian). He convened what may have been the first medical convention, summoning the physicians of Gondishapur to debate the major medical questions of the day. During his long reign, Gondishapur became a leading center of scholarship; within its walls Greek, Jewish, Nestorian, Persian, and Hindu ideas were exchanged and enriched, and Islamic, Christian, and Zoroastrian ethical ideas mingled. The art of translation of the classic texts from Greek, Latin, and Syriac into Pahlavi and Arabic was fostered. The school of medicine existed for five centuries, creating from many sources the medical science generally known as Arabic or Islamic, and its great hospital, Bimaristan (House of the Sick), was the model for the Muslim hospitals of Baghdad, Damascus, and Cairo and the Christian hospitals of Jerusalem and Acre (Whipple).

Islamic Period (636–)

The victory of Arabian Muslim armies at al-Qādisiyah in 636 inaugurated the era of Islamic rule and culture in Iran. The distinctive ethic of Islam entered and eventually predominated in the rich mix of Persian life. Gondishapur continued to flourish under Arab rule and became more influential as its scholars, teachings, and books spread through rapidly expanding Islam, carrying Greek and Arabic medicine across Africa and, through Sicily and Spain, into Western Europe. The new Muslim rulers summoned scholars from Gondishapur to their capital at Baghdad, where they established a new center of medical science. Studies in biology, human anatomy, and pathology were encouraged. The caliphs in Baghdad, Damascus, and Cairo organized public-health administrations, staffs of public-health doctors, public hospitals, and a public examiner of physicians, responsible for their skills and their ethical standards.

Some of the greatest names of medical history were Persian: Ţabarī, Rhazes (known as the Galen of Islam), Haly Abbas, Avicenna (Ibn Sīnā), all of whom flourished in the tenth and eleventh centuries. Their scientific work was renowned. (Avicenna's *Canon of Medicine* was used as a text in many European schools as late as the seventeenth century.) All of these distinguished physicians wrote treatises on the ethical qualities of physicians. The text of one of these, *Advice to a Physician,* by Haly Abbas, reflecting Hippocratic and Islamic sentiments, can be found in the Appendix of this encyclopedia. A book by the eleventh-century Iranian philosopher-physician Ibn-Hindū praises the nobility and criticizes physicians who use medicine only to win wealth and reputation, recalling the story that Hippocrates, when summoned by the Persian ruler, disdained to give his service only for gain (Mohaghegh). Another scholar of the next century, Niẓāmī 'Arūḍī, summarized the moral principles that should guide a physician:

> A physician should be of tender disposition and wise nature, excelling in acumen, this being a nimbleness of mind in forming correct views, that is, a rapid transition to the unknown from the known, and no physician can be of tender disposition if he fails to recognize the nobility of the human soul; nor of wise nature unless he is acquainted with logic, nor can he excel in acumen unless he be strengthened by God's aid, and he who is not acute in conjecture will not arrive at a correct understanding of any ailment (Elgood, 1951, p. 234).

Modern Period

For many centuries medicine in Iran was more or less as has been described. The foundation of Dār-ul-Funūn (the Polytechnic School) in Tehran in 1852 changed the situation. At first it was a military academy, but it soon began to develop into a university. The foundation of the Faculty of Medicine was laid by a number of excellent European and Iranian teachers. The school curriculum at first was a combination of Iranian and Western medicine, and the ethical point of view was influenced by Iranian tradition.

Iranian students had been sent to Europe for medical studies for several decades before the founding of the medical school at Dār-ul-Funūn. With the return of these physicians and scientists and the establishment of a modern hospital in Tehran in 1868, the curriculum of Dār-ul-Funūn and the practice of medicine were gradually westernized. Also, during the nineteenth century, a number of Western physicians resided in Iran, the most famous being a Frenchman, Charles Fourier, physician to Shah Nāṣir al-Dīn.

Since the period of Reza Shah (1923–1941), the program of the medical school of the modern University of Tehran has been based completely on modern medicine; medical ethics and the history of the medical tradition are both taught. Graduates of the Tehran medical school are asked to take an oath, an excerpt from which follows:

> Now that I … have been found eligible to practice medicine, in the presence of you, the board of judgment of my thesis and others here present, I swear by God and the Holy Book of Koran and call to witness my conscience that in my profession I will always be abstemious, chaste, and honest and, as compared with the glory of the art of medicine, I will hold in contempt all else—silver, gold, status, and dignity. I promise to help the afflicted and needy patient and never divulge patients' secrets. I will never undertake dishonest work such as producing abortion and recommending a fatal drug. What I do, I will try always to be approved by God and be known for my uprightness.

In the Islamic Republic of Iran, founded in 1979, the interest in vivifying Islamic tradition and law touches medical ethics as well. Issues related to bioethics are sometimes treated in works dealing with Islamic religious law, the *shar'ia.* However, the premodern *shar'ia* contains little that can directly guide conscience and conduct in morally troublesome cases, such as the permissibility or prohibition of medical treatments. Muslim jurists have undertaken to provide new rulings, the most prominent of which states the rights of the patient in determining which modes of treatment are compatible with his or her religious and moral beliefs. These scholars are also grappling with the medical technology developed in the Western secular culture, technology that has altered conventional understandings of life and death and has posed perplexing questions for a new, religiously aware generation of Iranian physicians and their "believing" patients.

Some recent works in medical ethics, such as *Fiqh va ṭibb* (Islamic Jurisprudence and Medicine) and *Qānūn dar ṭibb* (Law in Medicine), reflect a change in the attitude of Muslim physicians, who have become increasingly aware of the role religion plays in the lives of Iranian men and women. Whereas in the early days of modernization and secularization, Iranian physicians, not unlike their counterparts in other Third World countries, "played God" in attempting to save and restore human health, the 1980s and 1990s are characterized by a growing concern about the religious and cultural values of the society. Thus, for instance, an important issue in Islamic law is the recommended segregation of females and males, which has implications for medical ethics. The ethical issue is whether it is permissible for a physician to treat a member of the opposite sex. While responses have varied among the Muslim jurists, there is a consensus that since a physician should never sexually abuse his or her patients, it is strongly recommended that a physician examine patients of the opposite sex only in the presence of a third person, as a safeguard. This applies to both male and female doctors. However, under special circumstances, when no doctor of the same sex as the patient is available and there is an urgency in treating the condition, the law permits male doctors to treat female patients and female doctors to treat male patients.

Advances in biomedical technology raise issues that challenge Islam to provide concrete and relevant solutions. A group of Muslim jurists and philosophers has begun to develop guidelines for dealing with ethical issues that confront the medical profession. Leaders in both secular and religious education have begun to prepare textbooks on medical ethics. Two of these works are especially significant: *Akhlāq-i pizishkī* (Medical Ethics), prepared and published under the supervision of the Ministry of Health in 1991, and a book with the same title, written by Manşūr Ashrafī and published by the Medical Faculty of the Open University of Tabriz in 1988. The former includes chapters dealing with the juridical decisions by major Iranian religious leaders, including Ayatollah Khomeini, on issues related to what is known in the West as bioethics. The latter work is based more on the Western secular discussion of bioethical issues without any reference to Islamic or other religious views. Both are used as textbooks in the Iranian schools of medicine.

Major obstacles persist for those who work to solve the problems created when medical technology is brought into a culture steeped in religion. The most serious problem that confronts Muslims in general, and Iranians in particular, is denial of the ethical problems stemming from technicalization of the society and its adverse impact on interpersonal relationships. A striking example is acquired immunodeficiency syndrome (AIDS). To date, the Muslim ethical response to AIDS has characterized the disease as God's curse on those who engage in illicit sexual behavior. In this direct or indirect critique of the moral decadence of the West, important issues are overlooked, including the cause of the disease and its prevalence in the Muslim world, as well as guidelines for treatment of those affected.

Muslim jurists in Iran have not yet formulated relevant responses to some of the most complex ethical issues—those that arise because of human endeavors to improve health and extend life. The highly cherished religious value of compassion has been overshadowed by the language of condemnation for moral failure of humanity.

III. TURKEY

The modern nation of Turkey is situated on the continents of Europe and Asia, with the majority of its landmass occupying the vast Anatolian peninsula of Asia Minor. Surrounded by three seas, the Mediterranean and the Aegean seas on the west and south, and the Black Sea on the north, its territory has been the home of many nations and civilizations. It was ruled by the Hittite and Phrygian kingdoms of the second and first millennia B.C.E., followed by the Persian, Hellenic, and Roman empires. In 330 C.E., the capital of the Roman Empire was moved to Byzantium, which was renamed Constantinople. In 1453, Mehmet II, the sultan of the Ottoman Turks, a people who during the previous century had invaded a great part of the deteriorating Byzantine Empire, captured Constantinople and established the

Ottoman Empire over Asia Minor (and, in the course of time, over much of the Islamic world, from the Crimea to Morocco and the Balkan peninsula). The Ottoman Empire lasted from 1299 to 1922, and in 1923 it became a republic under the leadership of Mustafa Kemal. Turkey's medicine and its ethics bear the marks of this long history.

The Turkic peoples, dwelling from time immemorial in Central Asia, migrated into China, India, the Caucasus, and Persia. The earliest Turkic religion was a shamanistic animism marked by totems and magic. Contact with the spirit world was mediated by male and female shamans, called *kam,* who healed the sick with magic and charms and music. Other healers, called *otaci,* are mentioned in various sources, and archeological findings related to *otaci* exist as early as the eighth century C.E. *Otaci* were described as wise people informed of the causes of illness, advising about healthy living and treating mainly with herbs, as well as by bone-setting, massage, acupuncture, moxa, branding, etc. *Otaci* joined in a guild of healers called *kutu.* They were, according to the sources, in frequent debate with exorcists, who taught that illness was caused by evil spirits and driven out by charms. This conflict was especially emphasized following the conversion of many of the Turkic peoples to Islam in the tenth century.

In Turkistan, where Turkic peoples were in contact with Chinese Buddhism, monks functioned as healers (*otaci bakshy* in Old Turkish). Although supernatural healing powers were often attributed to them, they practiced medicine without remuneration as a way of achieving Buddhahood. Monasteries were places of hospitality and healing. A medical literature in Uighur Turkish began to appear in the eighth century. During this period there was considerable mingling of Chinese, Indian, and Persian medical concepts. Although healers were no longer believed to have supernatural powers, the attitude of holding them in high esteem was part of the Islamic culture.

From the sixth to the thirteenth century, Turkish tribes formed kingdoms throughout Central Asia and the Near East. In the tenth century, many Turkic tribesmen who were employed in the armies of the Abbasid caliphs were converted to Islam (some tribes adopted Buddhism; others, Manichaeanism; and some followed Nestorian Christianity or Judaism). Following the rise and fall of several significant pre-Islamic and Islamic Turkic kingdoms, one tribe, the Seljuks, became the most powerful force in Anatolia. They extended their rule into Iraq, Iran, and Syria, and during the eleventh and twelfth centuries they created the first major Turkish state, which fostered a rich literary, artistic, and scientific civilization. In 1066, Nizamul Mulk, vizier of the Seljuk ruler Alp Arslan, founded the Nazamiye University in Baghdad. The first state university known in history, it included a hospital. The Nureddin Hospital, founded by the Seljuk Atabeg Nurredin Zenagi in Damascus in 1154, educated many famous physicians, such as Ibn Abi Usaibia, Ibn al-Nafis, and Ibn al Qutt, and was the center of medicine at that period. The curriculum of the medical schools in the Seljuk period was demanding; after training and the presentation of their theses, the graduates were examined in the course of medical practice by the *muhtasib,* a high-ranking public official, and then swore an oath to practice medicine with competence and virtue.

During the reign of the Anatolian Seljuks, the nobility founded charity hospitals: In Kayseri, the Gevher Nesibe Hospital was established by Princess Gevher Nesibe in 1206, and the Divriği Hospital in 1228 by Princess Turan Melik; both are still standing. The hospital and medical school founded at Sivas in 1217 also remains; and the original charter, still extant, shows that the staff consisted of physicians, surgeons, ophthalmologists, nurses, and pharmacists. All persons in need, Muslim and non-Muslim, were accepted for treatment in these institutions. Although a rich medical terminology had existed in the Turkish languages in the eleventh century, medical literature in Arabic and Persian flourished during the Seljuk era and hundreds of Arabic and Persian works were written by Turks. Turkish cities—Ferghana, Tashkent, Samargand, Bokhara, Khwarizm, Balkh, Maraghah, Kashgar, Farab, and others—were the birthplace of many famous Islamic scientists, including Ibn Sina, Ibn Turk, Biruni, Farabi, and Harezm, and were also the important centers of Islamic culture.

Medical literature in the Turkish language began to flourish again in the fourteenth century. After the conquest of Constantinople, the Ottoman Empire continued to promote care for the needy sick and to further medical science and education. It was common for the large complexes built around mosques throughout the land to have a hospital attached for the sick poor, whether Muslim or not. Sultan Mehmet II opened a hospital in his new capital in 1470. A great hospital and a medical school were established within the complex of the Süleymaniye Mosque (1536). According to the founding documents, the professor of medicine was expected to be a faithful Muslim, virtuous, charitable, self-confident, courageous, gifted with intuition and keen senses, and educated in the subtleties of logic and medicine. He was required to teach students both medicine and the virtues and duties of the physician. Those who sought admission to medical school were to have graduated from the *medresse,* or university. (The Ottoman *medresse* not only provided necessary services of religion, science, and instruction; it also trained administrative and judicial personnel to meet the

needs of the bureaucracy.) Medical school applicants were required to be persons of high moral character, and to be faithful Muslims. All received scholarships from charitable endowments. The professor as well as the students were supervised by a dean.

A chief court physician was the minister of health; he was responsible for public health, for the proper training of physicians and the administration of examinations, as well as for the safety of drug preparations. Physicians employed in the palace and hospitals outside were paid by the state, and their income increased in relation to their skill and rank. Still, there were more physicians practicing medicine in their special offices than employed by the state. Pharmacists, trained in an apprentice system, worked in hospitals and palace pharmacies. A school for surgeons and ophthalmologists existed in the sultan's palace.

Women were admitted to the practice of medicine during the Ottoman period, particularly for the care of women. The Topkapi Palace in Istanbul had a well-appointed infirmary for women in the harem, as well as an infirmary for royal pages. Renowned female physicians were summoned to care for women of the harem when necessary. Nurses were employed in the palace infirmaries as well as in hospitals outside the palace and were expected to be gentle, dedicated, and devoted to their patients. Midwives were respected and given official recognition after an apprenticeship. Women prepared and sold herbal extracts, and women inoculated against smallpox. Women were also influential in the founding of hospitals and the support of charitable works.

The ethics of Turkish medicine were formed by Islamic morality, Turkish mores, and the Hippocratic ideas inherited from Greek medicine. Many medical manuscripts from the thirteenth to the nineteenth centuries state these values in chapters generally titled "Advice for the Physician." Chief among the qualifications required of the Ottoman physician was good character, which included mercy, generosity, honesty, modesty, and an even temper. Physicians were expected to be clean and properly attired, and never to exaggerate. Such virtues were said to have a positive effect upon the sick person. Advice was also given about preserving confidentiality, charging fair prices, and serving the poor without charge. Physicians were warned not to make definitive statements about prognosis, since the course of disease is not predictable with certainty. Medicine made from unknown herbs, folk remedies, and experimental treatments were not to be used. Administering poisons and abortion, except for a therapeutic purpose, were strictly forbidden. In general, as the eminent fifteenth-century Ottoman surgeon Sabuncuoğlu noted, the conscience of the physician should prevail over his desires and passions.

Physicians and surgeons were held responsible for injuries that resulted from their ignorance, incompetence, or use of unorthodox methods. Islamic law required that patients give personal permission, in the presence of a judge and witnesses, before undergoing surgery. Many records of the religious courts bear testimony to this practice. Edicts were often issued to bar quacks from practice, and, in order to ensure that only qualified practitioners served the sick, examinations for medical licensure were frequently repeated and only the licenses of the successful renewed.

Although Turkish medicine had been in contact with European medicine since the sixteenth century (inoculation against smallpox was originally introduced into Europe from Turkey at the beginning of the eighteenth century) (Ünver), European medicine became influential with the founding, by Sultan Mahmud II, of a school of medicine in 1827 and a school of surgery in 1832; these schools were combined in 1836 and moved, three years later, to Galatasari, then a suburb of Constantinople. Although it was primarily a military school, civil students were admitted, too; all students were given scholarships by the state. European physicians joined the Ottoman instructors on the faculty, and from 1839 to 1870 the language of instruction was French. A vigorous flow into Turkey of faculty members from the European medical centers and a flow of students and specialists from Turkey to Europe marked nineteenth-century medical education. An Ottoman professor, Nahabed Roussignan, lectured on ethics in 1876–1877 at the University of Constantinople School of Medicine. The course was continued for many years by Professor Hovsep Nouridjan, who published his lectures as *Précis de déontologie medicale,* one of the earliest books on this subject printed in Europe. In 1933, the first department of medical history and ethics was founded by Süheyl Ünver in Istanbul University. Doctorates in medical ethics are now awarded, and as of 1994, ten of the twenty-eight Turkish medical schools had departments of ethics and such courses were given in all schools of medicine.

After establishment of the Turkish Republic in 1923, new laws and regulations were passed regarding healthcare, public health, and the duties of physicians. A successful fight was waged against epidemic diseases, and many municipal and state hospitals were founded all over Turkey. The Turkish Medical Association was founded in 1929, and the current version of the medical ethics code appeared in 1960; it comprises rules dealing with patient–physician and physician-physician relationships, confidentiality, advertising, human research, termination of pregnancy, malpractice, truth-telling, consultation, fees, and organization of practice. This code has juridical standing. Provincial medical associations have disciplinary authority over physicians

who violate the code. Dentists and pharmacists have formed associations in recent years and also have codes of ethics. A National Congress on Medical Ethics was organized by the Medical Faculty of the University of Istanbul in 1977. It opened discussion of many topics, such as organ transplantation, determination of death, reproductive technologies, and military medicine. A second such congress was held in 1994.

A law on organ transplantation was passed in 1979. It specifies procedures for consent, donation, and determination of death, and prohibits advertising and commercialization of organs. Regulations dealing with the education and duties of those who provide family-planning services, including abortion and sterilization, appeared in 1983. Abortion, available on demand for any reason if there is no medical contraindication for the mother, is permitted up to the tenth week of gestation, and therapeutic abortion after that time; married women must have permission of their husband, and minors, of their parents. Married persons seeking sterilization must have consent of their spouse. Centers providing assisted reproduction must be licensed by the Ministry of Health. Embryos are not to be used for purposes other than reproduction and cannot be sold. A professional committee has been established for the oversight of assisted reproduction.

The Turkish Medical Association endorses the Nuremburg and Helsinki declarations. In 1993, a state regulation governing research with human subjects required review committees in research hospitals, and a Central Ethics Committee was established in the Ministry of Health. Local review committees sometimes function as ethics committees as well. In 1992, the Turkish Human Rights Association, the Turkish Medical Association, and the Torture Victims International Rehabilitation Council sponsored the Fifth International Conference on Torture and the Medical Profession in Istanbul. This conference issued a declaration against torture and specifically against any physician's involvement.

IV. CONTEMPORARY ARAB WORLD

The Arab world comprises the twenty-one Arabic-speaking countries extending from the south of Iran westward to the coast of the Atlantic. Not all the people in these nations are descendants of the Semitic Arabs of the Arabian Peninsula, but the spread of Islam outward from Arabia in the seventh century led to widespread adoption of Arabic, the language of the Qur'an, Islam's scripture. Islam is the religion of 95 percent of the inhabitants of the Arab world. Of the world's nearly one billion Muslims, some 20 percent are Arab. Classical Arabic has been preserved through the constant standard in the Qur'an (the Islamic scripture that Muslims believe is God's very words received verbatim by Muhammad); colloquial dialects are used regionally but are easily understood by all.

Despite religion and language, the Arab world is not politically, socially, or economically homogeneous. Some countries are ruled by hereditary monarchies; others, by revolutionary military or quasi-military governments. Democracy is, on the whole, lacking, although it is the aspiration of the masses. Some countries are affluent (usually due to oil wealth), while others are poor; some are overpopulated and others sparsely populated. Currently the Arab world is categorized as belonging to the Third World. The average birth rate is 38.3 per 1,000, and the average infant mortality rate (first year of life) is about 68.2 per 1,000 (United Nations).

A characteristic of the region is the religious orientation of its people and the influence of religion on their lives. Islam recognizes both Judaism and Christianity as religions that come from God; all three religions hold generally the same prevailing moral values and thus have a unified ethical base. Society (of all religious backgrounds) tends to be conservative, sanctifying family integrity and family ties, upholding moralities prescribed by religion(s), averse to unchecked liberalism, and falling back on religion to categorize social trends and new lifestyles as acceptable or unacceptable.

Islam has a comprehensive framework of a legal system based on the Qur'an and tradition, covering all aspects of life, that serves as the source of legislation and the derivation of ethical rulings. And yet the great majority of the Arab world is not ruled by Islamic law, most of the governments

being practically secular. One area has uniquely remained under the jurisdiction of Islamic law: that of family law. It is in this area that the bulk of medical ethics resides. Although many non-Muslims are physicians and patients in Arab countries, there is little dispute about medical ethics among them, since many common positions are shared by Islam, Christianity, and Judaism.

The medical profession is highly esteemed in the Arab world, and the physician is still called "the wise man," a centuries-old nomenclature. The physician is very highly regarded, and the doctor–patient relationship, based on trust and confidence, tends to be paternalistic.

Seeking medical help when one is sick is a religious duty. Muhammad said, "Your body has a right over you," and "Seek treatment, for God has created a cure for every illness; some already known and others yet to be known." The establishment of the medical profession is a religious duty of the community, which should designate some of its members to study medicine and should provide for the needs and requirements of medical education. A doctor should be appropriately qualified, for Muhammad said, "Whoever practices medicine without the appropriate knowledge is liable to pay compensation [if harm comes to the patient]."

It is not uncommon for medical practitioners who enjoy the confidence of their community to be consulted on nonmedical problems faced by families or individuals. People tend to accept that therapeutic ability is not absolute, and as long as the doctor has done his (or her) best, there is a willingness to accept and even forgive undesired outcomes. Insurance against professional liability is nonexistent, and the judicial system heeds this fact; unless it is a clear case of neglect or inexcusable ignorance, the physician is rarely held responsible for damages.

Medical education has deep historical roots in the major capitals (Baghdad, Cairo, and Damascus) since the era of Islamic civilization (eighth to sixteenth centuries). Modern schools have emerged since the nineteenth century, and many are as recent as the oil boom late in the twentieth century. With one or two exceptions, all Arab countries have one or more medical schools, Egypt, as many as thirteen.

English is the common language of education, with French or Arabic used in exceptional cases. Conversion to Arabic is under debate. Medical education and practice are open to both sexes and all religions without discrimination. Coeducation is the rule except in a few schools. There is no ban on examining the opposite sex. Dissection of the human body and postmortem examination are permitted; some schools, however, have to import cadavers from abroad to satisfy the need for teaching anatomy.

Medical Ethics

The Arab world has known medical ethics since the writings of Imhotep of Egypt (3000 B.C.E.) and the Code of Hammurabi of Babylon (about the same time). The Oath of Hippocrates (ca. 460–355 B.C.E.) later took over, and since the ninth century various Islamic adaptions of it, as well as treatises and books on medical ethics, have been contributed by Al-Rahawi, Ibn Rabban, Avicenna (Ibn Sīnā), and many others.

In modern times, medical ethics has been taught as part of the curriculum of various disciplines, but since the 1940s it has become a separate course in the majority of medical schools, whether as a part of forensic medicine, community medicine, history of medicine, or on its own.

Although Islam is the principal source of medical ethics, the increasing complexity of biomedical discoveries and technological achievements during the latter half of the twentieth century have made it difficult for religious scholars to comprehend the issues and formulate rules on ethical acceptability from an Islamic point of view. There has been need for a forum in which religious scholars join with biomedical scientists and specialists in relevant disciplines such as law and sociology, policymakers, economists, and civic leaders of both sexes, to discuss specific issues in order to develop an Islamic consensus. To continue this collaboration, institutions have come into being since the early 1980s: the Islamic Organization of Medical Sciences (IOMS, Kuwait), the Islamic Research Congress (Egypt), and the Fiqh Congress of Makka (Saudi Arabia). The rulings of these government-approved agencies have a high moral weight and almost fill the legal gap that results because legislation usually lags behind new developments. These agencies have significantly contributed to Islamic medical ethics, addressing a number of issues that will be surveyed briefly.

An important milestone was the formulation of the Islamic Code of Medical Ethics (IOMS, 1981), ratified by the First International Conference on Islamic Medicine (held in Kuwait, January 1981) and endorsed by many Arab and Islamic countries. This code comprises eleven chapters: Definition of Medical Profession; Characteristics of the Medical Practitioner; Relations Between Doctor and Doctor; Relations Between Doctor and Patient; Professional Confidentiality; Doctor's Duty in Wartime; Responsibility and Liability; Sanctity of Human Life; Doctor and Society; Doctor and Biotechnological Advances; and Medical Education. All topics were authenticated by sources in the Qur'an and Islamic law. The code also includes the latest version of the Islamic Medical Oath, which reads (roughly translated):

> I swear by God: To regard God in practicing my profession; To respect human life in all stages,

> under all circumstances, and to do my best to rescue it from death, malady, pain and anxiety; To uphold people's dignity, cover their privacy, and keep their secrets; To be an instrument of God's mercy to near and far, virtuous and sinner, and friend and enemy; To pursue knowledge and to harness it for the benefit, not the harm, of humankind; to revere my teachers, teach my juniors, and cherish the fraternity with my colleagues; and to live my faith in private and in public … and God is my witness to this oath.

Derivation of Islamic Medical Ethics

The totality of Islamic law, called the Shari'a, is drawn from the Qur'an, the verbal teachings of Muhammad, followed by analogy and consensus. The Shari'a is expressed in a code of moral behavior that states what is sinful and what is not, as well as a body of laws that states what is legal and what is not. These two systems need not coincide. (An example is a person who commits adultery in the privacy of a closed room. Such a person has committed a sin but not a legal crime, since Islamic law requires four witnesses in order to establish the legal charge of adultery. The fate of such a sinner is left entirely to God, who will punish or forgive upon the perpetrator's repentance and appeal for mercy.) When ruling on the admissibility (or inadmissibility) of an issue, jurists take into consideration a number of rules such as "Necessities overrule prohibitions," "Choose the lesser of two evils if both cannot be avoided," "Public interest outweighs individual interest," and, especially in matters not specified in the primary sources of Shari'a, "Wherever welfare goes, there goes the statute of God." Examples of applying some of these will follow later.

Sanctity of Human Life

Human life should never be violated except in situations explicitly specified in the penal code and observing the rigorous criteria it establishes. Commenting on the killing of Abel by his brother Cain (the two sons of Adam), the Qur'an states: "On that account We ordained for the Children of Israel that if anyone killed a soul, unless it be for murder or mischief in the land, it would be as if he killed the whole people. And if anyone saved a life, it would be as if he saved the life of the whole people" (5:32). This principle has been invoked when ruling on abortion and euthanasia.

Abortion

In general terms abortion is legally prohibited and punishable. However, some physicians perform abortions illicitly, mainly in the private sector. In some countries, if abortion is done to avoid tarnishing the family name (pregnancy of the unmarried is a great shame in the Arab world), this circumstance is considered a mitigating factor if the case ever goes to court. Tunisia has gone a step further and legalized abortion after the third child, thus allowing it to be considered a form of family planning.

Among the religious community, various views on abortion have been held over the centuries. The writings of early scholars differed according to their perception of the beginning of life, and their views continued to be followed by generations of their adherents. On the belief that life started when the mother felt the movements of the fetus inside her (quickening, usually at the end of four months), some thought that abortion before then entailed no aggression on life. Others maintained that the fetus attained its human form at the end of the seventh week, and aborting it at or beyond this date would be unlawful. The majority, however, espoused the views of the great jurist Al-Ghazālī (eleventh century C.E.), who believed that life started with the fusion of the male and female seeds, and that it proceeded through an occult phase to the palpable phase felt by the mother. This view of the beginning of life therefore outlaws abortion and makes it reprehensible at any stage of pregnancy.

Modern juridical opinion has put an end to the historical diversity of opinion and settled for Al-Ghazālī's, following a number of conferences in the 1970s and 1980s (see, e.g., Gindi, 1989b) at which religious scholars met with medical scholars and a full account of the process of conception and early development was illustrated by ultrasound and cinematographic recordings of the fetus in utero. Five criteria were collectively acknowledged as signifying the beginning of life: (1) it is a fairly clearly defined event; (2) it exhibits the phenomenon of growth; (3) such growth, unless interrupted, leads to the known subsequent stages of life; (4) it contains the genetic package characteristic both of humanity and of a unique individual; and (5) it is not preceded by any stage combining the first four criteria (Gindi, 1989a).

Abortion is permitted if the continuation of pregnancy poses a serious threat to the life of a sick mother (the choice of the lesser of the two evils if both cannot be avoided). In Shari'a the mother is the root and the fetus the offshoot, and it is lawful to sacrifice the latter if it is the only way to save the former.

Selective abortion for the sake of sex selection is doubly unlawful, being an aggression on life as well as discrimination against the female (almost invariably the unwanted sex). The Qur'an severely rebuked pre-Islamic Arabs (up to seventh century C.E.) for practicing female infanticide (16:59). Sex selection by means not entailing embryocide, to suit the

wishes of individual families, has been debated. There is consensus that its admissibility would eventually lead to an upset of the sex ratio in favor of male preponderance, which could lead to grave social consequences.

Euthanasia, Suffering, and Care of the Elderly

Euthanasia and suicide are completely unacceptable in Islam. There are no euthanasia proponents, and therefore there is no debate. Suicide and complicity thereto are legal crimes, but the problem is of minute dimensions. The Prophet Muhammad told about a man who took his own life due to an illness that taxed his endurance, upon which God said, "My subject has himself forestalled Me; I have forbidden him Paradise" (narrated by Al-Bukhari). Resort to medical or surgical means for alleviation of pain is lawful, but the taking of life is a matter of God's sovereignty.

Patience in the face of unavoidable pain or adversity is an important value, and the Prophet teaches that through such patience a person's sins are washed away by God, like a tree shedding its leaves. The right to die is therefore not recognized because humans do not own life; they are only entrusted with it. The same applies to the "duty to die," recently proposed for human beings who, through age or infirmity, become consumers but not producers. Caring for a growing group of old and disabled can be very costly, as modern budget figures show, but under Islamic law society has to meet this need by rearranging expenditure priorities rather than allowing euthanasia. Care of the old is a principal value in Islam, especially with regard to one's parents: "Your Lord has decreed that you worship none but Him and that you be kind to your parents.… Whether one or both of them attain old age in your life, say not to them a word of contempt nor repel them, and lower to them the wing of humility out of compassion, and say: 'My Lord, bestow on them your mercy even as they cherished me in childhood'" (Qur'an 17:23, 24).

However, it is generally agreed that in his or her defense of life, the doctor is well advised to realize the limitation of medical efforts. It is the process of life that the doctor aims to maintain, not the process of dying. When treatment holds no promise, it ceases to be mandatory and withholding or discontinuing the artificial means is justified. No active intervention, however, shall be made to terminate life.

Death

Under ordinary circumstances the time-honored recognition of death based on cessation of heartbeat and respiration is workable, followed by a waiting period of two hours before the death certificate is issued. Nevertheless, advances in transplant surgery and the occasional need for a fresh heart for transplantation have called for a more sophisticated definition of death. Such a heart can usually be procured from a trauma victim whose brain—including brain stem—is dead and who therefore has been pronounced dead although artificial means are employed to maintain the functions of respiration and circulation.

The issue was discussed in a number of conferences bringing together high-ranking religious scholars and medical scientists (see, e.g., Gindi, 1989a). An old juridical rule, "The movement of the slain," was reviewed. Centuries ago it was ruled that if an aggressor stabbed a victim in the abdomen and the bowel extruded, this was considered a fatal injury; although the victim could still move, his or her prospects for life were practically nil. "The movement of the slain" was the descriptive term given to the death throes. If a second aggressor finished the victim off, the first aggressor would still be charged with murder for having dealt the fatal injury; and the second aggressor would be punished, but not for murder. Realizing that abdominal trauma with extrusion of the bowel is no longer considered a fatal injury by contemporary surgical standards, the scholars removed it from the category of "the movement of the slain." In its stead, the condition of brain death including the brain stem fulfills the description, since the victim has practically departed from life without the prospect of return and, in spite of the signs of life (circulation, respiration, etc.), is subject to the rulings governing the dead, including taking the heart for transplantation into a needy recipient, without the death of the patient being legally or morally attributed to the surgery. The disconnection of artificial life-support apparatus from such patients would be permissible.

Transplant Surgery

Transplant surgery is practiced in many Arab countries, and some have excellent units. The Qur'anic saying "And whoever saves a life, it is as though he has saved all the people" (5:32) is the basis of considering organ donation as an act of charity. It is a religious duty of the community to provide necessary donors, in analogy with the decree of Umar (the second caliph) that if a person dies due to lack of sustenance, the society should pay legal reparations as if they killed him. The human body is honored whether living or dead, but its surgical violation to procure a needed organ is ruled permissible by invoking the juridical rule of "choosing the lesser of the two evils," for the alternative would be the death of the prospective recipient. Bodily organs should not be offered for sale, but if purchase is the only source, then buying is permissible under the rule "Necessities overrule prohibitions."

In reality, however, apart from close relatives, most donors receive a price under the pressure of poverty. The need is felt for a governing authority to regulate the process, lest an exploitative market be created and patients with limited means be excluded. Donation should be purely and truly voluntary through consent of the living donor, bequeathed in a will or with the consent of the next of kin.

Transplantation of fetal suprarenal medulla to the brain to ameliorate certain diseases is lawful, although abortion performed specifically to obtain that tissue remains unlawful. The anencephalic fetus may be used as a donor, and its maintenance by artificial means for that purpose is acceptable, but removal of organs is permitted only after its natural death, without artificially terminating its life. Transplantation of sex glands to provide sex cells (ova or sperm) is unlawful because the prospective fetus would have been formed by elements not bound by a marriage contract. Sterile sex glands providing only hormones are devoid of that objection, but obviously their use is not medically feasible (Gindi, 1989c).

Hygiene and Preventive Healthcare

"Cleanliness is part of the faith," Muhammad said. Ritual ablutions are necessary before prayers several times daily, including a full bath (*tuhr*) after sexual intercourse, menstruation, and the puerperium. Muhammad forbade overindulgence in food and drink, and enjoined physical fitness. Circumcision of male children is required by Islam. Female circumcision, not an Islamic commandment, has been practiced in Sudan and Egypt since pre-Islamic times, and is now waning.

Preventive healthcare is well heeded. One of Muhammad's pertinent teachings is "If there is pestilence in a locality, do not enter it, and if you are already in it, do not go out." Alcohol is categorically forbidden by Islam (as are stupefying drugs, in order to protect mind and health). Nevertheless, the law in many Arab countries allows the sale and consumption of alcoholic beverages. Currently, there is widespread objection to the practice, and steps have even been taken to avoid alcohol in medicinal preparations. Extramarital sex is forbidden in Islam, although it certainly takes place in a clandestine manner. The virginity rate of girls at the time of marriage approaches 100 percent. The sexual revolution and its sequelae in the West since 1960 have not erupted in the Arab world, although the powerful influence of communications markets the Western model and at the same time evokes a strong reaction expressed in a revival of religious values.

Care of the environment is emphasized in Muhammad's teachings, but unfortunately poverty, overcrowding, and unbridled movement from rural to urban regions with limited and failing infrastructure have led to a gap between the real and the ideal in many Arab cities. Muhammad taught, "Faith has many branches, including the removal of dirt from the street," and "Beware of the triple curse of polluting water resources, shady spots, and trodden roads." On water conservation he instructed those expending much water while making the ritual ablution: "Economize, even if you are at a flowing river." Encouraging agriculture, he said, "Whoever farms land will be rewarded by God every time a person eats from its crop, even if a thief steals and eats from it." Another of his recommendations is "If the end of the world comes and you have a little shoot in your hand to plant, then plant it if you can."

Kindness to animals is a religious dictate. They should not be overburdened or worked to exhaustion or tortured, and they should not be killed except for food. Muhammad spoke of God's pleasure with a man who, encountering a thirsty dog unable to reach water in a well, filled his shoe with water and offered it to the dog, and—conversely—God's anger with a woman who imprisoned a cat. These concepts were borne in mind when discussing the ethics of animal experimentation. Although it is approved when necessary for medical research, due care and humaneness should be shown in keeping and handling the animals.

Contraception

Contraception is lawful provided both husband and wife agree. Contraceptive measures are easily available and in some countries are subsidized by the state to curb overpopulation. Family planning should not be directly or indirectly imposed; the method should not be harmful; it should not entail abortion. Governmental and voluntary agencies use propaganda and education to promote family limitation in overpopulated countries, whereas incentives for a larger family are given in the underpopulated, affluent countries. However, family limitation policies are often attacked by some religious elements for a variety of reasons (Hathout, 1989), including the accusation that they are "imperialistic" designs against poor countries (see Information Project for Africa). The use of the intrauterine contraceptive device has been controversial for fear that it acts by inducing abortion, but its use is widespread. The 1987 World Health Organization (WHO) announcement that its mechanism of action was contraceptive and not abortifacient was welcomed by religious authorities.

Breast-feeding is highly recommended in the Islamic tradition; the Qur'an says: "The mothers shall give suck to their offspring for two whole years, for those who desire to complete the term of lactation" (2:233). This would have

been a potent measure for wider spacing of pregnancies at the level of the society at large, being associated with a high rate of ovulation suppression (of course it would not be a reliable prescription for contraception for the individual family). Unfortunately, the growing number of women joining the labor force does not work in its favor. Surgical sterilization (both male and female) is frowned upon except for pressing medical indications or at an advanced age (nearing menopause) for the highly parous woman.

Reproductive Interventions

The quest for fertility is legitimate, and treatment of infertility by medical or surgical means is lawful and available within the Shari'a. Artificial insemination is permitted only if the husband's semen is used; donor semen is forbidden (by religion and by law) because it is outside the marriage contract. Since legitimate marriage is the only approved venue for reproduction, in vitro fertilization technology is permitted only if it involves a married couple and is carried out during the span of their marriage. No alien "element" should be involved, be it donated sperm, donated ovum, donated embryo, or surrogate uterus. When the wife is widowed or divorced, she is no longer the wife of her husband, and she can no longer be impregnated by his semen that had been preserved in a semen bank, for the marriage contract has come to a conclusion. Surrogacy is outlawed, and contracts for surrogate pregnancy are null and void.

Alternative family structures, not based on legitimate marriage, have no place in Arab societies.

V. ISRAEL

Medicine in Israel, like the country itself, is a blend of contrasts and contradictions, of compromises between tradition and modernity, between myth and reality. Israel, a tiny country made up of a dominant religion and culture (18 percent of the population are non-Jewish), is neither homogeneous nor monolithic. Over fifteen political parties are represented in the Knesset (parliament), and many Israelis are concerned about an ever-impending Kulturkampf between religious and secular factions.

Like all else in Israel, healthcare has been shaped by diverse inputs from a variety of lands of origin, and by the dialectic between the Mosaic and rabbinical tradition and modern Western secular humanism. Each of these major streams is itself heterogeneous. Lip service is paid to myths violated in practice, while traditions overtly denied and rebelled against often provide the spiritual sustenance in which rebels' values are rooted.

The ties that bind Jews to medicine are powerful and deeply rooted. Rabbinic leaders in the Middle Ages often practiced medicine for their livelihood, Maimonides being perhaps the best known in this tradition. In almost every society, Jews have been disproportionately represented in medicine. The most recent example is the 2.5 to 3 percent of Jewish immigrants to Israel from the former Soviet Union who are physicians, a ratio ten to fifteen times higher than that encountered in developed Western countries. The extraordinary value that Judaism places on human life explains in part the attraction of Jews to medicine. The Talmudic statement "He who saves a single life is regarded by the Scripture as if he saved an entire world" (Babylonian Talmud, Sanhedrin 37a) has led to the useful myth that life is of infinite value and to the "sanctity of life" concept that so permeates Jewish tradition.

The foundations of healthcare in modern Israel were laid by Zionist pioneers several decades before the creation of the State of Israel. These individuals were largely secularist, socialist ideologues with deep roots in the social justice ethos of Judaism and in the value placed on human life. Workers in 1912 created a "sick fund" for mutual assistance and healthcare insurance, similar in many ways to the *Krankenkasse* of Central Europe from which they had emigrated. But the principles underlying this Jewish institution were derived no less from the traditional principles of *gemilut hadisim* (loving charity or mutual aid) so clearly spelled out in the Torah, whose rituals the pioneers had often discarded or drastically modified. All were to be equal in the receipt of health care, and money was not to be collected from a person in time of need and distress. This nongovernmental Histadrut labor union sick fund continues to be the major healthcare provider in Israel today. It is both an insurer and a provider of healthcare, owning and operating hospitals and community clinics, and insuring about 80 percent of the population. Smaller sick funds, also funded by mandatory employee and employer contributions, cover the rest of the population.

During the last few years, as healthcare financing has become problematic worldwide—with citizens often placing a higher priority on such personal amenities as choice of physician and attractive waiting rooms than on the concept of equality—the egalitarian foundations of the healthcare system in Israel have been threatened. Gaps in the public sector are being met by a growing fee-for-service private sector. Nevertheless, Israel has managed to maintain both a respectably high level of healthcare and reasonably equal availability of this care, in spite of a relatively low national expenditure. Israel currently spends about 7.5 percent of its gross national product on health care, but since its GNP is considerably smaller than those of most Western European countries, the absolute per capita expenditure is modest.

Manifestations of the strong ethos for saving human life at all costs include the relatively high renal dialysis rates in Israel and the intense efforts made by the military medical corps to provide physician coverage virtually at the battle line, in order to enhance every possible chance to save soldiers' lives. Public appeals by private individuals regularly raise tens of thousands of dollars to send patients abroad for complex surgical procedures that are not performed in Israel.

Yet, simultaneously, there is much evidence that the myth of the infinite value of human life is often shattered in the face of economic realities. Open-heart surgery is rarely offered to those over eighty, and long waiting periods for critical surgical procedures are not uncommon because of limited resources. The distribution of physicians and facilities is not even, with development towns and Arab villages sometimes at a disadvantage compared with the major metropolitan areas. The continued public tolerance of preventable deaths due to smoking and traffic accidents also exposes the mythical nature of the commitment to human life "at all costs." Recently, however, there has been improvement in all these areas.

Consonant with the high priority given to life, the Jewish tradition, unlike Anglo-Saxon law, requires the physician to respond to a patient's call for help. This requirement to render assistance to someone in distress is not confined to the physician; it obligates any individual to come to the aid of a fellow human being. To refuse would fall under the prohibition "Neither shalt thou stand idly by the blood of thy fellow" (Lev. 19:16). A physician who does not respond to a sick patient's request is regarded as one who spills blood. This attitude is incorporated into Israeli secular law, under which a citizen's failure to render assistance at the scene of an accident is a criminal act. Just as the physician is obligated to render care, so is seeking of care by the patient mandatory. The reason for this obligation is that in Judaism, human beings do not possess full title to life or body. Humans are but the stewards of the divine possession they have been privileged to receive. The terms of that stewardship are not of human choice but are determined by the Almighty's commands. Jewish law forbids suicide and requires that all reasonable steps be taken to preserve life and health. When beneficence conflicts with autonomy, the former is given precedence by Jewish tradition, a view clearly in conflict with the modern Western consensus (Beauchamp and Childress).

While such a violation of autonomy for the patient's good is not enforceable in modern pluralistic societies, it is sanctioned in the Jewish tradition; and were Jewish courts fully empowered, they might force medical treatment on a patient if it were indisputably indicated. In modern Israel, in contrast with most Western countries, the courts have not always decided unequivocally for autonomy over beneficence. There has been at least one case where the Israeli Supreme Court permitted a surgical procedure against the expressed will of the subject in order to prevent danger to his life (*Kortam v. State of Israel* 40 [III] P.D. pp. 673–698).

Several medical ethical issues have attracted public attention in Israel over the years and provide interesting insights into the dynamics of Israeli society. For several decades, the issue of postmortem examinations and the laws regulating them were a major public and political issue (Glick). Judaism emphasizes respect for the human body in death as well as in life, and mandates early burial with integrity of the body preserved. Autopsies are permitted only if the information may contribute directly to the saving of a human life. With the creation of the first Israeli medical

school, the rabbinate reached an agreement with the medical profession whereby autopsies would be permitted if three physicians attested that the cause of death was unknown. This exclusion of the deceased person's family from decision making and the subsequent frequent performance of postmortem examinations, even over strenuous family objections, turned the issue into a source of festering conflict. Subsequently, with a change in the political constellation that gave more power to religious parties, the law was changed radically as part of a backlash against the previous "liberalism." Not only is family consent now required, but other provisions, such as veto power for any member of the family, have led from one extreme to another. In all likelihood, the last word has not yet been said on the subject.

In spite of the religious limitations on postmortem examinations, the use of organs from the dead for life-saving transplants is religiously acceptable and even mandated. For many years, the hesitation of the rabbinate to accept brain death as the end of human life created difficulties for heart and liver transplants. After careful study, Israel's Chief Rabbinate in 1986 officially permitted heart transplants when donors' total brain death can be assured. This view has not been accepted by all rabbinical authorities, but religious objections now play a relatively minimal role in the limitations on organ transplantation.

Another area of conflict, as in most Western countries, has been abortion policy. Many factors lead to a restrictive policy in Israel. The Jewish tradition accords major rights to the fetus. The demographic and geopolitical situation of the Jewish people, particularly after the Holocaust, would seem to favor a strongly pronatal and antiabortion approach. Yet the Israeli public is quite permissive sexually, and its youth is very much a part of Western society.

The Israeli compromise, meant to satisfy all parties, includes a law forbidding abortions except for a "valid" medical or social reason, as determined by a hospital committee. These indications are liberally interpreted. Abortions performed outside this framework are illegal, thus satisfying religious sentiments. But no physician has ever been prosecuted for such illegal activities, thereby soothing the libertarians. This precarious balancing characterizes many of Israel's solutions to such conflicts.

Israel has a national committee appointed by the minister of health that advises the minister on many of the more complex and controversial areas in medical ethics, such as in vitro fertilization, genetic engineering, and the like. The committee, called the Supreme Helsinki Committee, is an outgrowth of a committee originally charged with the regulation of research in human subjects according to the Helsinki Declaration. It includes physicians, nonmedical scientists, jurists, philosophers, and clergy. It prefers to work by consensus rather than by vote, and makes every effort to weave its way through the maze of potential legal, religious, and sociopolitical conflicts. In the area of reproduction, the problems are great, since—unlike most areas of law that are adjudicated by the secular courts—marriage, divorce, and family law are largely in the hands of rabbinical courts (Shapira, pp. 12–14). Permissive decisions in the area of new reproductive technologies, unacceptable under religious law, might label the offspring of such practices as bastards, with serious consequences for them in their attempts to marry.

Israeli medical schools now have courses in medical ethics. Most provide the largely secular students with philosophical as well as religious approaches. The Israel Society for Medical Ethics serves as a forum for discussion, for the issuing of position papers, and for raising the consciousness of healthcare professionals regarding medical ethics.

Some militant secular Israelis, chafing under the restrictions of Jewish tradition, have taken a number of bioethical issues to the courts in attempts to force rulings in favor of their position. Cases pressing the right to die have been brought before the courts without clear-cut resolution. Similar suits have been brought with respect to the restrictions placed on surrogate motherhood. These and other court decisions may bring about changes that legislators have been reluctant to press because of their hesitance to upset the "status quo"—which, in this case, refers to a freezing of the situation regarding the influence of the Jewish religion within Israel's public life prior to statehood.

In summary, Israel is a relatively young country that sees itself as part of the modern Western world, yet is the heir to an ancient and wise cultural tradition dating back thousands of years. Jewish tradition is characterized by a strong duty ethic, with emphases on both physician and patient responsibility; a high value on human life; and a strong sense of justice. Time will tell how successful Israeli society will be in distilling and blending the best of both these worlds.

MEDICAL ETHICS, HISTORY OF SOUTH AND EAST ASIA

• • •

I. GENERAL SURVEY

The entries that follow deal with the complex and varied traditions of medical ethics and practice in east, south, and southeast Asia. In many respects these three areas have always represented very different cultural and geographical entities. The Indian subcontinent derived its cultural and linguistic influences from central and western Asia, but produced in Hinduism and Jainism its own religious, cultural, and intellectual forms, shaping attitudes toward disease and the ethics of medical practice. Concepts of human life and disease evolved quite independently in east Asia, where an agrarian society grew up isolated from other Asian peoples both by steep mountains and by what were for the early Chinese equally impenetrable oceans. Chinese society developed its own characteristic political and social practices—particularly its religion focused on the present world, and orientation toward its ancestors. Early Japanese attitudes toward nature differed from the Chinese, as the conceptions of an island people dependent on the seas for a living differed from those of plains-dwelling farmers. Nonetheless, significant interaction between China and Japan from about the seventh century C.E. infused Confucian ideas into early Japanese foundations. Southeast Asia, today comprising Vietnam, Laos, Thailand, Malaysia, and Indonesia, and vividly characterized by Anthony Reid in *The Lands Beneath the Winds,* also evolved from independent social origins. As Reid writes: "Fundamental social and cultural traits distinguish Southeast Asia as a whole from either of its vast neighbors—China and India. Central among these are the concepts of spirit or 'soul-stuff' animating living things; the prominence of women in descent, ritual matters, marketing and agriculture; and the importance of debt as a determinant of social obligation" (Reid, 1988, p. 6).

Despite their very different cultural orientations, these societies are treated here as a group because they offered in traditional times a common contrast to Western medical practice and ethics, and have had throughout their histories a common influence from Buddhism. In more recent periods, the societies of east Asia have faced the common problem of reconciling the possibilities of Western medical technology with their own social goals. These common themes are explored here, by way of introduction to the more specialized articles that follow.

In traditional times, the societies of Asia never adopted the exclusively biological conception of disease that has become the norm in modern Western societies. In traditional Indian Ayurvedic medicine, as Desai Prakash argues, physicians classified the etiology of disease in three categories: external or invasive diseases caused by foreign bodies or possession states; internal diseases caused by disturbances of humors brought about by lapses in discretion; and a third category of disease brought about by the inexorable workings of karma. In ancient China, the metaphors were different but the origins of disease were understood to be equally complex, with health and illness deriving from the baneful or benevolent influence of departed ancestors, or the influence of demons. In Japan, the apprehension of human beings' relation to *kami,* (sacred world), and the southeast Asian conception of the relation of magic, religion, and health, allowed the possibility of social as well as strictly organic origins of disease.

These views of disease may reflect a general tendency in Asia to view the human order as more fully integrated with the natural and social orders than in the West. This contrasts with modern European conceptions of disease, which reflected a European, perhaps Promethean, notion that the human world could understand, analyze, and ultimately control the natural order. Asians' more complex vision of disease had important consequences for the relationship of the medical practitioner and his patient. Since disease could arise from a variety of sources, the Asian medical practitioner addressed a wider spectrum of issues in a patient's life than

did his Western counterpart. Moreover, the Asian patient might be free to consult many more types of practitioners than the European counterpart. Hence varied traditions of medical practice existed side by side, with no single system of medicine having an exclusive legitimacy.

In part, this pluralism of Asian medical practice made it possible for Buddhist practitioners to spread throughout Asia, beginning in about the second century C.E. The notion of loving friendship, and its institutional expression in the establishment of charitable hospitals, dispensaries, and comfort stations on the way to famous shrines and temples, was one of the concepts Buddhist monks carried with them as they made their way across the trade routes of central Asia from India to China between the second and the seventh centuries C.E. Once in China, Buddhist monks found a social environment quite different from the one they had left, for although the Chinese intellectual world was open to Buddhist doctrines, Chinese society was not as open to monastic life with its implied rejection of family and ancestors. In China Mahayana or devotional Buddhism, which stressed the activities that the believer could perform while remaining within the realm of family and community, developed. Thus, in China, Buddhist healing practices not only were carried out within charitable institutions formally run by the Buddhist establishment but also came to merge with folk medicine and healing practices from other traditions.

By about the thirteenth century, the spread of Buddhism throughout Asia had provided a unity to traditional medical practice that had not existed previously. But this was at best a loose unity, in which Buddhist medical ideas came to coexist alongside traditional healing practices and institutions. When Western medicine came to Asia in more recent times, it experienced a similar fate. The importation of Western medicine to Asia was largely a product of colonial times; the earliest Western medical practitioners in Asia were often missionaries supported by European and American political or religious establishments. Twentieth-century Asian governments, consciously or unconsciously aware that Western medical technology could provide the same control over life and disease that Western military and social technology provided over political affairs, often vigorously pursued Western medical techniques. The Minister of Education of the government of Nationalist, or Guomindang, China declared in 1914 that he had "decided to abolish traditional Chinese medicine." Similarly, in 1874 the Meiji government in Japan decreed that all Japanese physicians had to have Western medical training.

Despite the vigorous efforts of Asian governments to promote Western medical education and practice, Western medicine has failed to supplant traditional medical practices in any of the countries under consideration, for several reasons. In part, the problem has been the absence of trained medical professionals: In China, for instance, despite the commitment of the government of the People's Republic to scientific medical practice, a realistic assessment of resources dictated that medical workers trained in traditional as well as modern Western techniques be employed. Possibly because of the paucity of trained personnel throughout Asia, Western medical practice has been and remains a largely urban and elite phenomenon. In part as well, traditional medical practices have proved their value as effective and inexpensive treatments for many of the maladies of modern life. As Pinit Ratanakul notes in the article on Southeast Asian countries, "This traditional method of healing may be especially suitable today for Southeast Asians, who, living in societies with increased urbanization and industrialization, need physical, psychological and spiritual care to enable them to cope with such change and the strains and stresses of modern life." Today, then, as in the past, different disciplines of medical treatment, each with its own ethical standards and requirements, exist side by side throughout much of Asia.

If modern Western medicine has not fully supplanted traditional medicine in Asia, the power and technology of modern medicine has in almost every country posed new ethical dilemmas. In some instances, as in the case of reproductive medicine, Western medicine has made accessible courses of action more radical than traditional medicine permitted. Abortion, though known and disapproved of in traditional Chinese and Indian medicine, has become much more common throughout Asia as population control has become an accepted political goal. Amniocentesis to determine the sex of a fetus has become a common practice in India, with female feticide often the consequence of the traditional religious imperative to produce a male heir. China's enthusiastic embrace of the Western market for blood products and the technology for obtaining them fostered the spread of AIDS in the 1990s in a population totally oblivious to the dangers of the technology and the disease.

In other areas of medicine, Western technology has fostered new and rather ominous practices in Asia. In China in the late 1980s, debate arose about the merits of sterilization of the mentally retarded and other types of genetic experimentation. Sadly, Asian practitioners of Western medicine have proved somewhat more willing to engage in experimentation on human subjects than have their Western counterparts, as well. Wartime experimentation during WW II by Japanese doctors in Manchuria has, of course, been condemned not only in the West but also in Japan. Unfortunately, such experimentation has also been carried out in

contemporary Southeast Asia, though such action is increasingly condemned by Southeast Asian and Western governments. As a result of the new ethical dilemmas posed by Western medical technologies, medical ethics has become both a heated issue throughout contemporary Asia and the subject of frequent international conferences and journal articles.

II. INDIA

In this article, India refers to the entire Asian subcontinent south of Afghanistan and the Himalayan range, including the modern nations of India, Pakistan, Bangladesh, and Nepal (often referred to as the "Indic" region) as well as the island nation Sri Lanka. In the third millennium B.C.E. there flourished a civilization in and around the Indus Valley known as the Harrapan city culture. Gradually, from the second millennium, the subcontinent was infiltrated by Indo-European tribes from Central Asia. These people formed the classical culture that survives to modern times with many transformations. In the eighth century, Muslim invasions began in the north, culminating in the powerful Mogul empire of the fourteenth and fifteenth centuries. Historic India is the home of two of the world's major religions, Hinduism and Buddhism, as well as of Jainism, and host to Islam, now the majority religion in Pakistan and Bangladesh, as well as to ancient Christian and Jewish communities in the south. From the interaction of Hinduism and Islam grew another religion in India, the Sikh faith. In the sixteenth century, India's cultural and religious influence extended into China and Tibet, as well as to the lands of Southeast Asia.

The origins of medicine in India stretch back to antiquity. The urban architecture of the earliest civilization, in the cities of the Indus Valley, demonstrates knowledge of sanitary techniques. One of the Vedas, the sacred lore of the early Indo-Europeans (ca. 1500–1000 B.C.E.), contains chants to ward off disease, and lists of herbal medicines. The ancient texts extolled by the *bhesaj,* persons skilled in the medicinal uses of herbs. Priest-physicians prescribed prayers and fasts, as well as herbal medicines. Out of this text, the *Atharvaveda,* and other systems of philosophical speculations developed a system of medicine based upon a theory of bodily humors and a therapeutic regimen of herbs and plants. The term "Ayurveda," meaning knowledge of vitality and long life, designated this classical Indian medicine that is widely practiced in India today. Ayurvedic medicine developed in the fifth century B.C.E.; its earliest classical treatise, *Carakasamhita,* can be dated to the first century C.E. The oldest known Sanskrit medical manuscripts, discovered in a Buddhist monastery in China and dating from about 450 C.E., reveal a developed medical system, mentioning elixirs for long life (including garlic), eye lotions, enemas, aphrodisiacs, and ways of caring for sick children. The text mentions Indian physicians of renown, including the most famous, Sushruta (second century C.E.). After the adoption of Buddhism by King Ashoka (273–232 B.C.E.), Buddhist monks, who were not bound by the rigorous Hindu laws of purity and pollution, were free to mingle with common people and to invite them into their monasteries, thus bringing their medical skills to the needy and hospitality to the sick. They also seem to have brought Ayurvedic medicine to Tibet and China. Monks of the Jain tradition, which arose about the same time as the Buddhist tradition, also contributed to the development of the medical system. Early medical speculations and observations about the body, mind, and illness were consistent with tenets of all three major religions.

There appears to have been a flowering of medicine during the first millennium C.E. (Jolly; Winternitz). In the course of time, six classic texts of Ayurveda were recognized. Two of these, *Sushrutasamhita* and *Carakasamhita,* are named after the most famous physicians of the tradition, Sushruta and Caraka (first century C.E.); it is suggested that the word "caraka," which also means "one who moves about," refers to the itinerant Buddhist monks; Sushruta was a physician to a Buddhist king. The other four—*Ashtangahridaya,* attributed to the physician *Vagbhatta; Madhavanidana; Sarangadharasamhita;* and *Bhavaprakasha*—date from the eighth, ninth, thirteenth, and sixteenth centuries, respectively. The latter two reveal the influence of Arabic medicine, and the last mentions *phirangi roga,* the disease of the Franks (the Portuguese who came to India in 1498), probably syphilis. The use of opium as a therapeutic agent is prescribed in these later texts.

Assumptions of Ayurveda

Ayurveda is deeply rooted in the great religious and philosophical traditions of India, whose visions of human nature and the universe informed medicine and, in turn, were

enriched by the concepts formed in medical practice (Dasgupta). Ayurvedic constructs of the self and the body, concerns central to the medical enterprise, grew in tandem with the faith traditions. Ayurvedic physiology and pathophysiology rest on a doctrine of humors (*doshas*) and bodily substances (*dhatus*). The principal humors are wind (*vata*), bile (*pitta*), and phlegm (*kapha*), representing movement, heat, and moisture in the body, respectively. The primary body substance, *dhatu,* is "organic sap" (*rasa*) derived from food, transformed in various ways as it moves through the body, stored in various reservoirs, and excreted as waste. Sap is first transformed into blood, then into flesh, fat, bone, marrow, and semen, the last being the purest product of the transformation.

Health is a state of balance of bodily humors and substances (*dhatusamya*); illness is disequilibrium. The body is affected by external factors, such as food and climate, as well as internal influences, such as anger and jealousy; social experiences, such as praise or scorn, also affect bodily states. Each of these may cause disease or restore health. This interactive universe of substances blurs the boundaries between inside and outside, and makes for a constant flux. The body is in dynamic relationship with the cosmos, whose elements of wind, fire, and water are reflected in the body; similarly, the body is seen as a reflection of the mythic cosmogony, in which the primordial person arises from chaos and is differentiated into multiple forms. Breath (*prana*) is the supreme force that unites bodily parts and becomes the definition of life (*jiva*): "People say of a dead person, that his limbs have become unstrung," say the *Upanishads* (ancient religious discourses). Ayurvedic medicine visualizes the sick person as in a state of fragmentation; his or her bodily components must be taken apart, cleansed, and put together again (Desai, 1989). Breath also becomes equated with the narcissistic and metaphysical components: *ahamkara* and *atman. Ahamkara,* "I-ness," literally the saying of the word "I," is the perishable self; and *atman,* cognate with the Greek *atmos,* is visualized as a self beyond death, without properties, pure consciousness, and transcendental. Although Hindu, Buddhist, and Jain traditions have differing notions of the self, they share common beliefs about the transience of the perishable body, often a source of pain, and the consubstantiality of the body with the universe.

The theory of *gunas* (literally "strands" or "qualities") is an aspect of *samkhya* and an important foundation of Hindu ethics. Inherent and substantial, *sattva* (goodness), *rajas* (vitality), and *tamas* (inertia) are found in all material substances in various combinations and determine the overall constitutional disposition of persons, foods, activities, bodily substances, and so forth. Physically *sattva* is cool and light; *rajas,* hot and active; and *tamas,* heavy and dull. Psychologically they are calmness, passion, and lethargy or stupidity, respectively. In character they are purity or virtue, happiness or sorrow, and darkness or evil, respectively. Contemplation, meditation, silence, devotion, and fasting promote goodness; love, battle, attachment, pleasure seeking, and emotionality enhance vitality; sloth, sleep, and idleness increase inertia. In the hierarchy of values, the *sattva* categories tend to reign supreme and become less material and closer to the idea of *sat* (truth or essence); in Ayurvedic discourses they are understood to be the same as the mind or the self. The ethical aim, therefore, is to transform physical and mental dispositions from inertia to activity to goodness. Such transformations are promoted by ingestion of foods and performance of activities that are conducive to the higher strand. Therapeutic aims are also to transform the self and the body to higher levels of functions: from imbalance to equipoise, from idleness to activity, from agitation or pleasure seeking to calmness and contemplation.

The Physician

An Ayurvedic physician, called a *vaidya,* is one of the quartet (the physician, the drugs, the attendant, and the patient) responsible for amelioration of diseases. Although esteemed for their powers to bring about health and disease-free states ("the cause of virtue"), physicians were regarded with mixed feelings in ancient India; anxiety concerning disease and death was displaced onto them. Physicians contracted impurity from their handling of body products, lesions, and corpses, and through their "democratic practice of mingling with the common people" (Chattopadhyaya). Religious texts enjoined people not to receive food from physicians and to avoid them at religious ceremonies. Taboos concerning touching caused palpation to fall into disuse as a diagnostic tool.

The Ayurvedic texts demand that a physician excel in theoretical knowledge, have extensive practical experience, be dextrous, and observe the rules of cleanliness. A physician began his education as an apprentice, teacher and pupil choosing each other. A good teacher was free from conceit, greed, and envy; the student was calm, friendly, and without physical defects. The physician must be compassionate, virtuous, of high lineage, devoted to learning, rational, and always ready to act. The *Carakasamhita* regards the profession as suitable to the upper castes: Brahmins (for the welfare of all living beings), Kshatriyas (for their own protection), and Vaishyas (for livelihood). The *Sushrutasamhita* also permits the Shudras, the lowest caste, to be physicians. Later the vaidyas became a caste, an occupational division, and the

profession passed from father to son. In modern India, physicians, Ayurvedic or otherwise, may be from any caste.

Carakasamhita contains an extensive ethical treatise in the form of an initiation oath to be sworn by one entering the practice of medicine. Among its injunctions are these:

> Day and night, however you may be engaged, you shall strive for the relief of the patient with all your heart and soul. You shall not desert or injure your patient even for the sake of your life or your living.
>
> You shall be modest in your dress and appearance and speak words that are gentle, pure, righteous, pleasing, worthy, true, wholesome, and moderate.
>
> When entering a patient's house, you shall be accompanied by a man who is known to the patient and who has his permission to enter. Having entered, your speech, mind, intellect, and senses shall be entirely devoted to no other thought than that of being helpful to the patient, and of things concerning him only. The peculiar customs of the patient's household shall not be made public.
>
> Though possessed of knowledge, you should not boast very much about it. Most people are offended by the boastfulness of even those who are otherwise good and knowledgeable.
>
> There is no limit at all to which knowledge of Ayurveda can be acquired, so you should apply yourself to it with all diligence. The entire world is the teacher of the intelligent and the foe of the unintelligent. Hence, knowing this well, you should listen and act according to the words of instruction of even an unfriendly person when they are worthy and such as to bring fame and long life to you, and are capable of giving you strength and prosperity. (Menon and Haberman, 1970, pp. 295–296)

Sushrutasamhita describes procedures that include an ingenious method of making a new nose when the original has been cut off (a form of humiliation that was a common punishment for criminals and unfaithful wives). The text also contains directions for dissection of the cadaver. However, dissection for purposes of teaching and study was not normally practiced. The objection to dissection was based on the deep-seated Indian taboo on contact with dead matter of any kind. The doctrine of *ahimsa* (nonviolence), which was taught by Buddhism and Jainism, did not prevent dissection of a dead body, provided the body was not deliberately killed for that purpose; but *ahimsa* did act as a check on vivisection of any creature.

Care of animals such as cows, horses, elephants, and even birds formed an integral part of the prevailing religious beliefs. Mention is made in the literature of hospitals for sick and wounded birds. Although ancient Indian physicians were taught the care and treatment of animals, there were also veterinarians who cared only for animals.

Quacks and charlatans were unequivocally condemned. They were known by their loose tongues, superficial knowledge, pretense, and arrogance. When the patient worsened, they abandoned him. The fate of their patients was worse than death; one can survive a thunderbolt, says *Carakasamhita,* but not the medicine prescribed by quacks. A physician, on the other hand, was to hold his tongue, not enter into needless debates, and apply himself continuously to new learning. He was to avoid women who belong to others, not to enter the house of a patient without the presence of a person known to the family, to maintain confidentiality, and never to mention a patient's approaching death.

Modern Indian physicians, especially those trained in Western medicine under the British, took the Hippocratic oath. The Indian Medical Council promulgated its code of ethics in 1970. The code directs physicians to serve humanity without regard to religion or race, social or political affiliation. A physician must provide pro bono services, maintain confidentiality, and hold teachers in esteem with a sense of gratitude. An adulterous relationship with a patient or with a patient's family member is considered a breach of ethical principles (Medical Council of India).

The Origin of Life

The origin of life is a major concern of the authors of traditional medical texts. An embryo is formed through the union of the woman and the man when both have appropriate humoral dispositions and appropriate nourishment. The life principle is thought either to enter at the moment of conception or to be a latent property of the seeds; the latter is comparable to fire in the rays of the sun becoming manifest on passing through a lens, or the combining of male and female germinal substances. At other times the moment of quickening or the descent of the fetus in the womb is seen as a moment of independent life or viability. Defective germinal substances, "unnatural" coitus, failure of nourishment or inappropriate nourishment, and weakness or disturbance in humors explain the unexpected, such as multiple pregnancies and infertility. Initially the fetus is visualized as genderless and becomes male or female in the third to fourth month of pregnancy. Among the rites of passage, *samskaras,* there is one that is performed at this stage of pregnancy to promote the development of a male child.

Having a male child is a Hindu religious obligation, for the performance of funerary rites by a son secures passage to

the land of the forefathers. In this rite of passage, the son symbolically reconstitutes the body of the dead father and reunites him with his lineage. Therefore, a man must have a son; if necessary, he must take another wife to beget a son, invite his younger brother or a Brahmin of good conduct to impregnate his wife (a custom called *niyoga*), choose another willing woman, or otherwise adopt, procure, or purchase a son. The epic *Mahābhārata* provides examples of *niyoga*—the birth of the father of Pandavas, the protagonists, and of the Kauravas, the antagonists of the epic—and of in vitro fertilization—the development of embryos in pots, as in the case of the Kauravas. The birth of the last liberated sage of the Jain tradition, Mahavira, provides an example of embryo transfer from one womb to another, as does the birth of an older sibling of Lord Krishna (Desai, 1988). In light of these traditions, modern forms of surrogacy or new technologies present few problems.

Contraception and abortion also have precedents in Indian tradition. The medical texts dwell upon ways of enhancing the possibilities of conception through manipulation of a number of variables; the same variables can be manipulated to retard the chances of conception. In practice, sexual congress outside the Hindu religious Law was not prohibited for men, but women were scorned if found lacking in virtue—especially widows, who were forbidden to remarry—and means had to be sought to prevent unwanted pregnancies. *Bhavaprakasha,* a sixteenth-century medical text, provides a list of oral contraceptives. Modern methods of contraception have been introduced in India, and a massive family-planning campaign includes male and female sterilization. Research work on antipregnancy vaccine and depot preparations (large doses suspended in oil so that they are slowly released over a long period of time) of hormones is ongoing.

Medical texts, especially the *Sushrutasamhita,* describe various forms of arrested fetal development, fetal death, stillbirth, and obstructed deliveries, and the treatments for them that consist of induction of labor and/or destruction of the fetus. The text cautions against hasty action and requires royal permission to induce abortion and extraction of the fetus in case of danger to maternal life. Although early religious texts consider abortion to be a sin, equal to the killing of a Brahmin, by the seventeenth century Ayurvedic physicians were advising the use of an herb, administered vaginally, for the induction of labor, "a useful remedy for pregnant women in poor health, widows, and women of liberal morals" (as quoted from Vaidya Jeevanamin Chandrashekar, p. 45).

In colonial India abortions were governed by English law; in 1972 the government of India legalized abortion, mainly to prevent illegal abortions and to give further impetus to family planning. Abortions in the first trimester, and under special conditions in the second trimester, are available on demand. More recently, RU-486, "the morning after" pill, has been introduced in India on an experimental basis.

Amniocentesis has become extremely popular in India. Overwhelming preference for boys, permissive abortion laws, and the crushing burden of dowries have led parents to seek to ascertain the sex of the fetus, so that a female can be aborted. A vigorous debate, both for and against using the new technology for sex selection, has ensued, one camp arguing in effect that feticide is better than infanticide and the other decrying the culture's age-old cruelties against women (Desai, 1991).

Disease, Death, and the Laws of Karma

Karma is the operative principle of Hindu ethics and has come to mean that every action has a consequence: "As you sow, so shall you reap." Karma has explanatory power for questions like "Why me?" and encourages action for future rewards. The cycle of birth, death, and rebirth, as well as that of health and disease, is governed by the laws of karma. The laws of karma also have dominated Buddhist and Jain ethics.

The ancient physicians classified the etiology of diseases into three categories. External or invasive diseases were caused by foreign bodies, war injuries, possession, or infestation. Internal diseases were disturbances of humors brought about by lapses in discretion, which included faulty diets, overexertion, sloth, sexual indulgence, and mental disturbances. The third category was reserved for the workings of karma, fruits of action from past deeds or previous lives. Some disease states were also seen as the workings of time, as in aging. The unseen hand of karma was invoked in all diseases, a schema that brought ordinary actions like dietary habits and seasonal observances under the umbrella of ethics. Mental illnesses also arose from these etiologies: possession by spirits, disturbances in humors, and lapses in discretion. Like other conditions that defy easy explanations, epidemics and natural disasters were thought to be caused by the collective misdeeds of a population or of a ruler. Physicians of the era of Caraka and Sushruta paid homage to the principle of karma but argued that passivity on part of a physician who assumed predetermination of disease or death made the whole medical enterprise meaningless. Human effort was always a factor in the workings of karma, and the human body was the object of physicians, who held alleviation of diseases and restoration of health as their primary objectives.

On the other hand, there were incurable diseases. It was prudent of physicians to be wary of heroic efforts to prevent the inevitable, which not only brought loss of income but social censure and ignominy as well. If the physician knew that a case was hopeless, he was to do no more than sustain the nutrition of a dying patient. Thus, prolonging life with artificial means is not always acceptable. Those who have led a full life must, like ripened fruits, fall from the tree; untimely death of the young is another matter. Yet, death is not the opposite of life; it is simply the other end, the opposite of birth. Those who are born must die.

Debates in the West on the issues of aging, the care of the terminally ill, and euthanasia have prompted a reexamination of medical ethics in the East. Not surprisingly the Hindu, the Jain, and the Buddhist views converge and have a place for a "willed death" or, more correctly, "hastened death" (Young; Desai, 1991; Bilimoria, 1992; Fujii, 1991). Shrinivas Tilak (1989), after examining Hindu and Buddhist texts, concluded that aging represents points in a life cycle, indicating both growth and maturity as well as eventual decline and loss; at the end point it is an indicator of ultimate dissolution of life. Hindu texts bemoan the inevitability of death, and the Buddhist texts point to pain and unhappiness as inherent in life. In the face of approaching or inevitable death or debilitating and painfully long suffering, traditional ethics provides "permission to leave" voluntarily. Also, the anxiety occasioned by the uncertain timing of death is to be mastered by death that is willed; choosing the moment of death is permitted to ascetics or otherwise superior and elevated souls. Each of the three traditions provides for taking a vow to gradually refrain from taking food and water (and medications, when relevant); thus one ultimately starves to death. The early discourses do not regard this as suicide, which is a death brought upon oneself in a state of desperation and imbalance, and therefore belongs to a different category. The three traditions, which uphold *ahimsa* as central to the view of sanctity of all life, find little difficulty with death that is hastened by starvation. A telling episode in the life of Mahatma Gandhi illustrates this debate (Parekh). A calf that had no hope of surviving and was suffering was put to death with Gandhi's consent. Gandhi rejected the view that killing was never justified and always represented violence. He said that there is violence when the intention is to cause pain; otherwise it is simply an act of killing. When confronted by his critics, especially the Jain merchants of Gujarat, with the problem of euthanasia, Gandhi gave the following response:

1. The disease from which the patient is suffering should be incurable.
2. All concerned have despaired of the life of the patient.
3. The case should be beyond all help or service.
4. It should be impossible for the patient in question to express his or her wish.
5. So long as even one of these conditions remains unfulfilled, the taking of life from the point of view of ahimsa cannot be justified.

Although Gandhi believed that he had arrived at his position independently, he was building on the position advanced by ancient medical authorities.

Other Systems of Medicine

Yoga philosophy and the related tantra have enriched the Indian medical system on the periphery. In classical yoga thought, the *Yogasutra* of Pantanjali, the aim is to bring the mind to focus by inhibiting its waywardness, through successive disciplines of body and thought and by regulation of body functions. Thus body and mind are yoked and come into correct conjunction. Later elaborations have included arduous physical practices and other forms of meditation. Modern relaxation techniques and biofeedback, popular in the West, owe their origin to the discipline of yoga.

Yogic thought visualizes the body in concentric layers, proceeding from the less important outside to the vital inside, from gross to subtle, from hard to soft, and from more material to less material. The body is penetrable and its boundaries permeable; only the innermost self, which must be realized through yoga, is an adamantine core of permanent joy and bliss.

Other forms of yoga, especially the kundalini yoga, advance a concept in which the spine is a vertical axis along which are chakras (wheels or lotuses), centers of energy and impulses. The lower chakras represent vegetative functions (e.g., genitoexcretory, digestive, circulatory, and respiratory); the higher ones, centers of thought and emotion. In this dualism, kundalini, the spiritual aspect of a person, lies dormant in the lowest chakra at the base of the spine; it must be awakened through yogic exercises and made to travel up the spine, activating other chakras on the way and finally uniting with the highest chakra, where the principle of consciousness resides. The regulation of breath is critically important in these exercises, for the breath is the source of energy and must travel through the chakras into the various nerves or channels (*nadis*). The left-handed form, tantra, is a fringe discipline emphasizing esoteric sexual practices. The feminine powers are invoked and sought for the purpose of incorporating them in the self of the practitioner. The way to accomplish this is literally to reverse the flow of sexual fluids from men to women. Ultimately the enriched semen will be forced up the spinal axis to repose in the head as a collection of the most vital and purified energy.

Another Indian medical system is the siddha tradition, practiced mainly in southern India. Based on the Ayurvedic principles, it favors the Greek pharmacopoeia, especially the metallic oxides. The use of astrology in diagnosis and treatment, including the wearing of precious and semiprecious stones, is quite common in India. There is also a rich tradition of folk medicine, including exorcists, bonesetters, snakebite curers, and those who use mantras for cure.

The Yunani or Arabic system of medicine was brought to India by the Muslim invaders. Accepted by the rulers, it began to displace the older Ayurvedic practice to the periphery but also interacted with it. Its humoral thinking, based on Galenic principles, was congenial to Ayurveda. The examination of the radial pulse became a central feature of Ayurvedic diagnosis, and whereas the Ayurvedic pathophysiology had until then been exclusively humoral, the liver and blood were now implicated in folk pathophysiology. Muslim rulers patronized the system and founded publicly funded hospitals and dispensaries. Hakims, the practitioners of Arabic medicine, enriched the Ayurvedic herbal apothecary with their metallic oxides. They often specialized in the treatment of male sexual dysfunctions. This system is especially patronized by the Muslim population of the subcontinent.

"Allopathy" is the term by which modern Western medicine is known in India. European missionaries, especially from Portugal and France, brought it in the fifteenth century, and the British introduced the system in the delivery of care of their own personnel, later founding hospitals and medical schools in the major Indian cities. Allopathy pushed Ayurveda and Yunani to the periphery of medical practice. Today in India all systems are patronized, allopathy more in the cosmopolitan areas and the indigenous systems more in the rural. Patients often move from one to the other, depending on their own explanatory system or the success or failure of one or the other. The indigenous systems are more often chosen for the treatment of chronic conditions, which by definition have failed to be cured by modern methods. Although antibiotics have changed the epidemiology of acute conditions, they are seen as heavy and harmful with many side effects, in contrast to the gentler herbal preparations. Preparations for internal use have to meet the test of culturally constructed theory of inputs and fluxes. The most significant impact of modern antibiotics has been on maternal and infant morbidity and mortality.

In the 1990s most hospitals are staffed by practitioners of allopathic medicine. There are over 100 allopathic medical schools, over 500,000 hospital beds, and over 300,000 licensed medical practitioners. About 100 Ayurvedic colleges exist, and over 250,000 practitioners, but they have only 20,000 hospital beds. Research in Ayurvedic and Yunani medicine has been organized under central institutes.

Surgery, for which ancient India was famous, has passed into the domain of modern Western medicine. With anesthesia, asepsis, and blood transfusion, modern surgical practice has totally excluded the traditional forms. Organ transplants are becoming common, since traditional beliefs about construction of the body from discrete parts allows for removal and replacement. However, extreme poverty has created a widespread and unregulated market in which poor people offer corneas and kidneys for sale to the wealthy.

A fragmented, either commercialized or bureaucratic system of care that is neither easily accessible nor affordable is the major ethical problem of India. Emigration of physicians and nurses to the West has not helped. Multinational drug cartels and fly-by-night Indian drug firms with little regulation in manufacture or prescription form a lethal combination with diagnoses made by divination or without examination. The cultivation of public health and prevention points a way out of the current problems.

III: CHINA. A. PRE-REPUBLICAN CHINA

The following article has been retained from the first edition, with minor revisions by the original author.

The cultural history of China, as reflected in its literature, shows that for at least two thousand years the Confucian worldview, an ideology concerned with the structure of social life, dominated Chinese society until the collapse of the empire early in the twentieth century. Although less obvious, the philosophy of Taoism exerted a strong influence on Chinese society in the same period. A third major influence in ancient China, that of Buddhism, was introduced from India about the first century C.E. Buddhism exerted its greatest impact on social life and scholarship in China from about the sixth to the early ninth century. Subsequently some of its metaphysical concepts were integrated into Confucianism, its worldly assets were secularized, and its teachings continued mostly on the level of a folk religion. Medical ethics in China, as a consequence of the parallel existence of these three major ways of life, reflects some of the values of all of them.

This article will focus on the history of explicit medical ethics in prerepublican China. By "explicit medical ethics" is meant those norms allegedly present in interactions between medical practitioners and their clientele. The historian has no way of investigating whether norms, as they were expounded by various groups providing health care in China, actually formed the basis of these groups' actions; it is a well-documented fact that explicit ethics are usually far more rigid than the norms actually followed. One can only infer, then, the ethical norms proposed as an appropriate basis of the actual relationship between individual practitioner and patient in prerepublican China. Evidence of appeals to a code of ethics is extant only with respect to a few individuals. One cannot infer from the explicit ethics of a few practitioners the ethics of the whole group. Professional organizations of medical practitioners that might have attempted to enforce a single code of ethics were unknown in prerepublican China.

Historical sources allow for an understanding of the values regarding life and death contained in various ideologies propagated in China. These values, of course, have their immediate bearing on norms regarding the provision of healthcare and medical services. The historical sources further make possible an understanding of the relationship

among various practitioner groups and between these groups and the general public. In addition, the historical material forces one to distinguish between traditional explicit medical ethics and modern explicit medical ethics. The former was characteristic of a period in history during which no group of independent practitioners achieved a place in the top ranks of the respective culture's social hierarchy; values dominant in society concerning life and death seem to have been quite stable during this epoch. One purpose of traditional explicit medical ethics, then, may be understood as an attempt by the medical group expounding it to demonstrate its continuous adherence and conformity to fixed, well-defined values.

Modern explicit medical ethics, in contradistinction, results from technologically based advances in Western medicine during recent decades. It represents an attempt to transform values into norms for new situations. The age-old values regarding life and death cannot simply be extended to the consequences of recent developments in healthcare. In contrast to the past, medical scientists in all modern societies work at the forefront of medical progress, and new norms, often representing differing values, have had to be created to cope with situations that formerly were inconceivable, for example, organ transplantation, allocation of scarce primary medical resources, and the maintenance of physiological functions in the terminal patient.

Although statements about medical practice and practitioners are found early in various branches of Chinese literature, the first lengthy and explicit statement on medical ethics of physicians, that of Sun Ssu-miao, appeared in the seventh century. The probable causes for the emergence of such statements at that time demand closer investigation. Medical practice, in whatever form it is carried out, represents a basic necessity for survival not only of the individual but also of the society. Although communities are known that severely restrict, or even totally deny, medical practice, on grounds of the religious beliefs they follow, one otherwise finds an active acceptance in all cultures known so far.

The utilization and the improvement of available primary medical resources (i.e., medical knowledge and skills, drugs and medical technology, medical equipment and facilities) may be viewed as an integral part of most cultures. The problematic variable is which segment of society utilizes and controls these primary medical resources. At the beginning of the Confucian era in China, about two thousand years ago, several groups already participated in the utilization and control of the primary medical resources then available. These resources included preventive and curative therapeutic strategies that derived from separately conceptualized understandings of health and illness. These included a metaphysical perspective concerning the origin of health and illness, which identified the influence of ancestors and demons as responsible for illness, and a naturalistic concept that focused on the relationship between humankind and its physical environment.

The ancestral paradigm is the earliest known conceptual response in China to the experience of illness and early death. It is documented in inscriptions on oracle bones dating back to the Shang dynasty (approximately from the eleventh century B.C.E. on). Even though this perspective lost its dominant position as an explanation of illness and for the design of strategies to prevent or cure illness by the middle of the first millennium B.C.E., it has survived in China until the present. Ancestral healing places living humans in a community with their ancestors, who, although dead, continue to exist. The ancestors guarantee the health of the living as long as the latter adhere to certain norms, and they send individual illness or social catastrophe when they notice a departure from these norms by an individual or society. Prayers and sacrifices by the living may cause the ancestors to withdraw their wrath and restore health or social harmony.

The ancestral paradigm was superseded during the period of the Warring States, in the middle of the first millennium B.C.E., by a belief in the power of demons (i.e., metaphysical entities not directly related to a living human being) to cause illness. Demons, it was assumed, will cause harm to a person regardless of that person's lifestyle; protection is achieved not by adherence to specific moral tenets but by alliances with the forces of stronger metaphysical entities, especially those of sun, moon, the stars, or thunder. Spells and talismans served to demonstrate these alliances and scare away demons in the lesser ranks of the supernatural hierarchy.

When in the early 1970s, a tomb sealed in 167 B.C.E. was unearthed near Changsha in the Chinese province of Hunan, the artifacts found included numerous texts related to healthcare and therapy. These manuscripts offer the earliest available evidence of the development, in ancient China, of a broad gamut of empirical therapeutic strategies, ranging from minor surgery and massage, dietary concerns and recommendations concerning sexual intercourse, to cauterization and, most prominently, elaborate pharmacotherapy. The resort to herbal, animal, and mineral drugs, as well as man-made substances, to cure and prevent illness remained the most important strategy in Chinese medicine until the twentieth century. Most of traditional Chinese medical literature consists of a long series of ever more comprehensive and sophisticated herbals discussing all possible facets of drug lore, and an even greater number of prescription collections, ranging from specialized treatises focusing on one problem to encyclopedic works. Inherent in the use of

drugs against illness is an ontological notion that derives from demonologic beliefs. If they did not serve to cure symptoms such as pain or diarrhea, fever, and cough, drugs could kill intruders causing trouble in the organism. At about the time China was united in the second century B.C.E., a further approach to understanding health and illness found its way into medical literature: the ideology of systematic correspondence. Based on a dualistic paradigm of yin-yang and on a scheme of five phases, the entirety of observed phenomena in the human organism and its environment was seen as a system of interrelated, and hence corresponding, items and processes. A person remained healthy as long as he or she was able to live in accordance with the underlying laws of this system; departure resulted in illness. Healthcare on the basis of these ideas was not so much focused on the treatment of manifest diseases as on prevention and on intervention at the earliest signs of change from a perceived status of normalcy. This system of healthcare did not rely on drugs but on an application of needles meant to exert stimuli that serve to regulate imbalances. Nevertheless, the medicine of systematic correspondence also included strong ontological notions. On a more abstract level, if compared with pharmaceutics, the medicine of systematic correspondence harbored as one of its central notions an idea of "evil" entering the organism from the outside or being generated inside. This "evil" could be transmitted inside the body through a complicated system of conduits and network vessels, and had to be located in order to be purged or eliminated.

The theoretical framework and the terminology of the medicine of systematic correspondence closely paralleled the basic tenets and the language of the social theory of Confucianism. Health of the individual body was achieved by the same means as harmony of the social organism, that is, by adherence to specific moral rules. Deviance resulted in illness or social disorder. Just as no enemy was believed to be able to disturb society from within or to enter from outside as long as these rules were upheld, no illness could emerge in the body or be stimulated by an intrusion from the outside as long as an individual followed a specific lifestyle.

For this reason one may call the medicine of systematic correspondence *Confucian medicine.* Confucian medicine, into which the utilization of drugs was integrated in the twelfth century C.E., was successfully challenged as the officially sanctioned healing system only with the downfall of the imperial society early in the twentieth century.

At the beginning of the Confucian era in the second century B.C.E., medical practice appears to have been in the hands of a variety of practitioners following the principles of the different known medical sciences. In addition there were practitioners, such as a mother treating her child or a neighbor, who possessed and utilized primary medical resources regarded as empirically effective. One has to keep in mind, then, that there was no group with any degree of professionalism practicing medicine in China at that time. In other words, no group of medical practitioners can be said to have been close to having control over all primary medical resources that were available in China almost two thousand years ago.

While it may readily be assumed that the motivation for some people to practice medicine was to help a family member or friend, there is no way to investigate the motives and the actual ethical bases of those persons who chose medicine over any other occupation to earn a living or to exert a social impact. Chinese texts concerned with medical ethics, however, clearly indicate that the desire for control over secondary medical resources (i.e., material and nonmaterial rewards that accrue from medical practice, such as financial wealth or social influence) was a major determinant of the way in which medicine was practiced. At the beginning of the Confucian era, medical practitioners had little control over secondary medical resources. The evaluation of their practice depended on public opinion, that is, on the satisfaction of the laity.

During the following twenty centuries, various groups attempted to reach higher levels of professionalization, that is, to increase the proportion of their control over available primary and secondary medical resources at the expense of the public. One of the important means employed to achieve this end was the appeal to medical ethics (Unschuld, 1979).

Prior to the seventh century C.E., outside of the imperial court in China, no systematic attempt to teach practitioners in medical schools or similar institutions is known. In the first half of the seventh century, the establishment of medical teaching institutions both in the capital of the empire and in the most important provincial cities was decreed. This may be interpreted as an attempt by Confucian decision makers to preserve control over medical resources for the ruling class, the gentry-bureaucracy. The founding of these medical institutions reflects a basic tenet of Confucian ethics, the prevention of the accumulation by any one group in society of control over primary and secondary resources of any kind, which might result in a shift of power and possibly a social crisis or even change.

The underlying principle of many political decisions made in Confucian China was the suppression of emerging groups that had been able to gain control over specific resources. Medical resources were obviously recognized by

Confucian decision makers as potential sources of power if accumulated and controlled by specific groups. Several political measures were undertaken to prevent the emergence of socially accepted, influential groups of practitioners. One was to emphasize the unethical character of practicing medicine for a livelihood by pointing out the evil practices employed by those doing so. It was urged that every educated man should possess sufficient medical knowledge to be able to care for his relatives. Another means was to place all extrafamilial care in the hands of civil servant physicians who were representatives of the Confucian class. Thus, it is not surprising that the education of medical officers in the seventh century was designed to supplement the common basic Confucian education. This tendency was further strengthened during later centuries.

The first noteworthy text of medical ethics appeared during the period when the first medical schools began to produce graduates. The author, a noted physician named Sun Ssu-miao (581–682?), was heavily influenced by both Buddhist and Taoist thought. Despite the fact that he was also well versed in Confucian scholarship, he refused on several occasions to accept calls to serve at the court. Sun Ssu-miao may well be called an outstanding representative of free-practicing physicians outside the Confucian group. By "free-practicing physicians" we mean those practitioners who traveled or stayed at home and treated all kinds of patients, in contradistinction to those physicians who had acquired their knowledge solely to assist family members or friends in need, or to serve as civil servants on medical assignments. The fact that Sun Ssu-miao's explicit medical ethics appeared at the same time as the establishment of the medical schools might suggest that it was a well-timed presentation designed to expound to the public the medical ethics of the group he represented.

In his voluminous medical work Ch'ien-chin fang (The Thousand Golden Prescriptions), Sun Ssu-miao chose the heading "On the Absolute Sincerity of Great Physicians" for the chapter devoted to medical ethics. The selection of the term *ta-i* (great physician) implied on the one hand that Sun Ssu-miao did not intend to speak for all medical practitioners of his time, but only for those whom he regarded as "great." It is a common characteristic of medical professionalization in East and West that at some time or other a few individuals form an elitist group that attempts to distinguish itself from the mass of its colleagues through the demonstration of its exclusive possession of superior primary medical resources. It should also be noted that Sun Ssu-miao's choice of the term *ta-i* was meant to imply that his group had a status similar to that of the most highly regarded imperial court physicians, or *t'ai-i.* The Chinese characters for these two terms are closely related in structure and meaning. Considering the low-ranking social position officially accorded to free-practicing physicians in Confucian China, the use of this title represented a bold demand for the social elevation of their elitist group of practitioners.

Sun Ssu-miao's treatise was meant to serve two purposes. First, by laying stress on the evaluation of treatment procedures rather than on the outcome of treatments, as was common at the time, he provided a measure of protection for the practitioner in instances where prognosis was unfavorable or outcome unsuccessful. The second purpose was to imply that his "great physicians" should be trusted more than was usually the case. As an introduction to his explicit medical ethics, Sun Ssu-miao provided his readers with a framework of the healing system he and other great physicians allegedly adhered to. It was based on the same theories and concepts that underlay the Confucian-supported medicine of systematic correspondence. Other writings of Sun Ssu-miao reveal, though, that he also favored demonic medicine, a healing system persistently repudiated by Confucians. In his explicit medical ethics, Sun Ssu-miao chose not to mention this aspect of his medical beliefs. He laid a great emphasis on thorough training for those who wish to practice medicine successfully and thus aspire to the title "great physician." Such tactics were important at that time, because the medical practitioners approved for governmental service were being institutionally trained in official medicine and were thus calling into question the background of free-practicing physicians.

It is characteristic of explicit medical ethics, as propounded by individuals who strive for a higher level of professionalism for their group, to incorporate the basic social values of the dominant groups in society. Therefore, Sun Ssu-miao's explicit ethics frequently stresses certain values central to Confucian and Buddhist thought, such as *jen* (humane benevolence) and *tz'u* (compassion). Furthermore, certain maxims are emphasized, for example, the obligation to maintain life and to treat human beings regardless of their status, origin, appearance, or the kind of disease they have.

Sun Ssu-miao seems to have grasped some important psychological aspects of the patient-physician relationship. He apparently realized that in order to gain the confidence of patients, and thus unlimited access to secondary medical resources, the physician must appear neutral and above normal human emotions, uncorrupted by even the most tempting worldly rewards.

One recognizes as well Sun Ssu-miao's sense of belonging to the larger group of medical practitioners when he

points out the inappropriateness of abusing physician-colleagues in public. The detrimental effects of such short-sighted behavior, directed toward individual gain, have been recognized by the best minds of the East and West as impeding group professionalization. Thus, from the very beginning of explicit ethics in medicine, elements were incorporated that seem to have little to do with the actual performance of medical treatment and may be regarded as beneficial solely to the medical practitioners.

Finally, Sun Ssu-miao touched on the problem of remuneration. Greed seems to have been one of the gravest complaints raised by the public against practicing physicians. Many statements, promulgated by Confucian interests, expressed this view. If the public were to be convinced that at least the "great physicians" did not intend to cheat their patients, then another system of equitable remuneration had to be elaborated. Sun Ssu-miao referred to a saying of Lao-tzu (604–? B.C.E.), the founder of Taoism, to the effect that good deeds would certainly be rewarded by fellow humans and that evil practices would induce retaliation from the spirits. Thus Sun Ssu-miao approached both the Confucian ideal of virtue as its own reward in the continuation of one's name or fame in posterity and the Buddhist idea of reward or retaliation through supernatural forces, in either this or a later life (if not in another world).

The history of explicit medical ethics in China in the centuries following Sun Ssu-miao very much resembles a debate among three main groups. These were the free-practicing physicians (including Buddhists, Taoists, and others) in whose interest Sun Ssu-miao had spoken, the orthodox Confucians, and a group within Confucianism consisting of ordinary scholars (and at least part-time medical officials) who practiced medicine as a paid profession.

About 150 years after Sun Ssu-miao had published his ethics, Lu Chih (754–805), a well-known scholar from the top ranks of the Confucian bureaucratic hierarchy, made some statements on medical ethics that might be regarded as a direct answer to Sun Ssu-miao. He elaborated on the idea that medical knowledge, and the ability to practice medicine, must be regarded as open to everyone. The implication is that practitioners who specialized in medicine would become superfluous. Lu Chih also chastised those who practiced medicine for living in a manner characterized by greed and evil, and noted that they did so without suffering any kind of retaliation. This observation put Sun Ssu-miao's system of retribution in question. However, Lu Chih also pointed out that those who had practiced medicine without undue concern for material gain but, rather, as an obvious consequence of their concern for humanity had been rewarded one or two generations later, through the happiness and prosperity enjoyed by their children and grandchildren. Lu Chih closed his remarks with an open critique of Taoist and magical practitioners, among whom Confucian historians counted Sun Ssu-miao. At the beginning of the thirteenth century a Confucian scholar-physician named Chang Kao published twelve short stories concerning medical ethics. While decrying the non-Confucian practitioners as "common physicians," Chang Kao recognized the need to allay the fears of orthodox Confucians, who were always suspicious of attempts to gain control over specialized resources.

In his stories, entitled "Retribution for Medical Services," Chang Kao conspicuously resorted to Buddhist concepts of reward and retaliation by forces of another world. These stories center on four major dimensions of medical ethics: greed vs. altruism; exploitation of sexual opportunities; conscientiousness in medical practice; and the problem of abortion.

The last is of special interest because other medical authors showed little concern over the practice of abortion. Relevant prescriptions are frequently provided in major collections. During the reign of the Mongol Yuan dynasty (1260–1367) an official decree prohibited unqualified women from performing abortions. Chang Kao's exceptional handling of this problem was certainly based on his adherence to Buddhist principles. The structure of his entire message seems highly psychological. In the first story, Chang Kao extolled the use of primary medical resources as an appropriate way to gain merit by giving assistance to others. In the second story, he recounted an example of very laudable behavior of a Confucian scholar-physician designed to reinforce confidence in that group. The third through the tenth stories portrayed the decay of morals and depicted examples of many "evil" practices (among them abortion) performed by physicians and others who openly practiced for money with the ulterior motive of cheating the patients. All of these characters received their proper punishment through the actions of gods, spirits, or demons. The last two stories again helped to create confidence in the group to which Chang Kao belonged.

About one century later Ko Ch'ien-sun (fl. 1348), a free-practicing physician, made an ethical statement that was somewhat different from others. In contrast to Confucian ethics, which stressed the study of literature, he emphasized the necessity of gathering clinical knowledge at the bedside as a prerequisite of the well-versed practitioner. Ko Ch'ien-sun departed even farther from official medicine in stating that the origin of his miraculously effective prescriptions rested with a supernatural being who had handed them to him and they were not, in fact, derived from concepts and theories of nature underlying Confucian medicine. Ko Ch'ien-sun is mentioned here as only one example of the vast

heterogeneity often overlooked in Chinese traditional medicine.

Most interesting in Ko Ch'ien-sun's statements was the emphasis placed on the outcome of his own practice and the paucity of details concerning his treatment procedure. His reversion to outcome evaluation and other such evidence reminds one that ethical statements found in the literature cannot be taken as representative of the medical group as a whole. It must be assumed that they represent the views of a progressive minority, where "progressive" means an intention to increase professional control over the resources available in society.

In 1522, Yü Pien wrote an interesting modification of the orthodox Confucian claim that everyone ought to possess medical knowledge. Speaking for the group of practicing physicians, he stated that not everyone needed to have medical abilities but that those who called on "common physicians" for assistance could not be regarded as showing sufficient filial piety, and added that medical knowledge was imperative for those who wished to assist their relatives. This very cautious, almost paradoxical, statement may be interpreted as an attempt to legitimize free-practicing Confucian physicians and at the same time to discourage the public from resorting to practitioners outside the Confucian sphere of influence.

New dimensions were incorporated into medical ethics by Kung Hsin, who lived around 1580, and by his son Kung T'ing-hsien (fl. 1625), both of whom had been imperial court physicians. Kung Hsin explicitly rejected patient solicitation, a practice common in China in his time and later. Patient solicitation implies that a particular physician may be better than at least some of his peers. The awareness of differences in standards of performance necessarily leads to public distrust of the group as a whole and, therefore, constitutes an obstacle to further professionalism. Only where the notion predominates that all members of the practitioner group are alike in their standards of performance will there be confidence among potential clientele.

Kung T'ing-hsien, the son, wrote short treatises entitled "Ten Maxims for Physicians" and "Ten Maxims for Patients." In the first of these he underlined the mastery of Confucian knowledge as a prerequisite for medical practice, a point his father had not explicitly mentioned. In his ethical prescriptions for patients, Kung T'ing-hsien demanded that they resort only to "enlightened physicians," willingly take their medicines, start treatment early, avoid sexual intercourse, refrain from belief in heterodox medical resources (i.e., not Confucian-sanctioned), and not worry over medical expenditures. This last point was underscored with the familiar rhetorical question "I ask you what is more valuable to you: your life or your property?"

Ch'en Shih-kung (fl. 1605) also belonged to the free-practicing group of Confucian physicians. He was the first known Chinese physician to suggest that such persons as prostitutes could be treated without risking defamation. Ch'en Shih-kung also offered his colleagues what may be the first investment counsel for physicians when he advised them to invest excess capital in real estate and not to spend money in unethical places like wine houses. His profound sense of belonging to a larger group led Ch'en Shih-kung to urge his peers not only to avoid open criticism of each other but also actively to display benevolent loyalty among themselves despite differences in training and opinion. Finally, he elaborated upon the prohibition of patient solicitation. He counseled that it was inappropriate for physicians to give extravagant presents or costly dinner invitations to other people. His remarks represent a most pragmatic view of medical ethics (Lee). The progress in professionalization that becomes evident through the claims made in explicit medical ethics reached its peak at the end of the era of imperial China. Hsü Yen-tso (fl. 1895), the last author to be cited in this regard, followed the trend when he offered advice to both physicians and patients. He held that in order for a practitioner to maintain a proper level of morality, he was obliged to treat anyone who requested help, regardless of social or financial status; to provide conscientious treatments; to show extreme sincerity; and to respond to any call as soon as possible. In a statement regarding the patient-physician relationship he reminded his colleagues that patients await the arrival of the practitioner as if he were a supernatural being, like the Buddha himself. From this perspective it is not surprising that he asked patients to place themselves entirely in the hands of the practitioners. He demanded that patients have no secrets; that they bind themselves permanently to the physician, not only temporarily in case of an emergency; and that they be isolated from their normal social environment during treatment. The last stricture was possibly meant to prevent discussion of the case and the treatment provided, and had the effect of precluding criticism or interference from outsiders. Thus, at the end of the era of Confucianism, control by a specialized group over medical resources had progressed to a stage incompatible with the original Confucian maxims.

III. CHINA. B. CONTEMPORARY CHINA

Republican Period (1912–1949)

In January 1912, after decades of social upheaval and a failed struggle to achieve a constitutional government, the Qing dynasty, which had ruled China since 1644, collapsed and the Republic of China was inaugurated, with Sun Yat-sen (1866–1925) as its first president. Although the Republic was enmeshed in constant political and social turmoil, a strong movement of visionary intellectuals pressed for the modernization of Chinese life in all its aspects. While many reformers called for the wholesale abolition of Chinese culture and customs, others sought to blend Western political forms and scientific technology with what they saw as "the essence of Chinese culture." The Chinese attitude toward medicine during most of the twentieth century has been formed by these conflicts.

Western medicine had achieved recognition, principally among the elite but to some extent in the general population, during the latter decades of the nineteenth and first years of the twentieth centuries, largely due to the influence of Christian missionary physicians and nurses, and the hospitals they maintained. The effectiveness of the Northern Manchuria Plague Prevention Service, organized along Western lines to combat the 1910–1911 epidemic of pneumonic plague in Manchuria, heightened the prestige of Western medicine, particularly in its preventive and public-health aspects. (It was on the occasion of this epidemic that two practices abhorrent to Confucian morality, cremation and autopsy, were permitted by imperial edict.) This service was the first, and the prototype, public-health service in China (Wu). Peking Union Medical College, founded in 1915 with support from the Rockefeller Foundation, became the center of medical science and education in the Western mode. Although only a tiny segment of China's doctors practiced Western medicine, they attained positions of influence in government, education, and circles of intellectual reform. In 1914, Minister of Education Wang Daxie told a delegation of traditional physicians, "I have decided to abolish Chinese medicine" (Croizier, p. 69). In the next few decades, eighty-nine Western-style medical schools were established, and thousands of Western-trained students graduated. Although this development was frequently interrupted by wars and civil unrest, the values of modern medicine gradually took root in the Chinese soil, where they grew in uneasy association with traditional values.

The abolition of traditional medicine, however, much desired by reformers and government, was not a simple matter. Three times the Republican central government attempted to abandon traditional medicine and prohibit its practice, but each time it met with strong resistance. In 1913, the central government promulgated regulations that excluded the teaching of traditional medicine from the curriculum. In reaction, some intellectuals insisted that traditional medicine could be made more scientific and even integrated with Western medicine. They also noted that

traditional doctors were likely to be the only sources of care for most people for many years to come. In 1929 Yu Yan, a physician and an official of the Ministry of Health, outlined administrative measures to curb and eventually abolish the practice of traditional medicine: traditional doctors were to be reeducated and were not allowed to organize schools or to advertise. Traditional doctors responded by organizing the first national association, the Institute for National Medicine (1931), with the goal of protecting and promoting traditional medicine. Even this group, however, affirmed that traditional medicine must be made more scientific, advocating research on the pharmacological basis of the thousands of drugs used in Chinese medicine.

Nevertheless, during the 1930s almost all Western-trained physicians refused to compromise and adamantly rejected traditional medicine. Westernizing authors, physicians and nonphysicians alike, argued that traditional medicine was unscientific, as different from Western medicine as astrology from astronomy, geomancy from geometry, alchemy from chemistry. Efforts to make traditional medicine more scientific or to ally the philosophical views of traditional medicine to the scientific principles of modern medicine were repudiated as nothing more than another example of the reactionary conservativism that had harnessed Chinese life for centuries. Such proposals were called "ignorant, nonsensical, blind, babbling." In the harsh words of one prominent physician, "Why should modern medicine accept this marriage proposal from such a lazy, stupid wife with bound feet wrapped in yards of smelly bandages?" (Croizier, p. 107). In 1933, the president of the Executive Department of the central government, Wang Jingwei, declared any discussion of yin yang or the five elements without anatomical dissection scientifically untenable, and the therapeutic efficacy of unanalyzed drugs doubtful. With his support, licensing authority over all physicians, Western or traditional, was located in the modernized Ministry of Health, thus holding traditional practitioners to standards they could hardly meet. Even so, attempts to abolish the practice of traditional medicine failed in the end. In 1949, 65 percent of all physicians practiced traditional medicine. The uneasy relationship between Western and traditional medicine would continue into the era of the People's Republic.

MEDICAL ETHICS. *Ethics of Medical Practice* (1933), by the Western-trained physician Song Guo-Bin (1893–1956), might be called the first modern book on Chinese medical ethics. The author sought to integrate Western medical ethics with traditional ethics drawn from Confucianism. Ethics is the *tao*—path or way and, by extension, principle or reality—of practicing medicine, and is constituted by the Confucian concepts of humaneness and righteousness. Song defined humaneness as the Western concept of fraternity, and righteousness as what is appropriately done in compliance with humaneness. Physicians should have a spirit of love for people and a zeal to do good. The principle of humaneness requires physicians to treat poor patients at no charge when necessary; the principle of righteousness requires physicians to be competent, not to do harm, not to take advantage of the patient's vulnerability for their own benefit, not to experiment uselessly, and not to practice favoritism. On the moral character of physicians, Song followed his predecessors, emphasizing the right ordering of one's thoughts and feelings and the right ordering of one's world: the physician who is not ordered in body and spirit can hardly order the body and spirit of his patient. The physician should have the virtues of diligence, devotion, warmheartedness, and dignity. The responsibility of the physician to the patient is to treat disease, promote health, and relieve suffering. Song was the first Chinese medical ethicist to argue systematically for the obligation of confidentiality, although he recognized that this obligation is not unconditional. The patient's consent to disclosure, possible harm to others, or the legitimate needs of criminal justice release the physician from confidentiality. Among colleagues, physicians should respect self and others, and should maintain a friendly feeling and a modest attitude. The obligation of the physician to the state and society is prevention of disease and death, applying remedial measures, research on the cause of death, and the support of public charities. Song rejected contraception and abortion as immoral. Although Song's volume was known principally within the academic world, it was acknowledged as the standard statement of ethics for modern Chinese medicine. In contrast to Song's ethical idealism, the life of the woman physician Yang Chongrui (1891–1956) represents ethics in practice. After graduating from Peking Union Medical College in 1917, she went to the countryside as one of the first Chinese physicians to bring modern medicine to the peasants, in accord with her personal maxim, "Sacrifice in order to benefit the people." She established the first school of midwifery in China and, at the end of her life, was chief of the Bureau of Maternal and Child Health. She is one of the heroines of Chinese medicine and is often cited as the ideal physician.

People's Republic Period (1949–)

On October 1, 1949, the People's Republic of China came into being, a "people's democratic dictatorship" based on Marxist principles as interpreted for China by Mao Zedong. This event marked a radical break with Chinese tradition, which, based on Confucianism, had long been in decline

and was considered by the new rulers to be incompatible with progress in a revolutionary society. Medicine and healthcare were to be thoroughly modernized, first on the Soviet model and later in harmony with indigenous practices. Medical ethics was to be reformulated to serve politico-ideological work performed by healthcare providers.

The availability of healthcare to the whole Chinese population was a major goal of the People's Republic, and remarkable successes were achieved, given the resources available. From the beginning, Chairman Mao took a personal interest in policies that would improve personal and public health. Statistics for life expectancy for the population as a whole and for newborns in particular were greatly improved over those of other Third World countries, and approached the statistics of developed countries. Many endemic infectious diseases, such as cholera, smallpox, and plague, as well as many nutritional diseases, were brought under control.

HEALTHCARE IN RURAL AREAS. The first national conference on healthcare was held in August 1950. Policies that would govern healthcare were announced: they were designed to respond to the needs of workers, peasants, and soldiers; to emphasize prevention; to effect cooperation between Western and traditional medicine. Soon thereafter, the policy of mass movements was added, that is, highly organized and rapid campaigns to eradicate filth and pests and to instill habits of good health and exercise. For the first time in Chinese history, affordable and competent healthcare became available to millions of laboring people and peasants.

In June 1964, Mao Zedong issued "Instruction on Putting Stress on the Rural Areas in Health Care," in which he criticized the existing healthcare system for its elitist and urban orientation. Urban practitioners, even scientific researchers, were sent to the countryside to practice and to train the public-health workers known popularly as "barefoot doctors." The implementation of this instruction did much to promote healthcare in the rural areas; nevertheless, at the end of the twentieth century, much remains to be done and, indeed, some deterioration has occurred. At the same time, these policies were detrimental to medical education and to scientific advances in medicine and healthcare.

TRADITIONAL AND MODERN MEDICINE. In the early years of the People's Republic, Marxist thought clearly favored modern scientific medicine and labeled traditional medicine as reactionary. Western medicine, however, was viewed as capitalist and imperialist. A realistic assessment of the need for healthcare made it clear that all available resources, including traditional medicine, had to be engaged in the vast work of bringing care to the masses. Mao Zedong issued "An Instruction on the Work of Traditional Chinese Medicine" (1954) ordering the integration of traditional and Western medicine into a unified new medicine. In research, education, and care, efforts were made to bring these two forms of medicine together. In *united clinics,* both sorts of practice were encouraged, Western-trained physicians were required to study traditional techniques, and many large hospitals had sections for Western and for traditional treatment. A document of 1958 stated, "The objective is … a new type of doctor, versed in both Chinese and Western medicines, and one who has acquired communist consciousness under the leadership of the Party committees" (Croizier, p. 185). The ancient practice of acupuncture, for example, was applied to surgical anaesthesia. Reports of this experiment stimulated great interest in acupuncture throughout the world (Risse).

Official policy now favors the coexistence and competition between traditional Chinese medicine and modern or Western medicine, and the integration of these two into a new medicine (Qiu, 1982). Now the debate focuses on whether traditional medicine should be taught in its pure form, which would make it difficult to attract young people, or whether it should be modernized, leaving an uncertainty about what it would then offer. By 1987, the number of traditional physicians had declined to 279,000, while the number of modern physicians had risen to 1,132,000, 80 percent of all physicians. A 1986 survey showed that only 7 percent of respondents depended exclusively on traditional physicians.

HUMAN EXPERIMENTATION. Traditional medicine had no place for human experimentation in the modern sense; research came to China with Western medicine. In the 1950s, the government revealed that during the 1930s and 1940s, some foreign and Chinese physicians at Peking Union Medical College had used poor patients as experimental subjects without their informed consent. One such experiment, done by the American physician Richard Lyman in 1936, involved filming drug-induced seizures of healthy rickshaw drivers, who had been paid the equivalent of two U.S. dollars. This film was shown publicly with sensational effect during the "Ideological Transformation" of 1951–1952 and again during the Cultural Revolution. Since that revelation, many health officials and members of the public have been hostile to human experimentation. As a result, some insufficiently developed or inefficacious therapies became widely available without adequate human testing. In the 1950s, for example, during the movement known as "Learning from the Soviet Union," Vladimir Filatov's tissue therapy, in which human or animal tissues were inserted under the skin as a "biogen" for the cure of a great variety of diseases, was widely used with some fatal results. At the same

time, some medical researchers used themselves as subjects for herbal medicines or new drugs and died of poisoning. After 1980, the method of clinical pharmacological trials was introduced into China, together with the principle of informed consent. Institutional review boards to provide oversight began to be set up at the request of foreign groups sponsoring research in China, although as of 1993 there is no universal governmental regulation of research.

MEDICAL ETHICS. During the early years of the People's Republic, Mao Zedong's writings were required reading for every Chinese. In the field of healthcare all medical personnel were required to read his essays "In Memory of Dr. Norman Bethune" and "Serve the People," in which Chairman Mao urged the people to cultivate their moral character in terms of the values of life and death. When one died for the people, he argued, it was a worthy death, weightier than Tai Mountain; otherwise, it was lighter than a feather of the wild goose, as Chinese ancient historian Sima Qian put it. Mao held up as an exemplar for healthcare workers the Canadian physician Norman Bethune (1888–1939), who dedicated himself to the care of Chinese soldiers and civilians during Japan's war against China (1937–1945), praising him as a virtuous person, selflessly committed to those in need, conscientious in his work, warmhearted toward all people, and continually improving his skills. The essay on Bethune was viewed as an incomparable formulation of medical ethics during the Maoist era. Contemporary Chinese bioethics can be dated from 1979, when a conference on the philosophy of medicine, sponsored by the Chinese Society for Dialectics of Nature and the China Association of Science and Technology, was held in Guangzhou. Philosophers, physicians, and health administrators who attended this conference focused on two issues in medical ethics: the concept of death and the justifiability of euthanasia, and the delivery of healthcare without discrimination. The latter problem arose because the Cultural Revolution's emphasis on serving workers, peasants, and soldiers led to discrimination in healthcare services against persons labeled *capitalists* and *bourgeois reactionaries,* and to deaths of well-known persons as the result of negligence (Cai).

Until the 1980s, the discussion of medical ethics was confined to academic circles, specialized journals, and conferences on philosophy of medicine. Two journals, *Medicine and Philosophy* and *Chinese Journal of Medical Ethics,* appeared in the early years of the decade. In 1986 and 1987, however, two legal cases, one on active euthanasia and the other on artificial insemination by donor (AID), drew the attention of lawyers, journalists, policymakers, legislators, and the general public. The first two National Conferences on Philosophy of Medicine and Medical Ethics, devoted to social, ethical, and legal issues in euthanasia and in reproductive technology, were held in July and November 1988. The Chinese Society for Medical Ethics was established in 1988 and affiliated with the Chinese Medical Association. During the decade, most medical universities and colleges, as well as nursing schools, instituted required or elective courses on medical ethics. The curriculum includes study of the moral tradition, medicine in society, the patient-physician relationship, euthanasia, genetics, experimentation, reproduction, and health policy. Dozens of books on medical ethics were published, including Zhi-Zeng Du's *An Outline of Medical Ethics* (1985) and Ren-Zong Qiu's *Bioethics* (1987). Teachers of medical ethics, drawn from philosophy and medicine faculties, were trained in doctoral and master's programs and in special workshops.

DEATH AND EUTHANASIA. During the Cultural Revolution, the concept of brain death was criticized as "bourgeois, capitalist and reactionary," created by "Western doctors … to unscrupulously open up a source for organ transplantation" (Jiang et al., p. 225). In fact, the problem of brain death arose not so much because or organ transplantation, which is not widespread in China, but because respiratory support was increasingly being employed for terminally ill persons. This was considered both futile for the individual and wasteful of health resources. At the 1988 conference on euthanasia, all participants, including physicians, ethicists, and lawyers, endorsed the concept of brain death, following guidelines widely accepted in Western countries, such as the Harvard criteria (Qiu, 1982). As of 1993, however, no administrative or legislative rules legalize the definition of death by brain criteria. As modern techniques for life support, such as ventilation, dialysis, and artificial nutrition, have become more common, particularly in urban hospitals, the problem of their appropriate ethical use has been noted. Academic discussion of euthanasia has centered on how it might be identified as a special modality of death differentiated from natural death, accidental death, suicide, murder, and manslaughter. Ancient Chinese physicians were aware of the limits of medicine and asserted that when disease attacks the vital organs, it is beyond cure. Passive euthanasia for the terminally ill, long a part of traditional Chinese medicine, has been extended without qualm to the irreversibly comatose, seriously defective newborns, and very-low-birth-weight infants. At the 1988 conference, ethicists argued for the justifiability of euthanasia on the basis of the principles of beneficence, respect for autonomy, and justice. In the resolution passed at the conference, participants endorsed the right of terminally ill persons to choose the way of dying and encouraged the use of living wills. These principles and practices, while borrowed from U.S. bioethics,

are compatible with the Confucian concept of *humaneness.* Other deeply embedded Chinese attitudes influence thought on this subject. For example, euthanasia for the defective newborn is rendered more acceptable in view of Buddhist beliefs that such an infant must have failed in virtue in a previous life, while Confucian filial piety often causes reluctance to allow one's parents and the elderly to die (Qiu, 1980).

Active euthanasia, however, remains a subject of debate. In 1986, in Hanzhong, Shaanxi Province, two children of a comatose woman suffering from liver cirrhosis asked physicians to end her life by an overdose of morphine, without informing their siblings. The legal case brought against them evoked widespread media discussion. After their conviction on murder charges, they appealed to the Supreme Court, which in 1991 ruled that the defendants were not guilty since the harm to the decedent was minor in view of her inevitable death. Several surveys in 1986 and 1988 showed that the majority of respondents accept passive euthanasia, and even active euthanasia in certain circumstances.

REPRODUCTIVE TECHNOLOGY. Under the influence of the Confucian view of the importance of having a male successor to carry on the ancestors' lineage, infertile couples experience heavy psychological and moral pressure. In a traditional family, the woman is often blamed for the infertility of the couple and stigmatized or abused. Eagerness for offspring is stimulating the development of reproductive technology that replaces the traditional customs of "wife borrowing" and, among the wealthy, concubinage. At the 1988 conference on social, ethical, and legal issues in reproductive technology, artificial insemination by husband (AIH) and by donor (AID) were asserted to be widely practiced among the population. Sperm banks existed in eleven provinces, most of them without procedures to address ethical and legal issues. Except for a few centers in large cities, AID is undertaken without policies relating to the selection of donors and recipients, and the legal status of the child remains unresolved. The clash of traditional values and modern society was manifested in the first legal case involving reproductive technology, in which a Shanghai family refused to accept a baby boy conceived by donor sperm. In some clinics, prenatal sex selection has been practiced. The participants in the 1988 conference argued against it on the grounds that it could worsen the sex imbalance and cause negative social consequences. In the following year, the Ministry of Health prohibited the practice. In vitro fertilization (IVF) is limited to a few centers.

FAMILY PLANNING. In the early years of the People's Republic, China's enormous population and its prospect for continuous growth were recognized as a serious threat to all the social and economic gains expected from the modernization. During the 1950s, limitations on childbirth were encouraged by mass propaganda and contraceptive education. In 1980 the government announced an official policy of "one couple, one child" (the census of 1982 showed China's population had surpassed 1 billion people). This policy has caused thorny ethical problems. Although there is widespread agreement that control of population growth and limitation of reproductive freedom are ethically justifiable in view of China's vast and growing population, argument continues over whether "one couple, one child" is the best policy and over the means employed to implement it. Not only does it conflict with the traditional value that associates more children with better fortune; it also imposes significant hardships on families in rural areas, where labor needs and the care of elderly parents require several children. A 1979 survey by the Chinese Society of Sociology found that a majority of peasants in the villages near cities want two or more children, whereas the majority of respondents in cities are satisfied with one child. The one-child policy is implemented by intensive contraceptive education, by economic incentives and penalties, by sterilization (sometimes compulsory), and by abortion (sometimes coerced). Although population-control programs are officially designed as programs of incentives, education, and persuasion, the line between persuasion and coercion is not always clear, and the efforts of zealous officials in some places have clearly crossed the line. Again, the policy is most burdensome on dwellers in rural areas, where contraceptive services are often inadequate and local officials, under pressure from above, may employ abusive means. In recent years, reports of compulsory sterilization and coerced abortion have convinced certain international agencies and foreign governments to withhold financial support for population-control efforts in China.

Traditionally abortion has not been seen as a serious ethical issue in China. Most Chinese would agree with the ancient sage, Xun Kuang (286–238 B.C.E.), who argued that human life begins at birth; abortion (and contraception) were rarely discussed in pretwentieth-century medical literature, even in treatises on gynecology. Today, however, repeated and late abortions do arouse concern among healthcare workers and ethicists. Unmarried women who become pregnant often seek a late abortion. Late abortion puts physicians in a dilemma, since it involves a conflict between obligation to the health of the patient, due to the dangers of late abortion, and obligation to the society to limit births. Finally, the socially imposed limits on reproduction and the desire for male offspring have encouraged some, especially in rural areas, to revive the ancient practice of female infanticide. This practice, long judged immoral by

many commentators, such as the great philosopher Han Fei (third century B.C.E.), has always been abetted by the widespread and deep poverty of the peasants, for whom a girl child was a burden rather than a benefit. Condemned as criminal by the Law Protecting Women's Rights passed by the National People's Congress in 1992, this practice remains difficult to detect and to prosecute.

REFORM OF THE HEALTHCARE SYSTEM. Since the founding of the People's Republic in 1949, the healthcare system of China has consisted of four main components: workers' healthcare in state-owned factories or institutions; public medical service; free preventive immunization; and rural cooperative medical service. In all but the free preventive service, the costs of care are funded by the government, by employer/cooperative contributions, and by a small registration fee (typically less than the equivalent of ten cents per visit, although the fee can be graduated up to about one dollar if the patient wishes to see a professor in an academic hospital). The self- or privately employed must pay the full cost of their care. These programs have extended healthcare far more widely than ever before in China's history and have significantly improved the health of the population. Throughout most of China, patients have access to well-organized health services, provided by many levels of professionals at little cost.

Despite such progress, however, programs have faced major problems: the demand for treatment always exceeds the supply; ordinary people often receive less adequate care than officials; and almost all hospitals suffer large deficits, making renovation and replacement of equipment impossible. Since the implementation of a 1980 policy to dismantle the cooperative farms, the rural medical services have deteriorated and, in some poor rural areas, health care is not accessible to villagers. The government's most recent efforts to reform the healthcare system involve implementing the contract system that has proven successful in agriculture. In this way, hospitals can supplement their government budget by increasing fees for registration, tests, and drugs, after approval from the local Bureau for Prices. A portion of these increases will be paid by the patient and the remainder by the factories and institutions for which they work. Since 1988, economists, ethicists, health administrators, and officials of the Ministry of Health have argued over whether it is ethically justifiable to consider healthcare a market commodity.

PROFESSIONAL ETHICS CODE. In December 1988, the Ministry of Health promulgated an ethics code for medical personnel that consists of seven articles: (1) rescue the dying and heal the injured, carry out socialist humanitarianism, always keep the patient's interest in mind, treat disease and relieve suffering by every possible means; (2) respect the patient's person and rights, treat patients as equals without discrimination on the basis of nationality, sex, position, social status, and financial situation; (3) serve patients conscientiously and politely, deport oneself in a dignified manner, speak to patients in a refined manner, be amiable, care for patients with compassion, concern, and solicitude; (4) be honest in performing one's duties, conscientiously observe discipline and law, do not serve selfish interests with medicine; (5) maintain confidentiality for patients, saying nothing that would harm the patient or reveal the patient's secrets; (6) deal properly with the relationship between colleagues and coworkers, learning from each other and holding each other in respect; (7) be rigorous and dependable in work, vigorous in spirit and eager to make progress, endeavor to improve professional proficiency, continuously renew knowledge, and increase technical competence.

This is the first code of ethics promulgated in the People's Republic of China, although the Chinese Medical Association had published a very brief seven-article "Doctor's Creed" in 1937 (Wang). While the new code is quite similar to medical codes around the world, it should be noted that "respect for the patient's person and rights" does not directly translate into the Western concepts of autonomy and informed consent. While it is now much more common to inform patients fully and to allow them to choose the course of therapy, older paternalistic practices, such as refraining from telling patients their diagnosis and depending on families and even work units for decisions about a patient's care, still prevail. In China, "informed consent with the aid of family and community" might more accurately express the ethical standard.

COMPULSORY STERILIZATION OF THE MENTALLY RETARDED. A regulation for compulsory sterilization of the severely mentally retarded, promulgated in Gansu Province in 1988, specified that mentally retarded persons are to be sterilized when (1) retardation is caused by familial genetic factors, inbreeding, or other congenital factors; (2) the IQ is below 49; and (3) there is behavioral disability in language, memory, orientation, and thinking. Persons who meet these criteria are permitted to marry only after they have been sterilized. Women who meet the criteria and are pregnant must undergo abortion and be sterilized (Lei et al.). Other provinces, following Gansu's lead, drafted similar regulations on compulsory sterilization, while others were more cautious, incorporating sterilization into their comprehensive regulations on family planning. Proponents of such regulation argue that the proportion of mentally retarded

persons in the population is too high, that the burden to support them is too heavy, and that the heavy burden has seriously impeded social development and will influence future generations.

At a 1992 national workshop on ethical and legal issues in limiting procreation, participants pointed out that genetic factors play only a minor role in the epidemiology of mental retardation and that data on the incidence, prevalence, and etiology of the mentally retarded population are of variable reliability and subject to widely differing interpretations. Conference participants argued that if the goal is to reduce the mentally retarded population, only those whose mental retardation is known to be caused by genetic factors should be selected for sterilization—a policy requiring an adequate number of medical geneticists to perform genetic tests and identify the causal factors of mental retardation. The effort to reduce the incidence of mental retardation should focus on improving perinatal care and maternal and child care, developing prenatal diagnosis and genetic counseling, preventing inbreeding, and implementing programs of community development. When sterilization is recommended, it should be in the best interest of the retarded person, as a contraceptive measure that reduces personal misfortune; proxy consent should be obtained. Also, it was argued that the relatively high proportion of mentally retarded persons is not a cause of economic underdevelopment, but an effect of it. From the legal perspective, compulsory sterilization infringes upon some civil rights laid down in the Constitution and other Chinese laws, such as the right to inviolability of the person and the right to guardianship for the incompetent. The considerations raised by the 1992 workshop were delivered to the government and apparently have impeded the expansion of compulsory laws. However, existing laws have not been repealed or revised, and there is no strong public protest against them.

CONTROLLING THE SPREAD OF SEXUALLY TRANSMITTED DISEASES. As a result of a major health campaign in the early years of the People's Republic, the incidence of sexually transmitted diseases in the Chinese population was drastically reduced through a combination of medical, educational, and social policies (sometimes quite harsh, particularly against prostitutes). After three decades of dormancy, sexually transmitted diseases (STD) began to rise in the 1980s: from 1980 to 1992, some 700,000 cases of STD were reported (the actual number is probably much higher), including about 1,000 persons who have tested positive for infection with human immunodeficiency virus (HIV). Countermeasures have been taken in recent years to check the epidemic of STD, and several laws, ranging from management and surveillance to prohibition of drug trafficking and prostitution, have been enacted. However, programs for controlling STD are inhibited by several factors. One is the revival of an ancient concept in which disease is seen as punishment for misbehavior instead of being caused by a particular microorganism. Sexually transmitted disease is sometimes called "Heaven's punishment for moral deterioration." The Chinese National Expert Committee on acquired immunodeficiency syndrome (AIDS) attempts to counter this view in "An Open Letter to Medical Care Workers," asserting, "The disease is not the punishment to an individual, but a common enemy to the whole of mankind.… Every medical-care worker ought to be full of love in the heart, and help our compatriots who are threatened by AIDS with our hands and knowledge" (National Expert Committee, p. 1). The second factor is discrimination against patients and infringement upon their individual rights. HIV-positive persons have been expelled from their jobs or schools; AIDS patients have been refused admission to hospitals. Many medical workers have expressed reluctance to care for AIDS patients. A Health Department requirement that doctors fill out an STD patient card and send it to the public health office drives patients away from care, sacrificing the opportunity for education and treatment. The third factor is the lack of legitimate and effective policy to change at-risk behavior such as drug use, prostitution, and unsafe sexual behavior. In 1992, some cities set up hot lines to provide counseling and to protect patients' rights to confidentiality and privacy.

Conclusion

Since the new policy of reform and openness initiated at the end of the 1970s, China has been undergoing yet another fundamental change. Marxism faces challenges from internal pressures and from Western ideas and economics. Confucianism is still deeply engraved in the Chinese mind, but Buddhism, Taoism, Islam, and Christianity are experiencing a revival. Tension and conflict are inevitable as diverse and often incompatible values come to the fore at this historical juncture. Many fields, including medicine, face new challenges, and in this environment the field of medical ethics is flourishing as never before in China. As in many other nations, scholars have delved into problems, published articles, initiated courses, and formed organizations devoted to bioethics.

The word *ethics* is now translated into Chinese as *lun li,* two characters signifying "hierarchical human relationships" and "principle" or "pattern." Combined, these two characters designate guidelines for interpersonal relationships. In

Chinese thought, ethics, or the guide for interpersonal relationships, blends with the laws that govern the universe. Thus, traditional Chinese philosophy, particularly Confucian, has a predilection for ethics, teaching how to be human within an orderly human community. In the last two centuries, Western influence in ideas and commodities has introduced an individualism not native to Chinese thought. Since the late nineteenth century, Chinese scholars have studied Western science and philosophy, with a particular interest in philosophical pragmatism. Marxist philosophy pays relatively little attention to ethics as such, since ethics is considered to be formulated by political ideology. Despite Western and Marxist influence, traditional Chinese ethics still weighs powerfully in the Chinese mind and in Chinese society.

The current interest in bioethics in China has been stimulated and influenced by American bioethics. Several leaders in Chinese bioethics are familiar with the American literature and participate in international bioethics activities. Also, since Western scientific medicine has long prevailed in China, Western ethical concerns are readily recognized, particularly as medical technologies are diffused. Thus, the principles of American bioethics—beneficence, nonmaleficence, autonomy, and justice—are frequently cited in Chinese discussions. However, these principles are not simply foreign imports: they correspond to significant Chinese values. Beneficence corresponds to the paramount Confucian virtue, *ren,* translated "benevolence" or "humaneness," which traditional Chinese medicine proposed as the primary virtue of the physician. It requires compassion and help for the sick, and the duty to avoid harm, as well as the obligation to care for the poor without charge (Qiu, 1988). Respect for autonomy, while not a traditional virtue in Chinese thought or medicine, which was strongly paternalistic, does correspond to the aspirations for personal freedom and social emancipation that marked the powerful current of modernization, sometimes known as the May 14th Movement, that began in the early twentieth century and continues to influence Chinese intellectuals (Spence, 1982). While not encouraged in the culture of the People's Republic, personal autonomy plays a real, if limited, part in modern thought about bioethical issues. Finally, justice in healthcare corresponds to the socialist ideal that a healthcare system accessible to all persons, regardless of social class or economic status, is best realized by a centrally controlled, nonentrepreneurial service system (Sidel and Sidel). This ideal prompted the vast extension of health services in the 1950s and inspires debates over contemporary plans to reorganize those services. Thus, while Chinese bioethics may occasionally speak in terms similar to Western bioethics, its spirit and ideas are properly Chinese: it is a blend of traditional, modern, and socialist Chinese thought, created in the unique conditions of an evolving great nation.

IV. JAPAN. A. JAPAN THROUGH THE NINETEENTH CENTURY

The following is a revision of the first-edition articles on (1) the same subject by the same author, and (2) "Traditional Professional Ethics in Japanese Medicine" by Takemi Taro. Portions of the first-edition articles appear in the revised article.

The history of Japanese medical ethics must be seen in the context of the stratified development of Japanese culture. In each of the four layers discussed here, particular attention will be paid to medicine and ethics and the ways they were constituted with respect to changes in law, religion, custom, tradition, and social and political institutions.

Early Japan

The earliest layer of Japanese cultural stratification is the magico-religious universe of the ancient Japanese people, which persisted in subsequent periods (often submerged under later cultural layers and foreign traditions). From archaeological evidence, early mythic narratives, and poetry, we surmise that the ancient Japanese worldview was based on a mythic mode of apprehending the origin and nature of human beings, *kami* (usually translated as "deities"), the world, and the cosmos. This indigenous Japanese religion was later called Shintō or the "way of the *kami.*" Early Shintō understood life to be essentially good and beautiful; evil was simply that which was unclean, ill omened, or inferior. Even the term *tsumi* (often translated as "sin") meant defilement or lack of beauty—for example, sickness, disaster, and error, all due to the influence of evil spirits and removable by ablution and lustration. The early Japanese believed that there were numerous *kami* and *mono* ("spirits," especially those of the fox, snake, badger, and other animals), which could possess humans and cause sickness. As a result, people

depended on diviners, shamans, healers, and magicians to deal with physical and mental problems, to prevent disasters or sicknesses, and to avoid pollution. For example, early writings refer to medicinal fruits and plants as well as to common practices to avoid pollution, such as avoiding contact with sick people, menstruating women, and death. The early Japanese resorted to herbal infusions, hot-spring baths, frequent bathing, or gargling for prevention and healing. These practices are mentioned in the eighth-century *Kojiki*, a compilation of Japanese mythology, and even in fourth-century Chinese chronicles that describe Japan.

Socially, early Japan was organized by *uji* (a lineage group often translated as "clan"); the Yamato kingdom, an old designation for Japan, which emerged around the third or fourth century, was in effect a confederation of semiautonomous *uji*-groups under the nominal political authority of the chieftain of the leading *uji,* later known as the imperial household.

The Ritsuryo System

In the wake of the political changes on the Asian continent in the sixth and seventh centuries, Japan acquired a second cultural layer, with the heavy influx of Chinese civilization through Sinified Korea, including Confucianism, Taoism, and the Yin-Yang school, as well as law, medicine, philosophy, ethics, and various sciences and technologies and Buddhism. Stimulated by the unification of China, Japanese leaders made a serious attempt to unify Japanese culture and society. The Ritsuryo system—an important and early synthesis of religious, cultural, social, and political ideas—is the concrete embodiment of this second layer of Japanese culture. Its basic principles, especially the doctrine of the mutual interdependence of Shintō-, Confucian-, and Taoist-inspired imperial ideology and Buddhism, survived until the sixteenth century. Thanks to the emerging synthetic cultural matrix, the Japanese learned that it was possible to apprehend a universal structure governing the world of nature and the human body. Especially noteworthy was the popularization of an East Asian tradition of medicine much later called *kampō-i,* or "Chinese-style medicine." As early as 602, a prominent Korean Buddhist monk, Kwalluk, brought to Japan a series of books on diverse subjects, including astronomy, medicine, and magic. From that time on, with active support from the Yamato court, Chinese medicine was spread rapidly throughout Japan by émigré Korean and Chinese physicians, pharmacologists, and Buddhist priests, who utilized their medical knowledge for healing as a part of their religious activities. Many Japanese physicians were especially attracted by the medical theories of the Chinese scholar Sun Ssu-mo (581–682?).

In the main, Chinese medicine combined an emphasis on the prevention and healing of disease with a concern for *ethical behavior,* in the belief that the body is not an individual's own possession but a gift from one's parents, and that one's health depends on the harmonious interaction of the negative (*yin*) and the positive (*yang*) principles. Thus it was one's filial duty to maintain one's health by maintaining harmony with the environment, inasmuch as sickness was believed to arise from imbalance at the physiological, psychological, or cosmological level. Chinese medicine also encouraged acupuncture (*hari*), massage (*amma*), moxa treatments (*akyu* or moxibustion, the application of plants as counterirritants, set on key acupuncture points and burned slowly), and herbal medicine. Chinese medicine did not stress anatomical studies and surgery, largely because of the Confucian emphasis on the sacredness of the human body.

Significantly, Buddhist leaders in Japan affirmed that what one learned from the Chinese medical-ethical tradition was in complete harmony with the fundamental Buddhist principle of compassion. In keeping with this principle, when Prince Regent Shōtoku (573–621) built a temple in what is today Osaka, he provided an asylum, a hospital, and a dispensary on the temple grounds. Following his example, pious monarchs and aristocrats sponsored medical and philanthropic works. Buddhism introduced to Japan not only the savior deity Amida (Amitâbha), and the bodhisattva of great compassion, Kannon (Avalokitesvara), but also the Buddha of Healing, Yakushi-nyorai (Bhaisajya-guru). The Chinese-inspired Taihō Code, promulgated in 702, stipulated the establishment of a Ministry of Health, to be staffed by ten physicians, who were massage specialists, herbalists, and magicians. Judging from the records of the imperial storehouse, the Shōsō-in, built in the mid-eighth century in the capital city of Nara, the Yamato court imported a variety of continental herbal medicines. Another subdivision of the government, the Onmyō-ryo ("*Yin-Yang* bureau") was staffed by specialists in divination, astrology, and calendar making; its main task was to combine magico-religious features (e.g., geomancy, divination techniques, fortune-telling, and exorcism) and the semiscientific art of observing planetary movements.

During the seventh and eighth centuries the imperial government supported the officially sanctioned Buddhist schools but also strictly controlled the activities of their clerics by enforcing the Sōni-ryo ("law governing monks and nuns"). The government also made a serious effort to (1) discourage the popularity of the unauthorized Buddhist clerics—the rustic shamans, magicians, and healers who came under the nominal influence of Buddhism and wandered from village to village, offering divination, magic and healing; and (2) confine legitimate monks and nuns to

monastic quarters, keeping them from exercising black magic and practicing medicine. On both accounts, the government failed miserably. The unauthorized clerics, called *ubasoku,* continued their preaching, philanthropic, magical, and healing activities among the lower strata of society, which were all too often ignored by official Buddhist schools. On the other hand, some of the officially sanctioned Buddhist monks, notably Genbō (d. 746) and Dōkyō (d. 772), were reputed to have miraculous healing and incantational powers, and they wielded great influence in court circles.

During the Heian period (781–1191), two new Buddhist schools, Tendai and Shingon, were introduced from China, bringing with them new forms of magic, incantations, and cosmological speculation, all of which greatly facilitated the blending of indigenous Japanese (Shintō), Chinese, and Buddhist traditions. Similar eclectic tendencies appeared in medicine and ethics, as exemplified by the thirty-volume medical work *Ishimpo,* compiled in 984 by Tanba Yasuyori. This work integrated native Japanese insights into the T'ang Chinese medical framework and coupled this with ethical exhortations. From the Heian period on, the term *kampō-i* ("Chinese-style medicine") was used in Japan to refer to this hybrid system comprising Buddhist, Confucian, *Yin-Yang,* and Japanese beliefs and practices, and covering a wide range of subjects: acupuncture, herbalism, moxibustion, massage, cures for the diseases of various internal organs, nutrition, dermatology, hygiene, pediatrics, obstetrics, and so forth. It was also during the Heian period that the government actively promoted its health service and the training of physicians.

For the most part, however, medical services were monopolized by the upper strata of society. The masses had no recourse except to traditional, indigenous folk or popular practices, for example, moxibustion and massage coupled with talismans and incantations. Ironically, the Heian period also witnessed, among both the elites and the masses, the popularity of native as well as Chinese forms of omen lore, demon lore, directional taboos, and exorcism. In this situation, even though learned Buddhist leaders expounded the lofty themes of the compassionate Buddha Amida, their teaching was easily transformed into a "*nembutsu* [recitation of Amida's holy name] magic" by the peasantry.

During the Kamakura period (1192–1333), the Japanese polity was split between the courtier-based Kyoto court and the samurai-based feudal regime (*bafuku* or shogunate) in Kamakura, not far from present-day Tokyo. Understandably, the Ritsuryō ideology declined, as did the Heian government-inspired health service. In its place a new class of professional physicians emerged who charged fees for their services. The thirteenth century witnessed an unusual heightening of Buddhist spirituality, which added luster to outstanding medical and philanthropic activities by saintly Buddhist monks. One monk, named Ninshō, of the Ritsu school, is credited with having cared for 46,800 patients in his medical relief station in Kamakura, and with having established a leprosy sanatorium in Nara. Among the many dedicated priest-physicians of the Kamakura period, mention must be made of Kajiwara Shozen, the compiler of two important medical works—the *Tan-i-shō,* a fifty-volume work in Chinese, and the *Man-an-pō,* a sixty-volume Japanese work.

During the Muromachi period (1338–1578), a semblance of the feudal regime under the Ashikaga dynasty was maintained even as the social order steadily broke down. Toward the end of this period, three strongmen—Oda Nobunaga (d. 1582), Toyotomi Hideyoshi (d. 1598), and Tokugawa Ieyasu (d. 1616)—terminated the moribund Ritsuryō religious, cultural, social, and political synthesis. During the later Muromachi period, the various schools of Buddhism were unable to exert significant spiritual influence, the only exception being Zen, which inspired art, culture, and learning, and was instrumental in transmitting the syncretistic Neo-Confucianism of Sung Dynasty China (960–1279), as well as legal, philosophical, and medical classics of the Yüan (1276–1368) and Ming (1368–1644) dynasties. During the Muromachi period a number of Japanese physicians (both secular and clerical) studied in China, and able Chinese physicians migrated to Japan. Warfare among warrior families, especially the devastating Onin War of 1467–1477, promoted interest in surgery. Many prominent surgeons of this period were military men who combined medicine, Zen, and the martial arts.

The Muromachi period is also uniquely important in the history of Japanese medicine because of the coming of European medicine with the arrival of Portuguese traders and Roman Catholic missionaries. In the mid-sixteenth century, Jesuit missionaries established clinics, hospitals, dispensaries, and leprosy sanatoriums in Japan. One of the famous medical missionaries was Luis de Alameida, a successful surgeon-turned-Jesuit. For the most part, the European missionary-physicians admired the high quality of *kampō-ijutsu* (Chinese-style, mostly *internal* medicine) then available in Japan, and they contributed new knowledge and techniques in surgery, which were badly needed in the war-torn nation. After 1560, when the Society of Jesus terminated its medical activities, Japanese physicians who had been trained by European missionary-physicians carried on their work until the feudal regime decided to exterminate all traces of Catholic missionary influence from Japan in the mid-seventeenth century. Although the tradition of Namban (literally, "Southern Barbarian") medicine was short-lived,

its scientific approach, coupled with an altruistic spirit and ethical imperative, left a significant imprint on the history of Japanese medicine and medical ethics.

The Tokugawa Era

In 1603, Tokugawa Ieyasu, one of the three strongmen mentioned above, inaugurated a shogunate that lasted until 1867, when the last Tokugawa shogun returned the prerogative of ruling the nation to the young Emperor Meiji. A different synthesis of religious, cultural, social, and political elements developed during the Tokugawa period. The Ritsuryō system discussed above tried to subsume two *universalistic* principles—*tao* ("the way"; *michi* in Japanese) of Confucianism and *dharma* ("the law"; *hō* in Japanese) of Buddhism—under the indigenous tradition represented by Shintō and the imperial system. The Tokugawa synthesis of religious, cultural, social, and political elements (the third layer of Japanese stratification) was based on universalistic Neo-Confucian principles of immutable natural laws and natural norms implicit in the human social and political order, grounded in the Will of Heaven (*t'ien*; *ten* in Japanese). Ironically, it was the Confucian thrust that stimulated the nativist *kokugaku* ("national learning") movement, which in turn fostered the resurgence of Shintō as the guiding principle for restoration of an imperial regime in 1868, inaugurating Japan's *modern period.*

From the perspective of medical history, the Tokugawa period was rich in variety, propelling the development of Chinese (classical Confucian and Neo-Confucian) and nativistic Japanese medicine, and the return of Western medical science. During the Tokugawa period, following the regime's policy in favor of Neo-Confucianism, Japanese medicine separated from its Buddhist underpinning and sought a new foundation in Neo-Confucian metaphysics, physics, psychology, and ethics. Under Neo-Confucian influence, *idō* (the "way or ethics of medicine") was summed up in the phrase *i wa jin nari* ("the practice of medicine is a benevolent art"). Significantly, the first systematic treatises on medical ethics written in Japan, the *Ibyo-ryogan* and the *Byoi-mando,* by Takenaka Tsuan, as well as the *Yojo-kun* ("Instruction on Hygiene"), by Kaibara Ekken (d. 1714), were published in the early Tokugawa period. About that time, among the physicians of *kampō-i* ("Chinese style medicine"), a group called *gosei-ha* ("school of later centuries") taught an intricate fusion of medicine and Neo-Confucian philosophy and became quite influential.

One of the most influential works on healthcare was the *Yojo-kun* ("how to live well"), by the samurai and physician Kaibara Ekken. A Neo-Confucianist scholar, Kaibara wrote widely on various subjects for the edification of people in all walks of life. His lifelong dedication to the cause of healthcare is summarized thus: "Medicine is the practice of humanitarianism. Its purpose should be to help others with benevolence and love. One must not think of one's own interests but should save and help the people who were created by Heaven and Earth." This represents the view that human beings are created by the union of Heaven and Earth, that is, the parents. Since medicine is an art that can make the difference between life and death, it is a profession of utmost importance. This means that physicians must be culturally and intellectually accomplished. Kaibara urged physicians to be conversant with the best medical books, to think logically and precisely, and to acquire important theories, practicing *lifelong education.* He proposed an ideal image of the physician, who excels in qualities of character and scholarship, in contrast to the *inferior physician,* who serves his own interests rather than saving others. At the end of his treatise Kaibara lists eight requirements for the physician: (1) to have a high goal in life; (2) to be cautious; (3) to acquire scholarship of broad knowledge; (4) to make the medical profession a full-time pursuit; (5) to be thirsty for new and ever greater knowledge; (6) to be humble; (7) to be clean at all times; and (8) to be magnanimous.

Meanwhile, in the latter part of the seventeenth century two interesting phenomena developed: (1) the emergence of "ancient studies" (*kogaku*) within the Japanese Confucian tradition, which encouraged *kampō-i* ("Chinese-style medicine") physicians to react against the Neo-Confucian orientation and to return to classical Chinese medicine; and (2) the emergence of the Japanese "national learning" school (*kokugaku*), inspired by Confucian *kogaku.*

Clearly, the *ancient studies* school was a reaction among Japanese Confucianists against the regime-sponsored Neo-Confucian orthodoxy that involved advocating a return to ancient Confucian sages. *Ancient studies* precipitated the rise of a school of medicine called *koihō-ha* ("school of ancient medicine") among Japanese *kampō-i* physicians, who advocated a return to ancient (i.e., Han dynasty, 206 B.C.E.—220 C.E.) Chinese medicine and, more specifically, tried to retrieve the medical work of a Han physician, Chan Ching-chung. For example, Chan's book on fevers and their remedies, the *Shokan-ron,* became widely read in Japan.

Paradoxically, the philological-philosophical approaches of *kogaku* inspired some nativists to apply its scholarly method to the study of ancient Japanese classics, thus developing the school of "national learning" (*kokugaku*), which soon grew into an influential movement and eventually joined with other nativists in the anti-Tokugawa and pro-royalist movement. One of the leading theoreticians of

this school, Motoori Norinaga (1730–1801), was a physician. We are told that in his youth he studied both Neo-Confucianism and the Neo-Confucian-inspired *gosei-ha* tradition of medicine, but gradually discarded Neo-Confucianism in favor of national learning and repudiated the *gosei-ha* medical orientation, turning to the *koihō-ha* tradition. Other "national learning" scholars, such as Ueda Akinari (1734–1809) and Hirata Atsutane (1776–1843), were also physicians. Hirata attached great importance to mental therapy and excelled in taking his patients' psychosomatic conditions into account.

Western medicine, briefly introduced by the Jesuits, returned to Japan under Dutch influence. In order to exterminate Catholic influence, the Tokugawa feudal regime had proclaimed the policy of national seclusion in 1639, terminating all contacts with Western powers. It had allowed only non-Catholic Holland to maintain a small trading post in Nagasaki. Through this minimal contact, Dutch medical supplies and surgical methods continued to influence the Japanese medical profession. As early as the mid-seventeenth century a Dutch physician, Casper Schambergen, spent nearly a year at Nagasaki, teaching Dutch medicine. His influence greatly enhanced cosmopolitan (Westernized) medicine, especially surgery, then called the *aranda-ryu geka* ("Dutch surgical school"). This school became popular through a translation of the *Tavel Anatomia* (*Kaitai-shinsho*) by Mayeno Ryotaku, Sugita Gempaku, Nakagawa Jun'an, and Katsuragawa Hoshu in 1774. In 1823–1828, Philip Franz von Siebold, a German physician and scientist attached to the Dutch trading post in Nagasaki, was permitted to operate a clinic and an academy that attracted a number of able Japanese medical students. He revisited Japan in 1859–1862. Those Japanese students who studied Dutch learning had been well grounded in Confucian learning, which to them was essential for moral cultivation, whereas Dutch (and later, other Western learning in general) was considered practical learning. Hence the famous motto "Eastern ethics and Western science."

The Meiji Synthesis and Modern Japan

The once powerful Tokugawa feudal regime was exhausted politically when the last Tokugawa shogun surrendered feudal power in 1867. It was succeeded by the Meiji-era synthesis of religious, cultural, social, and political ideas that survived until the end of World War II in 1945. Unlike the Tokugawa regime, which authenticated its policy and culture in terms of *universalistic* Neo-Confucian principles, the Meiji regime reverted to *particularistic* Shintø and imperial traditions reminiscent of the Ritsuryō synthesis of the seventh century, notwithstanding the Meiji emperor's Charter Oath to the effect that "uncivilized customs of former times shall be abolished" and "knowledge shall be sought throughout the world." (Understandably, the basic contradictions of the Meiji synthesis have haunted modern Japan until our own time.)

In the modern period Japan welcomed Western knowledge and technology, which inspired, among other things, modern Westernized law, philosophy, ethics, and medicine. In medicine, the Japanese government officially adopted the German system of medical education in 1869. In 1873, there were slightly over five hundred Westernized physicians and twenty-three thousand traditional *kampō* doctors (or *kampō-i*). From 1876 on, the government required all physicians to study Westernized medicine, although *kampō* medicine, which never lost its official recognition, continued to flourish throughout the nineteenth century and into the twentieth. In retrospect it becomes evident that from early times to the modern period, through all the cultural layers, Japanese medicine and ethics—nurtured by Sino-Korean culture, Buddhism, and Western influences—never completely lost its ancient, indigenous orientations, including magico-religious beliefs and practices.

IV. JAPAN. B. CONTEMPORARY JAPAN

Due to Japanese society and its distinctive historical understanding of medicine and the role and responsibilities of the physician, it was not until the 1960s that the bioethical and sociolegal concerns about the practice of medicine began to be deliberately reflected, and only during the 1980s that the notions of autonomy and rights in medicine, and of bioethics in general, became gradually influential (Kimura, 1979, 1987a, 1987b).

In the long tradition of Japanese medical practice, the Confucian notion of *jin* (benevolence) has been one of the most important ethical elements; medicine itself is known as *jinjyutsu* (the art of *jin*). Physicians, as conduits of *jin,* were required to act with benevolence toward their patients and were responsible for the welfare of patients in a fiduciary (trust) relationship (Kimura, 1991a). It was obligatory to use medicine, a gift of benevolence, for the good of others even without payment. Physicians fulfilled their responsibility toward their patients and the patients' family members by acting in a paternalistic and authoritative way; the Japanese, nurtured in the Confucian ethos to respect law, order, authority, and social status, acquiesced without murmur to the superior knowledge of the physician.

Traditionally, the socially reinforced mentality of thinking of oneself as a member of a group rather than as an individual could be seen as one key element to understanding the sense of "related-ness" in the Japanese society (Doi; Mitchell; Johnson). This unique character can be interpreted in the framework of "related-autonomy" or the making of autonomous decisions in relationship striving for harmony (*wa*) with other people in the Japanese cultural bioethics. The sense of relatedness and codependence extend to all living beings and to one's bond with the environment.

In keeping these twin notions of related-autonomy and harmony (*wa*) in mind, this entry will discuss the contemporary Japanese approach to various issues and problems of bioethics, in light of the social, cultural, and historical milieu in three stages of chronological development.

Confucian Virtues in a Paternalistic Medical Tradition (1868–1937)

In 1868, feudal samurai in particular *han* (local provinces), such as Satsuma, Choshu, Tosa, and Hizen, initiated the restoration of political power to Emperor Meiji after the Tokugawa shogunate's reign of 265 years (1603–1867). The Confucian ethical teaching, dominant among the samurai during the Tokugawa shogunate, was integrated into Kyoiku Chokugo (the Educational Edict of the Emperor, 1890) as the basis for moral teaching in the elementary school curriculum; the classes were compulsory. (This edict was not abolished until 1948.) Confucian ethics, as embodied in this edict, attributes great mercy and benevolence to the emperor and affirms the importance of virtues such as loyalty to the emperor as the head of the "state-family," and filial piety and respect for parents. It also emphasizes the importance of brotherhood and sisterhood, obedience to law and maintenance of order, the necessity of education, and devotion to the state (exemplified for men in military service). Grassroots movements for liberty and civil rights in the political process (*jiyuu-minkin undo*) were increasingly popular but were suppressed by the emperor's proclamation of the Meiji Constitution in 1889, which consolidated political power in the hands of the emperor and established the Diet (parliament) in his name. Modern Japanese medical ethics cannot be isolated from this social and political milieu. The strong paternalistic nature of Japanese medical practice is the natural outcome of Confucian teaching, which calls for respect of the master and for his authority as a source of unquestionable wisdom and truth.

As Japan became more open to the West, the Dutch ceased to be the sole source of Western culture, and other nationalities replaced them. The process of modernizing Japan began in the second half of the nineteenth century and continued into the twentieth century, aided by *oyatoi gaikokujin* (foreign advisers) from Western countries, hired by the Japanese government to provide development advice in industry, education, government, finance, science, technology, and medicine. Japan, seeking models for modernization, was drawn to the German approach because of the success and progress of German science and technology, and the similarity of the German authoritarian political system under the Prussian Kaiser to its own under the emperor. Official acceptance of Western, particularly German, medicine guided the development of Japanese policy on medical administration and education and set the course for the future (Oshima).

German physicians left a legacy of authoritarianism in medical education and practice that had far-reaching effects on the majority of the Japanese medical community. This approach, combined with the Confucian self-righteousness in rendering benevolence to the patient, undermined the development of any notion of patients' rights. Research became the supreme interest at many university hospitals, and patients who presented interesting cases were treated as research material. All of these influences can be seen in the Isei (seventy-six guidelines for medical administration) drafted by Sensai Nagayo in 1874. Traditional Japanese medicine (*waho*) and Chinese medicine (*kanpo*) have been out of the mainstream of medical science in Japan since the adoption of Isei, although acupuncture and moxibustion (quick, light heat from an ignited powder of medicinal leaves at key points of the body, called *tsubo*) have remained as folk medicine with popular support among the public (Otsuka).

As capitalism became established in Japan, serious social and economic inequities exacerbating the health problems (e.g., widespread tuberculosis, malnutrition) of factory workers, miners, farmers, and fishery workers became evident, particularly in the Taisho era (1912–1926). Even though the socially privileged physicians' group was not eager to address these health issues through social reform, some young physicians and medical students working for the settlement movement, introduced into Japan from England at the turn of the century, provided medical care in the slum areas of big cities such as Tokyo, Osaka, and Kobe in the 1920s. In 1919 the Medical Cooperative Movement (Iryo Seikyo Undo), which sought to establish community medical centers offering equal access, found great support among many Japanese (Seikyo).

During this period, Japanese medical ethics, guided by the two powerful influences of Confucian teaching and German authoritarianism, was generally understood simply to govern a physician's personal attitude in providing medical service to patients within the traditional model of a paternalistic trust relationship. It is important to note that during this time the eminent Japanese medical historian Yu Fujikawa asserted that physicians were bound by special obligations and responsibilities and must develop a special ethical consciousness in their daily practice. His advice was not accepted by Japanese medical experts, who were obedient to the military regime during the following war years.

Medical Loyalty to State and Authority (1938–1968)

Increasing concern about the health of the Japanese population led to the establishment of Koseisho, the Ministry of Health and Welfare, in 1938. The National Health Act and additional laws protecting factory workers were promulgated that same year. Many young radical physicians dealing with serious health problems among the population, such as tuberculosis, raised questions of justice and equitable distribution of resources, but concerns associated with the war with China (which began in 1937) now dominated. In reality, one of the government's main purposes in establishing the Koseisho was to strengthen the health of the nation to wage war. Similarly, the National Eugenic Law of 1940, promulgated ostensibly for the health of the people, reflected the government's desire for increased family size and the elimination of genetically transmitted diseases and defects. To achieve the latter goal, it authorized the use of a "eugenic operation"—voluntary or involuntary sterilization of individuals with mental illness or retardation and those thought to be at risk of transmitting genetic diseases or physical deformities to offspring. With the approach of war, the traditionally authoritarian, yet basically well intentioned, practice of medicine came under the control of a militaristic state regime; this had dreadful repercussions for medicine and medical ethics in modern Japan.

Several horrible and unethical human experiments performed during World War II were uncovered after the war. The similarity of response to state authority exhibited by Japanese physicians and by Nazi physicians has been viewed with dismay. German defendants accused of committing crimes against humanity were put on trial at Nuremberg, and the medical atrocities and experiments there recounted led to the development of the Nuremberg Code in hope of preventing such practices in the future. But Japanese medical experts serving in Unit 731, officially called the Water Supply and Epidemiological Disease Prevention Corps, who carried out and supervised experiments on Manchurian Chinese captives using bacteriological infections, frostbite, and mustard and poison gases, were not prosecuted by the international military court (Powell; Williams and Wallace).

Official documents exchanged between the United States and U.S. General Headquarters in Japan, now declassified and available at the U.S. National Archives, show that the U.S. military decided not to bring this case to trial. The interrogation task force of the occupation forces in Japan granted immunity to members of Unit 731, including the corps chief, on the condition that all related medical records and specimens be handed over to the United States (Kimura, 1997). The matter was regarded as highly important to national security because the United States wanted to prevent transfer of the medical knowledge gained through these experiments to the Communist governments in China and the Soviet Union (U.S. National Archives, 1949). The

Soviets held their own military trial at Khabarovsk for members of Unit 731 they had captured. Based on documentation and the testimony of witnesses, the accused were found guilty (Ivanov and Bogach).

The Kyushu University Medical School vivisection case also serves as an example of unethical experimentation. Eight American bomber pilots were captured in Japan after an air raid on Tokyo in 1945; some of them were sentenced to death by the local unit of the Japanese Imperial Army, but instead were used as objects of medical experimentation. To avoid prosecution by the Yokohama District Military Tribunal, one key person involved in this experimentation committed suicide; full details may never be known (U.S. National Archives 1949). The case served as the basis for a popular novel by Shusaku Endo, titled *Umi to dokuyaku* (1960), in which he dramatically depicts the quandary of a medical scientist tempted by unethical but very interesting experimentation. Endo's novel forced consideration of the meaning and place of ethics and medicine in Japanese society—which, he argued, lacked a standard of absolute value (Kimura, 1997).

Justified by state authority, professional experts in Japan sometimes lose critical consciousness and judgment. The Japanese national character nurtured during the Tokugawa era, and by an authoritarian government since the Meiji restoration, demands absolute obedience to the state and to authority. As Endo points out in his novel, such pressure often creates serious problems when individuals must make independent, and individual, ethical decisions. As a member of a group—such as a family, corporation, or community—and as a citizen, the individual Japanese tends to follow what other people do. Harmony (*wa*), or getting along with others, is an important element of the Japanese ethos for maintaining good relationships. To insist on individual opinions is regarded as egoistic and arrogant. Suppressing oneself in order to cope with other people is a daily practice in every aspect of life for the Japanese. This has serious ethical implications, especially in terms of weakening critical consciousness necessary in professional experts. The majority of Japanese medical experts and the lay public are not interested in drawing serious lessons from the horrible wartime human experiments because they reason that such actions are performed only in "abnormal war settings by abnormal people."

After the defeat of Japan, one of the first pieces of legislation implemented was the Eugenic Protection Law of 1948. Unlike the National Eugenic Law that it abolished and the Japanese Criminal Code, which since 1907 had held abortion illegal, the 1948 law permitted abortion for medical, and later for social and economic, reasons. Under the Japanese Criminal Code, abortion for other reasons remained a prosecutable offense. Nevertheless, because of vigorous opposition from advocates for the disabled, the new law did not provide legal justification for the abortion of a genetically defective fetus. The endorsement of this abortion law by the General Headquarters of General Douglas MacArthur aroused adverse reactions from religious bodies in Japan and the United States (Kimura, 1987a, 1987b). MacArthur defended the policy, saying that it had arisen from and was implemented by the Japanese Diet.

The way survivors of the atomic bombs dropped at Hiroshima and Nagasaki were treated by the Atomic Bomb Casualty Commission (composed of U.S. medical and genetic experts) is one of the historical sources of the development of Japanese bioethics because of its significance in discussions about the relationship between human beings and science, technology, and research. Individuals suffering from the effects of radiation came seeking treatment, but instead became material for research on radiation and collection of genetic data that were stored at the U.S. Atomic Energy Commission (AEC). This situation raised the serious issue of the researcher's responsibility to obtain fully informed consent for research. At that time, no government regulation or review boards existed to deal with the situation. The AEC is in fact the forerunner of the U.S. Energy Department, which initiated the Human Genome Project in the early 1980s on the basis of the voluminous data from the survivors of Hiroshima and Nagasaki (Cook-Deegan).

In 1951 the Japan Medical Association (JMA) issued a statement on physicians' ethics. This action clearly ushered in a new epoch in medical practice in Japan and signaled a return to the prewar state of medical ethics. Article I explicitly reaffirmed the fundamental and central place in medical practice of the ancient principle of *jin,* the benevolence of Confucian teaching, and asserted that physicians, as the elite of society, must embody the spirit of *jin,* always thinking about the welfare of the patient and the benefit of the treatment. Further, in cooperation with other professionals, physicians should take the initiative in social reform and, as ethically oriented people, should exercise great self-discipline (JMA, 1951).

In the 1960s Japanese society felt the effects of the worldwide trend of questioning established authority. Revolts occurred in many universities as dissatisfied medical students stood up against the traditionally paternalistic and authoritarian medical faculty they felt was exploiting them. Special legislation eased the unrest, but this first and radical challenge of the medical establishment, a very politically powerful group, had permanent ramifications for Japanese society and moved it into a new era.

Communal Involvement in Medical Decision Making (1969–2000s)

Toward the end of the 1960s, numerous social issues competed for attention in Japan. Health-related issues that drew increasing notice included air and water pollution, food additives, iatrogenic diseases (diseases caused by physicians), and the revival of *kanpo* (traditional Chinese medicine). There was also an increased emphasis on health. The growing number of older people focused attention on the need for healthcare for the elderly. Japan has been one of the most successful countries in decreasing the birthrate, and life expectancy in 2001 was the longest in the world, nearly eighty-five years for women and just over seventy-eight years for men (Minstry of Health, Labour, and Welfare). In 1997 the Long-term Health Care Insurance Law for the Elderly was enacted to create national mutual support systems for the elderly, who were traditionally cared for mainly by the family in the community. Advances in medical technology and healthcare have raised additional issues for the Japanese medical profession and society in general. The period from the late 1960s to the early 2000s has seen increased involvement in discussions about medical treatment and a strong desire to establish guidelines to protect the patient.

ORGAN TRANSPLANTATION. Progress in organ transplant technology created a demand to regulate and endorse cornea transplantation. A special law to this effect was enacted in 1958; it was combined with a law governing kidney transplantation in 1979.

The most vigorous public debate on bioethical issues was generated by the first heart transplant in Japan (1968), in which a heart was taken from a drowning victim and transplanted to a patient with heart failure. The patient died after eighty-three days. A surgeon at Sapporo Medical College, Juro Wada, was accused of mishandling the surgery on both the donor and the recipient, and questions arose about the justification for the transplant and about the criteria used to determine death; but Wada was never formally prosecuted. The aftermath of this case, however, gave rise to strong criticism of high-tech medical applications on ethical grounds. Concerns focused on the use of brain-based criteria of death, organ transplantation from brain-dead bodies, and the need to develop ethical guidelines to control the behavior of individual physicians who might seek fame through ill-prepared and drastic use of medical technology supposedly for the benefit of the patient.

This incident spawned the Patients' Rights Declaration in 1970 (Owatari et al.). This short, spontaneous expression of feelings, stating that the Wada case was a violation of the human rights of the patient and an example of the corruption of medicine and ethics, occurred in the public meeting at which Wada was accused of violating the donor's right to life.

In 1997 the Law on Transplantion went into effect. This law, reflecting the legal and ethical uniqueness of the Japanese situation, makes harvesting organs difficult because of two rigid consent provisions. The first provision is the requirement for advanced consent in accepting brain death. The "brain death criteria for death" box must be checked on the donor card, expressing the intention of the organ donor when alive. The second provision is the requirement for the consent of the family for harvesting organs from a brain-dead body. Article 6, Section 1, allows organ donation "in the event that a deceased person had during his lifetime expressed in writing his intent to donate organs to be used for organ transplants." Section 3 of the same article also states that "when the donor during his lifetime had expressed in writing his consent to the diagnosis—made based upon the provisions—and his family, informed of the removal, did not object to the diagnosis," organ transplants can be legally permitted (Kimura, 1998).

This law is supposed to promote—by endorsement—organ transplantation. From enactment through early 2003, however, Japan has had an only a small number (twenty-three) of organ transplants. Furthermore, these two elements of ethical and legal rigidness have made the enactment of more relaxed applications—such as allowing organ transplants involving infants—almost impossible to perform.

CRITERIA FOR DEATH. Leading objections to brain-death criteria are the fears that organs will be removed prematurely and that transplants will be performed in unacceptable circumstances (Kimura, 1991b). In Japan, transplantation of vital organs from dead bodies is rare because of a concern about causing the death of the donor. To a limited degree, anencephalic infants (those born without a brain or without a major part of the brain) have been used as sources for donor organs because they will die anyway, and because it is believed that they do not possess the fundamental consciousness necessary to be a human being. Declaration of death in the cases reported has ostensibly been based on the total cessation of heartbeat. Nevertheless, the use of organs from anencephalics has not been officially reported since 1981, because of clinical concerns about the condition of the organs from such donors and public concerns about the appropriateness of such practices (Kimura, 1989a).

Resistance to hastening death and harvesting organs also comes from the traditional Japanese image of human beings as completely integrated mind–body units, rather than as being composed of distinct and separate units of mind, body, and spirit. This mind–body unit, according to the Japanese, continues after death, so that removing an

organ from a cadaver is seen as disturbing this spiritual and corporeal unity, not merely altering the physical body. It also explains why autopsies are abhorred in Japan (Fujita). According to the Buddhist and Shinto ways of thinking, this unity extends beyond the individual to all living things. To the Japanese, death disturbs the rhythm of all living things and therefore should not be hastened. Also, Confucian teaching places strong emphasis on family relationships and filial piety. There is a strong prohibition on harming one's body, because it is derived from one's parents (Kimura, 1991b).

In addition, in accepting the reality of human mortality, some Buddhists regard the extension of life by accepting organs from another individual's body as unnatural and unethical, because the procurement of those organs depends on the death of another person. Such an expectation of the death of someone else for the purpose of egoistic extension of life is not acceptable. Also, the totality of life should be supported by the notion of *arayashiki* (*alaya-vijnana*) (the fundamental consciousness within each individual being). This Buddhist notion holds that consciousness is not located solely in the brain; therefore the cessation of any one part or one organ (including the brain) of the individual does not extinguish consciousness and consequently cannot be regarded as the death of the individual person (Tamaki; Fujii). The basis for the uneasiness in accepting brain criteria for death and organ transplantation thus comes from both Confucian and Buddhist thought, which incorporate some ideas from Japanese traditional folk religions and Shintoism.

EUTHANASIA. Media coverage has made euthanasia one of the most debated topics in Japanese bioethics. The Japanese Euthanasia Society was established in 1976 (and was later renamed the Japan Society for Dying with Dignity [JSDD]), and the first international conference on euthanasia was held in Tokyo that same year. The Ninth International Conference of the World Federation of Right to Die Societies was organized by the JSDD and held in Kyoto in 1992. No legally established procedure for euthanasia exists in Japan, but as in many other countries, the use of elevated doses of narcotics to relieve suffering and pain is acceptable even at the risk of hastening death. According to Buddhist thought, the prolongation of life and suffering is not absolutely necessary, and ending the life of a dying, suffering patient might be regarded as a merciful act (Murakami).

A 1962 precedent-setting decision by the Nagoya High Court, which accepted the idea of euthanasia in principle, involved the case of a son who prepared poisoned milk as a result of his terminally ill father's repeated requests to die; the glass of milk was found by the man's wife, who, not knowing it was poisoned, gave it to her husband. Although the court found this case to involve unacceptable mercy killing, the court's ruling established six criteria for allowable mercy killing:

(1) the patient's condition must be terminal and incurable, with no hope of recovery, and death must be imminent (as determined by modern medical knowledge and technology);
(2) the patient's pain must be so severe that no one should be expected to endure it;
(3) the sole purpose of the act must be to relieve the patient's suffering;
(4) a sincere request and permission are required from competent patients;
(5) in general, the act should be performed only by physicians; and
(6) an ethically acceptable method must be used.

The Nagoya High Court ruled that, although the first four criteria had been met, the final two conditions had not. The son was sentenced to four years' imprisonment with three years' suspended sentence.

In the light of medical and technological advances, the conditions once considered fatal can now be treated effectively or even cured. Better methods of pain control have been developed, and new centers for palliative care have been developed.

The ruling of Yokohama District Court on March 28th, 1995 is significant for its clear statement of the principle of individual autonomy based on the patient's own intention to stop treatment. In this case, the physician prosecuted for murder claimed he had a clear request from the patient's son to alleviate his father's suffering. Later, the son denied, when questioned, any intention to end his father's life. The ruling does not endorse familial decision making based on the presumed wishes of the patient, however, if the patient has communicated openly enough with family members about his or her view of life, character, and values, the family will be able to make a conjectural decision to end his or her life in a natural way without aggressive over treatment (Kimura, 1998).

TREATMENT OF THE MENTALLY ILL. The Japanese Mental Health Act was passed in 1950 to prevent private home confinement of the mentally ill in violation of an identified right to be cared for in institutional situations. In the 1980s, however, disclosures of violations of rights of psychiatric patients led to serious questioning of the routine admittance and institutional treatment of the mentally ill. In 1987 an important amendment to this act passed after a nationwide campaign in its favor by the mass media and a strong recommendation for its passage by a special investigative

mission of the International Commission of Jurists in Geneva, Switzerland. The amendment enacted more rigorous procedures for involuntary hospitalization of the mentally disabled and established rehabilitation and treatment centers to protect the rights of patients with mental disabilities. The commission's involvement underscores the importance and necessity of international cooperation on bioethical issues, especially those related to patients' rights.

EDUCATION OF THE PUBLIC IN BIOETHICS. Bioethical issues raised in the 1960s caught the attention of much of Japanese society, and in the 1970s concerned citizens formed bioethics study groups in Tokyo, Kyoto, and Nagoya. By the 1980s, members of these groups participated as bioethics volunteers in medical service organizations. The nationwide concern with health and medical services in Japan led to a new declaration of patients' rights, which was issued in 1984 by a group of patients, lawyers, physicians, and journalists. While this document carried no official authorization, it was more systematic than its 1970 precursor and showed the impact of discussions in other countries. The General Assembly of Japanese Medical Cooperatives, an official medical service organization of the Japanese Association of Life Cooperatives Union with 250 hospitals and clinics and a membership of 1.5 million individuals, endorsed its own version of a patients' bill of rights in May 1991—the first such action by a medical organization (Seikyo). The Patients' Rights Legislation Movement, largely initiated by medical malpractice lawyers and other members of the lay public, began in 1991 to urge passage of a statute on informed consent and respect for patient autonomy in medical decision making.

ETHICS COMMITTEES FOR ADVANCED MEDICAL RESEARCH. The first medical ethics committee in Japan was established at the Tokushima University School of Medicine in 1982 in order to review in vitro fertilization (IVF) technology and its application to infertile women. As of 2003, each of the eighty medical schools and major hospitals had its own medical ethics committee reviewing cases such as segmental liver transplantation, gene therapy, and embryonic stem cell research. Due to a lack of national legislation regarding these review committees for the advanced medical research, each has a different composition. With the exception of a few lawyers and ethicists, the majority of the committees are composed of the same medical faculty and are male.

In 1991 the Greater Tokyo Metropolitan Government established the first hospital ethics committee with membership of nonmedical practitioners, and the committee opened all its meetings to the public. This committee serves as a policymaking body for the fourteen hospitals operated by the Tokyo Metropolitan Government. One of the epoch-making outcomes of the committee was the adoption of the "Patients' Bill of Rights for the Hospitals of Tokyo Metropolitan Government" in 2001.

BIOETHICS ORGANIZATIONS. Since the mid-1980s, medical professionals and government organizations have been involved in the study of bioethical issues. In 1984, the Ministry of Health and Welfare set up the Special Advisory Board on Life and Ethics; it published an official report in 1985, after a series of research conferences, then ceased activity. The Japan Medical Association also set up the interdisciplinary Bioethics Council, consisting of medical experts and professionals from philosophy, anthropology, biochemistry, law, and industry. The council dealt with topics related to technological applications in clinical settings such as IVF (1986), sex selection of the fetus (1987), brain death and organ transplantation (1989), and explanation and informed consent (1990).

The Japanese Association for Bioethics, established in 1987, publishes a journal and a newsletter, and has more than 800 members who attend the annual national meeting and international meetings. The Japanese Association for Philosophical and Ethical Research in Medicine, the Japanese Society of Ethics, and the Japanese Society of Medical Law are also concerned with bioethical issues as they affect their respective disciplines.

In the early 2000s, the Bioethics Committee of the Science and Technology Council (part of the Ministry of Education, Culture, Sports, Science and Technology) has been active on bioethical issues relating to biomedical research, such as cloning. The Health and Welfare Council of the Ministry of Health, Labour and Welfare is also dealing with bioethical issues, mainly relating to clinical medicine. These two ministries worked with the Ministry of Economy, Trade and Industry to prepare a document titled "Ethics Guidelines for Human Genome/Gene Analysis Research," which was released in 2001. They jointly made an official announcement of the Guideline in 2001 for the first time as a result of cooperative work in bioethics public policy in Japan.

BIOETHICAL TRENDS IN COURT DECISIONS, CODE OF ETHICS, AND LEGISLATION. One of the most controversial legal issues relating to bioethics in the 1990s was the revelation that HIV-contaminated blood products were used for hemophiliac patients without heat processing, resulting in around 1,600 people being infected with HIV. After more than seven years of legal struggle, the Ministry of

Health and Welfare, pharmaceutical corporations, and the plaintiffs in the case agreed to a settlement involving a compensation fee of about 400,000 U.S. dollars per person.

In 1996 the Eugenic Protection Law was amended, and its name was changed to the Maternal Protection Law. In addition to deleting the word *eugenic* from the name, the new law eliminated all provisions related to eugenic operations, including the lists of genetic diseases that were the subject of eugenic operations, such as Hansen's disease (leprosy). The discriminatory Law for the Prevention of Leprosy, in effect since 1907, was abolished in 1996 following the initiation of legal action against the government of Japan. Later, in 2001, the Kumanoto District Court ruled against the Ministry for its responsibility and the government gave up the appeal. Diet members adapted an unanimous resolution on the issue of Hansen's disease expressing sincere remorse and apologized for committing human rights violations for over 90 years.

The bioethical principle of autonomy was strongly affirmed by a 1997 decision of the Tokyo High Court relating to a Jehovah's Witness who had been given a blood transfusion, a medical treatment forbidden by his religion. The decision was made in favor of the plaintiff, as he had not been told that he might be given a blood transfusion under certain circumstances. The notion of "informed consent" was thus taken seriously in legal terms in the context of religious beliefs and bioethical conflicts of decision making when life is at stake (Kimura, 2000).

In 2000, the Japan Medical Association adopted the "Code of Medical Ethics" in six provisions in simplified form. The emphasis on the public role of medical service and contribution to the society through medical works can be seen in provision five (JMA, 2000).

The social concerns facing the increasing number of elderly population and the need of mutual support systems by the local and state and government has led to the realization of "The Long Term Care Insurance Law " in 2000. This was the reflection of the shift in values from traditional ethos of family support to the mutual, societal support mainly to be managed by the community (Kimura, 2002; Ministry of Health, Labour and Welfare, 2003).

Toward Bioethics of Cultural Harmony: The Cloning Prohibition Law in Japan

The contemporary discussion of bioethics in Japan started as a movement among the lay public in the late 1970s. This fact remains symbolic and important in many respects, as evidenced by the increased degree of individual decision making about desired medical treatment, as well as in all areas of daily life.

Japan continues to struggle to recognize bioethics as integral to all spheres of life and to discuss public policy and the environment, as well as to deal with the tension between Western values and traditional Japanese cultural practices. Bioethics has been proposed and developed in Japan as a supra-interdisciplinary endeavor embracing all traditional academic disciplines in equal partnership, for the valuable exchange of ideas and criticism each field has to offer (Kimura, 1986)

There are specific cultural values and customs that are distinctive and non-Western in pattern, but there is heterogeneity, too, and in any case, ethical values change, particularly among the younger generations in Japan. It is true that different cultural and ethical values should be respected, such as key concepts of the dignity of each human person, the importance of the family unit, and community life. But justification of any act or behavior against human dignity and the rights of the person for the sake of cultural tradition is not acceptable.

The notion of harmony is reflected in Article 1 of the Law concerning the Regulation of Cloning Technologies and Other Similar Technologies Relating to Humans, which went into effect in June 2001. This article states that one purpose of the law is to "harmonize the society and peoples' lives with the development of science and technology."

In the international community of the twenty-first century, with the globalization of values focusing on a universally accepted notion of fundamental human rights, the reality of limited resources, and the increasing necessity of mutual cooperation, it is useful to emphasize the twin notion of "related-autonomy" and the Japanese principle of harmony (*wa*) in cultural bioethics.

V. SOUTHEAST ASIAN COUNTRIES

Southeast Asia is part of the continent where the major faiths arose; it is still a melting pot of different religious traditions and cultural beliefs, including animism and magic. Despite the rapid social change Southeast Asia has been undergoing, these religious and cultural beliefs remain vital, conditioning people's perceptions, values, attitudes, and behaviors in health and all other areas. An understanding of these beliefs is imperative for the implementation of projects in medicine and public health, and for the maintenance and improvement of public welfare.

This article will first analyze the different types of traditional medicine in Southeast Asian countries, particularly Thailand, the Philippines, Malaysia, and Indonesia, their concepts of health and disease, methods of healing, their practitioners, and their ethics. Second, it will discuss some central biomedical issues in the practice of modern medicine, and the current efforts to teach the new medical ethics at medical schools in these countries. Finally, it will argue as a matter of great urgency the need to promote and strengthen bioethical education and research in Southeast Asia, in order to enable its medical community to cope with the new ethical and moral dilemmas, challenges to its traditional morality and religion.

Magic, Religion, and Naturalism

Medical systems in Southeast Asian countries may be classified into two types, traditional medicine and modern (scientific) medicine. Traditional medicine in turn can be very broadly grouped into three general types, depending on whether it is dominated by magic, religion, or naturalism. Beliefs concerning health, disease and its treatment, and preventive measures are in accord with the type of traditional medicine practiced. When magic is the focus, disease is believed to be caused by sorcery, and countersorcery and other spells are used as medical remedies. Similarly, when religion predominates, disease is attributed to supernatural forces, which must be appealed to or propitiated. When it is dominated by naturalism, disease is defined in terms of natural processes and the imbalance of elements or opposing forces in the body, and a judicious equilibrium is the basis of medical practice.

These traditional medical systems are often a blend of two or more types. Traditional Chinese medicine in Singapore, for example, is largely secular or naturalistic but includes magico-religious elements. Traditional Thai and Malay medicine is mainly magico-religious but is also permeated by elements of naturalistic medicine.

Healers, Shamans, and Mediums

Traditional medicine is integrated into a complex of beliefs and values comprising the worldview of Southeast Asian peoples. The magico-religious medicine of Southeast Asian countries is derived from magico-animistic beliefs that suffuse their cultures. In this cultural orientation, healers are shamans and mediums, and healing is effected through sorcery, exorcism, and spirit possession, assisted when necessary by herbal concoctions and massage.

Spirit possession is believed to be a channel by which deities or spirits of a high order (e.g., spirits of monks or saints) use their divine power to heal the sick. Healing includes a diagnosis of illness and the performance of corresponding magical rites. These magical activities are usually conducted within the religious framework of the healer. Thai Buddhist shamans, for example, do not practice on *wan phra,* a Buddhist Sabbath observed at the four phases of the moon, and they make use of recitations from the Pali Buddhist texts. The Malay Muslim shamans add verses from the Qur'an to their healing, while the Taoist shamans in Singapore recite Tao incantations in their practice.

Herbalists, Folk Medicine Doctors, and Monks

While the magico-religious medicine of Southeast Asia is tied to its culture, its naturalistic medicine is heir to the Indian ayurvedic medical system and traditional Chinese medicine. In these medical traditions disease is understood as a disturbance of inner equilibrium that can be corrected through the administration of herbal solutions. Thus this form of medicine is designated as naturalistic or herbal, and its practitioners are known as herbalists, ayurvedics, or folk medicine doctors. In Thailand many of these healers are Buddhist monks, who usually combine herbal treatment with religious rituals (e.g., the taking of religious vows and the sprinkling of lustral water) and meditation. Some of these monks have been credited with successful rehabilitation of drug addicts. The use of meditation differentiates traditional Thai medicine from the medicines of other Southeast Asian countries.

Medical Ethics in Traditional Medicine

The preoccupation of traditional medicine with magic, religion, and herbal concoctions is due to its holistic approach to health and healthcare. The practitioners work on their patients at both the physical level and the psychological/spiritual level. While herbal concoctions are mainly used to cure patients' physical illness, magico-religious rites have a therapeutic effect on their minds. The rites reassure patients of divine blessing and protection, and strengthen their self-confidence.

This traditional method of healing may be especially suitable today for Southeast Asians, who, living in societies with increased urbanization and industrialization, need physical, psychological, and spiritual care to enable them to cope with such change and the strains and stresses of modern life. Modern Western medicine with its advanced knowledge and technology has more effective means of healing, but it divides the patient into organ systems and treats only those parts of the person that are afflicted by a specific disease, rather than the whole person. Southeast Asians, who do not divide the person in such a way but need treatment with scientific medicine, will often seek traditional medicine as a supplement to scientific medicine. For example, a patient with a brain tumor might request magico-religious rites from a Buddhist shaman in order to ensure the success of an operation to be performed by a neurosurgeon. It was reported in the Thai press that the patient who uses this approach experiences such an operation with great calm and recovers more quickly.

Medical ethics in Southeast Asian traditional medicine is not codified but is inherent in the values and practices of its practitioners. Some of these healers are Buddhist monks whose ethic of conduct approximates the Buddhist ideal of showing compassion and loving kindness. For example, they do not charge fees and solicit no gifts for their healing. Other healers may demand fees for their service, but their code of ethics requires that they be under some self-imposed moral restraints, for example, that they not practice for monetary gain; that they serve their patients impartially, with only their benefit in mind; and that they not take cases that they cannot treat successfully. Having no common standard of practice to follow, the healers' success depends on their own virtues and healing powers. Their services are sought as long as they can instill belief and faith. They sink into anonymity when they are seen as charlatans or when doubt about their powers arises.

Modern Medicine and Healthcare Allocation

Modern medicine came to Southeast Asia during the colonial period, starting in the eighteenth century. Since then it has made tremendous progress. It has greatly benefited people in Southeast Asia, but beneath the surface of these benefits there is a multitude of attendant ethical problems.

The most important concerns the macroallocation of limited healthcare resources, specifically, grave inadequacies and inequalities in their distribution. Nearly 80 percent of the population of Southeast Asia lives in rural areas. Most of these people are poor and need more medical services than affluent people. Their health depends mostly on medical services provided by the government through hospitals and public health centers. Yet many of these services are inaccessible to them. In Thailand, for example, 62 percent of doctors and nurses are in Bangkok, where most of the country's hospitals are, while there are too few doctors and nurses in the provinces, where most of the people are. There are also too many hospitals in Bangkok and too few neighborhood clinics and public health centers in rural areas.

Southeast Asian countries, eager to bring the benefits of modern medicine to their people, have modeled patterns of healthcare and education of health personnel in their countries on those in more affluent and developed nations in the West, particularly Britain and the United States, without regard to social, economic, and cultural differences. As a result, limited healthcare resources are allocated to catastrophic or hospital-oriented medicine, despite the fact that most of the diseases afflicting the majority of people in these countries are preventable. Even though it has become increasingly clear that these patterns are irrelevant to the health needs of developing Southeast Asian countries, Western-trained health policymakers are very reluctant to deviate from these models, which are being questioned even in the developed nations where they originated.

Politically pressured to show more concern for the poor, governments in some Southeast Asian countries are now acting to correct some of the imbalance of resource allocation. The present Thai government, for example, though still following Western models, has increased funding for preventive health measures and public health services. More provincial hospitals and health clinics are being built, and paramedics and auxiliaries trained to staff them. Thai medical schools now require medical graduates to spend at least three years in the provinces and rural areas, and a plan is being devised to provide incentive subsidies to doctors and nurses working in poor rural areas. Many more corrective measures are needed to create a just and reasonable allocation of the country's overall healthcare resources such that the general standard of health and healthcare can be raised nationwide.

Shortages of health personnel in Southeast Asia have been aggravated by the fact that so many doctors and nurses are lured from their homelands, where they are in desperately short supply, to serve the less critical health needs of affluent nations. The Filipino Department of Health, for example, reported in 1990 that two hundred towns in the Philippines had no resident doctors and that seven out of ten persons died without even being seen by a physician. Only an estimated 32 percent of all qualified Filipino doctors and nurses practice their profession in their own country. This shortage of doctors and nurses, typical of developing Southeast Asian countries, makes it much more difficult for governments to provide adequate healthcare to many of their people.

Human Experimentation

Another important ethical issue in Southeast Asia concerns human experimentation. Since the adoption of modern medicine in the nineteenth century, medical schools in Southeast Asian countries have become more research oriented and are increasingly moving into the area of human experimentation. In violation of international agreements, Western researchers who have been restricted in the kind of human experiments they may do in their own countries are turning to Southeast Asia to conduct their research where there is less public awareness of the issue and less government regulation. These researchers are usually assisted by Southeast Asian colleagues, who engage in all kinds of human experimentation no longer permitted in the West, including forms of psychosurgery and genetic experiments. Drug testing and tests of new contraceptives have been carried out in Southeast Asian countries on a massive scale. Nearly all of these experiments use poor people as subjects, without their informed consent. Abuse of poor patients and the violation of their human rights in public hospitals often occur.

The governments and the medical communities in Thailand and the Philippines have taken some measures to prevent the exploitation of the poor by researchers. In 1985 the National Research Council of Thailand formulated guidelines for research involving human subjects; these guidelines were later revised and made more elaborate. In 1987 the Philippine Council for Health Research and Development published *National Guidelines for Biomedical Research Involving Human Subjects,* similar to those delineated by the World Medical Association at Helsinki in 1964 and revised at Tokyo in 1975. These guidelines on human experimentation laid special emphasis on voluntary informed consent of research subjects. Unfortunately, both in Thailand and in the Philippines there is as yet little compliance with these guidelines or accountability for their violation.

The creation of national ethics committees and institutional review committees in Thailand and the Philippines is another Southeast Asian response to the issue of human experimentation. These institutional committees are concerned primarily with the evaluation of the scientific value of research proposals; the national ethics committees are expected to deal with the ethical aspects of experiment proposals and their protocols. Both the proper role and the composition of national ethics committees are still being debated. At present such committees are far from being instruments for effective control of experimentation in Southeast Asian countries. The Thai committee, for example, does not scrupulously supervise procedures for gaining the needed informed consent. Nor does the committee intervene when it believes an experiment is being conducted without proper ethical consideration. A 1988 study in Thailand indicated that often the procedures followed in many hospitals made it unlikely that the patients were fully informed or gave genuinely voluntary consent. Though

many questions are being raised about it, this national committee could become an effective means to prevent morally questionable experiments on human subjects from being performed.

Traditional Morality and New Ethical Issues

The traditional morality of Southeast Asia is permeated by the ethical traditions of Hinduism, Buddhism, Christianity, and Islam. The emergence of modern medicine has produced many new ethical issues that challenge traditional morality. For example, within this morality is the cardinal Buddhist principle of *adhimsa,* which directs that life not be taken and harm not be done. Modern medicine with its advanced technologies has produced ethical dilemmas concerning how to abide by these precepts. For example, does removal of a life-support system constitute violation of these precepts? Is allowing a seriously defective infant to die untreated a form of *harming* or *killing*? Is it morally acceptable for patients to take their own lives in cases of lingering terminal illness or chronic severe pain or disability? Is it morally acceptable that doctors or nurses act upon the expressed desire of patients and assist them in committing suicide when they are unable to act for themselves or to find the means to do so? Is removal of a kidney from a live donor a morally justified form of harming?

Traditional morality also dictates that we not deceive others. One of the five precepts of Buddhist morality prohibits falsehood. Does this include failing to tell a terminally ill patient the truth about his or her prognosis? Is administering placebos a morally justified exception to the moral rule against deception? Can the patient be deceived about a treatment if the doctor or nurse thinks it is in the patient's best interest? Must all the truth about a double-blind trial in human research be told in order to obtain the *informed consent* that the new medical ethics calls for? These are examples of new questions raised as a result of the encounter between modern medicine and traditional morality in Southeast Asia. Traditional morality is no more prepared to deal with these new moral issues than are the Southeast Asian scientists and physicians caught in the middle of them.

The development of modern medicine has raised questions about the adequacy of traditional morality. For example, the traditional Buddhist concept of death as the cessation of all vital functions cannot accommodate the recent development in modern medicine, in which some cells or organs may be sustained by artificial means after the cessation of all vital functions. Nor does it facilitate early retrieval of organs for transplantation. Southeast Asians must rethink and reinterpret the applications of their traditional morality to cope with the advanced knowledge and technologies of modern medicine. For example, as technologies for behavior control and modification are available through drugs, electrostimulation, electroshock treatments, psychological manipulation, psychosurgery, and genetic engineering, the traditional precept of "do no harm" to an existent being may be stretched to cover the question of whether we have the right to *create* a being of our own design.

Teaching and Other Bioethical Activities

Southeast Asian medical students usually learn about medical ethics in classes, and from time to time through lectures outside of regular classes. They are also encouraged to follow the example of morally respected elder doctors. In the past the teaching of medical ethics at medical schools in Southeast Asian countries was integrated into other courses and was primarily concerned with professional etiquette as developed in the West or culled from the teachings of Buddhism, Hinduism, or Islam.

The new medical ethics, or bioethics, was initiated in Southeast Asian countries as a response of scholars and medical professionals to the impact of modern medicine on the life and well-being of people in their countries. Through the combined efforts of Christian clergy and doctors, the Center for Biomedical Ethics Development was established in Indonesia in 1983, primarily to enhance the development of bioethics and Christian values in medicine. Its present activities include the formulation of hospital ethical codes for Indonesian doctors and nurses, and the promotion of bioethics education at hospitals and universities through lectures, seminars, and regular meetings.

Also in 1983, the Bioethics Study Group, consisting principally of Western-trained philosophers and doctors, was established at Mahidol University, a major education and research university in Thailand, to initiate the teaching of bioethics at the university and to bring the awareness of bioethical issues to the public and concerned authorities. By 1988 three full-credit, separate courses were being taught. Through these courses students are exposed to bioethical issues and the way these issues are being addressed and resolved in the United States and other Western countries. They are also encouraged to engage in ethical reflection on those issues as they arise in Thailand, and to find solutions that reflect Thai cultural values. The group has planned to initiate a graduate program in bioethics in 1993 and has created small teams at six other medical schools to stimulate and promote bioethical activities there.

The Southeast Asian Center of Bioethics was established in the Philippines in 1987 by a group of Catholic

priests and doctors as a result of the visit of the International Federation of Catholic Universities in the same year. Since its inception the Center has focused its activities on the promotion of interest in and concern with bioethics through teaching, research, seminars, and monthly meetings to discuss bioethical issues confronted by the scientific and medical community in the Philippines. Thus the value of bioethics is appreciated in Thailand, Indonesia, and the Philippines, but it is less recognized in other countries.

All the work done in bioethics has been based on Western models of health and healthcare delivery systems, and on principles derived from the Western moral tradition and specific ethical issues that are relevant to the particularities of Western culture. It is urgent that Southeast Asian academics and medical professionals begin the task of defining and clarifying bioethical issues as they affect their own countries' health and healthcare systems, and that they find resolutions in keeping with the moral principles, values, priorities, and social needs of their countries.

MEDICAL FUTILITY

• • •

For the first three decades after the introduction of life-sustaining medical technology in the 1970s and 1980s, a central question was: When can patients or their families refuse life-sustaining interventions—including interventions wanted by physicians? More recently, an opposite question has been asked and heavily debated: When can physicians unilaterally refuse patient or family requests for life-sustaining interventions on the basis that such interventions would be futile? This debate has shed light on many issues, including the difference between positive and negative rights; the difference between futility and rationing as a basis for denying care; the nature of professional responsibility; and the optimum way to discuss end-of-life choices with patients and their families. In the end, however, futility has remained an elusive concept, and most commentators have rejected unilateral decisions by physicians in favor of good communication and institutional policies for negotiating disputes.

Positive versus Negative Rights

Arguably, the most prominent debate in bioethics from the early 1960s to the early twenty-first century has been the one surrounding the right to refuse treatment. From Karen Quinlan to Nancy Cruzan, the United States has seen a series of court decisions, professional guidelines, and laws that establish the rights of patients or their surrogates to make end-of-life decisions. These cases, however, all involved patients or families who sought to limit life-sustaining treatment in the face of physicians or institutions who wanted to continue treatment. It is simply mistaken to argue that because patients have a right to refuse treatment they also have a right to demand it.

The rights delineated in treatment refusal cases were negative rights, the right to be left alone and to not be touched without consent; such rights can be traced to the Constitutional rights of privacy, liberty, and religious choice, or to the common-law right against battery. In contrast, a positive right, the right that something be done, implies both the patient's right to choose a specific intervention and a coexisting obligation of the physician to provide it (Brett and McCullough). Claims to negative rights are generally considered to be more powerful than claims to positive rights.

It is obvious that patients do not have rights to treatment that falls well out of the standard of care—for example, hip replacement surgery when there is nothing wrong with the patient's hip. But do U.S. citizens have a right to beneficial care? The answer to that question is being hotly debated in the political arena and does not appear to be near resolution. Those in favor of limiting futile care argue that a patient cannot demand a treatment that is futile when a general right to medical care that is clearly beneficial has not yet been established.

Defining Futility

While the word *futility* has a categorical ring, it is actually quite difficult to define with precision. Futility must always be discussed with a specific intervention and result in mind. Intervention A is futile if it is not successful in achieving goal B. In contrast, intervention A might be successful in achieving goal C. Without specifying interventions and goals, discussions about futility can be misleading or confusing. For example, asking a patient if she would like to be put on a mechanical ventilator identifies a specific intervention, but no goal. One goal might be to stay alive as long as possible, even if this means spending the last weeks of life in an intensive care unit, attached to the machine. Another goal might be to recover, be removed from the ventilator, and return home. Without discussing specific goals, the patient's acceptance or refusal of mechanical ventilation leaves too much to the imagination.

In their 1990 article, "Medical Futility," Larry S. Schneiderman and his colleagues distinguished between the effects of a given medical intervention and its benefits. They argued that "the goal of medical treatment is not merely to cause an effect on some portion of the patient's anatomy, physiology, or chemistry, but to benefit the patient as a whole" (Schneiderman, Jecker, and Jonsen, p. 950). They also stated that futility should be defined within the context of evolving standards of care and that the goal of medicine is to achieve a benefit above a certain minimum qualitative or quantitative threshold.

Quantitative futility implies that the chance of achieving a specific goal, while statistically possible, is very improbable and cannot be systematically produced. Critics point out that physician experience is insufficient to form a consistent and reliable basis for quantitative judgments about futility. Moreover, physicians themselves do not agree about what the threshold should be for quantitative futility (McCrary et al.). Published series of cases are few in number and do not take adequate account of patient variables such as severity of illness or other, co-existing medical problems.

Qualitative futility, according to Schneiderman and colleagues, involves an intervention that may have a good chance of having a specific effect, but the effect provides no benefit to the patient. The problem here is that *benefit* is a value-laden notion, and patients may not have the same values as physicians (Youngner, 1988). Schneiderman and colleagues' two examples of qualitative futility illustrate this point. Their first example is the state of permanent unconsciousness. A patient in this condition, they argued, has no right to be sustained in a vegetative state. Critics, however, point out that a minority of persons (including a minority of physicians) does see such life as meaningful, and that in a pluralistic democracy it would be wrong for individual physicians to impose their *majority* values on others.

Schneiderman and colleagues cited patients who require constant monitoring, ventilatory support, and intensive care nursing as their second example of qualitative futility. While acknowledging that sometimes such patients might have worthwhile goals, for example, living long enough to say good-bye to a relative, Schneiderman and colleagues argued that judgment about the validity of the goal should be left to the *compassion* of the physician. Many would see this as an outmoded and unacceptable form of paternalism.

Thus, while the notion of futility captures an important concern about the harmful overtreatment of patients at the end of their lives, it remains difficult to define with precision. As we will see later, rather than serving as a trump card that physicians can play to unilaterally overrule the wishes of patients and family, discussions about futility may be most useful in stimulating a process of communication and negotiation about setting realistic patient-centered goals.

Futility and Rationing

The notion of futility is often confounded with that of rationing and justified by the need to limit the cost of healthcare. Despite important parallels between the concepts of rationing and futility (both have implications for resource consumption and the cost of care), they have distinct moral and conceptual meanings (Jecker and Schneiderman). Futility represents a clinical judgment that a specific intervention will not be successful in achieving a specific goal for a specific patient. Rationing means that interventions that do provide benefit will be denied to at least some persons who could benefit from them. While it is true that withholding futile care could save money, a treatment is futile whether resources are scarce or abundant. Futility is a judgment based on empirical evidence and clinical experience. Rationing is based on theories of social

justice—that is, who is more deserving of limited medical resources. Rationing is a public issue and, in a democracy, should be resolved through the political process. Futility, at least according to its defenders, is an objective medical determination. As such, they argue, it can be defined by physicians. Certainly, in a rational scheme of cost management, futile treatments should be eliminated before beneficial ones are rationed.

Professional Responsibility

Much of the impetus for acting on futility judgments has come from physicians and nurses who think they are violating important professional values—to help and do no harm—when they cave in to demands for futile interventions, such as cardiopulmonary resuscitation (CPR). Physicians are more than body mechanics who follow the orders of patients no matter what the consequences to those patients. CPR, for example, is a very aggressive, but notoriously ineffective, intervention in severely debilitated and dying patients. It involves multiple invasive procedures that often cause tremendous suffering (e.g., broken ribs) and a loss of dignity.

Avoiding Futility Confrontations

Too often, confrontations about futility are the result of poor communication and the conditions under which care is delivered in acute care settings. For example, health professionals sometimes fail to identify and set treatment goals. In their discussions with patients and families, health professionals focus on specific treatment interventions rather than on the goals that such interventions may or may not achieve. Questions such as, "Do you want us to start your heart again if it stops?" or "Do you want to be placed on a mechanical ventilator if you stop breathing?" are confusing, and even misleading, until potential goals of those particular interventions have been discussed and agreed upon.

Medical interventions are not ends in themselves; they are means of achieving desired goals. The job of the physician is first to help identify patients' goals and then to help them select among the treatments that can achieve those goals. For example, if a specific patient's goal is to return home with an independent lifestyle, aggressive interventions such as CPR and mechanical ventilation might well fail to meet that goal. On the other hand, if the patient's goal is extended life, even if its quality is significantly compromised, the aggressive intervention may not be futile at all. Sometimes the most difficult task of the physician is to help the patient and family come to terms with the reality that the goal they seek—for example, recovery and return home—cannot be achieved. Until goals have been understood and agreed upon, conversation about a particular treatment intervention is unlikely to be productive.

Sometimes, patients or families make unreasonable demands for care because they simply do not understand the clinical realities. It is not good practice to ask people if they want to be resuscitated when they do not know that the chances of resuscitation are small (near zero in patients with multiple failing organs) and the harms great (e.g., broken ribs, collapsed lungs). In a 1988 article, Donald J. Murphy reported that only 10 percent of multiply impaired elderly patients in a particular nursing home had "do not resuscitate" orders. A new medical director began informing patients and their families about the seriousness of their medical conditions, the burdens of aggressive intervention, and the small likelihood of success. As a result, twenty-three of twenty-four patients chose not to be resuscitated in the event of cardiac arrest.

Confusion is another reason patients and families demand treatment that physicians think is futile. There is no evidence that physicians agree on what counts as futility. Therefore, a patient or family may well become confused after talking with different physicians, each of whom has a different notion about whether the situation is futile. Moreover, confusion is aggravated by fragmentation and discontinuities in patient care. In large medical centers, patients are often seen by several specialist consultants. Each is responsible for one organ system and may communicate information that does not accurately reflect the overall prognosis of the patient. Communication may be further confused in academic teaching hospitals by the fragmentation of care caused by monthly rotations of medical trainees and supervising physicians, and shift changes for nurses and other healthcare professionals. If patients are lucky enough to have primary care physicians in the community, those physicians are too often not available to coordinate and manage the care of their patients who are in the hospital. The most important strategy for resolving conflicts about care at the end of life is to help everyone involved in a patient's care operate with a common understanding of the realistic medical prognosis and to then focus on the goals of the patient and family that are achievable (Youngner, 1994).

Sometimes, demands for futile treatment grow out of mistrust. Although some people are suspicious by nature, people often have good reasons for mistrust. For example, patients and families may have heard previous predictions of doom that were not fulfilled. Others may have had dealings with physicians who were not straightforward. Socioeconomic and cultural factors may also influence perceptions

and attitudes. African Americans, for example, have good historic reasons for mistrusting physicians and the institutions where they receive care. The legacy of the Tuskegee Syphilis Study, during the middle of the last century, remains a part of African-American consciousness. During this study, in which African-American men were enrolled, the researchers left the subjects untreated for syphilis so that the natural course of the disease could be studied. Even today, remnants of racial inequities remain in the U.S. healthcare system. For example, in many urban hospitals, few members of the medical staff and administration are minorities, whereas large numbers of the patients are. In addition, many people who are poor or members of minority groups have inadequate access to healthcare unless they are extremely ill. There is also evidence that minority and lower economic status are associated with preferences for more aggressive care (Garrett et al.). It is little wonder that some persons are suspicious when told by strange physicians in the middle of the night that further life-sustaining efforts would be futile.

Conclusions

There seems to be a growing consensus that futility has not been adequately defined or accepted by the medical community and the public. By and large, courts have rejected the notion that physicians should make unilateral judgments about what counts as a benefit to a patient or what chance is a chance worth taking. Paul R. Helft and his colleagues, in their 2000 article, "The Rise and Fall of the Futility Movement," concluded that a consensus has not been reached regarding the arguments for the supremacy of the rights of physicians or patients/families in judging futility. Instead, many clinicians and institutions have shifted the focus to developing a framework for discussing and resolving futility disputes. For example, some authors have emphasized a preemptive approach in which primary care physicians take responsibility for setting goals and discussing futile treatments before a crisis develops. In both Denver and Houston, community-wide policies have been developed that neither define futility nor give physicians unilateral power to act on their futility judgments (Murphy and Barbour; Halevy and Brody). Instead, these policies outline formal steps for conflict resolution in healthcare institutions.

MEDICARE

• • •

At its inception in 1966, the Medicare program was understood as a way to assure elderly persons a stable place in the

mainstream of American medicine. Over the first quarter-century of its operation, however, Medicare increasingly came to be viewed as an instrument to influence the character and costs of doctors, hospitals, and health insurance. In 1986 Medicare marked its twentieth birthday with considerable fanfare. In 1991, along with American medicine, Medicare faced severe financial pressures, and its silver anniversary was not celebrated; nor was its thirty-fifth anniversary much celebrated on June 30, 2001.

The Origins of Medicare

When the Great Depression made economic insecurity a pressing national concern, the social insurance reformers thought health insurance should be part of a comprehensive American scheme of social protection. From 1936 through the late 1940s, there were recurrent calls to incorporate universal health insurance within America's nascent welfare state. But, despite the broad public support for national health insurance, a conservative coalition in Congress defeated such measures (Marmor, 1973).

By 1952 the original architects of Social Security, well aware of this frustrating opposition, had formulated a plan of incremental expansion of government health insurance. The proponents of what became known as Medicare restricted the category of beneficiaries to retired persons, while retaining the conceptual link to social insurance. Medicare would provide retirees with limited hospitalization insurance—a partial plan for that part of the population whose financial fears of illness were as real as their difficulty in purchasing health insurance at an affordable cost. So began the long battle to turn a national health insurance proposal acceptable to the public into one passable by the Congress.

These origins had much to do with the initial design of the Medicare program—and with the expectations of how it would develop over time. The incrementalist strategy assumed that hospitalization coverage was the appropriate first step in benefits and that wider benefits would be enacted later under a common pattern of Social Security financing. Likewise, the strategy's proponents assumed that eligibility would be expanded gradually to include most, if not all, of the population, extending first, perhaps, to children and pregnant women. Medicare enthusiasts took for granted that the rhetoric of enactment should emphasize the expansion of access to medical care, not its regulation and reform. The clear aim was to reduce the risks of financial disaster for older people and their families, and the clear understanding was that Congress would demand a largely hands-off posture toward the doctors and hospitals providing the care Medicare would finance. Some twenty-five years after the program's enactment, it is taken for granted that how—or how much—one pays for medical care affects the care given. In the buildup to the passage of the Medicare bill (in July 1965), however, no such presumption existed.

Once this incrementalist proposal was outlined, who and what shaped its fate? Medicare's principal antagonists, and their adversarial methods, illustrate a familiar American form of ideological politics. The most prominent opponents—national medical, business, and labor organizations—engaged in open, hostile communication and brought into their opposing camps many groups whose economic interests were not directly affected by the Medicare outcome. Both the contest and the contestants remained remarkably stable from 1952 to 1964—two well-defined camps with opposing views reigned, and few groups remained impartial or uncommitted.

The particular features of the political environment in 1965 help explain details of the original Medicare program that remain problematic decades later. The overwhelming Democratic victory of 1964 seemed to guarantee that hospitalization insurance for older Americans would pass in 1965. President Lyndon B. Johnson's commitment to Medicare was made plain in his presidential campaign, and the new Congress of 1965 acted to prevent further delays in the president's Great Society agenda. The result, however, was far more complex than expected. The certainty that a Medicare bill would be enacted transformed the struggle from a polemic over Medicare's wisdom to a complicated strategy game about exactly what the program would do. Out of that game came the benefits, financing, and administrative design of the operational Medicare program. Few participants had expected Medicare to pay physicians at all, let alone their "reasonable and customary" charges in a new "Part B" of the program. And, while reimbursing hospitals (under Part A) using the Blue Cross formula of reasonable costs was anticipated, the Department of Health, Education, and Welfare hardly imagined the inflationary impact this would have.

The Development of Medicare

Initially, Medicare's administrators accommodated the demands of medical providers for a largely hands-off stance by public regulators. Out of this period—described by Columbia University political scientist Lawrence Brown in 1985 as "consensual corporatism"—emerged rapid inflation in Medicare's expenditures and the fumbling efforts to find acceptable means to control its costs.

From 1972 to the beginning of the 1980s, Medicare's woes were masked by the national preoccupation with the mix of inflation and unemployment known as stagflation, with broader proposals to reform American medicine, and with the growing appeal of *pro-competitive* alternatives to public regulation of discrete programs like Medicare and Medicaid. This period was characterized by the growing dispersal of government regulation among federal and state agencies (what Brown called "inverted corporatism"). The frustrating experience with health planning, with experiments in hospital reimbursement, and with the rapid growth of costs prompted broader reform approaches. A striking illustration of both the problems and the frustration was the addition of a special disease program under Medicare: one for all Americans suffering from renal failure. Enacted with great fanfare in 1972, the End-Stage Renal Disease Program grew rapidly—in beneficiaries, in costs, and in complexity. And it soon became a symbol of disappointment with traditional ideas of government health insurance (Starr). Throughout the 1970s, health policy experts produced a bewildering array of reform proposals, but Medicare's reform remained a special world of policy specialists, congressional committees, and the responsible executive agency, Social Security's Bureau of Health Insurance, until the Health Care Finance Agency (HCFA; now called the Centers for Medicare and Medicaid Services, or CMS) took over in 1977.

A third period of Medicare's administrative history—which Brown labeled "technocratic corporatism"—flowered in the 1980s. With universal health insurance dislodged from the national agenda, the attention of policymakers and technical experts returned to Medicare itself. Medicare and Social Security had been protected under the mantle of social-insurance theories of entitlement, and by the elderly population's reputed political clout. That protected status was what the budget and tax politics of the 1980s were to challenge.

Three developments exemplify this period, which extended to the mid-1990s. First, there were continuing efforts to reduce the rate of expenditure growth in Medicare, efforts that initially shifted costs to the elderly population, and later burdened hospitals and physicians. Second, there was the surprisingly rapid enactment in 1983 of a new form of hospital reimbursement within Medicare: the widely noted diagnosis related group (DRG) method of prospective payment. Developed by technocrats in the academy and within HCFA, supported by policy experts within the Congress, and with some operational trials in New Jersey, DRGs dominated the hospital world of the 1980s and symbolized the faith in scientific, apolitical answers to Medicare's troubles. At this time, there was no specific provision for monitoring the quality of hospital care, though there was no question of the potential effects on patient care of changing hospital financial incentives so drastically (Smith).

The third development, a new federal institution named the Prospective Payment Commission, became the monitor of DRGs, and later in the decade it spawned a similar institution for Medicare's Part B medical insurance, the Physician Payment Review Commission. It was assumed that the associated peer review organizations would take care of balancing Medicare's cost and quality.

The irony of the Reagan era is that an administration committed ideologically to free markets produced the most obvious examples of administered prices—the payment of hospitals by the diagnosis related group method—in American medicine. At the same time, increases in the medical expenses paid directly by elderly persons prompted what came to be known as the *catastrophic debacle* of 1987–1989. The Reagan administration proposed, and the Congress more generously delivered, a complicated piece of legislation to cover the catastrophic expenses of the elderly. A firestorm of protest erupted over the financing of this benefit expansion (affecting largely the more affluent elderly), and in 1989, for the first time in Medicare's history, the Congress repealed a benefit that had been regarded as a gift to the program's beneficiaries.

Twenty-five years after enactment of the Medicare program, its budget woes were part of the national preoccupation with increasing public deficits. The catastrophic debacle had symbolized and worsened the charges of *generational inequity,* with *greedy geezers* caricatured as the enemies of America's children, future, and tradition of fairness. With deficits untamed, further cuts in Medicare's rate of expenditure growth remained on the policy agenda in 1992 and thereafter, even as the nation debated more comprehensive forms of medical-care reform.

Attempts at Reform

In fact, the period between 1992 and 2002 was full of surprises. Anyone who observed the fight over the Clinton health-reform proposal would hardly have expected Republican leaders in the Congress to later promote a system of vouchers for Medicare that resembled Clinton's model of universal vouchers. In debates over the Balanced Budget Amendments of 1997 and later, previous critics of managed competition for all Americans became advocates for using that model for Medicare. The puzzle is why this apparent reversal took place.

Understanding the reversal requires distinguishing Republican philosophical distaste for *big government* initiatives

(like the Clinton proposal) from Republican pragmatism about how to control the budgets of existing federal programs (like Medicare). Vouchers for Medicare seemed, in the mid-1990s, an acceptable way to reduce federal expenditures and secure the balanced budget that fiscal policy conservatives had long sought (White). The presumption of the voucher advocates was that Medicare beneficiaries with a fixed sum (euphemistically described as *premium support*), would shop for the insurance plan they wanted, with competition among plans holding down inflation. Relying on that reasoning, advocates projected considerable savings from what Medicare had been predicted to spend in the decades ahead. And, with that, the game shifted to promoting expanded benefits, especially the coverage of prescription drugs that Medicare did not insure outside of the hospital environment. With cost control predicted, benefits expanded, competition at work, and choice to be enhanced, the conventional claim by the late l990s was that Medicare would finally be ready for the twenty-first century.

The suggestion that Medicare required fundamental alteration is precisely what a substantial proportion of the elite political community believed at this time. What is striking upon reflection is how unsubstantiated were the premises from which the reform proposals proceeded. Medicare was supposedly not sustainable in its traditional form. Sure to "run out of money" over time, Medicare was regularly labeled as archaic and out of touch with medical realities. This was what the Bipartisan Commission on the Future of Medicare sought to communicate in 1999, though their proposal fell short of enough votes in the commission.

In fact, Medicare was hardly unsustainable. In 1997–1998, Medicare's outlays increased by only l.5 per cent, and for most of its history its costs have increased no more than the private health insurance plans with which it has been compared. The claim that Medicare was archaic represented sheer perversity. The developments in American medical care during the 1990s had made managed care a source of jokes among ordinary Americans, not a model to be followed. The appeal to the supposed virtues of competition among managed-care plans was more interest-group rhetoric than a reflection of popular consultation or defensible policy analysis.

Just as with the birth of Medicare, the changing partisan composition of the Congress made a crucial difference in the nature of the claims about Medicare at the close of the century. The question for Medicare's future in the spring of 1999 was whether liberal Democrats could persuade President Clinton to reject the type of reform proposal his own rhetoric had helped to generate. And, by the fall, they succeeded.

Efforts to change Medicare reflect presumptions about the proper role of government in American life and the purposes of social insurance in paying for medical care. Medicare's fate will be linked to controversies about managed care and whether Medicare should embrace or reject its expansion. The agenda—and Medicare's place on it—is subject to transformation by both electoral and economic shifts, and no one can claim with certainty what the political and economic environment will be like a few years hence, let alone decades. What can be concluded, however, is that the politics of Medicare will continue to produce two types of policy disputes. First are the relatively narrow policy conflicts in which the ideological cleavages in the larger public are substantially irrelevant, and second are those relatively rare but important disputes where the deepest divides in the American political world are crucially relevant. This is what Medicare's origins and programmatic history reveal.

MEDICINE, ANTHROPOLOGY OF

• • •

Medical anthropology is the cross-cultural study of health, illness, and medical systems. Medical anthropologists describe how the collective meanings, social institutions, and dynamics of political power in a particular society construct local forms of medical knowledge and therapeutic action that are differentially distributed across gender, age, ethnic, and class lines. From hundreds of studies a deeper understanding has been gained of variation in illness beliefs and behavior and of pluralism in healing practices (see, e.g., Good, 1977; Janzen; Kleinman, 1980; Leslie; Lock; Nichter). Yet there are also universals in the mediation of suffering and in the therapeutic process about which the comparative method provides a special insight (see Kleinman, 1988a, 1988b).

Medical anthropologists or anthropologists of medicine (the terms are interchangeable) have brought different paradigms to bear on the study of health and disease. Ecological, political-economic, and applied public-health or clinical perspectives are all to be found in the literature. Yet since the 1970s the most original anthropological contribution is what has come to be called a meaning-centered or social constructionist paradigm.

In this perspective, the central concern is with the way that illness categories and experiences reflect culture, and in turn contribute to social change. Thus, Gilbert Lewis (1975), working with a small-scale preliterate society near the Sepik River of Papua New Guinea, shows how that society's master symbols are reflected in the illness behavior of withdrawal and isolation of seriously sick members and in the "days of shining red" animated by healing rituals. The smells, tastes, sights, sounds, and sensibility of everyday responses to shamans' songs among aboriginals in the Malaysian rain forest and Malays in rice-farming villages (Laderman, 1991; Roseman); of routine coping processes through which Haitian villagers make accusations about the sources of AIDS (Farmer); and of the social as well as personal experience of sadness among Yolmo Sherpas in Nepal (Desjarlais)—all are patterned by deep cultural codes and social structures. Much the same cultural dialectic between persons and collective institutions has been shown to pattern interactions in psychiatric emergency rooms in North America (Rhodes); in the training of medical students to see patients through the lens of biomedical reductionism at Harvard Medical School (Good, 1993); and in the practices of oncologists in Tokyo, Rome, Oaxaca, and Boston (Good et al.).

Global social change has proliferated, not limited, the numbers and types of traditional healers in both richer, industrialized societies and poorer, industrializing ones (McGuire). Industrialization on a worldscale has neither undermined traditional medical beliefs nor foreclosed on folk health practices; yet such global social change has made much less clear the division between *traditional* and *modern.* One finds in the so-called East Asian industrial dragons, for example, a greatly complex mesh of attitudes, values, and practices. There is no simple giving way of *tradition* to Western orientation; indeed, both tradition and Westernization are routinely reinvented. The Japanese may be moving to accept brain death as a marker of the end of human life, and thereby facilitate organ transplantation, which has been severely constrained by Buddhist ideas; but it is a movement strongly contested by large numbers of Japanese who maintain traditional values about death together with the most advanced technological orientation.

Patients and their families, when it comes to serious illness, are pragmatic; they cross back and forth between the professional and folk domains of healthcare. Scientific knowledge has not replaced cultural common sense but been integrated with it (Kleinman, 1980; Nichter). Biomedicine has been the leading edge of a worldwide culture of science, yet in Asian and African societies biomedical institutions and relationships have become indigenized in ways that reflect those societies' master values and particular forms of social life. As a result there are both certain similarities and even greater dissimilarities in the ways professional and lay members of those societies make therapeutic decisions, handle life and death events, respond to chronicity and disability, and negotiate the complexities of care (Laderman, 1983; Last and Chavunduka; Rhodes; Sargent; Young, 1977).

Because of their concern for value orientations and everyday decision making, anthropologists have written

about the ethical sides of health and healthcare. For example, Peter Kunstadter (1980) and Morton Beiser (1977) wrote about the ethical quandaries that development projects, including medical ones, introduced into traditional communities, because the services they provide are temporary and therefore raise expectations that eventually will be frustrated. Mary Jo Good and colleagues (1993) and Margaret Lock and Christina Honda (1990) examined the moral exigencies of truth telling about cancer and determining death in biomedicine in Japan. Paul Unschuld (1979) analyzed the corpus of Confucian and traditional Chinese medical writings on ethical issues, and concluded that professional and cultural values of the literati class colluded to control the medical marketplace. Arthur Kleinman (1980) found that healers in Taiwan in the 1960s and 1970s—whether traditional Chinese medical practitioners, shamans, or physicians—were viewed ambiguously: as morally powerful to heal, yet potentially immoral sources of economic gain and even of evil power (sorcery). This finding is rather widespread cross-culturally.

Horacio Fabrega (1990), writing explicitly about an ethnomedical approach to medical ethics, saw biomedicine's ethical preoccupations growing from Greek medicine and the popular morality of ancient Greece. Following many anthropologists, he asserts that in small-scale, preliterate societies, healing and religion are inseparable; thus, for Fabrega medical mores are tied to ritual and theology in these societies. In larger-scale societies—both peasant and posttraditional—the specialized division of labor leads to practitioners who are popularly viewed both as healers and as financially benefiting from the healer's trade. Fabrega argues that all the great non-Western traditions of healers use ethical injunctions to control access to practice and to proscribe certain alternative healers as quacks. He asserts that *bioethics* is a unique version of medical ethics made possible by the development of biomedicine with its knowledge of biology and powerful biological applications.

Writing for a collection of social-science treatments of bioethics, Richard Lieban (1990), himself an anthropologist, focuses on anthropological interest in the ethical aspects of controversial folk practices—such as female circumcision, differential assistance to male children, and the lack of regulation of folk healers—as examples of what anthropologists can offer to bioethical issues in international health (see also Scheper-Hughes; Korbin; Gruenbaum; Kleinman, 1982). Allan Young (1990), in the same volume, demonstrates the value of ethnographic accounts of the hidden moral dimensions of psychiatric practice in a Veterans Administration unit for treating combat-related posttraumatic stress disorder among veterans who had served in the Vietnam War.

What characterizes anthropological approaches to ethical issues, in medicine as well as other fields, is an emphasis on questions that emerge out of the grounded experiences of sick persons, families, and healers in local contexts. Anthropologists have critiqued universal ethical propositions just as their professional perspective has led them to critique universalist models for economic development. In place of universalist propositions—philosophical or political-economic—anthropologists have focused upon the local interactions of everyday life and the moral issues in which they are clothed. In Isaiah Berlin's (1979) apt metaphor, they are more the fox than the hedgehog. The latter type of intellectual (e.g., the moral philosopher or the psychoanalyst) knows one big thing about the human experience, while the former (e.g., the historian or anthropologist) knows many small, particular things.

The remainder of this entry will adumbrate what anthropological studies tell us about health, illness, and care that is relevant to the practice of bioethics. Starting with a cross-cultural critique of leading bioethical orientations and commitments, the more powerful anthropological contributions will be reviewed, followed by a brief discussion of the possibilities and problems with a culturalist orientation. From the anthropological perspective, bioethics shares with biomedicine several determinative cultural orientations that constrain the standard approach to ethical issues in patient care. The anthropological approach, therefore, becomes particularly useful because of the comparative understanding it offers of often unexamined biases.

The *ethnocentrism, psychocentrism,* and *medicocentrism* central to biomedicine are prominent in the standard bioethical approach (see Lock and Gordon; Weisz). Most philosophically trained bioethicists draw on what Charles Taylor (1989) describes as the orthodox sources of the self in the Western philosophical tradition. The great works in that tradition, from those of the Greeks down to the present, assume an individuated self, set off from the collective—single, unchanging, and self-defining. Thereby, inter alia, the autonomy of the person is claimed to be a paramount value along with the ideas of justice and beneficence. From a cross-cultural perspective this intellectual commitment is problematic.

In the major non-Western societies—such as China, India, Japan, Indonesia, and most African societies—few people hold that the isolated individual is the locus of responsibility for therapeutic choice, or that therapy should work to maximize the individuation of the sick person. Rather, there is a paramount sociocentric consensus in which social obligation, family responsibility, and communal loyalty outweigh personal autonomy in the hierarchy of ethical principles. The self is viewed as sociocentrically

enmeshed in inextricable social networks, ties that make interpersonal processes the source of vital decisions. More than 80 percent of the planet's population lives in cultures outside of North America and Western Europe or are members of minority ethnic groups outside of the Euro-American majority. That bioethics is able to avoid serious engagement with these alternative ethical traditions must represent one of the last tenacious holds of ethnocentric mentality. Indeed, there is evidence that bioethicists are commencing such decentering cultural engagements (Jennings; Loewy).

Similarly, from an ethnographic perspective, the use of abstract concepts of justice and beneficence as universal ethical principles in decision making is suspect because of the failure to take into account the local worlds in which patients and practitioners live—worlds that involve unjust distributions of power, entitlements, and resources. It is utopian, and therefore misleading, to apply the principles of justice and beneficence to practical clinical problems, unless we first take into account the brutal reality of the unjust worlds in which illness is systematically distributed along socioeconomic lines and in which access to and quality of care are cruelly constrained by the political economy. Beneficent social contracts may make good theory, but they deny empirical experience in local social worlds. Loewy's "beneficent community," which he claims is concerned with minimizing the suffering of its members, is a charming romance; no one lives in such a utopian state. Rather, real communities are sources of suffering at least as much as potential sources of assistance. They do not contain social contracts; but they are filled with different interests, status differences, class divisions, ethnic conflicts and factionalism. Little is gained by instantiating utopian virtues; indeed, much is lost, since illusion and exaggeration distort the practical realities of living.

The third "centrism"—medicocentrism—emerges from comparative studies as yet another bias of standard bioethical discourse. Like biomedicine, bioethics begins with professional definitions of pathology. The disease viewed as pathological physiology, and the professionally authorized array of treatment interventions, define the clinical situation (see Canguilhem). The experience of illness is made over, through the application of ethical abstractions such as those described above, into a contextless philosophical construct that is every bit as professionally centered and divorced from patients' suffering as is the biomedical construction of disease pathology.

The bioethicist, of course, is supposed to take into account the patient's perspective. But by and large the contextually rich illness narrative is reinterpreted (also thinned out) from the professional biomedical standpoint in order to focus exclusively on the value conflicts that it is held to instantiate. The folk categories of patients and indigenous healers are provided with only limited legitimacy. If they can be restated in the abstract terms of the standard bioethical orthodoxy, they are provided a place in the analysis. But if they cannot, then folk categories lose their authoritative imprint to define what is at stake for patients and families.

Take ideas, for example, of *suffering*—a powerful folk category worldwide. One is surprised to find so many professional ethical volumes in which this word does not appear as an entry in the index. Ethical systems that leave the problem of suffering (and related concepts of endurance and courage) to particular theological traditions cannot adequately engage the human core of illness and care. Here perhaps the standard version of bioethics shares yet another biomedical bias, the rejection of teleology. Biomedicine banishes the concepts of purpose and ultimate meaning to religion; yet most patients and practitioners struggle to make sense of illness with respect to great cultural codes that offer coherent interpretations of experience (cf. Frye).

Medicocentrism also leads bioethicists to construct cases that are centered in the professionally approved institutional structures of biomedicine—such as hospitals or nursing homes—despite the fact that most illness episodes, as social studies reveal, are experienced, interpreted, and responded to in the context of the family. The family—the mundane cultural setting of illness and care, where local social processes are so greatly influential—and the workplace frequently disappear in bioethical discourse, to be replaced by the biomedical staging of more extreme, even exotic value conflicts. Of course, the immense panoply of settings for healing is even less visible or audible in the bioethical construction of clinical reality.

This all too black-and-white portrait of bioethics is intended to draw out and highlight its deep difficulties and their cultural sources. In the practical flow of events, the working bioethicist struggles to overcome the constraints that limit his or her engagement with the obdurate particularity and inexpedient uncertainty of human subjects. And for that very reason he or she will find an ethnographic orientation to be liberating.

In contrast with the bioethicist, the ethnographer begins with the lived flow of interpersonal experience in a deeply particular local world. Not the Western tradition or North America, nor even New York State—which are too unspecified to provide a positioned *view from somewhere*—but, rather, the Puerto Rican community in the South Bronx, upper-middle-class Scarsdale, a working-class section

of Queens, or a network of Russian immigrants in Brooklyn becomes the setting for grounding moral analysis in the concrete historicity, micropolitical economy, and ethnicity of a local world. Even within such a localized flow of experience, perspectives and preferences are further defined by gender, age, and other social categories of persons: for example, the cultural situation of poor women in rural Haiti who are responding to AIDS (Farmer and Kleinman). These indexes of social experience situate groups and their individual members along axes of power such that the forces of macrosocial pressures—economic depression, war, forced uprooting, ethnic conflict, state violence, the organizational control of substance abuse, the social structural sources of chronic illness and disability—are systematically attenuated for some, yet amplified for others. Some become successful or at least are protected; others are victims.

Each local world is characterized by what is at stake for its members. That structure of relevance—compared to a belief or a convention—gives to the meanings of illness and to treatment expectations the sense of something much closer to natural law. Families hold the world to be a certain way as an article of fundamental faith in local reality. In the infrapolitics of family, workplace, and community, which is empirically discoverable, the processes of strategic negotiation and interpersonal engagement over what is at stake can be properly regarded as processes through which a local moral order is constituted and expressed. Culture, then, is built up out of the everyday routines and rhythms of social life. It is the medium of experience, for example, in which one person's chronic pain affects an entire work unit, a family member's Alzheimer's disease is shared as an illness reality by the entire family, and cancer care is negotiated among parents, child, and professional care providers.

Hospitals, clinics, and disability programs also are grounded in the particularity of local worlds, as is the bioethicist. The ethnographic task for the practicing bioethicist, then, becomes the discovery of the meanings and relationships in distinctive local worlds, and their actual impact on particular patients, families, and practitioners. This is a kind of cultural analysis of moral conflicts and negotiations over plans and practices that make up the flow of everyday living. As part of this ethnographic work, the bioethicist needs to elicit the perspectives of the participants and place them in the contexts of family, workplace, and medical system. The bioethicist's involvement should be to facilitate communication and to help negotiate conflicting orientations. In this work, it is necessary to protect the participants from the dehumanizing imposition of hegemonic principles. This focus on the positioned, intersubjective perspectives of participants in a local context is a radically different vision of how to proceed with the ethical analysis of a case than that which originates in a philosophical quest for an illusory *transpositional objectivity*, a synthesis valid for an entire context, which in the anthropological vision is the problem, not the solution (Sen).

More specifically, anthropological analysis draws attention to the institutional context of ethical decision making (see Bosk; Fox; Mizrahi). Social institutions—a particular type of hospital, a clinic for alternative care, or a religious facility—refigure ethical issues in terms of efficiency and other technical criteria that make up everyday social routines. Hence, the special characteristics of a Veterans Administration hospital, a university-based teaching hospital, a military hospital, a member of a for-profit hospital chain, or a highly cost-conscious HMO constrain the day-to-day social processes that create the local moral order. What is at stake for a resident in training in a teaching hospital—generating new knowledge, securing a place in the academic hierarchy, and so on—is noticeably different from what is at stake for a senior physician at a small community hospital. The difference signals a distinctive institutional context for deciding what level of treatment is *routine,* which kinds of issues will be highlighted as *ethical* problems, when families will be involved, and so on. Quite obviously, such institutional contexts will also be distinctive cross-culturally.

In Japan, even in a university teaching hospital, the practice has been not to disclose to patients that they are suffering from cancer but to allow key family members to decide if and when the *truth* will be told. In China, family members will stay in the hospital with the patient to do the nursing, prepare meals, and make all the major decisions, even for the family head when he is seriously ill.

In Zaire and Senegal, members of the kinship-based therapy management group, including perhaps the doctor and the nurse, will decide if the patient is to be part of a research protocol (Beiser). In a Seventh-Day Adventist mission hospital run by American staff in Borneo, the structure for identifying and resolving a moral dilemma draws on a religious ideology that suffuses the institutional context in a manner that greatly differentiates this hospital from nearby hospitals run by transplanted Javanese Muslims or local animists. The responses of North American and Chinese psychiatrists to depressed patients in the United States and China have been compared with respect to their decidedly different institutional contexts for determining what kinds of therapeutic behaviors represent good care and what kinds of moral messages will be given and received in the patient-doctor interaction (Kleinman, 1988b). Renée Fox and Judith Swazey (1984) have shown how physicians in a Chinese hospital draw on both Confucian views and

Communist ideology to authorize local patterns of ethical decision making that challenge North American orientations. And cultural historians disclose how bioethics in North America has emerged out of the social problems and responses of a particular era (Rothman).

Besides cultural critique and comparison, what practical contributions can anthropology make to bioethics? The cultural formulation of diagnostic and therapeutic issues clearly should be as significant to the consulting bioethicist as it frequently can be made to be for the consulting physician, especially when the patient and family come from cultural and ethnic backgrounds that differ from those of their professional caregivers, or when the setting is outside North America (Kleinman, 1982). That formulation involves systematic steps in placing the illness and treatment experience in the culturally grounded context of family, work, and medicalsocial welfare systems, through the application of a mini-ethnography—a description and interpretation of how those settings affect, and are affected by, the illness. Cultural formulation identifies lay and professional explanatory models, compares them for evidence of cultural bias or conflict, and sets out a process of negotiation to assure cultural sensitivity (see Helman, 1984; Kleinman, 1988a; Rogler). These are technical procedures that should be part of the repertoire of the bioethicist. Ethnographic knowledge of the core ethical orientations and social patterns of different communities will be especially significant in planning and implementing medical research in ethnic minority and non-Western settings (Christakis).

What are the limits of cultural analysis, cross-cultural comparison, and the sensibility to variation and differences that come under the term *cultural relativism*? While epistemological and even ontological relativism—willingness to entertain the idea that there is no single form of knowledge or being in local worlds—will seem defensible to many, ethical relativism of the radical variety—the idea that there are no ethical standards cross-culturally—will not. Are such practices as infanticide of female children in South Asia, ritual murder of elderly women accused of being illness-causing witches in East Africa, and rationing of care based on color status under apartheid acceptable because the dominant group says they are? Clearly, this would be an unacceptable conclusion. Behind it lurks the terrible transmogrification of medicine under the Nazis, when biomedical ideology and technology, dominated by Nazi values, prepared the way for the death camps (Kleinman, 1988b; Proctor).

The anthropological argument advanced in these pages is for elicitation and engagement with alternative ethical formulations, a constrained relativism; it is for affirmation of differences, not automatic authorization of any standard or practice as ethically acceptable because it is held by some people, somewhere (Shweder; Wong). The limit to ethical relativism is that the bioethicist must compare alternative ethical formulations with those ethical standards he or she holds for the evaluation of a particular problem in a particular context. The outcome of such an evaluation could be acceptance or rejection of the alternatives or of the bioethicist's own standards, or some form of negotiation and compromise.

The idea of radical cultural relativism is unacceptable to all but a small group of diehards. It is, moreover, a serious misinterpretation of what ethnography, cultural analysis, and cross-cultural comparison have contributed: the idea that before we apply an ethical category we hold to be universal, we had better understand the context of practice and ideas that constitute a local moral world. The job should be to situate a bioethical problem in that local ethos in order to understand what is at stake for the participants, what is contested, and thereby to offer a cultural formulation of conflicting ethical priorities. That having been done, there are at least three further steps. First, we need to systematically compare local and professional bioethical standards for that particular problem; second, we need to negotiate that part of the difference on which both parties deem it ethical to compromise; and third, where a cross-cultural ethical conflict cannot be so resolved, both parties should specify the nature of the problem for further adjudication (Kleinman, 1982). This ethnographic strategy does not commit the deep error of assuming that "all goods, all virtues, all ideals are compatible, and that what is desirable can alternately be united into a harmonious whole without loss" (Williams, p. xvi). Compromise and negotiation may not resolve ethical conflicts; and even where they do, some losses must occur. The quest is not for integration and unification, but for multicultural pluralism.

Where possible, it is the obligation of the bioethicist not only to respect the specific views of others and to affirm the validity of the process of alternative moral formulations, but also to develop deep knowledge about those viewpoints and to test those alternative categories and practices for potential ways to resolve ethical conflict. This ethnographic approach emphasizes the process of engagement and negotiation with the lived moral orientations of others; it attempts to minimize the application of those bioethical standards that derive from the Western philosophical tradition, to settings for which they lack coherence and validity. In all other areas of cross-cultural research and practice this is the established procedure. This approach also protects the responsibility of the professional bioethical consultant not to accept value decisions that contravene human rights and other pannational moral conventions. But it makes this universalist responsibility the final stage in a process of cultural translation that gives priority, initially at least, to alternative worlds

of experience interpreted in their own terms. Perhaps the cardinal contribution of the medical anthropologist to bioethics is to deeply humanize the process of formulating an ethical problem by allowing variation and pluralism to emerge and receive their due, so that ethical standards are not imposed in an alien way; rather, these standards will then be realized as the outcome of reciprocal participatory engagement across different worlds of experience.

MEDICINE, ART OF

• • •

In the art of medicine physicians themselves become the diagnostic and therapeutic instruments that apply the knowledge and skills of medicine. The art of medicine includes not only what is required for a physical diagnosis and for healing, but also the ability to apply the generalized knowledge of medicine and medical science to individual patients. This latter aspect includes knowing the particularity of the patient, knowing how to shape the doctor's knowledge of medicine to the particular patient, and developing the relationship between patient and doctor. Discrete skills serve these goals, among them understanding the behavior of patients and doctors, using the doctor-patient relationship for diagnostic and therapeutic ends, good judgment and decision making, and effective communication.

For bioethics, considering the art of medicine offers challenges because aspects of the art arise from the singular traits of sick persons and the special character of the doctor-patient relationship. These put in doubt the validity of some ideas about patients' independent self-representation and self-determination that have been important in the recent development of bioethics.

In this context art does not refer to the general meaning of aesthetics or the fine arts. Instead, it is derived from the Greek word *techné,* meaning craft or skill. This distinction is important because it is commonly said, in error, that the art of medicine cannot be taught. Crafts and skills are said to be learned from others. The ancient Greeks classified medicine as one of the original arts, along with weaving, carpentry, and geometry. On the other hand, mere skill is not all there is to this art, which must be served by a deeper practical understanding of its complex subject, as in Aristotle's *phronesis* (sound, considered judgment) or the Hippocratic phrase, "Life is short and the art is long." It was only with the rise of science in the seventeenth century that the term began to have its current meaning of the personal skills of physicians. In the twentieth century, the "art of medicine" has been sharply distinguished from the "science of medicine" and has come to have a somewhat pejorative connotation.

The Effects of Science on the Art of Medicine

The identification of the art of medicine with subjectivity and particularity is what has led to its recent loss of stature. It has been an article of faith of medical science in the twentieth century that objective scientific evidence would eventually replace the subjectivity of the transaction between an individual patient and physician. A further canon of medical science is that the knowledge and the science make the diagnosis and effect the treatment. The individuality of the physician is irrelevant; doctors are interchangeable. However, as Samuel Gorovitz and Alasdair MacIntyre have pointed out, generalizations of scientific medicine from systems that may not involve humans and by abstraction from observations of particular patients must be reparticularized to this patient, at this time, in this context, by this physician (Gorovitz and MacIntyre). In the care of sick persons, there are no sharp distinctions between medical science and the art of medicine, since both kinds of knowledge reside in the individual physician. It is his or her individuality that allows the physician to practice the art of medicine. An impersonal agency like a computer can deploy the science of medicine, but a particular doctor must adapt this knowledge to an individual patient. To do this appropriately requires both tacit and manifest knowledge within the doctor.

Patterning knowledge to the patient is generally known as medical judgment—acquiring and integrating both subjective and objective knowledge to make decisions in the best interests of the patient. Recent advances in studies of the theory and practice of medical decision-making do not fully encompass clinical judgment, because they have focused more on solving problems that arise from the uncertainties of medical information than on the consequences that follow from the relevance or meaning medical information may have for the particular patient.

The tendency of physicians and medicine to conflate the patient with the disease obscures the importance of the art of medicine. It is impossible, however, for physicians to confront or treat diseases. Because they can only treat the

patient who has the disease, the art of medicine will always be essential.

How the Individuality of the Patient Makes a Difference

THE DISTINCTION BETWEEN DISEASE AND ILLNESS. *Disease* is the pathoanatomical or pathophysiological entity that manifests itself in symptoms that the patient experiences and the doctor discovers (Cassells, 1985a). Diseases are abstractions that have no concrete existence except as instantiated in particular patients. *Illness* is the patient's experience of the effects of the disease process; it includes not only the symptoms—alien sensations or perceptions of distorted function—but the interpretations and meanings of the symptoms. The illness also embraces the impact of altered function on behavior and social existence. It is the illness that the patient presents to the physician as reported symptoms and dysfunctions. While the physician may be primarily interested in the disease, the ethicist should be concerned with the illness because of its effects on the patient, his or her relationships, and the community that put in doubt the moral agency of the sick person.

THE EFFECTS OF THE INDIVIDUALITY OF THE PATIENT. Onset, course, treatment, and outcome of identical diseases vary from patient to patient because of individual variation from the molecular level to the whole person to the community. The contribution of the individual to differences in his or her illness is sometimes difficult to appreciate if one thinks only about the acute infectious diseases or trauma. Chronic diseases, which produce the greatest burden of illness in the U.S. population, provide better examples. For example, diabetes in adults is genetically determined, but its severity and manifestations are influenced by variation in diet and exercise pattern from person to person. In addition, the availability, type, and utilization of medical care play parts in the effects of diabetes. Because disease is a process that occurs over time, the responses of the patient to the disease manifestations become part of the illness itself, as they alter the patient's behavior and change the illness. For example, whether patients report symptoms, visit physicians, take prescribed medications, alter their lifestyle, accept illness as inevitable, or fight its every intrusion—each of these factors has an influence on the illness and expresses the individuality of the sick person. Each modification requires a change in the approach of the physician dictated, for the most part, not by medical science but rather arising from the doctor's art. The physician can affect the patient only through the doctor-patient relationship, which is central to the practice of medicine and its art, but differences among individuals—for example, their degrees of trust versus suspicion, openness versus shyness, or friendliness versus hostility—influence the kind of relationship formed.

The Different Perspectives of Patients and Physicians

The patient's perspective on his or her affliction is different from the physician's. In such crucial dimensions as time, space, and the meaning of specific medical objects (such as bodily organs, technological devices, and medications), patients' experience of their world diverges from that of the physician, whose scientific perspective on their disease includes objective measures of time and space and precise definitions of objects (Toombs). In the case of hypertension, for example, patients may feel threatened with a stroke by this moment's elevated blood pressure, even though the dangers of hypertension lie in its effects on the heart, kidneys, and blood vessels over long periods. To patients, the felt immediacies of other disease threats also seem more a result of their seriousness than of their actual temporal proximity.

A patient's focus on a particular symptom depends more on the patient's interpretation of the symptom than it does on the actual experienced events. For example, a patient who interprets his or her chest pain as signaling heart disease may not be aware of, pay attention to, or report associated shoulder or neck pain that would tell the doctor that the chest pain is secondary to an entrapped cervical nerve and not heart disease. Further, patients rarely understand the probabilistic nature of medical information—that the facts of a case are most often not simply true or false, but only true with degrees of confidence—and even when they do, it is difficult for them to understand the meaning of these probabilities for them. Objectivity, always difficult, is virtually impossible for the sick person because of the nature of illness. Important alterations in thought processes, such as the inability to see things from the perspective of others and a concreteness of thought usually characteristic of children, accompany only serious illness, but this is where the reflections generated by bioethics are most important (Cassell, 1985b).

More than just medical science determines the physician's perspective of the patient's illness. Besides diagnostic and treatment goals that draw heavily on medical science, physicians have other aims. Some, such as the desire to save or prolong life, relieve pain, avoid doing harm, and provide information, are patient-centered. Others, such as being trustworthy and truthful, relate to their relationships with patients. As physicians among other physicians they also

want to maintain their knowledge, to be considered good doctors by their peers, and to uphold the standards of their profession. Many of these ends are professional in nature, are part of the socialization of doctors, and reach back to antiquity. They, too, distinguish the doctor's point of view from that of even informed patients.

Although doctors and patients may appear to speak the same language about the same subjects, their differing viewpoints ensure that a physician may remain within the medical-scientific worldview and not attend to the patient's concerns. The care of the terminally ill often exemplifies such dissonance. Here, one of the ends of medical practice—staving off death as long as possible—may be at odds with the patient's desire not to be in pain or suffer. A necessary aspect of the physician's art is to understand the patient's goals and adjust professional aims and medicine's tools to these ends. This is the meaning of sayings throughout medical history exemplified by that of Bela Schick, "First the patient, second the patient, third the patient, fourth the patient, fifth the patient, and then maybe comes the science." That this principle is often violated or ignored does not obviate its centrality for the art of medicine.

The Doctor-Patient Relationship

The special nature of the relationship between doctor and patient has been appreciated since antiquity (Laín Entralgo). As much a part of sickness and medicine as the diseases that make people ill, this relationship makes a sick person a patient and a medical person a doctor and a clinician. It is the vehicle through which physicians exercise their authority (not to be confused with authoritarianism), without which the practice of the art is impossible (Needleman). An examination of the way the relationship is formed and its potential for effectiveness suggests that this special bond is a basic part of the human condition with cultural and social dimensions (Cassell, 1991).

In emergencies, when doctor and patient have never previously met, the power of the relationship can become effective immediately. Within moments a doctor who is a stranger can ease pain, make panic subside, and improve breathing. (Physicians can also worsen symptoms and exacerbate panic by wrong actions.) The bond between doctor and patient is effective across cultural boundaries, even in the presence of antagonisms, and despite sometimes formidable social and environmental impediments.

Physicianhood is a role—a set of performances, duties, obligations, entitlements, and limitations connected to a function or status. The socialization of medical students includes learning about the doctor's role so that they emerge both as physicians and in the role of physicians. Given its sociocultural nature, it has its counterpart in the patient, who provides for the doctor's words and action access to the patient and the patient's body not available to ordinary relationships. Because the connection between doctor and patient is bilateral, the power of sickness to make patients susceptible to change at all levels of the human condition is matched ideally by the power of this benevolent relationship to induce physicians to extend themselves at all levels.

Physicians, because of the relationship, are enabled to see the authentic person through the mess of sickness, read the history of self-determined purposes in the life before illness, and understand the aesthetic whole that is the patient's life prior to the unwelcome intrusion of disease. In a modern extension of the art, they therefore have the opportunity and obligation to help the patient maintain autonomy, which, for the sickest, would be almost impossible outside the relationship. Clinical ethicists share in this opportunity when and if the patient extends this special bond to them (Zaner).

These aspects of the doctor-patient relationship are frequently obscured from view or even contravened in the high technology atmosphere of modern medical centers. The patient's trust is necessary for the most successful diagnosis and treatment, and therapeutic intimacy arising out of the relationship creates confidence. As part of their art, skilled practitioners actively nurture the relationship, not only encouraging its growth and promoting trust by the patient, but negotiating between empathic intimacy and objectivity. One skill in the art of clinicians lies in coming as close as ethically possible to intimacy while maintaining independence of action. A strong bond is essential in negotiating the difficulties and uncertainties of serious illness. It is equally important in supporting and teaching patients through the long trajectory of chronic illness.

The Behavior of Sick Persons and Doctors

THE BEHAVIOR OF SICK PERSONS. Even mild sickness alters behavior; profound sickness alters behavior profoundly. This is culturally acknowledged by what has come to be known as the sick role, the exemption from everyday duties and obligations granted to sick persons. Changes in functioning are not merely those associated with the disordered part—for example, the inability to move around because of back pain. Sickness induces changes in cognitive function and in relationships with self, body, and others. Patients who are sufficiently ill—for example, in life-threatening infectious diseases, congestive heart failure, for a few days

after bypass surgery, or in long-term hospitalizations—although they are cognitively normal by conventional measures, have patterns of reasoning that Jean Piaget showed in children under six. For example, the sick frequently fail a classic test of reasoning about the conservation of volume. Two containers identical in size, shape, and the volume of water they contain are shown to the patient with the statement, "These two glasses have the same amount of water." The contents of one glass is then emptied into a tall thin cylinder and the patient is asked, "Which one of these has more water?" Sick persons will frequently indicate the tall thin cylinder. They may say, "I know that it shouldn't have more water, but it does" (Cassell, 1985b).

Sick persons usually are also unable to alter their perspective sufficiently to understand the viewpoint of another. A child's alphabet block shows this in its simplest form. Even if the block is rotated so that they have seen all of its sides, when looking at one face, they cannot report what is on the opposite face. One can routinely demonstrate many other similar changes in reasoning, of which the patient is almost always unaware. Because of the similarity of their reasoning (and other traits) to children, these characteristics have been considered regression. To avoid the error of treating the sick like children, it seems wiser to realize that this altered behavior is sickness expressing itself. Thus, in appropriate circumstances, patient self-determination will be enhanced by offering no more than two concretely worded alternatives at a time and avoiding choices couched in abstractions.

The sick are attached to their caregivers. How their attachment is expressed varies from love to anger or rebelliousness. The skillful physician is aware that these emotions are not directed at the doctor as a particular person (about whom the patient usually knows very little) but at the doctor in the role (Landis). As such, they are not to be taken personally but should be used in diagnosis or treatment. Changes in the patient's relationship to the body are also a common characteristic of illness. The patient may become angry with the body because of what it has done to the patient, as though the disease was something the body "did" to the patient. Relationship to the body influences the patient's other illness behavior and reactions to the events of the sickness and its treatment.

Illness brings about dependency on others and often induces feelings of loss of control, helplessness, inadequacy, and failure. As a result, it may awaken unconscious conflicts and cause the patient to act toward the physician as if he or she were the patient's parent. The artful physician, aware of the problems that may follow reawakening of early childhood experiences or feelings and behavior brought on by illness, knows and acts in the knowledge that the sick person within the doctor-patient relationship may seem quite different in presentation and behavior from the same person when he or she is well.

THE BEHAVIOR OF DOCTORS. Physicians, too, may behave differently in the presence of the sick than they do outside the doctor-patient relationship. Physicians' interactions with their patients may evoke feelings of anger, sexual attraction, sadness, grief, failure, rejection, and omnipotence, among others (Maoz et al.). Many years ago a psychiatrist, Michael Balint, recognizing that physicians are not trained to deal with the feelings clinical events evoke in them, organized physician discussion groups (Balint). Although sometimes replicated, these so-called Balint groups have not been widely employed. Awareness of whether and how doctors' feelings and behavior interfere with their care of patients is important because physicians' experience of their patient's feelings is an essential source of information about the illness.

Physicians are powerful people who must employ their power judiciously if it is to do good and not harm (Brody). Yet, doctors are rarely trained in how to use their power or even to be aware that they have power, which may be abused perhaps more easily than it is used. An irreducible inequity of power between patient and doctor inheres in the clinical situation. Codes of medical ethics reaching back to antiquity and modern bioethics directly address this problem. It is widely recognized, however, that if physicians are not virtuous, all the precepts, principles, and regulations surrounding their conduct will be useless. Edmund Pellegrino and David Thomasma explain the virtues necessary to achieve the ends of the clinical encounter and the good of the patient, namely, to be made well again if possible, or to cope with sickness, pain, suffering, and impending death if necessary. These virtues include conscientious attention to technical knowledge and skill, compassion, beneficence, benevolence, honesty, fidelity to promises and to the patient's good, prudence, and wisdom (Pellegrino and Thomasma). Walsh McDermott believes that thoroughgoingness and self-discipline are also central virtues of the good clinician (McDermott). It requires a good person to be a good doctor—now, as in times past. As Paracelsus said, "The art of medicine is rooted in the heart. If your heart is false, you will also be a false physician; if your heart is just, you will also be a true physician."

It is difficult for a scientific (and cynical) era such as ours to accept the unavoidable necessity for virtue in doctors. As a consequence, the active training of doctors in the

virtues of the good physician has largely been abandoned in the untested and probably wrong belief that medical virtue cannot be taught. During medical school and in postgraduate training, however, those who become doctors do learn, even if only through socialization, to restrain the employment of their skills in situations where more harm than good may follow, to be self-critical and admit error (at least to each other), to pursue the good of the patient, and to act benevolently (Bosk).

Medical Decision Making

Physicians are constantly making judgments, many of which are moral. The skill of exercising judgment, which has defied systematization, is the ability to apply the general to the particular; in medicine, this means to the particular patient, clinical situation, or context. To do this, physicians must obtain information of three distinct kinds—brute facts (also known in medicine as hard data); values; and aesthetics (patterns, relationships among the elements of a situation, and degrees of order or disorder). Often doctors are not aware of much of the information in the latter two categories that enters their judgments. Because of the necessity for such information, which is often neither obvious nor easily demonstrated, the art of medicine requires heightened skills of observation and synthesis. The art also requires that some systematic understanding be brought to judgment.

Alvan Feinstein was the first to closely examine the logic that underlies physicians' decisions; his work generated the field of clinical epidemiology (Feinstein, 1967, 1985). Feinstein's primary concern was the background evidence that the study of groups of people would provide for clinical decisions in patient care. Those who have followed him have elaborated his basic message and methods to assist physicians in judging the utility of a piece of evidence or information in the diagnosis or treatment of a particular patient (Wulff; Fletcher et al.; Sackett et al.). These writers have elaborated basic principles that determine the diagnostic meaning of a piece of clinical information, for example, a finding on physical examination, the result of a blood test, or a clinical measurement. The accuracy and validity of the test or measurement are important, as might be expected, but so is the likelihood that *any* similar patient would have the disease or state that is being tested for.

Put another way, to know how helpful a piece of information is diagnostically, one has to know the chance that any such patient truly has the disease. For example, even if a test for a rare disease is 99 percent accurate, when a large population of healthy people is tested and someone has a positive test, the chances are small that the person has the disease. The test will probably have been a false positive. Alternatively, in a population in a region where the disease is common, a positive test probably means the person has the disease. The test will have been a true positive. Because many conclusions of the clinical epidemiologists based on Bayesian mathematics are counterintuitive, their work has been extremely important in bringing objectivity and precision to decision making. (In the example given above, when the test is 99 percent accurate but the disease is rare, a patient who tests positive has only about a 10 percent chance of having the disease.) Terms such as specificity, sensitivity, and positive predictive value, which denote quantified measures of modern medical decision making, are now commonly heard in discussions about particular patients. Modern physicians must not only be conversant with these methods; they must also explain them to each patient so that the patient can participate effectively in the decision-making process.

Physicians rarely realize the degree to which each patient is different. Consequently, particularizing the generalizations of medical science to fit an individual patient requires great skill. The desires, needs, concerns, intentions, and purposes of patients are statements of values that must be elicited if they are to enter decision making. They are often faulted as hopelessly subjective and consequently not up to the standard of the hard data employed in the decision-making methods discussed above. A patient's desire for a certain outcome may be subjective, but the statement of that aspiration is objective and can be validated and given precision within degrees of confidence through discussion with the patient and attention to the pattern of the patient's previous actions and purposes. The artful physician is obligated to develop the mastery that gives these values decision-making weight—they are expressions of the patient's autonomy. Attempts to circumvent the need for such mastery by developing standardized methodologies, such as scales and questionnaires to assess individual values, have not proved clinically useful. It remains necessary, therefore, for the clinician to know the sick person to the greatest degree possible so that good clinical judgments can be made.

The clinical situation, like the disease and the illness, is always changing; therefore, decision making that integrates values and other clinical information constantly occurs in clinical medicine. Shifts occur not only because of the evolving process of the disease, but also because of the ongoing responses of both doctors and patients. In addition, the place care is given (home, doctor's office, hospital, etc.) and who else is involved (family, friends, medical students, etc.) influence the process of the illness. It is obvious why

clinical judgments are not confined to the initial diagnosis or decisions about therapy.

The art of medicine requires that the physician be always mindful of changes in the circumstances, the illness, and the capacity of the patient. Although the formal principles of modern decision making may not always be applicable, newer ideas about the probabilistic nature of judgment and the need to integrate hard and soft data constantly inform the work of the artful physician.

Doctor-Patient Communication

The ability to employ the spoken language to obtain information from and about the sick person, gain the patient's cooperation, and provide information to the patient is a central element in the art of medicine. Doctor-patient communication is unlike many other verbal transactions, despite its use of ordinary language. The patient is in the conversation with the doctor for a specific purpose that is vital for the patient and diagnostically or therapeutically significant for the physician. The patient and the doctor have important joint purposes in the service of which the conversation is both necessary and crucial.

The patient wants the doctor to pay attention to his or her symptoms and concerns about the illness, and is worried lest these not be properly expressed or their importance not be appreciated. Doctors want to hear the clues to the diagnosis that only the patient's story can convey. Yet, some things that are important to the patient may not be of interest to the doctor and vice-versa. If the doctor attends solely to the evidence for disease, discarding everything else the patient says as irrelevant, then he or she may find the disease, but discard the sick person. A person's utterances convey not only the overt description of his or her actions and beliefs, but also the significance of the objects and events under discussion to the speaker. This other aspect of the speaker's message—the description of self of which the speaker is often unaware—lies in the specific choice of words, syntax, and paralanguage (Cassell, 1985c). The attentive, artful physician, listening to these specific aspects of the spoken language, has the opportunity to know more about the patient.

Conversation with the patient offers the doctor the opportunity to discover the patient's presuppositions and the beliefs according to which the patient assigns meanings. Similarly, doctors can inform their patients about the medical presuppositions and concepts that inform the doctors' actions. Such exchanges help avoid or correct the miscommunications that inevitably arise because of the differing perspectives of doctor and patient. Just as the patient's language informs the doctor about the patient, the doctor's utterances reveal himself or herself to the patient. The virtues of physicians are not abstractions, but are displayed in speech and actions. Trust is built by means of conversation as well as by action; compassion is communicated in words, in nonverbal communication, and in action. The constant flow of spoken (and unspoken) language provides a doctor the opportunity to build his or her knowledge of the patient and provides a patient evidence of the physician's skill and fidelity.

The doctor also has the specific responsibility of informing the patient about what is the matter, what it means, what actions might be taken, what options exist, and what choices the patient must make. The same is true, on occasion, of communication with the patient's family or significant others. Information, however, is also a therapeutic tool. Doctor-patient communication provides the physicians the opportunity to convey information that reduces the patients' uncertainties, enables the patient to act in his or her own best interests, and strengthens the relationship between the doctor and patient. On the other hand, poorly or inadequately communicated information can increase uncertainty, paralyze action, and destroy the relationship.

A specific aspect of doctor-patient communication is breaking bad news. When it is done poorly, it can destroy hope and leave a patient in shambles. As part of the art of medicine, doctors must learn to convey bad news so well that patients are enabled to make truly self-representative and self-determined choices (Buckman).

Patients, like everybody else, act and react because of what things mean to them. Meaning includes not merely denotative aspects of words, objects and events, but their connotative, or value-laden, content as well. With its cognitive and affective aspects, meaning has an impact on the physical and spiritual responses of the sick. By changing patients' meanings, physicians can alter, sometime profoundly, the patient's experience of illness (Cassell, 1985a). The effective use of spoken language, with its power of creating and altering the meaning of wellness and illness, is an important aspect of the art of medicine.

MEDICINE, PHILOSOPHY OF

• • •

Over the last two and a half millennia—since the beginnings of Greek philosophy and medicine—there have been rich conceptual reflections regarding medical findings, reasoning in medicine, the status of knowledge claims in medicine, and the special concepts that structure the science and art of medicine. The philosophy of medicine is a corpus of considerations and writings uniting these reflections by contributors as diverse as Plato, Aristotle, and Galen; René Descartes, Immanuel Kant, and Georg W. F. Hegel; and contemporary thinkers. Because these examinations of medicine are philosophical in different senses, the term *philosophy of medicine* is ambiguous, covering a heterogeneous field of intellectual concerns. For the purpose of this overview, they have been collected under four categories.

The first category, speculative philosophy of medicine, has existed from the beginning of medicine. Speculative medicine may be characterized as the attempt to discover the basic philosophical principles that lie behind the practice of medicine. Here philosophy attempts to discover theoretical frameworks or foundations that give shape or content to clinical data. In this sense, philosophy of medicine provides a priori points of departure for medical knowledge and practice. The second category, the logic of medicine, brings together attempts to clarify the character of scientific reasoning in medicine. It identifies the basic principles that make medicine a coherent science. This category of philosophy of medicine studies, for example, the way in which diagnoses are made and judged to be accurate in medical practice and research. A third area of the philosophy of medicine may be understood as a subspecialty of philosophy of science. This area is concerned with what is accepted as *knowledge* in medicine and the healthcare professions. Much of the recent exploration of the status of concepts of health and disease or

the status of the unconscious and explanation in psychoanalysis falls into this third category. Finally, a fourth category describes the explorations of other philosophical issues that have special salience in healthcare, for example, the nature of persons and its implications for the morality of abortion. Philosophy of medicine in this fourth sense would include bioethics.

Just as there is ambiguity concerning the meaning of "philosophy" in "philosophy of medicine," so there is ambiguity about the compass of medicine. Medicine can be construed as a body of knowledge, skills, and social practices concerned with the health and pathology of humans. In its modern sense, medicine encompasses theory and practice, science and art. Traditionally medicine is the origin of all systematic concerns with healing, including nursing and the allied health sciences. The focus of the philosophy of medicine, as a consequence, can have a broad or narrow scope.

The Philosophy of Medicine as Speculative Medicine

The ancient Greek philosophers sought to understand the world on a rational rather than a supernatural basis. Early Greek medicine was influenced by philosophers who held that the primary goal of a scientist was to find one basic principle or set of principles that would explain the natural world known by the senses. These physicians developed theories as to how the body worked and how diseases might be understood and controlled. At first, there was little concern to justify these theories in experience or observation. One finds, then, a tension in early Greek medicine between those physicians who grounded medicine in rational speculation—the rationalists—and those who grounded medicine in experience—the empiricists.

This tension is evident in the Hippocratic corpus. In the corpus there is approval for theorizing that "lays its foundation in incident, and deduces its conclusions in accordance with phenomena" (Jones, p. 313). Nevertheless, the Hippocratic author rejects the systematic sweep of more speculative thought:

> Certain physicians and philosophers assert that nobody can know medicine who is ignorant what a man is; he who would treat patients properly must, they say, learn this. But the question they raise is one for philosophy; it is the province of those who, like Empedocles, have written on natural science, what man is from the beginning, how he came into being at the first, and from what elements he was originally constructed. (Jones, p. 53)

The author is rejecting what might be termed speculative or metaphysical medicine—namely, the attempt to construct a theory of medicine on the basis of self-evident, or basic, principles or concepts. The author also writes that medicine has no need of "an empty postulate," a concept that is not based in experience, because it has at hand the means for verifiable knowledge.

René Descartes (1596–1650) held that he could determine the fundamental laws of metaphysics, physics, and medicine (Descartes) by reason alone, without appeal to experience. On the basis of his work in speculative, metaphysical medicine, Descartes predicted that he would live an additional century or so, achieving a life span of one and a half centuries. He believed his own theories would issue in simple revisions of daily routine leading to such extensions of life expectancy (Descartes). Descartes's *Treatise of Man* (1662) attempts a mechanistic anatomy and physiology expressed in terms of matter and motion. Descartes explains how the human body works by comparing it to a machine. He found that this mechanistic approach could explain the physical functioning of the human body but not rational behavior. Still, Descartes's philosophical reflections concerning the body provided a framework for later explanations of human functioning that also relied on mechanical metaphors.

The success of Isaac Newton (1642–1727) in offering systematic explanations in physics inspired attempts to do this in medicine. The eighteenth-century Scottish physician John Brown (1735–1788), for example, suggested that the concept of excitability could serve medicine as the concept of gravity had served Newtonian physics: as the single concept upon which all explanations of health and disease could ultimately rest. Stimulation or excitation and response to it, he argued, resulted in an equilibrium or disequilibrium that defined *health* and *disease,* respectively. If an imbalance became too extreme, death would result. Brown's work attracted the attention of philosophers, including Hegel (1770–1831). This philosophy of medicine—as the gray area between scientific, empirical medicine and the philosophy of nature—led to the modern understanding of medicine that brings together empirical observation and theoretical construction (Tsouyopoulos).

Twentieth-century historians of medicine have appreciated this interplay between empirical and speculative medicine under the title "philosophy of medicine." William Szumowski in 1949 and Owsei Temkin in 1956 spoke of the importance of the philosophy of medicine. It is to Szumowski that much of the rebirth of the interest in this term, perhaps first coined by Elisha Bartlett in 1844, can be attributed.

Lester King (1978) has used the term to identify the theoretical reflections undertaken by both physicians and philosophers engaged in speculative as well as other conceptual explorations of medicine.

The Philosophy of Medicine as the Logic of Medicine

The relationship between medical reasoning and medical practice has been an area of perennial philosophical controversy and investigation. In ancient Greek and Roman medicine, the disputes between the rationalists and empiricists were, in part, disputes about how knowledge claims in medicine ought to be justified. By the Renaissance, medicine had failed to achieve the success in healing that is often attributed to it today. This failure to achieve therapeutic success led to attempts to make medicine more *scientific,* in the hope of duplicating the success of fields like astronomy and physics. Thomas Sydenham (1624–1689), whose *Observationes medicae* appeared in a third edition in 1676, proposed a disciplined methodology of observation and treatment. Sydenham brought to medicine the scientific method of Francis Bacon (1561–1626), which sought to ground reasoning in experience, observation, and data.

This method, however, raised questions about observer bias of which Syndenham was aware. The principal difficulty is that an investigator's findings may be influenced by his or her presuppositions. These concerns about observer bias were taken up in the eighteenth century by such theoreticians of medicine as Françlois Boissier de Sauvages de la Croix (1706–1767) in his *Nosologia methodica sistens morborum classes juxta sydenhami mentem et botanicorum ordinem* (1768). Influenced by the writings of Thomas Sydenham and Carolus Linnaeus, Sauvages organized diseases into a structure of class, order, genus, and species. In his *Nosologia* there is an appreciation of medical observation as well as a concern for a logical rigor that sought to coherently relate observations to predicted outcomes. Sauvages's principal undertaking included a classification of diseases primarily based on their signs and symptoms rather than on their causes. He also sought to tie observed signs of illness to relationships that had been noted between past, present, and predicted future states of patients. The logical rigor of disciplined observation and the collection of facts is also evident in the work of William Cullen (1710–1790) and Thomas Percival (1740–1804).

The major revolutions in medical understanding born of advances in anatomy and physiology in the late eighteenth and nineteenth centuries, along with the recognition that many established treatments did not work, required a fundamental reassessment of medicine. Philosophical reflections concerning medical reasoning gave way to major treatises concerning the character of reasoning in medicine. Works such as Sir Gilbert Blane's *Elements of Medical Logick* (1819), Elisha Bartlett's *Philosophy of Medical Science* (1844), and F. R. Oesterlen's *Medizinische Logik* (1852) range from listing the elementary principles of life to concern with material fallacies in medicine, including excessive deference to authority, fashion, or speculative reasoning without sufficient empirical observation. Oesterlen's work, which advanced criteria for inductive reasoning in medicine based on the work of John Stuart Mill, included an analysis of the methods and means of medical investigation, the character of the inductive method in medicine, and the status of experiments, hypotheses, analogies, terminologies, definitions, and classifications. He viewed medical logic as the application of general logical principles to the field of medicine for the purpose of securing a coherent inductive and empirical science that would be free from a priori speculation. His work was followed by other studies, including Władysław Bieganski's *Logika medycyny* (1894) and Richard Koch's *Die ärztliche Diagnose* (1920).

Growing philosophical sophistication characterizes twentieth-century assessments of medical knowledge and medical reasoning. Types of medical knowledge may correspond to the different functions of medicine. Medicine can be understood in a threefold manner: biological medicine, clinical research, and clinical practice. Biological medicine is concerned mainly with scientific research in biology, whereas clinical research is focused on the development of the knowledge and technology used in clinical medicine. Finally, the area of clinical practice involves the realities of patients and disease. A philosophical concern of those writing on the logic of medicine has been to clarify the nature of each type of medical knowledge and the relationship of these different areas of medical knowledge and reasoning to one another (Wulff et al., 1986).

Since the middle of the twentieth century, a renewed interest in the logic of medical reasoning and the character of medical decision making has been expressed in the computer reconstruction of differential diagnosis. This literature has examined the logic and principles of medical reasoning—for example, the applicability of Bayes's Theorem to medical decision making (Lusted; Wulff, 1976); the logic of the taxonomy of disease and classification, including the application of set theory to the analysis of clinical judgments (Feinstein); and the role played by morbidity, mortality, and other costs in determining when and how diagnoses are framed. For example, because of the human and financial costs, one will be much more concerned about false positive diagnoses of AIDS than of athlete's foot. Recent works have

given special attention to the process of making diagnoses, including the principles of differential diagnosis (Caplan, 1986; Engelhardt et al.; Wulff, 1976), as well as the elaboration of nosologies as instruments for gathering clinical information. Many of these reflections have stressed the hidden role of values and conceptual assumptions in the process and logic of medical diagnosis (Schaffner; Peset and Gracia; King, 1982).

The Philosophy of Medicine as the Philosophy of the Science of Medicine

Philosophy of medicine may also be understood as a self-conscious reflection on the status of special concepts, such as health and disease, deployed in medicine. Rudolf Virchow (1821–1902), for example, argued that designating a state of affairs as an *illness* has a stipulative character; that is, such concepts are defined by agreement and there are no clear natural types or divisions of nature corresponding to nosological categories. This sense of the philosophy of medicine places the accent on issues in the theory of knowledge and the examination of what should count as a medical theory or explanation. In this, it is distinguished from speculative philosophy of medicine and from the more narrow concerns with the rules of evidence and inference proper to medicine that are the focus of medical logic and medical decision theory.

Since the 1950s a considerable literature has developed that is directed to the status of concepts such as health, disease, illness, disability, and disorder. Whether such concerns constitute a subspecialty of the philosophy of science is disputed (Caplan, 1992; Wulff, 1992). There has also been interest in the character of medical explanation (Canguilhem). This literature has also explored the application of such terms to nonhuman animals. In addition, there has been attention to the extent to which these concepts are normative and the extent to which nonnormative, value-free concepts can be elaborated. Those who have argued in favor of weak or strong normative understandings of concepts such as health, disease, and illness have also addressed the character and kind of values that structure such concepts. Investigations have included the extent to which concepts of disease are instrumental to medical practice, or instead identify natural divisions in reality. In addition, there have been attempts to place medicine within the general compass of philosophical explorations of scientific theory (Kliemt). Finally, the significant changes about the relationship of theories, facts, and values in the understanding of the history and philosophy of science that occurred in the 1960s and 1970s were anticipated in Ludwik Fleck's 1935 study of changes in the meaning of syphilis and venereal disease from the fifteenth to the early twentieth century (Fleck).

The Philosophy of Medicine as the Collection of Philosophical Interests in Medicine

Even if one were to hold that medicine offers no conceptual or philosophical problems not already present in the subject matter of the philosophy of science or the philosophy of biology (Caplan, 1992), there would still be merit in exploring the ways in which philosophical study and analysis can be directed to the understanding of medicine, as well as to the healthcare sciences and arts in general. In this sense, the philosophy of medicine encompasses the ways in which the philosophy of science, the philosophy of biology, the philosophy of mind, moral philosophy, and so on are engaged in order better to understand medicine. Perhaps one would wish to characterize such explorations as philosophy about medicine rather than of medicine, in the sense that the tools, analyses, and insights of philosophy in general are brought to the particular subject matter of medicine. Calling this endeavor the philosophy of medicine underscores the heuristic advantage of treating the domain as a whole, as a single focus of attention. There is also the advantage of recognizing that general issues of justice, fairness, rights, and duties confront the special challenge of taking account of the development of humans from conception to death.

In medicine, special questions of intergenerational justice become salient, distinctions between human biological and human personal life are raised, the irremediable character of loss must be confronted, and comparisons must be made between claims for the alleviation of suffering versus the postponement of death. Though the definitions of futility, of ordinary versus extraordinary treatment, and of the beginning of life and the beginning of death may arise outside the compass of medicine, such definitions take on a special philosophical cast and character in the context of medicine. The recognition that there is this special concatenation of conceptual issues is appreciated in employing the term *philosophy of medicine.* This use of the term approximates the one employed by the European Society for the Philosophy of Medicine and Health Care (founded 1987), which encompasses bioethics within a constellation of philosophical concerns and undertakings. The philosophy of medicine as speculative medicine, as the logic of medicine, and as the philosophy of the science of medicine all spring from the acknowledgment that medicine constitutes one of the cardinal areas of intellectual and moral attention, central

to human life, and is worthy of sustained conceptual analysis and philosophical regard.

MEDICINE, PROFESSION OF

• • •

Professionalism is what distinguishes the professions. It gives each the character by which it is known. In our time many occupational groups have striven for professional status in a quest for authority, prestige, and income. "Professionalism, professionalization, and the professions are increasingly central to any grasp of modern societies," Nathan Glazer claims, "yet persistently elude proper understanding" (p. 34). Many sociologists have written about the characteristics of professions, but most agree that all professions possess the five elements identified by Ernest Greenwood:

systematic body of theory;
authority to define problems and their treatment;
community sanctions to admit and train its members;
ethical codes that stress an ideal of service to others;
a culture that includes the institutions necessary to carry out all of its functions.

Jeffrey Berlant, following German sociologist and economist Max Weber's (1881–1961) theory that professionalization is a form of monopolization, lists the steps in the process:

creation of a commodity—in the case of medicine and law, services for a fee;
separation of performance of the service from the satisfaction of the client, which means that a cure need not be guaranteed;
creation of scarcity by reducing supply and increasing demand;
monopolization of supply and control of privileges by legal means, such as licenses;
restriction of group membership, such as admission to study or to hospital staff;
elimination of internal competition;
development of group solidarity and cooperation.

The attributes used to describe professions include responsibilities and privileges, both derived by social contract. It is important to remember that the terms of the social contract change with changing social and economic conditions, and hence may vary from one region or historical period to another. Thus professionalism cannot provide a permanent set of values or standards. Instead it offers a series of guidelines designed to help specific people in specific places resolve important conflicts that arise from the nature of their duties. Each society has evolved some of its own standards, based on its own structure, values, and technological capabilities. Some standards of professional behavior originating in modern industrial societies may be meaningless in other cultural settings (Hughes).

In medicine, historical changes can be illustrated with the example of specialization. Today, specialization is cited as a hallmark of professions. In nineteenth-century U.S. medicine, however, the doctor who specialized was often looked upon as a quack (Rosen, Stevens). Today the physician who claims to have knowledge and expertise in all of medicine would be looked upon with suspicion.

To pose the question "When did medicine become professional?" is like asking "When did medicine become modern?" There are elements of professionalism and of modernity in ancient Greek medicine, as there are in the medicine of the Middle Ages, the Renaissance, and the eighteenth century. The definitions of a profession that appeared in the literature in the early part of the twentieth century, which stressed urbanization and industrialization as prerequisites for the existence of a medical profession, are no longer held. Although it has been true that an industrializing society is a professionalizing society, so far as medicine is concerned there was professionalization long before industrialization (Goode).

Professionalism in medicine developed in a continuous historical process, beginning in antiquity with institutions like state physicians and fraternities of physicians such as the Asclepiads, continuing with the medieval medical guilds, medical schools, and licensing requirements. The modern period, especially after about 1700, is characterized by the emergence of such institutions as medical societies, medical literature, licensing laws, and codes of ethics. In the twentieth century the professional is the recognized expert with special qualifications, and the professional ideal has become a hallmark of modern society (Bledstein, Perkin).

The medical profession of the mid-nineteenth century was very different from the profession of a century later. Yet in both periods many of the characteristics of professionalism were readily evident. The modern model of professionalism—university-based, peer-controlled, and based on merit rather than birth—is derived from the criteria we now use to study professions. Earlier forms of professionalism may have had quite a different set of characteristics; for this reason, the historical dimension of professions becomes increasingly central to an understanding of the development

of medicine. The professional character of medicine has always been derived, in good part, from the institutional participation of the physician. These social and legal institutions provide credibility for medicine as a profession (Hall).

Despite the centrality of the professions in the United States, scholars have only recently begun to trace their history (Brown; Calhoun; Haber; Hatch; Kett; Kimball). With a few exceptions, such as Daniel H. Calhoun, historians have not deemed it necessary to engage in comparative histories of the professions, leaving this to sociologists (Abbott; Berlant; Freidson, 1970; Larson; Mechanic, 1968; Rothstein). Although Eliot Freidson has claimed that the status of scholarship in the professions is in a "state of intellectual shambles" (Freidson, 1984, p. 5), the historian Thomas Haskell has noted that "there is really no longer any excuse for scholars working on the professions to be divided into two shops, one made up of people who try to explain what professions are, without ever grasping how they came into being; the other composed of people who try to understand how they came into existence, without being quite sure what they are" (Haskell). For medical historians, generally, as John Burnham has pointed out, it was not until after World War II that the subject of the professions moved to the center stage of history.

Andrew Abbott's review of the sociological literature of the professions is a concise summary of how modern societies have institutionalized expertise as professionalism. He describes the professionalizing process in terms of a series of jurisdictional disputes. These disputes over the professional boundaries of medicine in the nineteenth and twentieth centuries do explain much of medicine's history (Abbott). Samuel Bloom's history of the field of medical sociology traces its institutional formation.

During the last few decades of the twentieth century, when social historians began to depict medicine as oppressive and more interested in social control than in social melioration, medicine began to be subjected to much closer analysis of its professional attitudes, values, and styles. Medicine as a twentieth-century profession could not always get what it wanted, but until the mid-1960s and the passage of Medicare and Medicaid legislation, it had great success in resisting what it did not want. As the twentieth century drew to a close, this negative power had begun to diminish with increasing speed.

Medicine as a Profession in Antiquity

Much of what we have come to believe about ancient medicine we have inherited from the views of nineteenth-century scholars, who tended to create a picture of ancient medicine that reflected their own contemporary institutions (Nutton).

In early Greek antiquity, Homer portrayed doctors among the fighting heroes: "A doctor," he wrote, "is worth many men put together …" (Nutton, p. 15). Plato, in his *Laws,* described doctors and doctors's assistants, who were also called doctors: "These, whether they be free-born or slaves, acquire their art under the direction of their masters, by observation and practice and not by the study of nature—which is the way in which the free-born doctors have learned the art themselves and in which they instruct their own disciples" (Plato, p. 307–309). The Hippocratic physician was a craftsman, and despite the high status of some of the crafts, there were in ancient Greece as yet none of the restrictive practices of the guilds of later centuries (Edelstein; Temkin, 1953). Only in one of the Hippocratic works, the *Oath,* was there a clear description of a closed, family-like guild that restricted entry to outsiders. But this does not represent Hippocratic medicine as a whole (Edelstein). Since ancient times it has been true that there have been several classes of doctors, and patients have always received care depending upon their own station in life and that of their doctor. Recent new scholarship about the Hippocratic Oath reaffirms its historical importance but also stresses its complexity. It should not simply be ascribed to the followers of Pythagoras, as Temkin, in 2002, and Dale C. Smith have noted.

The Alexandrian Library was one of the earliest institutional influences on medicine. It was here, according to the second-century physician/scholar Galen, that the writings of Hippocrates and the Coan school in which he taught were first assembled (Nutton). The ancient Greek physician did not receive a scholarly or systematic training; such was left to those who became philosophers and rhetoricians. Galen claimed that the best physician is also a philosopher. This implied that medicine could be understood only in terms of natural philosophy—biology, chemistry, and physics. Such a lofty sentiment implied that medicine was for the benefit of the whole community rather than for the private gain of the physician. This was the ideal toward which medicine should strive, according to Galen. It is a professional ideal we still recognize (Horstmanshoff).

The Medieval Medical Profession

In the later Middle Ages, with the development of cities, the rise of commerce, and the creation of universities, doctors found an expanding market for their services. These developments, in turn, led to the development of medical faculties in the universities, the passage of laws that defined the

minimum education required for the physician, and a more rigorous definition of medical competence. Thus the trappings of professionalism and professional organizations became more evident after 1050. Debates began about what were the appropriate standards for a license to practice medicine, and who was to define the criteria and to enforce them. In the thirteenth century, the battle over training and licensing was between the new universities and their faculties of medicine, and the trade companies or guilds. University-educated physicians formed a professional elite. Guilds became the formal licensing bodies in some of the Italian cities, but generalization is difficult (Park, 1992).

In Florence, the medical profession can be traced to the medieval guilds, such as the Guild of Doctors, Apothecaries, and Grocers, established in 1293. It was a protective association and asserted monopoly privileges. Medicine was considered one of the prestigious occupations, along with law, banking, commerce, and notary practice. What really elevated some of the practitioners of medicine, and hence the whole profession, was that they taught and wrote. These activities, not just medical practice itself, elevated medicine from a mechanical to a liberal occupation and from an art to a science (Park, 1985). Medicine's place in the universities assured it an important and enduring role in the intellectual life of modern society.

Since the medieval period, universities have been the key to the professionalization of medicine, although in some countries, such as Great Britain and the United States, there were periods when medical schools were quite separate from the university. In antiquity the institutions that we associate with professionalization of medicine did not yet exist, though there were certainly groups of healers who were united by rudimentary professional bonds. In the Middle Ages, medicine became a more distinct, high-status, and terminal occupation (Bullough).

In the Middle Ages, then, medicine as a healing activity became distinguishable from medicine as a branch of higher learning. In the twelfth century, King Roger II of Sicily and his grandson, Frederick II, instituted licensing examinations by the masters of the School of Salerno. The objectives were to ensure competence and honesty to protect both society's and the profession's interests. There was as yet, however, neither uniform licensing nor a uniform medical profession in medieval and early Renaissance Europe (Siraisi).

Guild controls and restrictions were justified in the fifteenth century, as they would be in the twentieth, by members who claimed they needed to maintain high standards of competence and proper professional behavior. With an increasing service sector of the economy and an increase of prestige once it became a university faculty, medicine gained in stature (Cipolla).

The Medical Professions in Early Modern Europe

In late-fifteenth- and early-sixteenth-century England, there was little order in the practice or regulation of medicine. In 1511 Henry VIII introduced some governmental control. Although the parliamentary legislation he secured created no organized group of physicians, it brought a measure of state control over medical practice and made way for the conferral of substantial powers on medical groups. It stipulated that no one could practice physic or surgery in London or seven miles around without a license from the Bishop of London or the Dean of Saint Paul's Cathedral, and it required an examination of all candidates for licensure before a panel of experts selected by those officials.

The three main corporations or guilds of medical practitioners in early modern England were the Physicians, the Surgeons, and the Apothecaries. While they did represent a fairly distinct division of labor, their separation, particularly in the countryside, was not as rigid as often portrayed; in the early-sixteenth century there was as yet little order and no real regulation of practitioners. Margaret Pelling has argued cogently for the importance of the guild tradition in the history of medicine's professionalization in sixteenth- and seventeenth-century Great Britain. Earlier historiography of medicine often depicted professionalization as a continuous process, ultimately ending in the triumphal terms of the profession as we know it today. The strength of the social history of medicine, as that history is understood in the early-twenty-first century is to reveal the many complexities of and byways to what was earlier assumed to be a much straighter path to modernity (Pelling, 1987, 1998; Pelling and Webster).

In 1518, the humanist-physician Thomas Linacre (1460–1524) and five other physicians with university educations prevailed upon Henry VIII to grant them a charter for a Royal College of Physicians. Their resultant monopoly, however, extended only to London and its environs. The United Company of Barber Surgeons (made up of apprentice-trained barber-surgeons who carried out simple operations such as bleeding) received its charter in 1540, and the Guild of Apothecaries was granted a separation from the Company of Grocers (a rival guild) in 1617. Not until 1745 did George II grant the surgeons separate status from the barbers (Cook).

This tripartite division of British medicine is well known, but it should not be viewed as a simple or a unified

system. In the rural areas, the surgeon-apothecary came to act as a general practitioner, and by 1809 was so acknowledged by name (Loudon). The physicians, who were at the top of the social scale of the medical practitioners, considered themselves gentlemen, had taken a classical university degree, received honoraria rather than fees, and made diagnoses, prescribed appropriate remedies, and made prognostic declarations for their patients. It was up to the apothecaries to give the remedies at the direction of the physicians. To the surgeons were left the tasks of bleeding, pulling teeth, setting fractures, and performing the few operations, such as amputations, that were carried out in this pre-anesthesia and pre-antiseptic age. For most of the population the medical tasks were often combined, as noted, or they were carried out by other healers such as midwives or a variety of traditional practitioners, some of whom were outright quacks (Christianson, Parry and Parry).

By the end of the seventeenth century, the apothecaries were intruding into the domain of the physicians so often that the College of Physicians brought suit against an apothecary by the name of James Rose, charging him with the practice of medicine for which he was not licensed. In 1703, hearing the case on appeal, the House of Lords ruled that the apothecaries could charge for medical advice as well as for the drugs supplied to the patient. This landmark case legalized the function of the apothecaries as ordinary practitioners of medicine in London. They were already enjoying these rights by custom in the countryside. Adam Smith, in his *The Wealth of Nations* (1776), recognized the apothecaries as the physicians of the poor (Hamilton; Holloway, 1966a, 1966b).

In France, a medical profession also existed prior to the period of industrialization. The profession that appeared abruptly at the time of the revolution in France at the end of the eighteenth century replaced one that had existed in somewhat different form (Gelfand, 1981, 1984; Ramsey). It was especially the professional character of the surgeons that changed abruptly in the 1790s. Earlier in the century, the surgeons already had a legal status, received their initial training as apprentices, and had a versatile medical practice including medicine and pharmacy as well as surgery, but still had a relatively equal social relationship with their patients. Thus the French surgeons—the ordinary practitioners, as Toby Gelfand described them—were more socially inclusive than would be the case in the twentieth century. With the breakdown of elitist distinctions, the post-revolutionary profession in which surgery and medicine were now united was generally even less elitist and exclusive than the earlier French physicians had been. However, in the course of the nineteenth century, elitism appeared in French medicine as it did in the professions in other countries. The new elitism was increasingly based on merit rather than on status, on accomplishment rather than on birth. Much of the history of medical professionalism is included in the history of medical education, but until recently we had had little comparative work. In 1995, Bonner filled this gap for Western Europe and North America for the two centuries after 1750.

The Medical Professions in Early U.S. History

American professionalism originated in the traditions and practices of seventeenth- and eighteenth-century England. Although any occupation might be termed *a profession,* the recognized learned or liberal professions continued to be law, medicine, and divinity. These required a collegiate education; exposure to the classics and the liberal arts curriculum provided the breadth of mind and personal character necessary for a gentleman. As a gentleman, the physician had a professional duty to play a role in all community affairs.

The North American colonies did not offer an attractive field for professional physicians until well into the eighteenth century. Unlike England, the North American colonies provided few examples of organizational development in medicine. The colonial environment required that practitioners assume all functions of the healing art and eliminated a form of rivalry that had brought about organization in England, where some medical groups had united to prevent the encroachments of others. Frontier conditions usually isolated physicians and discouraged organizational growth. The shortage of the ideal gentleman-physician in the colonies broke the traditional distinctions and divisions of medical labor. Thus, prior to the early 1700s, in the first century of colonial history, there were few doctors, no medical institutions, and little focus on medicine as a profession. Some healers were mainly working as midwives; others were ministers, whose professional identity was with religion, not medicine (Benes and Benes, Watson).

After 1700, as some historians have noted, there was a deterioration of the public's health as measured by a variety of vital statistics. This produced some increased demand for higher levels of medical skills. Besides the needs presented by the changing diseases and diminishing life expectancy, there were also great strains in the occupational structure. Fathers had typically passed to their sons their pulpits and their land. When population increased and there were neither enough pulpits nor sufficient land, the sons began to seek alternatives. Since many ministers also practiced medicine, it was

natural that some of their sons turned to medicine as a career (Hall).

After 1750, some of the professional aspects of medicine became more visible, especially in the northern colonies. Young physicians with English and Scottish educations and degrees now began to want the institutional trappings for their profession. With the aid of Benjamin Franklin, the Pennsylvania Hospital was founded in Philadelphia in 1751. Modeled on the British voluntary hospitals, it was intended mainly to care for the sick poor and to provide medical teaching for young men who wished to become doctors. In the 1760s, the first medical schools appeared in Philadelphia and New York. The first colonial medical society was founded in New Jersey in 1766, and an early licensing law was passed in New York City in 1760. By the turn of the nineteenth century, a rudimentary medical profession existed, though it was responsive to local forces and conditions and had no national unity as yet. In many areas midwives continued to supply medical services to families and still routinely assisted at most births (Ulrich).

Although some medical leaders, such as John Morgan of Philadelphia, hoped to establish the British distinctions of physician, surgeon, and apothecary on the American side of the Atlantic, neither the social climate nor the political realities allowed it. As Richard H. Shryock has noted, it was not that the British distinctions were simply rejected in the more egalitarian ethos of the colonies. In fact, very few physicians had emigrated and there was no way to educate sufficient numbers in the colonies. The surgeon-apothecary or general physician simply assumed the title of doctor in the colonial setting. Like the merchants in North America, physicians, in the absence of a nobility, became part of the upper class (Shryock, 1960).

Licensing (and thus a rudimentary form of professional control) began to appear in the late eighteenth century, however these laws were not yet a means to restrict the practice of medicine as distinctly as they later would be. Licensing in the early nineteenth century merely gave those who were deemed legal physicians the right to sue for their fees. It did not as yet give the doctors any control over the medical marketplace. As a form of public recognition, licenses were uncontroversial; but as an attempt to be restrictive, they quickly became a source of sharply divided opinions. Some physicians, such as John Bard (1716–1799) and his son Samuel (1742–1821) in New York, favored restricting the practice of medicine. Others, such as Benjamin Rush (1745–1813) in Philadelphia, believed in "every man his own physician." Rush claimed medicine was sufficiently simple that anyone could learn to practice it.

Medical Practice in the Mid-Nineteenth-Century United States

During the mid-1800s in the United States, medicine was by no means a unitary profession. Its increasing professionalization was accomplished and stimulated by a similar process in science generally (Daniels). In both fields, compensation slowly increased. A wide variety of healers gave their allegiance to one or another medical philosophy, such as the Homeopaths and Eclectics, or followed the therapeutic doctrines of quite rigid systems, such as the Thomsonians or the water-cure doctors. Even among the so-called regular physicians, there was a wide diversity of education, medical belief, and medical practice (Kett, Rothstein).

In the three decades prior to the Civil War, the Jacksonian period, popular democracy had profound effects on the professions. Most states and localities repealed licensing laws for medicine, and what determination of professional competence there had been was transferred from the profession to the people. Contrary to the course of regulation in England, where the Apothecaries Act of 1815 and the Medical Registration Act of 1858 brought some order and governmental control to medicine, the North American states were abandoning regulatory efforts (Holloway, 1966a, 1966b; Shryock, 1967).

Between 1830 and 1850, the number of medical schools in the United States nearly doubled, from twenty-two to forty-two. The rising number of *regular* graduates produced by these largely profit-seeking, faculty-owned institutions competed with established practitioners, while the new schools lowered requirements to compete for students.

The physicians who established the American Medical Association (AMA) in 1847 had as their avowed goal the improvement of medical education (Davis). In drafting unrealistic requirements for admission to medical schools, however, they became vulnerable to charges that they sought merely to preserve the apprenticeship system and destroy most medical schools. By 1860, however, graduates of the many new medical schools founded in the nineteenth century outnumbered the so-called *irregular* doctors by a ratio of ten to one (Kett). Since the regular physicians as yet had no real claim to controlling medical activities, their professional strategy in these middle decades may be seen in the attempts to raise the standards of medical education by raising entrance and graduation requirements. Such strategy, while only partially successful before the ideology of science was added to the banner of reform at the end of the century, was aimed at reducing or at least controlling the number of doctors being produced.

The AMA, facing apathy among many regular physicians and hostility from sectarian groups, could do little to

reduce physician supply or improve the quality of medical practice (Rothstein). Nor could the association move effectively to enforce its own version of professional ethics. It adopted substantially the principles of Thomas Percival's *Medical Ethics* (1803), which deals with topics such as the duties of physicians and surgeons and their "moral rules of conduct." Robert Baker and his colleagues have told the story of the origins, evolution, and fate of the 1847 AMA code, and have included the code itself and supporting documents in their useful book.

At the time of the Centennial celebrations in 1876, John Shaw Billings characterized three classes of physicians among the predominant or regular members of the medical profession. There were a few among them, he noted, who loved "science for its own sake, whose chief pleasure is in original investigations, and to whom the practice of their profession is mainly, or only, of interest as furnishing material for observation and comparisons. Such men are to be found for the most part only in large cities where libraries, hospitals, and laboratories are available for their needs…." A much larger group of physicians, Billings claimed, was mainly interested in "money, or rather the social position, pleasures, and power, which money only can bestow." These doctors are well-educated because "it pays," according to Billings. But the great majority of physicians, Billings concluded, were not well-educated, having memorized only enough of the medical textbooks as was needed to gain a diploma (Billings, p. 479).

It was difficult enough for male physicians to achieve professional status in the United States during the nineteenth century, but for women it was even harder. Elizabeth Blackwell (1821–1910), the first woman to receive a medical degree from a regular American school, in 1849, thereafter wrote frequently on the important role women could play in bringing to medicine greater professional status (Blackwell). The admission of women to medical schools varied from region to region, but with only occasional exceptions it was less than 10 percent of the total. Not until the late-twentieth century did the proportion increase markedly, reaching 30 to 40 percent by 1990.

Like their male counterparts, women physicians also founded their own medical institutions, including hospitals, medical schools, and societies (Morantz-Sanchez). After 1876 there was token representation of women in the AMA; full membership was not granted until the early-twentieth century. The American Medical Women's Association was founded in 1915, but by then most of the women's medical colleges had closed or merged with predominantly male schools. In 1910, at the time of Abraham Flexner's report on U.S. and Canadian schools of medicine, only three of the seventeen women's medical schools still existed, and only half of all the 155 North American schools admitted women for the study of medicine. While virtually all accepted women by the middle of the twentieth century, as late as 1959, twenty-eight schools still explicitly said they preferred men (Walsh, 1992; Bonner, 1992; More).

Blacks who wished to study medicine had an even harder time. Todd Savitt has described ten black medical schools existing in 1900 (Savitt). A decade later only three survived. The AMA refused to accept black physicians for membership until the 1940s, so the National Medical Association, founded in 1895, served to promote the professional concerns of black physicians (Cobb, Morais).

Professionalization of Medicine in the Early Twentieth Century

Robert Wiebe and other historians have seen the increasing professionalization of medicine around the turn of the twentieth century as a key element in the emergence of a growing and more influential middle class in American society (Wiebe). The expanding middle class both increased the demand for professional services and also provided recruits for the professional ranks (Johnson). It also provided students for the growing universities and readily embraced science as the key to future progress of medicine. Science came to be the cornerstone of the reforms in medical education (Ludmerer, Rosenkrantz).

The reforms in medical education that occurred in the early years of the twentieth century were funded and spurred on by philanthropic foundations such as those established by industrialist and philanthropist Andrew Carnegie (1835–1919) and the Rockefeller family, but also came from within the profession itself. In 1900 only 8,000 of the country's 120,000 physicians belonged to the AMA. With reorganization based on a federation of the state and local medical societies, membership grew to over 70,000 by 1910, about 60 percent of all physicians.

The *new medicine* of the 1890s included a physiology heavily influenced by chemistry and physics. This new physiology in turn stimulated departures in experimental pharmacology as well as scientific hygiene. More medical schools, following the lead of a few such as Harvard and the University of Pennsylvania, became integral parts of universities—not merely in name, but in financing, administration, and educational philosophy as well. Schools of medicine began to assume what they called a university point of view, according to which research was an opportunity and a *natural* activity for all instructors (Weed).

In contrast to the medical professionalism of the early nineteenth century, which Thomas Bender has called a *civic* professionalism, the professionalism associated with the new medicine was based firmly on disciplinary loyalties. The values of late-nineteenth- and early-twentieth-century medicine were drawn increasingly from science and, by the middle of the twentieth century, from the medical specialties and their societies and journals rather than from localities or universities.

Science and research provided the main rationale for a firmer link between medicine and the university. For the would-be reformers of early-twentieth-century medical education, such as Henry Pritchett of the Carnegie Foundation, William H. Welch of Johns Hopkins, and Abraham Flexner, the future of medicine depended upon such a relationship. Flexner's 1910 survey, sponsored by the Carnegie Foundation and assisted by the AMA's Council on Medical Education, included visits to all 155 North American schools of medicine and osteopathy. The resulting report, a classic of the muckraking tradition of the Progressive period, is a landmark in the history of medical education. Now best viewed as a catalyst for continuing change rather than as a source for new or revolutionary ideas, the Flexner Report was a clear statement of the importance of science for medicine (Hudson). For Flexner, the data derived from the patient in the clinic or at the bedside was as scientific as that discovered in the laboratory.

The sciences basic to medicine—chemistry, physics, and biology—provided the foundation students needed to study and to understand the preclinical sciences such as anatomy, physiology, microbiology, pharmacology, and biochemistry. And from the advancing knowledge about health and disease derived from these preclinical sciences, the practice of medicine was to be placed on a firm scientific basis. Science—and therefore science-based medicine—was best taught and learned in the university setting.

In the decades after 1910, the Rockefeller philanthropies and other foundations provided millions of dollars to build up academic medicine in many universities. Teaching and research became full-time professional duties for an increasing number of faculty.

Flexner's report documented the inadequacies of many schools and accelerated the closing or merging of some of them. The number of schools fell from a high of 166 in 1904 to a low of 76 in 1929; it began only slowly to rise again in the following decades, reaching 127 in the early 1980s.

By the 1930s, with several newly discovered specific remedies available for diseases such as diabetes, pernicious anemia, and after 1937, for pneumonia, medicine was once again viewed by the public as a true profession, a special calling. But despite continuing discoveries of new therapies and spectacular new technologies for viewing the body and how it works, by the mid-1980s observers of the American medical scene were saying that "the profession is increasingly being seen as more nearly a commercial enterprise with vested economic interests than a calling of professionals whose foremost concern is the well-being of the patient" (Iglehart, p. 324). This profound shift in the public perception of medicine was accompanied by the increasing number of liability suits and the corporatization of medical care (Starr). The coming of the corporation doubtless has been both a positive as well as negative organizational force. A business view has become dominant in hospitals and medical schools, as well as in the private practice of medicine.

Medicine has never been a homogeneous profession. It is perhaps even more disparate at the beginning of the twenty-first century than it has ever been. Until the 1960s, most doctors in the United States ran their practices like independent small businesses. In the corporate world of the late-twentieth century, by contrast, bureaucracy came to define medical practice better than autonomy. Legal challenges to the status of the profession have also questioned whether medicine and the law have acted to restrain trade, as in the 1975 U.S. Supreme Court decision *Goldfarb v. Virginia State Bar* (Rodwin, Sheehan). In that case a young lawyer brought suit against his own profession because he found that no lawyer would perform a title search for a house he was negotiating to buy for anything less than one percent of the purchase price. This commonly fixed price, he argued, violated the Sherman Antitrust Act. The case became a landmark for application of the antitrust laws to all the professions.

Medical professionalism in the context of American culture has always been faced with two apparently conflicting ideals that have shaped its history. Professions, by their very nature exclusionary, have been forced to grow and to prosper in a society that has prized egalitarianism. Equal opportunity has been a basis for American society since colonial days, yet increasingly the medical profession has drawn its recruits from the more privileged strata of U.S. society.

Also, still characteristic of late-twentieth-century medical practice, the patient is often not in a position to judge the quality, the necessity, or the extent of the services provided by the physician. This has remained true despite much more consumer (patient) involvement in medical decision making since the 1960s. As is true for the notion of egalitarianism in society, this continuing separation of esoteric medical knowledge from that which is commonly held provides potential ethical dilemmas for doctors.

A continuing paradox has prevailed in medicine of the late-twentieth century. The more effective medical services have become, the greater has been the demand for them. At the same time they have become increasingly expensive and so more difficult to obtain by many, and nearly inaccessible to those with no insurance coverage. Thus two conflicting concepts of medical care that have always existed in American medicine continue: medicine as a public service and as a private enterprise (Brieger).

Organized medicine in current usage usually refers to the dominant professional societies that have worked in both the professional and the political realms to help doctors achieve or preserve desired ends such as social status, economic rewards, or professional authority. Since one of the hallmarks of a profession is its organizations, the term organized medicine is redundant, albeit commonly used. We have come to assume considerable political power on the part of organizations such as the AMA, the Association of American Medical Colleges, the American College of Physicians, and the American College of Surgeons. While their positive power may have waned somewhat in recent decades as consumer interests have become much stronger, medical organizations until the 1960s were very effective in preventing measures they did not believe were in their best interest from becoming public policy or law (Burrow, 1963, 1977).

MEDICINE, SOCIOLOGY OF

• • •

The sociology of medicine is characterized by a wide variety of concerns, approaches, and perspectives (Mechanic, 1978; Freeman and Levine; Fox; Waitzkin, 1991). The concerns of medical sociologists cover such diverse areas as the distribution and etiology of disease and impairments; disease concepts and their social construction; cultural and social responses to health and illness and the use of services; health and illness behavior and its determinants; sociocultural aspects of medical care and the social organization of helping services; the organization of the health occupations and the

processes of providing care; social factors affecting trends in death and illness; the sociology of the health occupations; the social organization of the hospital; and comparative health organization. In collaboration with other disciplines, the field includes the study of social change and healthcare; changing technology and its role in care; medical education; public-health organization; stress, disease, and coping; social and community psychiatry; the social context of legal and ethical dilemmas; and medical politics.

Many medical sociologists attempt to illuminate how individuals define and respond to situations as they cope with the expectations and demands of their physical and social environment, how some types of response lead to stress and illness, and how services are used to reestablish social and personal equilibrium. Helping institutions can be examined similarly in terms of how the behavior of health personnel and organizations responds to problems of resources, time, and other situational constraints. All people, whether patients or health personnel, seek to establish mastery over their life and work environments, to reduce uncertainty, and to obtain gratification and esteem for their efforts.

One important aspect of medical sociology concerns how certain problems become manifest in a population, how they are defined, and how patients with these problems enter particular channels of care. The field also deals with the nature of therapeutic encounters between patients and practitioners, modes of communication and influence, types of discourse, and how all these are influenced by the cultural context, social characteristics of patient and therapist, changing knowledge and technology, organizational and payment arrangements, and resource constraints.

From a sociological perspective, medicine can be regarded as a sustaining or integrative institution in society (Parsons). Not only does it provide assistance to persons afflicted with disease and other life problems; it also serves as an important means for alleviating social distress and for excusing failures in social functioning or failures to meet social expectations (Mechanic, 1978; Kleinman, 1986). Medicine also has important social control functions that facilitate the removal of individuals from social settings to relieve tensions—whether in the family, in work settings, or in the community at large. It may also facilitate financial compensation or social benefits, for example, access to services or products, such as drugs, that are restricted to those who are not deemed ill.

The role of the physician, then, has not only technical dimensions but also social and moral ones. While the technical expertise of practitioners refers to a limited range of situations, their clientele and the scope of problems they deal with are very broad. Many of the judgments a physician makes are not medical judgments but decisions based on social considerations and values. Even those aspects of the medical role that appear to be purely technical, such as the labeling of disease, the specific management of the patient, and the choice of medications or other treatments, have profound consequences for performance of social roles and obligations as well as for future life opportunities. Patients' problems often result in part from conflicts with other persons and social groups, and the physician can sometimes help resolve difficulties by taking either the patient's or an adversary's perspective. Such conflicts are particularly evident in such areas as military, industrial, and prison medicine, where the physician is not the patient's personal agent, but they occur to some extent in many private patient-care contexts as well.

Patient flow from a community population to various helping agencies is usually thought to result almost exclusively from the occurrence of illness in that population, in contrast with other factors. Indeed, other factors distorting the selection process, such as differential propensities to seek care, are seen as *disturbances* that require correction through patient education or such economic disincentives as deductibles and coinsurance. Although illness is usually the major determinant of help-seeking, it fails to explain by itself much of the evident variation between those who seek and those who do not seek assistance (Mechanic, 1978).

It is common, for example, for medical scientists to assert that discovering a cure for an illness such as the common cold, one of the most frequent reasons for consulting a physician, would profoundly alleviate physical limitations, industrial absenteeism, and the loss of productive labor. But to the extent that the common cold is often an excuse rather than the reason for work absenteeism or seeking medical care, a *cure* might have much less social effect than commonly believed. If people who seek care for the common cold do so because they are unhappy or hate their employment, then the visit to the doctor may be little more than a justification for more complex motivations and behavior. There are various social and cultural inhibitions against persons openly acknowledging personal life problems, and often such problems are shielded by presentations of seemingly trivial illness. This process is now commonly referred to as somatization (Kleinman, 1986).

Medicine involves a distinctive set of meanings that limit the interpretations of patients' concerns (Waitzkin, 1991). Such meanings may obscure social problems and dilemmas and their causes, narrowing the range of possible remedies. This *medicalization* subsumes important social and ethical issues within clinical judgments that escape careful scrutiny. The differential diagnostic approach, which

structures how doctors are educated and how they address problems, affects the ability of doctors and patients to explore comprehensively the sources of distress and disease as well as their implications for well-being (Waitzkin, 1983, 1991; Kleinman, 1986).

Social Distribution of Health, Illness, and Medical Care

Although the concept of health is difficult to define, numerous studies demonstrate that longevity, absence of impairment, and less illness and disability are associated with favorable socioeconomic conditions (Mechanic, 1989b). Many of the health problems of the poor stem from unfavorable environmental conditions, poor nutrition, and lifestyles harmful to health. Because persons of lower socioeconomic circumstances are less likely to receive high-quality services—whether because of limited income, less readiness to seek necessary care, or inaccessibility of facilities—they are more likely to suffer from disabilities, higher mortality, and secondary conditions (Bunker et al., 1989).

Secondary conditions, such as decubitus ulcers, cardiopulmonary problems, and psychological depression, are often causally related to an initial illness and occur because the primary condition is poorly managed (Institute of Medicine). Since 1965 social programs in the United States have given some attention to the equity in the provision of medical services, and the historic inverse relationship between socioeconomic status and use of physician services has been reversed. But socioeconomic differences continue to persist for many specialized services and for preventive care. Although mental disorders are very prevalent in the lowest socioeconomic groups (Robins and Regier), psychological and social services are particularly inadequate for the poor.

The poor suffer from other problems in the medical care sector. They are least likely to share assumptions and meanings with health practitioners, and thus most likely to suffer from misunderstandings and confusions resulting from such incompatibilities. They are likely to feel more embarrassed, anxious, and intimidated in dealing with medical personnel, and are less likely to receive care congruent with their values or life perspectives. They are frequently used as subjects for teaching and research, particularly in experiments that bring no particular benefits to the patient (Barber et al.); and they are more likely to have difficulty granting informed consent, particularly where explanations are quick and perfunctory (Gray). The poor not only have more illness and problems and less access to medical care relative to need but also are treated with less consideration and respect than affluent patients.

Above and beyond socioeconomic status differences, race and ethnic differences account for variations in health. Although much of the excess in mortality and morbidity among blacks and Hispanics is attributable to socioeconomic disadvantage, other factors associated with race and ethnicity are pertinent, including differences in culture and health-relevant behavior, discrimination, and biological differences.

Still other aspects of social stratification, including age and gender, are important determinants of health status. Age and gender affect exposure to risk and disease occurrence through both biological and social pathways linked to these characteristics. The prevalence of chronic disease and disability increases with age but is influenced as well by the individual's social participation and social networks, sense of personal efficacy, and subjective well-being, which vary over the life cycle.

Large differences in health indicators and health behavior are also found between men and women. The fact that women live longer than men is in part biological, but it is also substantially affected by different styles of behavior and response among men and women. Most of the higher mortality in men can be attributed to behaviors such as substance abuse, poor nutrition, risk-taking, and violence. Many other social factors, such as marital status and household structure, are associated with patterns of health and disease (Mechanic, 1978).

Organization of Medical Care

If medicine has social and ethical as well as technical dimensions, how do we develop organizational settings that can apply the necessary technical expertise in ways that respond to the patients and their unique individual and social needs? Even the very best hospitals and medical organizations often treat patients without empathy or respect, and show limited interest in managing their medical problems in light of their family, work, and community circumstances (Duff and Hollingshead; Kleinman, 1988). The personnel who carry out these institutions' medical functions behave as they do, not because they are inhumane, but because the pressures and constraints of work, the priorities they have been taught, and the reward structures of which they are a part direct their attention to other goals and needs. Successful modification of service institutions requires significant revisions in the organizational arrangements and incentives that affect the work of personnel and the tasks they perform. In a materialistic culture where persons may respond to money and prestige incentives more readily than to more lofty motivations, the design of economic and prestige incentives and an awareness of how they

affect decisions become important elements in shaping behavior.

Some attention has been devoted to how the economic structure of medicine affects the work of physicians and other personnel. Fee-for-service incentives often result in high levels of professional commitment, a willingness to work hard, and responsiveness to those who pay the fees. They also often encourage excessive use of medical, surgical, and pharmaceutical modalities to earn more income. Data from a variety of nations suggest that when attempts are made to manipulate the system by increasing payments associated with certain procedures, these incentives shape what physicians do (Glaser). The difficulty with any such piecework system is that it tends to discourage procedures that are important but for which only modest or no remuneration is provided. Since payment systems typically reward technical procedures, the most neglected aspects are those concerned with social care, listening to the client, patient education, and grappling with ethical issues. Physicians are best rewarded financially when they provide the largest number of discrete technical services.

One antidote to the perversities of piecework medicine is to pay by salary or capitation (a uniform payment for each person the physician cares for), but these approaches also have disadvantages. Under such systems physicians are more likely to limit their work efforts, appear less committed to their work, and seem less flexible and responsive to the individual needs and circumstances of their patients (Mechanic, 1989a). Thus, the same incentive conditions that make it possible for physicians to allocate their time within their own concepts of the value of varying types of caring and curing—conditions that may dampen a tendency to overutilize expensive and perhaps dangerous therapies—may also encourage withholding necessary services or result in an unwillingness to respond to important concerns of patients.

Doctors paid by capitation seem to adjust their efforts in relation to the payments they receive, a form of perceived distributive justice. This concept is shaped by knowledge of the circumstances of other doctors with comparable training in different work settings. Many of the difficulties in capitation payment result because patient load is heavy and payment is small for each patient. The heavy patient load and the doctor's limited work hours encourage a pattern of care that many patients find unresponsive. But time and patient demand are not the only factors involved in the way physicians deal with social and ethical problems in their practice. Physicians may have more or less tolerance for a wide scope of work; may be more or less willing, and feel more or less competent, to deal with family problems, alcoholism, sexual adjustment, or child-care problems. To the extent that physicians are properly trained to deal with the broader problems of medical care, and thus feel more competent in their clinical management, they may be more willing to deal openly with social and ethical challenges. Many physicians probably avoid dealing with psychosocial issues because they feel an effective therapy is lacking; however, they often readily accept the responsibilities to treat physical illnesses for which they also lack effective treatment. It may be that a sense of confidence and clinical experience are more important than the objective efficacy of the care.

In the creation of new medical settings, the problem is how to maximize the advantages of both fee-for-service and capitation medicine while compensating for their more undesirable aspects. People are ingenious in undermining and thwarting incentive systems that are not sensitive to their work problems, that increase their uncertainties, or that appear inequitable. To design an organizational system adequately requires intimate appreciation of how individuals actually manage their work, rather than utopian but unrealistic conceptions of how people should function.

Sociology of the Health Occupations

The attention in this article to doctors, in contrast with nurses, technicians, pharmacists, or social workers, is no accident. Although physicians constitute less than one-tenth of personnel in the health sector, they define and dominate the nature of decision making and the division of labor in medicine (Freidson; Starr; Mechanic, 1991). Physician dominance is in part a process in which doctors gain political legitimacy that protects them against economic competition from other health workers and helps preserve their professional autonomy. Increasingly, the physicians' dominance is being challenged by a variety of forces in the society: by administrators wishing to achieve economies of production through shifting traditional medical tasks to less trained personnel; by government wishing to control the growing costs of medical care; and by such professional groups as nurses who wish to improve their own political power, income, and status. Thus, the health sector is characterized by increasing political acrimony and collective politics (Stevens).

Ethical Dilemmas and the Sociology of Healthcare

The advances of medical knowledge and technology confront modern society with awesome social and ethical dilemmas. Among these questions is whether an ever-increasing proportion of our gross national product ought to be spent on expensive modalities that provide marginal gains in

health and longevity. Are such investments not better made in preventive approaches and environmental amelioration or in other social goals?

Bioethics has been more an activity with a normative focus than a field of inquiry that seeks to investigate the implications of varying courses of action (Wikler; Fox). During the two decades in which bioethics has grown as a discipline, relatively few bioethicists have utilized sociological materials and methods, and relatively few sociologists have studied bioethics (Weisz). Ethical reflection in healthcare could be very much enhanced by a sociological perspective that examines the empirical setting and implications of a given ethical choice. Whether to accept organs from live donors or allow subjects to participate in experiments posing possible danger to themselves must depend at least to some extent on the actual psychological and social consequences of such participation. The fact that such volunteers often experience great satisfaction from their participation is no small part of such policy considerations (Fellner and Schwartz; Gray). Similarly, the willingness to expend great resources in heroic efforts to extend life, irrespective of function, must be weighed against the consequences of extended lives for such patients and their loved ones. Sociological perspectives and methodology can contribute to the ultimate ethical decisions by clarifying some of the human factors relevant to resolving the conflicts between competing social and ethical values.

MENTAL HEALTH, MEANING OF MENTAL HEALTH

• • •

Notions of *health* and *mental health* neither arose nor developed in a cultural and conceptual vacuum; their ancestral and contemporary kindred and relationships are multiple and far-reaching. Traces of their past live on in present quandaries and controversies. The interpretation and analysis that follow are historical and sociocultural, as well as philosophical and clinical.

Historical and Philosophical Background

NEAR EASTERN AND CLASSICAL CONCEPTS. Our story begins with the high civilizations of the ancient Near East. Initially, disturbances in customary and acceptable human functioning were experienced and interpreted in magico-religious and moral modes. Ancient Near Eastern personhood blended into a cosmos permeated by the divine and comprising countless interactions among fluid and loosely bounded beings and forces. Demarcations such as those between religion and medicine, psychic and somatic, material and immaterial, or spiritistic, natural, and supernatural would have been incomprehensible to early Egyptians and Mesopotamians. Even surgical and pharmaceutical interventions were accompanied by prayer, rituals, and magical formulas and paraphernalia.

Much the same can be said for the people of Mycenaean and Homeric Greece, whose worldviews and concepts of human beings were inseparable and thoroughly magical, animistic, and religio-moral. Cognition, affect, and motivation were experienced as divinely or demonically implanted, or else literally *inspired* from the ambient air. The earliest Homeric internalizations of motivation were localized to a semiautonomous region of the midriff or diaphragm called *phthumos.* As in Near Eastern antiquity, all sickness or disease, including madness, was magical (caused by spells or curses), demonic, or religious and moral (caused by divine possession, or divine punishment for ritualistic infractions, taboo-breaking, and sins of all sorts).

Health or *wellness* referred equally to states of the cosmos, society, or person. For example, the Egyptian goddess Maat personified a diffuse constellation of truth, balance, and right ordering or right acting, understood as antithetical to the primal chaos of the universe. Likewise, preclassical Greek ideas of health or wholeness were religio-moral, the corrections of imbalances. These metaphors and concepts of equilibrium, refined and codified by the classical Greeks, have remained central to modern Western medical and psychiatric norms or ideals of healthy functioning.

Classical Greece is commonly deemed the birthplace of both the psychological individual and secular medicine. Actually, however, medicine's vocational identity, cosmology, and philosophical anthropology were still imbued with religious aspects. The Greeks invoked deities such as Asklepios/Apollo; and nature itself (Physis), and humanity as part of it, remained divinized. Maladies, healing, and health were at once medical and sacred. The more medical facet of Hippocratic doctors' *health* and *disease* concepts concerned the bodily humors and their ratios to one another (balance versus excess or deficiency). Madness was explicated humorally as well, in a sort of proto-"physiological psychology" and psychopathology (Jackson); and the brain was considered the organ of mental activity.

By contrast, Plato and his philosophical successors disseminated a psyche-body dualism that influenced Western medicine for centuries. Plato characterized as "divine" physicians who were also philosophers, who thus knew soul as well as body. Nevertheless, he apparently thought such practitioners so rare that he roundly criticized doctors' practices of "dietetics"—which included what we would call counseling, lifestyle management, and prevention. In line with his dualism, Plato argued that philosophers were the

rightful "physicians of the soul," thereby inaugurating a lengthy tradition of philosophical therapy. Such philosophers progressively adopted medical models and metaphors for the psyche in states of wellness and disease (*pathé*). In the first and second centuries C.E., Epictetus termed the philosopher's lecture room a "hospital"; he likened the pain necessary in spiritual and moral healing to that in medical measures such as the lancing of an abscess (see Edelstein). Centuries later, Sigmund Freud characterized analysis with surgical metaphors, and Henri Ellenberger thought psychoanalysis itself a latter-day version of philosophical healing.

The Hellenistic and Roman Stoics and Epicureans were other famous proponents of psychotherapeutic philosophy. Like all philosophical physicians, they were infatuated with metaphors of balance. The soul's health was equated with states such as *ataraxia* or *apatheia* (equilibrium, tranquility, serenity). The Stoic idealization of reason, and concomitant depreciation of passion, probably influenced subsequent rationalistic criteria for mind in health and illness. In any event, Plato and company, with their dualism and healing ambitions, paved the way for current concepts of mental health and psychotherapy. Nonetheless, their images of such health were spiritual/ethical, and their healing was dialectical and pedagogical—and, hence, a far cry from our ostensibly metaphysically and morally neutral mental health and psychotherapy; though Freud himself emphasized the educational and ethical aspects of analysis far more than any presumable medical ones (Wallace, 1986).

Aristotle, Plato's greatest pupil, avoided a frankly dualistic mind-body position and touted the philosopher's role as ethical teacher. The doctrine of the *golden mean* and prudential and moral virtues, or *character ethics,* held the place in Aristotle's philosophy that had been occupied by psychical or spiritual health in Plato's. This "golden mean," yet another manifestation of balance, was the cardinal feature of the virtues—for example, courage as the midpoint between temerity and timidity. In light of the individualistic thrust of ancient philosophical therapies such as Stoicism and Epicureanism, and of many present-day psychotherapies and notions of mental health, it is noteworthy that Aristotle considered his Ethics and Politics integral to each other. Citizenship, reflecting the individual's self-acknowledged embeddedness in a community, was central to Aristotle's idea of proper human functioning. Whereas we might accuse Aristotle of collapsing mental health into social ethics, he might have charged us with the reverse.

MEDIEVAL AND RENAISSANCE CONCEPTS. In the Christian West, institutionalized medicine was in priestly hands. The closest thing to medical schools were monastic, and most medieval infirmaries were operated by the Church. Medical theory and therapy followed the Hellenistic Galen's final codification of humoralism and anatomy. Madness was explained and treated somatically, as well as with the prayers and healing rites offered for any severe medical condition.

Somatic perspectives on madness meshed nicely with the Church's Platonic dualism, since the immortal and immaterial soul, unlike the body and brain, was not corruptible by disease. Meanwhile, the Church continued to use medical metaphors for many spiritual and moral problems. It is hard to know whether some of these approximated our nonpsychotic and less severe categories of mental illness—such as *dysthymia* or the *personality disorders*; aspects of the latter clearly falling under the traditionally moral purview. Medieval clerics themselves meditated over gray zones, such as whether acedia, a common monk's affliction, was sin (slothfulness) or disease (a mild form of melancholia) (Jackson). There was nothing corresponding to contemporary concepts of mental health. Norms and ideals were spiritual and moral, biblically and theologically derived.

Thomas Aquinas added loss of free will to irrational thinking and behavior as another cardinal sign of madness. This has influenced juridical processes up to the present, posing problems to psychiatrists espousing determinism (i.e., that all human mentation and behavior are causally necessitated). It has also borne on contemporary conceptions of mental health, some presupposing a capacity for nonnecessitated choosing (e.g., humanistic and existentialist) and others (e.g., classical psychoanalytic and neuromolecular) usually not. The ramifications for morality and ethics are obvious (Wallace, 1986).

As the great universities arose between the twelfth and the fourteenth centuries, they incorporated monastic medicine. Nonpriestly physicians returned to the scene, but medical theory and the treatment of madness remained much the same. There was no real secularization in Europe until the Renaissance, with its novel and heightened forms of individualism among certain educationally and financially favored segments of Europe's populations and its protopsychological concept *imaginatio,* a catchall for feeling, imagination, and fantasy (the very items ignored by hitherto hyperrationalistic norms of personhood).

This same period, however, witnessed the Inquisition, and its mass persecution of heretics and alleged witches. Medical men such as Johannes Weyer, with special interests in madness, argued that accused and "confessed" witches were actually insane, one of the few conditions that legally exonerated them. Still, Weyer's diagnoses were not purely medical, for he thought the witches' delusions had been

implanted by Satan. Many modern historians of psychiatry have lauded Weyer for his insight and courage (e.g., Zilboorg). Some psychiatrists and psychoanalysts, including Freud, followed Weyer's example and facilely diagnosed whole institutions and cultures as psychopathological. Several decades of careful scholarship suggest that most "witches" were not in fact psychotic (e.g., Spanos). Furthermore, concepts of normality and pathology are complex, and they vary greatly from one culture or historical period to another. Moreover, transferring concepts of mental health and illness from the individual domain to the arenas of groups, cultures, and even families is questionable at best (Ackerknecht, 1971; Wallace, 1983).

SEVENTEENTH- AND EIGHTEENTH-CENTURY CONCEPTS. The seventeenth century was characterized by the continuing expansion of individualism and by a rationalism that paid less attention to aspects of personality, such as *imaginatio,* explored by the Renaissance. Irrationality became the key criterion for madness, giving the social philosopher Michel Foucault (1965) the ostensible grounds for his thesis that seventeenth-century asylums were filled with persons who had violated their era's canons of reason and socially acceptable behavior. Foucault alerted us to possible linkages between sociocultural and political-economic special interests, and psychiatric institutions, concepts, and practices—including formulations of mental health and illness.

The epoch from 1600 to 1750, then, was a watershed in many ways. Its scientific paradigms, ultrarationalism, and sociocultural-economic developments paved the way for the West's ensuing secularism and capitalism. The coming age would require and give rise to different forms of humanity, with novel notions and modes of well-being, dysfunction, and distress. Not coincidentally, it would also spawn a new medical specialty: psychiatry.

Contemporary Concepts and Issues

The mid-eighteenth century constitutes the headwaters of the stream that culminates in the modern or postmodern mental-health complex. The rise of economic capitalism, with its emphasis on free-market competition and individual acquisitiveness, went hand in hand with the progressive breakdown of traditional social-political structures and cultural institutions, along with the Christian worldview that had hitherto sustained them. New modes of personhood appeared, modes that were exquisitely self-aware and self-oriented, shunning binding institutional and interpersonal commitments, and shrewdly combining hedonism with "social adjustment."

The Enlightenment witnessed novel varieties of what we would designate as *functional* (versus *organic*) psychiatric disorders: the *vapors, nerves,* and so forth, resembling *conversion, dissociative, anxiety, dysthymic, personality-disordered,* and *neurotic* categories (American Psychiatric Association, 1987). Initially comprehended and treated somatically with *magnetism,* or hypnosis, they were gradually conceptualized psychologically. Feminist historians (e.g., Decker) interpret these experiential and behavioral configurations as disguised forms of women's rebellion against male-dominated society.

Meanwhile, in early and mid-eighteenth-century Great Britain, a new breed of physicians began devoting their practices to madness. The most brilliant of these "mad-doctors," Alexander Crichton, influenced Philippe Pinel, generally called psychiatry's father. Previously an internist, Pinel flourished in post-Revolutionary and early nineteenth-century France. Until then, madness had not been institutionally medicalized. Asylums typically fell under lay management, with doctors no more than general medical consultants. Pinel's orientation was psychological as well as medical, and he came to favor abbreviated systems of diagnostic classification. However, his successors in the powerful French clinical school, presuming the inevitable degeneration of many conditions, became progressively and pessimistically *organic.* Notions approximating mental health were far from their minds.

Contemporary German psychiatry was pursuing a semimystical and Romantic psychological path (Ellenberger). Abstruse and difficult to summarize, it conceptualized nature and humankind as manifestations of a World Spirit or Soul. Although often obscure and moralistic, it contributed some genuine psychological insights, including many on unconscious mentation and motivation. In England and the United States, despite some admixture of somatic theory and practice, early nineteenth-century psychiatry—or *alienism,* as it was called (thus underscoring its subjects' social estrangement)—was predominantly psychologically and sociotherapeutically oriented. The Anglo-American *moral treatment* movement envisioned the then relatively small country asylum as a healing family, with the medical superintendent its *father.* For much of the nineteenth century, the word *moral* still denoted an amalgam of what was later divided into *mental* or *psychological,* and *moral* or *ethical.*

As the twentieth century approached, the number and size of asylums grew geometrically; treatment became custodial, and Anglo-American and European psychiatry grew increasingly neuropathologically inclined. Its interest in diagnostic classification and the results of autopsies contributed to what Foucault (1973) called the "objectification" of the patient. The rise of organic and custodial psychiatry

reflected many social and demographic changes in the United States: rapidly increasing population; greater social and geographic mobility; replacement of small and culturally homogeneous communities by urban centers swelled by immigration; the continuing disempowerment of institutional religion; movement toward monopolistic capitalism, an orientation toward productivity and consumerism; individualism and waning local charity; and generally changing social mores. Together, such factors made moral therapy unworkable and led to further transformations in popular conceptions of personhood in wellness and illness. Communities and even families transferred responsibilities for their psychiatrically disturbed members to the large central facilities.

It is likely that such facilities came to house many who were merely elderly, socially deviant but not criminal, and economically unproductive. Certain contemporaneous *diagnoses*—such as *volitional old maid, vagabond,* and *eccentric character*—would be laughable if they had not also been socially coercive. State hospitals usually fell under the autonomy of those social agencies that dealt with the socially and economically marginal and dependent (see Grob, 1973, 1983). Drawing on such historical sources, as well as on present-day events, a school of social scientists and political philosophers underlines the status quo-supporting and professionally self-serving features of psychiatry and its related disciplines, including their diagnostic schemata and notions of health and illness (e.g., Foucault, 1965, 1973; Ingleby; Horwitz). These include gender, socioeconomic class, and ethnic biases (e.g., Chesler; Russell).

The organic orientation of the second half of the nineteenth century promoted a seemingly paradoxical soul-body or mind-body dualism among Anglo-American psychiatrists. In their view, psychiatric disturbance or disease was wholly a function of body and brain; the soul or mind, being immaterial and immortal, was not susceptible to disease. Such a schema, which obviously protected their theological tenets, virtually ruled out ideas of mental health and illness, and practices such as secular psychotherapy. Nevertheless, psychotherapeutic perspectives began forming in the late nineteenth century. They emerged among outpatient neurologists who were encountering increasing percentages of functionally disordered patients, and among psychologically minded psychiatrists, who were treating ambulatory patients with milder problems. The distress and dysfunction these professionals were treating became less commonly experienced and interpreted in religious and moral terms. Such problems were therefore less amenable to healing through confession, penance, and recommitment to the Catholic ideology, institutions, and community, or to their Protestant counterparts, often including more counseling ("the cure of souls").

Twentieth Century

To serve these new varieties of troubled persons, innovative therapies arose in the latter nineteenth century and the first decade of the twentieth. These *mind-cure* or *healthy-mindedness* approaches, as William James (1902) named them, comprised purely secular healings; heterodox religious approaches such as Seventh-Day Adventism and Christian Science; Americanized variations of Eastern religions and philosophies; and various integrations of religious, medical, and psychiatric proposals. In Europe, psychoanalysis emerged, the prototype of twentieth-century secular therapies and the ultimate progenitor of most current psychological theories and treatments. Psychoanalysis and its offshoot dynamic schools would contribute significantly to the clinical and popular dissemination of concepts of mental health and mental illness.

By 1910, events were gathering momentum. The important Mental Hygiene Movement, a joint lay-psychiatric venture, had been formed in Boston in 1909 (by former mental patient Clifford Beers and Harvard psychiatrist E. E. Southard). Though it had been started to improve the plight of the severely mentally ill (formerly the *mad*), its concerns shifted swiftly toward mild-to-moderate psychiatric problems and to community mental hygiene, which led eventually to the burgeoning community mental-health movement of the 1950s, 1960s, and 1970s. This movement, like the dynamic therapies, fueled public preoccupation with mental health (Grob, 1983).

During these same decades, psychiatrists in the United States had begun moving toward acute-treatment psychiatric facilities and wards in general hospitals, the *psychopathic* units that treated less chronically severe patients—those with acute crises, neurotic symptoms, and personality problems of all sorts. Outpatient work continued to grow as well. Clinical psychology and social work started evolving as professions. General medicine's public-health and preventive wings, joined by lay *wellness* proponents, enlarged their territory, too. These developments have led many critics, such as Ivan Illich (1976), to speak of medical and psychiatric *imperialism,* the *medicalization* of society, and so forth. Indeed, as early as 1856, physicians such as Oliver Wendell Holmes contended that doctors and deterministic medicine should replace priests and religion as society's moral arbiters. The eminent medical historian Owsei Temkin (1977) charges that health has become a "summum bonum," whose values encroach on morality and ethics (e.g., the virtual criminalization of smokers). Don Browning (1987) points out the various ethical, social-valuational, and cosmological dimensions of the major psychotherapeutic approaches.

Many have commented on the normative-prescriptive aspects of the mental-health and mental-illness concepts of the multifarious psychiatric and clinical psychological vantages.

Definitions of *health* as broad as the World Health Organization's (1991) "state of complete physical, mental, and social well-being," certain epidemiologic projects (Srole et al.), and categorizations of *mental disorder* as extensive as those of the American Psychiatric Association (1987, 1994), seem to ground the accusations of Illich and others. Aspects of hitherto *normal* aging are deemed *disease* and treated as such, and similar attitudes toward features of other developmental periods could be cited. Indeed, pathology has narrowed the domain of human physiology to the point that doctors and the public alike view death itself as all but a potentially preventable disease.

In any event, though most philosophers of general medicine (e.g., Pellegrino and Thomasma; Kass) declare promoting *health* to be the physician's primary objective, few medical authors conceptualize and elaborate it very explicitly. More often it is a negative notion—the *absence* of significant disease or illness. Although conceptions of mental health in psychiatric and related practitioners' textbooks and treatises are frequently negative as well, the writers of such books are more likely to attempt *positive* conceptions than are their general medical counterparts. Daniel Offer and Melvin Sabshin (1966, 1984, 1991) list dozens of notions or definitions of mental health by theorists and therapists of many persuasions. These range from simplistic extremes such as "social adjustment" or "self-actualization," to more complex and reflective notions. Some assess mental health, like mental illness, by dimensions and degrees; others proffer categorical constructs of both. There are naturalistic-universal, psychological, sociocultural-contextual, and biopsychosocial ones. In short, the ways of classifying conceptions and criteria of mental health are potentially exhausting. Through surveying an immense range of pertinent sources, Marie Jahoda (1959, 1977) identified the six indexes of mental health that appear most frequently: (1) the individual's attitudes toward himself or herself; (2) the person's "style and degree of growth, development, or self-actualization"; (3) a central synthesizing psychological function, or "integration"; (4) "autonomy," or "independence from social influences" (the single most cited index); (5) adequacy of reality perception; and (6) mastery of the environment.

However useful they may be, these criteria can hardly claim to be purely natural or scientifically derived; they are clearly a function of time- and place-bound cultural contexts, as well as of presupposition-laden psychological orientations. It is not so much a question of whether they imply values, for no theories and concepts escape their authors' values altogether. Rather, the questions concern the kinds of values, and their relationships to one another and to those in other endeavors and institutions.

Of Jahoda's indexes, most are self-oriented, depicting the natural and social environment as something virtually inimical to personal well-being. The "healthy" are independent of its influences, mastering it to their self-actualizing ends—which, ironically, may be quite serviceable to those of the prevailing political economy. Of course, there are also formulations of "mental health" at the opposite, or socially conformist, pole; their professional exponents probably have frequently fallen into the service of dominant socioeconomic agendas. In any case, Jahoda's analysis suggests that there are other sorts of dangers associated with ideas of mental health. Such common extremes in positive conceptions of mental health make one wonder whether they should be attempted at all. The American Psychiatric Association (1987) avoids defining mental health.

Many of the profoundest students of human experience and behavior, such as Freud, have not issued definitive pronouncements on mental health. Freud's theories and observations contain many items relevant to assessing dimensions and degrees of psychic well-being and its reverse (Wallace, 1986; Vergote; Wallwork). Nevertheless, apart from hearsay attributions to him of the spare desideratum *Lieben und Arbeiten* (loving and working), Freud bequeathed us no extensive positive constructions of mental health. In fact, he stressed the continuum from neurosis to "normality." Nor did he harbor utopian ambitions for psychoanalytic therapy, firmly denying that it promised happiness or contentment. It was quite enough if treatment alleviated the analysand's more troublesome, historically determined psychic and interpersonal conflicts, misapprehensions of self and others, and modes of gratifying and inhibiting hitherto repressed or symptomatically expressed desires and strivings. Such imperfect but significant transformations enhance the patient's grasp of his or her particular life's realistic problems and possibilities. Freud had no notions akin to Abraham Maslow's and Carl Rogers's of the easy and automatic harmonization between "self-actualization" and the requirements for a humane and civilized society. His concept of adaptation, hardly collapsible into Darwin's, implied neither mastery of nor submission to the sociocultural and political-economic surround, but rather a prudent and moral interweaving of "autoplastic" (self-transformative) and "alloplastic" (environmentally altering) activities (see Hartmann; Wallace, 1986; Vergote; Wallwork).

Although Freud was capable of psychoanalytically masked moral and metaphysical judgments, such as those about religion, he was usually quite sensitive to the interface between moral/ethical perspectives and theoretical/clinical

ones. Psychoanalytic insights and findings might inform the ethical enterprise, but Freud did not think moral values themselves could be deduced from analytic premises. Regarding moral values in the psychoanalytic endeavor itself, he emphasized honest self-awareness and its potentially beneficent personal and interpersonal effects (Wallace, 1986; Rieff). Freud intended the clinician's analytic neutrality, with its customary suspension of explicit moral evaluation, purely as a means to enhance the patient's disclosure and self-discovery; it was confined to the consulting room and not suggested as a recipe for living.

Conclusion

Given the historical and cross-cultural variations in modes of conceptualizing personhood and ascribing abnormality, as well as the vicissitudes of sociocultural and natural environments, it makes little sense to seek timeless and placeless notions of health, illness, or even disease, psychiatric or otherwise. The extraordinarily complicated overlap and mutual determination among formulations and applications of mental health, and a host of external institutions, ensure that the former will reflect and affect myriad sociocultural dimensions and processes. Insofar as ethical and metaphysical purviews are separable from scientific and medical/psychiatric theories and findings, one cannot facilely deduce moral values and ethical systems from the latter.

A biopsychosocially oriented functionalism proffers the least metaphysical and reductionistic, and the most comprehensive and open, model of the human organism in its ongoing cultural and natural milieu. This conceives of self-conscious and symbolizing personhood as the complexly integrated function of a plethora of subsidiary structures and functions, interacting both among themselves and with aspects of the physical and sociocultural ambience. It avoids either a dualistic or a mechanistic stance on humankind; it affirms the necessity of psychosocial, as well as biomedical and neurobiological, approaches to persons in health and illness (Wallace, 1990). Moreover, it permits medicine, psychiatry, and the mental-health disciplines a public philosophy open to dialogue with vantages from ethics, theology, jurisprudence, politics, and elsewhere (Wallace, 1992). In other words, a *Homo sapiens* does not comprise separate ontological compartments of spirit, morals, mind, and body. Rather, he or she is appreciated as a self-consciously reflective whole, with a history in a community, whose various experiences and activities require separate, but overlapping and interrelating, spiritual, moral, medical/psychiatric, and social perspectives. However one understands mental health and mental illness, they point toward forms of distress, disability, and well-being that are real and pervasively human concerns.

POSTSCRIPT

Western definitions and concepts of mental health have continued to multiply into the twenty-first century—usually permutations and combinations of desiderata already treated. However, there is a strengthening minority position taking sociocultural (including political-economic) and even spiritual parameters into account—both in definitions of mental health and in theories of causation of mental disorders (Kleinman and Good). This cadre is led by transcultural psychiatrists and psychological/psychiatric anthropologists (GAP). Western psychiatry is being cogently examined as one ethnopsychiatry among others (Kleinman). DSM-III and DSM-IV Axis I disorders such as Major Depression differ in core, and not merely peripheral, signs and symptoms—begging the question of whether psychiatry is dealing with different nosological entities (Kleinman and Good).

On the positive side, the psychiatrist and philosopher K. W. M. Fulford has proposed a notion of mental illness as "failure of action," rather than as the DSM-IV's "disturbed functioning." The latter implies component pathophysiological lesions about which the evidence is still very equivocal (Wallace, Radden, and Sadler; Ross and Pam; Bentall; Lewontin, Rose, and Kamin). "Failed action" refers to a variety of distressing or disabling experiences and behaviors that the person is unable to control (i.e., consciously will and enact otherwise). A definition of mental health is of course implied in this, and could be worked out conceptually. Fulford's notion does not rule out the potential explanatory and therapeutic applicability of both neurobiological/pharmacological and psychosocial/psychotherapeutic approaches.

A far more complex and controversial theorist of disease/illness and, by implication, of what he now prefers to call "normality" rather than "health" is Boorse (Boorse, 1977). Attacked by most bioethicists and medical philosophers (Humber and Almeder), Boorse has staunchly argued for human species-specific biostatistical, ostensibly objective

and value-neutral, criteria for disease (Boorse, 1975). Initially limiting his argument to general medical *disease,* he later moved to biostatistically-based criteria for *illness* and for the mental disorders as well (Boorse, 1975, 1997). In a 1997 book chapter, he skillfully defended himself against a plethora of critics.

Since it is impossible to address his annexation of mental disorders (and, by implication, mental health) without appreciating Boorse's general medical concept of disease/illness, one must begin with the latter. His biostatistical criteria for disease/illness are extremely spare and Darwinian: the preservation of the individual (as opposed to the group or population) and his/her reproductive fitness. *Disease* is component pathophysiological dysfunction or subfunction *within* the organism. It is key to realize that Boorse is concerned with *medical scientific* (i.e., the pathologist's) or *theoretical* criteria for disease. He is not occupied with *practical* clinical diagnosis (which often deals with syndromes) or the *clinical* investigative and therapeutic manner of the physician. However, it is important to note that he appreciates the necessity for "disease-plus" concepts of humanitarian and ethical clinical behavior.

Moreover, in concerning himself with disease as *intra*-organismic component pathophysiological dysfunction or subfunction, he does not argue that the nexus of etiology is delimited to the subcomponent or even the organism itself. He includes physical environmental trauma and psychosocial causation (in the general medical, as well as psychiatric, realms). *Illness* is the systemic molar or total organismic (which may include the mind) subfunction or dysfunction accompanying the *disease.* Hence, *illness* represents the same sort of Darwinian impairment already addressed with reference to *disease.* By Boorse's criteria, it is possible to: (a) have a *disease* without an *illness* (e.g., molar dysfunction)—though eventually, of course, many or most diseases will also become illnesses; and (b) an illness (e.g., influenza) without a disease (e.g., delimited internal pathology).

One must also recognize that Boorse's biostatistical, Homo-sapiens-typical criteria are related to gender, age, and (to some extent) ethnic or racial reference-groups. This prevents a post-menopausal woman (who has lost reproductive fitness), a middle-aged man with some degree of "male pattern baldness," or a pygmy with group-wide growth-hormone subfunction from being deemed *diseased* or *ill.* Nevertheless, things become more complicated for Boorse with African or African-American individuals heterozygous for sickle-cell disease. On the one hand, this state is survival-promoting in malarial environments, but not at higher altitudes at which other "races" are not so vulnerable. Boorse attempts to sidestep this with his construct of "standard environment." This is problematic not only for general medical disease/illness, but especially for mental and behavioral functioning, since climatic, historical, and sociocultural relativity render the idea of a Homo-sapiens-specific standard physical and sociocultural environment suspect.

Finally, this author finds Boorse's insistence that component or circumscribed internal pathophysiology alone defines disease as bizarrely narrow; it excludes systemic dysfunction or subfunction, as well as the molecular level to which many pathological disease-formulations are now turning.

Turning especially to psychiatry, Boorse likewise stresses internal component pathology. To his credit, he considers psychological concepts a necessary subset of biological ones—to grasp human species-specific, symbolically-mediated mentation, communication, and behavior. This author has argued similarly in both monistic-dual-aspect and functionalist models of the mind-body relation (Wallace, 1988, 1990, 1997). In other words, Boorse contends that not only cerebral or extra-cerebral component pathophysiology (and here he chides biological psychiatry for its predominantly molecular approach) may be pathognomonic for mental disorders, but so might *component psychological functions* such as unconscious intrapsychic conflict among the psychoanalytically-conceived mental agencies and subsidiary functions. However, his delimitation of disease/illness criteria to individual self-preservation and reproductive fitness are problematic for notions of mental disorder and normality. For example, in non-Western cultures with intact, supportive kinship and community networks, psychiatrically-untreated schizophrenia does not pose the same personal survival or even reproductive fitness risks that occur in the urbanized West, with its relative dearth of community and kinship networks. And most DSM-IV Axis II sufferers (from perhaps Western culture-bound syndromes) often experience no increased physical survival or reproductive-fitness risks. In short, Boorse's two Darwinian criteria are insufficiently robust for a concept of mental disorder/illness, much less for *normality* or *mental health.*

Pending further research, some varieties of the major mental disorders may turn out to be diseases in the Boorsian circumscribed pathophysiological (or even molecular) sense. However, this author suspects that most (Axis II) mental disorders (which keep multiplying over time in new editions of the DSM) will remain best understood in the psychosocial categories of human biological discourse.

In conclusion, there is nothing in Boorse's argument as applied to psychiatry that would countenance psychiatry's recent (patently, if partly, economically-motivated) turn to a radical neurobiological/pharmacological reductionism. Such an approach entails the concomitant jettisoning of

psychosocial/psychotherapeutic approaches that demand a more laborious intimacy with the patient-as-person-in-an-ambience rather than as simply the epiphenomenon of a twisted molecule or component brain limbic pathophysiology. Again, Boorse asserts that disease- and illness-plus concepts and approaches are necessary to anyone who would be an ethical and competent clinician.

Space does not permit treatment of the recent evolutionary psychiatry of Randolph Nesse and George Williams, and others. They are obsessively committed to imagining historically remote conditions in which disorders is incapacitating as schizophrenia were once adaptive (i.e., atavism).

MENTAL HEALTH SERVICES

• • •

I. SETTINGS AND PROGRAMS

Since the mid-1950s, fundamental transformations have taken place in the size, location, diversity, funding, and attitudes toward mental health services in the United States, changing the organized response to the identification and treatment of mental health problems. These changes have altered the central policy and ethical questions that arise in the mental health system as a whole. When involuntary commitments to custodial mental hospitals dominated the system, the central issues involved inappropriate social control. In the diversified system based upon community care and treatment that has evolved, the most pressing issues include how to fund and deliver services to the most

seriously ill persons, allocate services to meet a potentially huge demand, and improve service delivery outside the traditional system of mental healthcare.

Evolution of Mental Health Services

Until the mid-1960s, two separate systems dominated mental health services: public mental institutions that treated a large population of inpatients and a smaller private sector that provided most outpatient psychotherapy. Large, impersonal, custodial facilities dominated the inpatient sector and housed poor, isolated, severely mentally ill persons (often elderly) for long periods of time (Grob, 1973). Most residents lacked family ties or were committed as a last resort by their families. The flaws of these institutions are well known: huge size, overcrowding, geographic isolation, involuntary confinement, depersonalization, coercion, and custodial emphasis (Goffman). Nevertheless, they provided the most seriously ill persons an integrated range of services—housing, food, symptom management, respite from stressful community conditions, medical treatment, and a locus for social interaction—in one centralized location. Alongside the core of state mental hospitals, a smaller outpatient sector dominated by private psychiatrists practicing analytic psychotherapy treated clients who could afford those services (Hale).

The mental health system at the beginning of the twenty-first century is much different. A revolution in mental health services began in 1955, when the average number of residents in state and county mental hospitals started to decline from a peak of 550,000, to 370,000 in 1969 and about 60,000 by 1998 (CMHS, 2001). Taking into account a growing general population, the number of residents in state and county mental hospitals fell from 339 per 100,000 persons in 1955 to 91.5 in 1975, and to only 21 in 1998 (CMHS, 2001). Typical patients in state hospitals have also changed: from the elderly to the young; from long-term to short-term patients; and from persons with deteriorating and untreatable diseases of the brain to ones suffering from concurrent substance abuse disorders.

As state mental hospitals became institutions of last resort for the most intractable patients, alternative forms of inpatient care grew substantially. Less than 10 percent of admissions to twenty-four-hour care facilities occurred in state and county mental hospitals in 2000, a four-fold decline since 1969 (CMHS, 2001). Most inpatient psychiatric services now take place in general hospitals, private psychiatric hospitals, specialized chemical dependency units, nursing homes, and residential treatment centers for children (Kiesler and Simpkins). These facilities generally do not treat the same types of persons who had been found in public mental institutions: Their residents are more likely to have affective and substance abuse disorders and less likely to have schizophrenia.

The overall growth in mental health service provision has also been dramatic. Between 1955 and 1997, the total number of patient episodes in mental health organizations rose more than 600 percent—from 1.7 million to 10.7 million (CMHS, 2001). By 1994, all expenditures for mental health and substance abuse services exceeded $68 billion (Mechanic). In constant dollars (with 1969 as baseline), spending by mental health organizations increased from $3.3 billion in 1969 to $5 billion in 1994.

Most of the growth in mental health services stemmed from the expansion of outpatient treatment. From only 23 percent of total mental health episodes in 1955, outpatient episodes grew to 76 percent of episodes in 1998. Nevertheless, inpatient episodes consume over 80 percent of expenditures for mental health (Kiesler and Simpkins). The number of mental health professionals also expanded commensurately during this period. For example, in 1975 about 20,000 licensed psychologists practiced in the United States; this figure grew to 46,000 in 1986 and to at least 73,000 by 1997 (CMHS, 1998). The growth of mental health professionals who are psychiatric social workers, school psychologists, marriage and family therapists, and counselors was even greater. For example, between 1972 and 1994 the number of full-time psychiatric social workers nearly quintupled and there were nearly twenty times the number of professionals in the category of *other mental health workers* (CMHS, 2001).

The analogue to the growing number of mental health professionals is the greater number of persons who seek help from them. By 1983, about 23 million people—15 percent of the adult population of the United States—sought some type of treatment for mental health or addiction problems over the course of a year (Regier, Narrow, Rae, et al.). Population surveys also indicate a growing readiness of the public to use mental health services. One large national survey showed that while less than 1 percent of respondents sought help from psychologists, counselors, and social workers for mental health problems in 1957, 18 percent of respondents reported seeking professional services in 1996 (Swindle, Heller, Pescosolido, et al.).

Another striking trend has been the expansion of psychotropic medications. In the decade between 1985 and 1994 alone, the proportion of psychiatric outpatient visits in which psychiatrists prescribed an antidepressant increased from 23 percent to 49 percent, and the number of prescriptions for psychotropic medications soared from about 33 million to about 46 million (Pincus, Tanielien, Marcus, et al.). Three of the seven most-prescribed drugs of any kind are now antidepressants (Horwitz). These drugs are not

imposed on unwilling patients, but are highly sought-after and valued therapeutic aids promoted to the general public through ubiquitous advertising campaigns (Kramer).

Reasons for Changes in Mental Health Services in the United States

A number of technological, ideological, legal, and economic reasons led to the steep decline in the use of traditional mental institutions and the growth of mental health services. The introduction of psychotropic drugs in the mid-1950s provided an efficient and effective technology that could be used easily in community settings. The ideology of mental health professionals after World War II emphasized a broad concept of mental illness, noninstitutional care, and treatment for a wide array of emotional and social problems (Grob, 1991). Judicial and legislative mandates regarding mental health services also began to change in the late 1960s toward specific and restrictive standards for commitment and the expansion of civil rights during and after commitment proceedings (Appelbaum).

The locus of authority for mental health services also shifted after World War II. Until that time, states and localities were responsible for providing services. The creation of the National Institute for Mental Health in 1949 and the passage of the Community Mental Health Centers Act of 1963 created partnerships between the federal government and localities that bypassed hospital-dominated state mental health systems (Grob, 1991). The hundreds of community mental health centers that emerged in the 1960s and 1970s, however, did not serve the same population as the state hospitals, but instead provided psychotherapy to people suffering from emotional, behavioral, marital, and family problems. These centers made mental health services more accessible, brought more services to lower socioeconomic and minority populations, and enhanced the acceptability of mental health treatment. They did not, however, replace the services state hospitals once provided to chronically ill persons, and generally neglected the most seriously mentally ill (Rochefort).

Out of the array of technological, ideological, judicial, and political reasons for changes in mental health service provision, shifts in patterns of reimbursement were especially important. Although not developed to serve the mentally ill, Medicaid (a program jointly administered and funded by federal and state governments to bring medical services to the poor and disabled) and Medicare (a federal program funding medical care for the elderly and persons who have received disability payments for two or more years) grew into large sources of funding for mental health services. The eligibility of facilities to receive Medicaid and Medicare funds contributed to the changing patterns of inpatient services outlined above. Elderly persons with mental illnesses were transferred from state mental institutions ineligible for Medicare dollars to nursing homes that could receive these funds. Likewise, treatment episodes in general hospitals increased because federal programs reimburse inpatient psychiatric episodes in these settings but not in public mental institutions.

Changing patterns of private reimbursement have also altered the nature of mental health services. Private insurance coverage for both inpatient and outpatient services greatly expanded between the 1950s and 2000, although not at a level comparable to that for physical illnesses. Expanded eligibility of nonphysicians, including psychologists, nurses, and social workers, for third-party reimbursement has increased the pool of mental health professionals who provide outpatient treatment. A multitude of practitioners with different disciplinary allegiances, therapeutic ideologies, and treatment techniques have come to serve clients with acute disorders (Frank and Frank). Despite the great expansion of mental health services, however, no comprehensive system in communities has emerged to replace the services that persons with the most serious and long-term illnesses received in state hospitals.

Another recent change in service delivery is the rise of managed mental healthcare (Mechanic). Managed care refers to a variety of organizational forms that impose routinized strategies to monitor, regulate, and review the treatment that professionals provide patients in order to provide cost-effective care. Managed care is becoming the dominant form of treatment for mental health problems, and about three-quarters of persons with private health insurance now are in some kind of managed care plan (Kiesler). The principles of managed care dictate more rule-following, standardization, and regulated treatments that often conflict with individualized treatment plans (Luhrmann). Because persons with mental illness often require extensive and varied services, the requirements for their successful treatment often conflict with the restrictions and rigidities of managed care organizations.

International Mental Health Services

The major trends in the United States mirror changes in the provision of mental health services in most developed nations. Although the pace of deinstitutionalization differs across countries, the use of public inpatient facilities has sharply declined throughout most of the West (World Health Organization, 2001; Goldberg and Thornicroft). Persons who do enter inpatient facilities usually have short lengths of stay that typically average about one month or

less. For example, the number of people occupying hospital beds in the United Kingdom fell even faster than in the United States, from a peak of 152,000 in 1954 to 39,500 in 1993. Italy has implemented the most ambitious plan of deinstitutionalization, which aims to completely eliminate all admissions to public mental hospitals (Donnelly).

The decline of public inpatient institutions has been accompanied by a decentralization of psychiatric services in most European and other developed societies (World Health Organization, 2001). Most of the smaller number of hospitalizations now occur in general hospitals and in facilities operated by non-profit or private agencies rather than by the national government. As in the United States, there has been a strong movement toward treatment in small facilities located in residential neighborhoods. Indeed, the ideology of community treatment—emphasizing keeping persons out of institutions, treating them in neighborhoods near their homes, and strengthening informal social support systems—is perhaps even stronger in Europe than in the United States. Client-centered movements of consumers of psychiatric services are also active in many countries. These movements have had a good deal of success in opposing mental hospitalization, coercive forms of psychiatric treatment, social stigma, and the power of psychiatric professionals, and in developing self-help groups of users.

There are exceptions to the general trend of declining use of inpatient hospitalization and increasing amounts of community treatment. For example, rates of occupied psychiatric beds in Japan increased between the 1960s and 1990s, and Japan has the highest number of inpatients of any country in the world (Shinfuku, Sugawara, Yanaka, et al.). Because public funds support inpatient treatment in private hospitals, these institutions have a financial incentive to admit many patients and keep them for long periods. In addition, most poor countries have rudimentary systems of outpatient treatment and the small amount of psychiatric care they provide typically occurs in large, antiquated inpatient facilities (World Health Organization, 1996).

Despite the success of most developed countries in reducing inpatient psychiatric populations, a number of common problems remain. Some of these problems are systemic. As in the United States, there is limited coordination between agencies that provide treatment, housing, social services, and social control. Insufficient amounts of adequate community housing also typify mental health systems. In addition, the most seriously disturbed and chronic patients continue to need inpatient care, severely straining the resources of most systems. Other problems stem from a poor fit between traditional modes of service delivery and particular types of clients (Goldberg and Thornicroft). The provision of mental health services to persons who are poor, homeless, immigrants, and substance abusers will be especially problematic in coming years. Most European nations have large immigrant populations who resist voluntary mental health treatment and are often subject to coercive forms of social control. Mental health systems rarely have enough personnel from minority backgrounds who could better relate to these patients. As in the United States, psychiatric patients who have co-morbid substance abuse problems are particularly difficult to treat within most mental health systems. As well, few mental health programs have established successful outreach programs to the homeless mentally ill. While the ideology of community treatment now dominates mental health service provision in nearly all developed countries, the implementation of this ideology lags behind.

Ethical Issues

The ethical issues that arose in a mental health system dominated by state hospitals were related to involuntary commitments, inappropriate hospitalizations, neglectful or abusive treatments and the validity of the label of *mental illness* itself (Szasz). In the huge but uncoordinated mental health system of the 2000s, the most pressing issue is to create coordinated service delivery systems for seriously disturbed persons. The dominance of medical models devised for specific acute conditions hampers efforts to create comprehensive services. Medicare and Medicaid, which were developed to finance treatment for acute physical conditions, usually do not cover long-term, comprehensive services that promote community living (although many states do use Medicaid options to finance a number of community-based services). Managed care organizations rarely have the expertise to provide appropriate treatment to persons with serious mental illnesses and lack the capacity to provide comprehensive mental health services (Mechanic). Drug therapies that form the core of medically-oriented treatment are effective in alleviating the symptoms of, although not curing, mental illness. These treatments are beneficial, but cannot address the needs for housing, monetary assistance, vocational training, and social interaction of seriously mentally ill persons who live in the community. The extent to which drug therapies cause harmful side effects is controversial (Healy; Valenstein). The dominant organizational forms and treatments in mental healthcare create great difficulties in developing comprehensive care programs for persons with serious mental illnesses.

COMMUNITY TREATMENT. A broad consensus has developed among consumers, families, and mental health professionals that community—rather than institutional—treatment is most consistent with the values of individual autonomy

and choice that underlie contemporary policies toward disabled populations. In addition, evidence is accumulating that most persons with serious mental illnesses benefit more—and at no greater cost—from comprehensive community treatment programs than from hospital care (Mechanic and Rochefort). Although there is little evidence that comprehensive community treatment is cheaper than hospital care, such programs need not cost more than inpatient treatment (Weisbrod, Test, and Stein).

With the exception of a minority of violent, dangerous, and self-destructive persons, outpatient programs can allow seriously mentally ill persons to remain in the community with the help of an intensive range of mental health, psychosocial, and vocational services. One effective model uses assertive community treatment teams of mental health professionals who provide services in clients' natural living environments on a seven-day-a-week, twenty-four-hour-a-day basis (Stein and Test). The staffs of these programs do not wait for patients to seek help, but aggressively offer treatment when they think it is needed. The aggressive enforcement of medication compliance and occasional hospitalizations has created concern that these programs can be overly paternalistic and coercive (Diamond and Wikler). Such interventions, however, might be necessary to keep the most difficult, disruptive, and noncompliant persons in community settings over the long term. The Fountain House program, which emphasizes job rehabilitation and the creation of a family-like atmosphere, is another effective, but less intensive, model for community treatment (Beard).

Despite the advantages of community-based treatment for the most seriously ill, skewed funding and administrative structures have precluded its widespread establishment. States continue to fund state mental hospitals disproportionately: 60 percent of state funding goes to hospitals that serve only 7 percent of the seriously mentally ill (Sharfstein, Stoldine, and Goldman, 1993). Opposition from public employee unions and local communities that are economically dependent on state hospitals often prevents shifting funds from inpatient treatment to intensive community treatment programs. Likewise, federal and private reimbursement programs fund relatively expensive treatment in inpatient facilities outside of public mental institutions, but will not usually cover treatment in clients' homes or in noncoercive residential facilities in the community.

Fragmented administrative authority for mental health services also prevents the development of integrated service systems. Service delivery for the seriously mentally ill typically involves an unplanned and uncoordinated mix of visits to emergency rooms, short-term stays in inpatient units, inadequate outpatient treatment, and a variety of entitlement programs that may not meet the special needs of the mentally ill (Bloche and Cournos). Different agencies with different missions provide housing, financial assistance, vocational training, medical treatment, and mental healthcare to the mentally ill (Mechanic and Rochefort). Mechanisms such as comprehensive case management and mental health authorities that assume organizational, financial, and clinical responsibility over a range of residential and psychosocial services can help coordinate the various agencies that provide these services (Morrissey, Callaway, Bartko, et al.). Solutions for serious mental illness must go beyond the development of effective drug treatments or psychotherapies to encompass a variety of systemic and organizational factors.

The philosophy of community treatment has also led to new and complicated issues regarding family responsibility for caregiving. Many family caregivers—typically mothers—are aging, ill, and lacking in resources to provide adequate care (Lefley). Yet the scarcity of community treatment programs means that families often must provide housing, monetary and emotional support, symptom management, and personal care to seriously ill adult children. Although mental health professionals are now less likely than in the past to view families as pathogenic, they still too readily blame or neglect family members instead of appreciating the value of family resources. Likewise, confidentiality requirements that allow widespread information flow between mental health professionals but preclude the sharing of information with family caregivers need reconsideration (Petrila and Sadoff).

The manifest failures of deinstitutionalization—especially the highly visible problems of the homeless mentally ill—have given rise to public demand to reinstitute civil commitment for the most obtrusive among the seriously mentally ill. In fact, federal entitlement programs have allowed most formerly institutionalized patients to avoid homelessness (Goldman, Adams, and Taube). The more visible homeless mentally ill are likely to be young persons in urban areas with concurrent substance abuse disorders who have never experienced lengthy hospitalizations and who are resistant to traditional mental health service delivery (Lamb). While young, chronic, and sometimes homeless mentally ill persons present a particularly challenging task for mental health service delivery, flexible and nontraditional programs of service delivery that emphasize the provision of adequate housing can best meet the special needs of this population (Bachrach).

INAPPROPRIATE SERVICE PROVISION. While the most seriously ill persons are often unable to obtain needed services, the mental health system overemphasizes inpatient services for persons who could more efficiently and economically be treated in outpatient settings. Particularly

troubling is the fact that reimbursement patterns and financial pressures to fill inpatient beds drive service delivery. Paradoxically, while many states have reduced hospital services for the most seriously mentally ill to save costs without providing needed treatment in the community, less seriously ill persons—especially those with affective and substance abuse disorders—are often unnecessarily treated through inpatient episodes in both general and private hospitals. Few data exist about the accessibility, quality, and effectiveness of mental health services in these settings, although good evidence from randomized studies shows that most patients who receive care in hospitals could receive more effective and less costly care as outpatients (Kiesler and Sibulkin). Youths under eighteen are particularly likely to be committed to residential facilities; contrary to trends in other age groups, inpatient treatment for youths rapidly increased from the 1980s to 2000 (CMHS, 2001). There is no evidence, however, that such treatment is necessary, effective, or appropriate, although it is very expensive (Kiesler and Simpkins).

A more effective and efficient mental health service system would place less emphasis on expensive inpatient interventions and more emphasis on comprehensive, long-term community services for the chronically ill. The disabilities associated with serious mental illnesses require long-term care that is responsive to the episodic and recurrent nature of these disorders. For the acutely disturbed, such a system would de-emphasize extended psychotherapy while supporting short-term, directed interventions of proven effectiveness (Kiesler).

Another obstacle to creating a more effective and efficient system lies in the largely hidden nature of much mental health service delivery. Despite the large and growing number of mental health professionals, general physicians are the leading providers of mental health services, accounting for about half of all mental health and addictive treatment services (Regier, et al.). Conversely, about 20 to 30 percent of medical visits are for mental, rather than physical, health problems. However, primary physicians often do not appropriately recognize and treat mental disabilities. Professional training of physicians should place more emphasis on the appropriate diagnosis and response to mental disorders in primary practice. Nonphysicians, such as nurse practitioners, could also play a greater role in the treatment of psychological problems in medical settings. Nursing homes—where growing numbers of the psychiatrically-disturbed elderly reside without receiving adequate mental healthcare—are another location where psychiatric need and mental health service provision are mismatched.

An additional problem of mental health services lies in the expansive definition of mental illness. Once equated with psychotic disorders, the definition of mental illness now includes a wide scope of emotional, behavioral, and psychophysiological disorders (American Psychiatric Association). These definitions encompass many ordinary problems of living as well as serious mental illnesses (Kirk and Kutchins; Horwitz). Those who hold an expansive view of mental health often call for mental health service provision to a wide spectrum of persons who suffer from mental disorders but who do not seek treatment. Advocates of this view cite statistics from community surveys showing that about 16 percent of the U.S. population has a current mental health or addictive disorder, about 30 percent have such disorders over a one year period, and up to 50 percent suffer a disorder over the course of their lifetimes (Regier, et al.,; Kessler, Beglund, Zhao, et al.). These surveys also indicate that only about 13 percent of disordered persons seek help from a mental health or addiction specialist, and only about 30 percent seek any help at all for their problem. In this view, there is a tremendous unmet need for mental health services in the community.

The emphasis on unmet need for mental health services has generated calls for parity in coverage of the treatment of mental and physical health problems. Most third party payers impose higher co-payments for mental health treatment, limit the number of mental health visits and total amount of payment for mental health treatments, and refuse to pay for the treatment of many mental health conditions. Advocates for parity argue that such restrictions unfairly discriminate against persons with mental health problems. Efforts to bring parity had some success when the U.S. Congress passed the Domenici-Wellstone Amendment in 1996. That legislation, with many restrictions and limitations, requires parity of limits on the treatment of mental health and other medical conditions (Mechanic). The Amendment, however, has not brought about major improvements in the funding of mental healthcare.

Advocates of parity between mental health and other conditions do not generally define the specific conditions to which parity should apply. A different view is that, instead of seeking parity in treatment for all mental health conditions, the highest priority for care should be the much smaller group of persons who have severe disorders that lead to serious functional impairments. Surveys that ask respondents if they or someone in their household has a serious mental illness that interferes with their daily life find prevalence rates of between 2 to 3 percent of the population (Kessler, et al.). Because these lower estimates still involve between four and six million people, and because services are finite, there is a clear need for some allocation criteria for mental health services (Boyle and Callahan). Targeting services toward individuals who neither perceive a need for

mental healthcare nor suffer from serious functional limitations could be wasteful and ineffective and could direct attention away from the many unmet service needs of the people who are in the most desperate circumstances. Mental health reforms can reasonably include high co-payments for persons with less severe disabilities who desire psychotherapy, as well as higher standards of accountability for psychotherapeutic techniques eligible for reimbursement. These principles could help reorient service delivery toward community treatment of the most seriously ill without generating the huge costs of meeting the total demand for mental health services (Frank, Goldman, and McGuire).

SUCCESSES OF MENTAL HEALTH SERVICES. The many failures of the current U.S. mental health system should not detract from its successes. The expanded federal role in funding mental health services through Medicaid and Medicare has the potential to create a more adequate community-based system that is sensitive to the needs of the seriously mentally ill (Koyanagi and Goldman). States with the will to do so have the ability to devise more effective mental health systems, especially through the creative use of Medicaid waivers. The growth of public mental health treatment has led to declining social class differences in the receipt of services. Changing cultural definitions and understandings of mental disorders have lessened, although not eliminated, the stigma of mental illness and have increased public willingness to seek mental healthcare. Although flawed in many ways, there is more accessibility to mental health services than ever before.

Conclusion

U.S. mental health services at the beginning of the twenty-first century consist of unplanned and uncoordinated services driven by patterns of reimbursement originally developed to treat problems of physical health. Deinstitutionalization diminished the role of state hospitals without replacing the services once found in these settings. The most seriously ill obtain the least adequate treatment, while reimbursement patterns that emphasize acute care in hospital settings create inappropriate and unnecessary inpatient episodes for persons who could be treated equally well through less expensive outpatient therapy. As costs for all types of healthcare have escalated to reach 14 percent of the gross national product, and as managed care organizations have proliferated, some sort of controls over mental health service provision are inevitable. Reforms that would lead to a more equitable and effective system would place less reliance on expensive inpatient care and long-term psychotherapy and more on comprehensive and continuous community care for the most seriously ill, and short-term and directed care for the acutely ill. The knowledge exists about what changes are needed in mental health service provision, although fiscal inefficiencies, administrative fragmentation, and professional resistance might prevent reform. It will be difficult to create a mental health system that responds as adequately to the most seriously disordered as to the less seriously disturbed—but such a system will be more humane.

II. ETHICAL ISSUES

At the beginning of the twenty-first century, American society is engaged in a continuing critical reexamination of fundamental issues in health matters. As healthcare reforms progress through the social and political process, the opportunity exists to remedy past failures in the management of health resources, to renew fundamental values and commitments to individual and public health, and to shape new priorities for a system of healthcare that is both fiscally sound and ethically justified. The most pressing challenge is to allocate health resources to those in need of them without unfairly compromising other cherished social goods such as education and defense, or other ideals such as economic prosperity and self-determination. This challenge is made even more complex by the relentless growth in technological and scientific achievements, and an ever-widening public concern about their responsible use and distribution in society.

Of increasing concern to many in American society is the system of goods and services to provide care to the mentally ill. The mental health system of the 2000s is a complex web of intersecting and often competing factors that reflect changing ideas regarding mental illness and the resources that are needed to deal with it. The mental health field is characterized by a stunning diversity of problems that reflect the complex shifts in society over the past several decades. Whether these problems are considered in terms of diagnosis, level of dysfunction or disorder, duration of symptoms or disease, or social attitudes regarding concepts of deviancy and dangerousness, mental illness is a problem of enormous complexity and heterogeneous characteristics. The ethical issues are no less complex, and raise some of the deepest philosophical questions regarding mind and body, the nature of suffering, the range of human potentialities, and the conflicts between individual and societal needs.

Although ethical considerations are implicit in nearly every aspect of mental healthcare, the emphasis in this article is on ethical aspects of the mental health service system. The most dominant issue is the problem of justice and the derivative question of how to strike a fair and equitable balance between the requirement that society protect its citizens from harm and its simultaneous duty to protect and promote the moral, legal, and civil rights of each individual. Answers to this particular question continue to be reflected in various mental health directives and policies that define the field of mental health services. In various ways, these directives and policies document the extent to which the problems of mental illness are valued or disvalued by society, the eligibility criteria of those persons who may receive society's goods and those who will not, and the perceived importance of mental health to the vitality and character of the nation.

This article addresses the issues of equity, parity, and fragmentation in relation to considerations of justice, and supports the argument that mental health concerns should be given higher priority in the healthcare system of the future.

The Mental Health Service System

Mental illness affects people throughout the entire life cycle, including all age groups and socioeconomic strata (Regier, Narrow, Rae, et al.; U.S. Surgeon General). According to one estimate, approximately one-third of Americans will experience some form of a mental disorder at some point in their lives; of the 28 to 30 percent of all adults who experience mental disorders in a year, 2.6 percent have chronic, severely disabling conditions such as schizophrenia (Kessler, Berglund, Zhao, et al.). Psychiatric patients are more likely than the general population to have substance abuse disorders as well. Furthermore, although 28.1 percent of the population received diagnosis of mental or addictive disorders in one year, only about 15 percent received any mental health services in that time frame (Regier, et al.; U.S. Surgeon General). In 1990, the annual direct cost of mental and substance-abuse services in the United States was estimated to be $99 billion. Indirect costs, such as lost days of work, has added another $79 billion (Rice and Miller; U.S. Surgeon General).

Many mental and substance abuse disorders are severe and chronic, and thus often produce emotional and financial burdens for patients and families that last a lifetime. Although 28 to 30 percent of all adults experience mental disorders in a year, only one third of this population receives mental healthcare (U.S. Surgeon General). Similarly, despite the fact that 7.5 million children in the United States under the age of eighteen suffer from an emotional problem severe enough to require treatment, as many as 70 to 80 percent do not receive the services they need (U.S. Office of Technology Assessment). Finally, Americans over sixty-five years of age are at high risk of developing mental disorders because of reputed stressors associated with aging, including

concomitant physical illness, increasing isolation, and diminished social supports. Studies demonstrate, however, that just over half of older adults with mental disorders are provided services through the mental health sector (U.S. Surgeon General). The rest, often referred by physicians—whose poor abilities to recognize the psychological symptoms of older adult patients have been documented—obtain services from the general health sector. Consequently, many older adults with mental health problems may not receive the services they need from qualified mental health professionals (Gatz and Smyer).

The current system of mental healthcare in the United States is enormously complex and has the following characteristics that differentiate it from the more general system (Phelen, Link, Stueve, et al.; U.S. Surgeon General):

1. Mental health services are dependent upon public funding and are frequently subject to a high degree of government regulation.
2. Mental health services are provided by an increasingly diverse set of professionals, including psychiatrists, social workers, psychiatric nurses, and mental health counselors. Increasingly, these services are offered in a variety of settings, including state and mental hospitals; general, private, and government hospitals with psychiatric units; community mental health centers; nursing homes; and specialized alcohol, drug, and addiction disorder treatment units.
3. These diverse settings may alter the transaction between a patient and therapist, and create threats to the often private and intimate character of the therapeutic relationship.
4. The chronically mentally ill and other severely disordered persons constitute a highly dependent population that presents extraordinary challenges for administrators and providers attempting to maintain a responsive, accountable, and humane program.
5. Disputes regarding the diagnosis and etiology of mental health disorders and the efficacy of their treatments persist and make it difficult to evaluate the utility of treatment programs.
6. The boundaries of mental health services are difficult to define, and create diverse sets of expectations and conflicts regarding *medical* and *social* models of disease.
7. Mental health services are generally perceived as having a poor public image and as valuable for only a small group in society who have aberrant emotional or behavioral conditions.

These characteristics provide a clear portrait of the complex issues faced by mental health practitioners and policymakers. They may explain some of the reasons why mental healthcare has a low position on the American agenda.

Vulnerability

Illness of any kind, but especially mental illness, exacerbates the need to depend on others for help and to trust that this dependence will not be exploited or manipulated. Many severely mentally ill persons remain dependent on the healthcare and mental health services systems to provide necessities of life. The human tragedies generated by severe mental disorders are considerable; often not only the health and well-being of individuals but also that of their families and communities are destroyed. Persons with chronic mental illness such as schizophrenia, bipolar illness, and psychoses that impair or distort decision-making abilities may be particularly vulnerable to possibly unjustified paternalistic interventions in their lives. Although the stigma attached to the use of mental health services may be diminishing, it still endures in some forms, thus increasing the vulnerability of the mentally ill to negative social judgments. These vulnerabilities create moral obligations on the part of society and its institutions to provide the resources to meet basic human needs and promote policies that include strategies to avoid discrimination, stigmatization, and the exploitation of dependence. These obligations are grounded in moral beliefs regarding society's duty to help those who are weak or vulnerable, and on the moral principles of care and trust that form the basis of the therapeutic relationship between patient and provider (Carter).

Historical Features of Mental Health Services

Although mental healthcare represents a significant part of the overall healthcare system, it has been separated from the mainstream of healthcare by historical, institutional, and conceptual barriers. Historically, mental healthcare was linked to social welfare policies; mentally ill persons incapable of living in society were separated from it not so much because they were sick as because they were viewed as disruptive to society. They were cared for in local or state asylums. These institutions, and the cycles of reform they mirror, have been the subject of well-documented historical works (Deutsch; Foucault; Grob, 1991). Of relevance in this article are the underlying moral and social reasons that justified the various services provided within these institutions. For instance, in the early 1800s social reformers and physicians began to lobby against a shared responsibility by the state and local governments for providing services to the mentally ill. As a result, many mentally ill persons become wards of the state (Boyle and Callahan). In the institutions of the mid-nineteenth century, *treatment* consisted of providing a calm, humane, and disciplined environment. The ethical justification for these services was that the state could

meet its responsibilities to the individual, family, and community by providing medical treatment for acute problems and humane, custodial care for those with chronic problems. Furthermore, the health of the general public could be served by protecting society from the threat of disease or dependency (Grob, 1992).

In the early twentieth century, the United States began to embrace the view that the individual is responsible for meeting the basic needs of life. Society, in the form of federal or state government institutions, would intervene only when an illness placed excessive burdens on the afflicted individual or family, when the disease posed a danger or threat to the community, or when the individual lacked the necessary resources to deal with it. Vulnerable people, such as those with tuberculosis, mental illness, or mental retardation, could obtain needed services such as those provided in the mental institutions of the day. There was no broad right of access to healthcare services; rather, the dominant social policy focused on the value of serving only those with special needs. Mental health policy in the 1940s was based on the assumption that society had an obligation to provide a severely and chronically ill person with both care and treatment in public mental hospitals. Gradually, in response to economic and cultural shifts, these mental hospitals became increasingly custodial and bureaucratic (Grob, 1992).

In the years following World War II, radical transformations shook American culture, and new ideas regarding individual and societal rights emerged. The social activism and political unrest of the 1960s provided the backdrop for a number of shifts in thinking about the nation as a whole. States began to reconsider their policies regarding the mentally ill, and people who had been cared for in mental hospitals were moved to newly created community alternatives. In the 1960s, the movement to deinstitutionalize the mentally ill was partly based on the idea that the chronically mentally ill could receive support in the community without infringement of their civil rights. The other assumption that fueled policies of deinstitutionalization was derived from intellectual and scientific disputes within the practice of psychiatry. Disagreements about the definition of mental illness, diverse explanations of its causes, and skepticism about treatment efficacy generated controversy and ambiguity. These disagreements in turn affected the nature of the services available to those with mental disorders.

Monumental revolutions in ideas regarding individual, civil, women's, and fetal rights provoked fundamental questions about the role of the state in a free democracy, and the power of technology to alter constructs such as life and death. As these social and intellectual events converged, new attitudes regarding the nature of medical care, research on human subjects, and the value components of therapeutic relationships began to be reflected in legal decisions, social policy, and ethical discourse. In the field of mental health, ethical concepts of autonomy, informed consent, and paternalism began to appear in the literature. Psychiatrists, social workers, psychologists, and other mental health providers began to critically examine their relationships with patients, colleagues, society, and the state. They were confronted with new puzzles, such as how to respect the recently enhanced rights to autonomy and individual freedoms, and yet protect society from the potentially harmful actions of a mentally ill person. Ethical values were often in conflict with other values, thereby dividing professional loyalties and obligations (Reiser, Bursztajn, Appelbaum, et al.).

In response to shifts in public values and attitudes, the federal government began to endorse social welfare programs aimed at prevention; new programs attempted to ameliorate the social problems that were said to foster mental illness. Mental health policy increasingly began to rely on federal government programs to administer, manage, fund, and reimburse for these services. The passage of the Omnibus Reconciliation Act of 1981 effectively eliminated previous policies that had emphasized community care outside the mental hospital (Kiesler). Federally-sponsored programs such as Medicare and Medicaid initiated cost-based reimbursement strategies that fueled the evolving rhetoric of the *right to healthcare,* and fed the expectation that such a right would be funded. Congressional passage of the Tax Equity and Fiscal Responsibility Act of 1982 and the Medicare Prospective Payment System (PPS) in 1982 altered this expectation by restricting future payments for inpatient hospital services.

These events, and many others detailed elsewhere, foreshadowed the current public debate regarding the existence and scope of this *right to healthcare* and its numerous philosophical, conceptual, economic, political, and social ramifications.

All of these transformations in ideology influenced policy directions and contributed to the evolution of a diffuse, heterogeneous system of services that provided a diverse set of services to assist the adjustment of the mentally ill to life outside the mental hospital. For instance, in the 1960s the view that mental illness did not require psychodynamic intervention, and that those experiencing *problems in living* could find the support they needed in the community, led to the policy of deinstitutionalization. This policy of transferring patients from public mental hospitals to community-based mental health centers, coupled with the emergence of psychotropic agents to control their symptoms, profoundly altered the mental health system.

Although many writers have analyzed the mixed impact on mental health services brought about by this policy (Mechanic and Rochefort), others underscore its abject failures in helping the seriously ill or reducing the number of inpatient services (Geller; Lamb and Bachrach). Other writers have argued that the community mental health policies not only overlooked the social and human needs of the severely ill, but also bifurcated therapeutic or treatment services from care and support services. The former were identified more with, and included in, the medical healthcare system, whereas the latter were affiliated with the welfare or social system. This bifurcation inadvertently distorted priorities, with more focus applied to providing therapeutic services in outpatient settings for a broadly defined population (Grob, 1992). Still others have argued that with the closure of state mental hospitals and related services, many chronically and severely ill individuals found themselves with nowhere to go for needed services and help (Lamb and Bachrach). Transformations in mental health laws to protect the mentally ill and promote their rights began to dominate intellectual discourse. New laws demonstrated the evolutions in understanding of the concepts of confinement, commitment, access to services, and the scope of individual autonomy in treatment decisions (La Fond). In the last decades of the twentieth century, mental health law became an able instrument of advocacy and protection of the civil, legal, and ethical rights of the mentally ill (Perlin; La Fond).

Access

Changes in the way mental health services are defined, distributed, delivered, and financed have produced a number of ethical concerns related to justice and other ethical principles. One of these is the problem of access to services. In the United States, healthcare is ordinarily covered by private or public insurance. Insurance reimbursement policies were originally constructed to shield both patient and provider against the worry about costs once an illness actually occurred. Reimbursements were quite generous and uncontested, with third parties acting as silent partners in the negotiation between physician and patient for needed services. The result of this is now obvious: a highly inflationary system with rapidly accelerating healthcare expenditures (Fuchs), which has in turn led to the growing managed care system.

Obviously, the 16 percent of the U.S. population currently estimated to be without public or private health insurance will also be without financial insurance against psychiatric or addictive disorders (Bureau of the Census). Yet even where insurance is provided, mental health insurance benefits are not on par with those in the general medical sector (U.S. Surgeon General). Moreover, Medicare and Medicaid place restrictions on the amount and setting of services for psychiatric and addictive disorders, thus further restricting the access and availability of needed resources for the mentally ill. While opportunities for mental health services increasingly exist under Medicare, only 5 percent of Medicare funding at present goes for mental health (U.S. Surgeon General). Finally, office-based care by psychiatrists, and often by other mental health providers, is generally covered by insurance firms but is rarely equivalent to other office-based physician care (Frank, Goldman, and McGuire, 1992).

Thus, although policies have been aimed at treating mental illness on an outpatient basis, all the incentives in insurance programs send the signal that inpatient treatment is what will be reimbursed. Of all mental health expenditures, an estimated 70 percent are designated for inpatient care. Many health insurance policies will reimburse fully for hospitalized care, but only partially cover outpatient care, and pay even less for prevention services. Nursing homes have not been integrated into any mental health system, although the Nursing Home Reform Act of 1987 mandates "active treatment." The predictable mental health needs of an aging population have not been factored into health policies, thus widening the gap between perceived need and access to service for a substantial segment of the population (Gatz and Smyer).

Moreover, simply being labeled as receiving treatment for a mental disorder can affect an individual's access to the general healthcare system. This occurs through the practice of medical underwriting, a process that denies individuals health insurance because of a *medical disorder* for which they received care in the past (Boyle and Callahan). These forms of discrimination not only impair the individual's access to services that are otherwise standard, but also further the antiquated idea of the dualism between mind and body.

These restrictions on the access and availability of services through insurance and financing mechanisms create inequities in many parts of the system. First, many Americans, especially the poor and underinsured, cannot afford the cost of needed mental healthcare. Second, many uninsured people at risk for major mental and/or addictive disorders will be denied appropriate prevention services and be inadequately protected against the possibility of catastrophic financial harm. Third, failure to provide meaningful access to services within the mental health system results in inappropriate and excessive use of the general resources of healthcare, creating further inequities for individual consumers and providers, and increasing the economic burden on the general medical economy as a whole. These inequalities of access to needed care are unacceptable to a decent and

humane society (U.S. President's Commission; U.S. Surgeon General). Some of them may be explained by historical accounts of the various ideological, political, and societal events that helped produce them, but they are not justified from an ethical point of view. Any society concerned with the well-being of its citizens cannot promote the importance of healthcare in achieving well-being while allowing people to suffer because of arbitrary barriers to healthcare.

Parity

A related ethical issue has to do with whether funding of treatment for mental health conditions should be equal to that of the general health sector. Many commentators have noted a lack of parity both between the two healthcare systems and within the mental health system itself. The latter can be expressed as both the disparity of treatment between kinds of mental illness, and the disparity of treatment between different degrees of mental illness severity.

Despite several major legislative efforts in the 1990s and early 2000s, there is little evidence that any significant change in mental health parity has occurred. Aside from failing to be passed by Congress, these bills failed to greatly affect parity for many reasons, including: covering only a subset of the population; covering only selected illnesses, often based on an archaic and fictional division of the mental and the biological; only covering certain severities of illness, often based on diagnosis of a specific illness or by level of debilitation; exemptions for small businesses, or for large cost increases; unequal limits on annual costs, lifetime costs, outpatient visits, days of inpatient care, per visit co-payments, or annual deductibles; and a variety of nearly nonquantifiable disparities in the quality of care provided (Rochefort, 1996; National Advisory Mental Health Council, 1998,2000; Geller; U.S. Surgeon General's Report).

One such piece of federal legislation passed into law in 1996 was the Mental Health Parity Act (MHPA) (Domenici/Wellstone), which required all group health plans already covering mental healthcare to have equal cost restrictions on yearly and lifetime benefits as traditional medical and surgical services. The MHPA had little effect on parity due to provisions within the act that allowed for exemptions for small businesses and for businesses that experienced an increase in cost because of the act. Moreover, 87 percent of employers' plans that complied with the MHPA had one or more methods of restricting mental health benefits more than traditional medical or surgical services. Congress allowed the MHPA to expire in 2001 and failed to pass the proposed 2001 Mental Health Equitable Treatment Act (S. 543), which attempted to address most of the problems with the 1996 MHPA (Gitterman, et al.; Barry and Frank; Geller; General Accounting Office).

The greater focus on mental health parity by the federal government spread to the state legislatures with similarly ineffective results. As of 2001, thirty-one states had adopted mental health parity requirements for employee health insurance, with all but five doing so after the passage of the 1996 MHPA. However, the 1974 Employee Retirement Income Security Act prevents states from regulating self-insured plans, thus limiting the affected population to those in group health plans (Gitterman, et al.; General Accounting Office; National Advisory Mental Health Council, 1998, 2000).

Two possible successes for parity have occurred, though their future is unclear. First, President Clinton announced at the First White House Conference on Mental Health in 1999 that health plans for all federal employees must cover mental health at full parity (though the durability of this order was unclear with the change in administration in 2000). Second, the Americans with Disabilities Act (1990) provides some hope for protection for people with severe mental disabilities to receive basic mental health services and protection from discrimination, but the constitutionality, and thus the future, of the ADA is questioned by some (Geller).

In general, parity legislation has thus far had only a small effect on parity itself. Parity legislation appears to encourage the presence of managed care, which results in lower or stable costs for mental healthcare. In general, these lower costs seem to come from a combination of increased efficiency and lower quality and accessibility (National Advisory Mental Health Council, 1998, 2000; General Accounting Office; U.S. Surgeon General).

For decades, U.S. health policy has been centered on the short-term, acute-care general hospital, despite the fact that this does not match the population's health needs; this continued focus points to the problems of parity of mental health services between different groups within the population. Preventive services have until recently been largely neglected, as have the needs of chronically ill elderly, children, and youth. While healthcare in the acute-care hospital in the United States is arguably the best in the world, in mental health, care *outside* a hospital is demonstrated to be better and less expensive than care in the hospital (Kiesler). This raises the caveat that simply mimicking the flawed policies of the general health system may not necessarily prove to be the best strategy for mental health policymakers of the future, even though it may lead to greater parity between the two systems (Kiesler; U.S. Surgeon General). Arbitrary limits on outpatient services, inpatient

hospitalizations, community-based health services, and higher co-payments for mental health services reflect the way mental health is disvalued in society, and its inferior status compared with physical health. Whenever a society establishes a priority system for the kinds of goods and services it makes available to its members, questions of fairness are evoked. If a society assigns insufficient or inadequate resources to a segment of the population at risk for or suffering from mental and addictive disorders without appropriate justifications, it violates ethical commitments to social beneficence, liberty, compassion, and justice.

Fragmentation

One of the most difficult ethical problems confronting the current mental health service system is the striking lack of coordination and collaboration among other human service agencies. The current mental health system is remarkable for a pronounced variation in the use of institutional and community-based services, admission rates, lengths of stay and services, and multiple funding sources and patterns.

Fragmentation in services is a consequence of developments in the larger healthcare system, as well as of the lack of integration in legal, social, economic, and scientific aspects of health policy. These problems stem from a cluster of ambiguities that prevail in the field of mental health: the diversity of beliefs regarding the concept of mental disease or disorder (Wakefield; U.S. Surgeon General); deeply-rooted cultural beliefs regarding behavior that seems inexplicable, bizarre, or threatening; and disagreement about which social policies to adopt in regard to persons whose autonomy is impaired by mental disorder, especially when this impairment may lead to the possibility of harm to self or others. Serious conceptual and normative questions regarding the definition of mental illness have led to practical disagreements about when and how to intervene. As of the mid-1990s, models of mental illness ranged from the purely medical model and its psychotherapeutic or psychoanalytical interventions, to a model that emphasizes the unity of biological, psychological, social, and personal factors in health and illness. Different mental health therapists subscribe to a variety of different theories on the nature of mental health. Specialists disagree, for example, about the boundary between mental illness and other forms of deviancy, and about the relative contributions of individual, family, environmental, and social variables in producing mental disorders (Rochefort, 1989). It has also been noted that a significant portion of the fragmentation and lack of coordination within the mental health system may be due to idiosyncratic factors related to politics, prejudice, and professional or civic self interest (Rochefort, 1989).

The lack of precise criteria to define and classify mental illness apparently has the following result: Both the person with catatonic schizophrenia, incapable of functioning in social life, and the person with an obsessive-compulsive neurosis, whose behavior is simply bothersome, are labeled as mentally ill. Both may be in need of some treatment to reduce distressing symptoms, but these services may be quite distinct from one another, and they raise significantly different concerns regarding what should count as a *mental health service* and what should not.

Thus, despite great expansion of mental health services, the system is remarkably fragmented. Without a centralized organization or locus of responsibility, quality of and accountability for services remain fragmented (U.S. Surgeon General). On the systemic level, the problem of fragmentation seems to have produced the following: under-treatment of the seriously and chronically ill; undervaluing of prevention services, rehabilitation, and long-term care; diminished access to available services for those with or at risk of mental and addictive disorders; restrictive barriers to insurance entitlement; and a generally lower position on the national healthcare agenda, despite data that demonstrate the efficacy of treatment for many forms of mental disorder.

These ambiguities exert a profound influence on normative and value questions, and can have a direct effect on the kind of mental health policy that is developed and the priorities it has in the overall healthcare agenda (Rochefort, 1989; Mowbray, Grazier, and Holter). Ultimately society's norms and values determine what kinds of services and resources will be made available, to whom they will be targeted, where they will be provided, and how they will be financed. Disparities of access and status provoke dilemmas of choice regarding principles of justice, on the one hand, and principles of cost-effectiveness on the other. They also expose the genuine difficulty of deciding which values should govern the policymaking process, when not all values can be equally promoted. For example, if society decides to purchase mental health services because of underlying commitments to humanitarian goals, then policy should probably be directed toward those individuals who have the most serious conditions and greatest needs. However, if society purchases mental health services because of commitments to principles of social or economic utility, then policy efforts would need to be driven by cost-benefit analyses and outcomes. In this instance, priority might be given to those individuals with depression, anxiety disorders, and alcohol addiction, because of the likelihood they would recover sufficiently to return to productive society (Klerman, Olfson, Leon, et al.). The principle of favoring the least well-off would have to be balanced against other considerations of justice that might be based on utilitarian assessments of what

might provide the greatest benefits to the greatest number of people.

These priority decisions ultimately reflect political and social value judgments about how much society is willing to invest in caring for its mentally ill citizens. Although disagreements persist on a number of conceptual, scientific, and professional issues, there does seem to be consensus on one essential point: Mental health must have a higher status in the healthcare system. Furthermore, setting priorities regarding the relative value of mental health services will require a decision process based on principles of fairness, non-abandonment of those in need, public accountability, and objectivity (Boyle and Callahan; U.S. Surgeon General).

Ethical Values in Contemporary Mental Health Policy

Since the publication of the influential Flexner Report in 1910, the U.S. healthcare system has been based on a medical model firmly anchored to the concepts of scientific, physical medicine and notions of medical treatment and cure. Ideas of prevention, health, and public health were relegated to the "back porch" (Smith). American society has structured its health policies, programs, professions, and institutions on this model for many decades, as though there were little relationship between mental and physical health. However, there is a growing body of empirical knowledge that documents the role of mental state in the maintenance and deterioration of good physical health, and in the treatment and recovery from physical illness (Praeger and Scallet).

Contemporary mental health policy, whether developed in terms of prevention, accessibility to needed services, rehabilitation, or maintenance of persons most greatly in need, is in a process of change. These changes reflect shifting concepts of mental illness, new etiological formulations of mental disease, treatment interventions, epidemiological trends, past program successes and failures, and the broader social, political, and economic currents (Rochefort, 1989; Rochefort, 1996). Ultimately, policies represent society's effort to deal with one of the most difficult and persistent human problems: how to balance the classic conflict between the power of the state to act for the good of society, and the responsibility of society to ensure the full expression of individual rights and freedoms. Questions concerning who has the legitimate power to control the lives of the mentally ill continue to provoke philosophical debate. In contemplating the public and scholarly discourse in the mental health field over the past several decades, several difficult questions regarding past policies must be confronted before new ones are generated. For instance, what ethical values, if any, were promoted by policies of deinstitutionalization? Has the goal of returning the mentally ill and disabled to the community for care enhanced the rights of individuals, or has it produced in them, or their communities, some greater harm? How will mental health policy of the future balance the competing claims of liberty, equality, and social beneficence?

Such questions represent difficult value choices, made more complex by a climate of increasing public distrust (Jellinek) and scarcity of fiscal resources (Morreim). Past assumptions of political liberalism and economic expansion are no longer valid. Instead, policies of allocation are becoming more explicitly value-directed, not simply regarding cost-containment or efficiency but on principles of equity, justice, and compassion (Jennings). Allocation policies, insofar as they are regarded as socially legitimate and politically acceptable, may then be understood to be a mechanism by which society seeks to define and to express its sense of self, its values, and its integrity (Childress). In a time of great transition and transformation of the healthcare system at large, American society is at a crossroad in its attempt to understand the health of the human mind and of all the forces that seek to promote and sustain it (Praeger and Scallet). It is a time of constructive chaos, in which the very mission and telos of healthcare are being redefined. Along with this redefinition, the opportunity exists to raise the status of the mental health services field from the "poor stepchild of the health care delivery system" (Boyle and Callahan, p. 53) to a level that conjoins mental and physical well-being and integrates biomedical and behavioral knowledge regarding health parameters. To accomplish this, it will be necessary to pay close attention to issues of equity in the access, availability, and efficacy of all health-related services, and to avoid arbitrary demarcations between mental and physical well-being (U.S. Surgeon General; Mowbray, et al.).

At the beginning of the twenty-first century, there is clear and urgent need for serious ethical reflection on which values and priorities should govern the mental health policies of the future. What is needed is an integrated, comprehensive, and equitable strategy that builds on knowledge and research in mental and physical health, and links these to appropriate and beneficial services for those in need of them. Problems of individual and social justice penetrate all areas of society, but are especially powerful in relation to the needs of the mentally ill, and to the communities in which they live. Undoubtedly, care and treatment of the mentally ill pose a range of ethical concerns that will continue to challenge society well into this century.

MENTAL HEALTH THERAPIES

• • •

The endless variety of mental health therapies can be sorted out and compared only if it is recognized that they differ both in the ends for which they strive and in the means they employ to reach these ends. Some therapies are directed toward straightforward and concrete goals such as symptom relief. Relaxation training to address performance anxiety is one example. Other therapies are directed toward more complex and abstract goals, such as an increased capacity for intimacy. Psychoanalytic therapy to improve the quality of one's romantic relationships is one example. Psychotherapeutic techniques can be compared and contrasted only if this difference in their goals is appreciated. The goals of therapy are at least partially implicit in the method of therapy employed by the therapist. Because no one therapist is skilled in all types of psychotherapy, choosing a therapist usually means choosing a therapy—a fact that patients choosing a therapist often do not understand.

The Goals of Therapy

This question of who should choose the goals of therapy is a form of the classic dilemma concerning paternalism in medicine, which involves balancing concern for patient welfare with respect for patient autonomy. Sidney Bloch (1982, 1989) has discussed this dilemma as it applies to psychotherapy. Beneficence dictates that therapists do whatever they think is best for their patients. Respect for autonomy means allowing patients the freedom to decide for themselves what is best. Because compromised mental health so often means compromised autonomy, balancing these values in psychotherapy can be particularly difficult. Therapists frequently believe that they should promote the capacity for autonomy in their patients even if the patients want only to feel better. In his 1989 article, Bloch described how he grappled with whether to address only his patient's distressing writer's block, as she preferred, or to explore the forces behind her general loss of autonomy. Her ability to choose rationally between short-term and long-term goals for therapy, such as relief from distress and greater capacity for choice, might itself have been compromised.

Clearly, psychotherapy must be conducted with some idea of mental health as a goal and a value. Thomas Szasz, a practicing psychiatrist who does not believe that mental disorders are diseases or that mental illness compromises personal autonomy, has long accused psychotherapists of inculcating social and ethical values under the guise of scientific medical treatment. If therapists are not restoring their patients' lost capacity for choice, then they can only be brainwashing them to make choices as the therapists would. Because psychotherapy aims for the value-laden goal of mental health, it blurs the boundary between science and ethics more than other medical therapy. It has features that are associated with science, such as theories of causation, experiments, and experts. But psychotherapy also must

always contain elements from ethics, because if it is not in part an "ideology of healthy conduct" (Karasu, p.91), it has no direction or goal. Doing psychotherapy is in part providing medical treatment and in part providing ethical education.

Because it is not possible to be perfectly value-neutral, vigilance and restraint concerning the imposition of values upon one's patient are among the foremost duties of the psychotherapist. Dynamically trained therapists are schooled concerning the dangers of *countertransference,* the distortion of the therapeutic process by the therapist's personal preferences and history. There are also dangers beyond the personal level. Each system of therapy operates with a value-laden notion of mental health, toward which it strives. Those therapies directed toward the relief of symptoms, such as depression and anxiety, strive toward distress-free function in a given environment. Normally this presents no particular ethical challenge. But in certain environments, relief of distress may be problematic. For example, Robert Jay Lifton, in his 1985 book, *Home from the War,* discussed the situation of American soldiers in Vietnam who were opposed to the war. The therapist treating patients in such situations faces the ethical question of whether the distress or the situation is pathological and needs changing.

Those therapies that operate with more elaborate models of mental health involving mature ego defenses, character development, or adaptive coping encounter different conflicts. Psychoanalytic thought long conceptualized homosexuality as a distorted or degenerate form of intimacy necessarily associated with character pathology. This evaluation of homosexuality has changed in recent years. But the challenge of distinguishing normal and pathological modes of human relationship will remain for psychodynamic psychotherapy because it defines mental health in terms of character. There are now those arguing that sadomasochistic or pedophilic relationships are not necessarily pathological.

In general, mental health treatment promotes adaptation to one's current social environment. It therefore tends to reinforce the prevailing norms of society. This is true both for *supportive* psychotherapy, which shores up a patient's usual ways of maintaining self-esteem, and for *uncovering* psychotherapy, which challenges these defenses in order to promote more mature modes of managing conflict and disappointment. The Austrian neurologist Sigmund Freud (1856–1939) proposed the capacity "to love and to work" as the mark of mental health. No better succinct summary of functions that indicate mental health has been made since. Nevertheless, the values of capitalist and bourgeois Victorian culture lie implicit in this prescription. Is adaptation to a repressive society indicative of mental health? Feminists have criticized models of love available to women. Marxists have criticized alienated labor as a legitimate lifetime pursuit.

Freud, and nearly all psychotherapists since, treated primarily upper- and middle-class Caucasians. The goals of therapy and the therapeutic means used have been derived within this class context. Public funding for psychotherapy has been and continues to be scant. Psychotherapy is considered by society to be less of a necessity than medical care. Community mental-health centers did do some psychotherapy in the 1960s and 1970s but are now directed toward medication and case management of the chronically mentally ill. It is virtually impossible in most states to obtain psychotherapy without insurance or discretionary income.

Whether psychotherapy can reach beyond its historical boundaries of class and race is not yet clear. It has traditionally addressed an educated, articulate, and motivated group of patients from the same social class and culture as the therapist. Because most psychotherapy is done with individual patients, it addresses individuals as the primary cause of their own problems. This is a valid approach to the denial practiced by middle-class patients concerning their life difficulties but may not be fair to lower-class patients facing poverty and prejudice. Proponents of *radical therapy* have tried to respond to this challenge by pathologizing the victimizing situation instead of the victimized individual. They thus construe the therapist as an agent for social as well as individual change. This approach avoids the problem of the therapist normalizing patients to the status quo. But it maximizes the problem of value imposition by the therapist, who now encourages the patient to reject society's view of the honorable life in favor of one advocated by the therapist. A middle ground has recently been explored through attempts to adapt psychotherapy to indigent patients through the addition of adjunctive social services (Wells et al.).

Mental health therapies not only respond to culture but also shape the culture within which they operate. As the values of mental health therapy have diffused into Western society, they have become a target for criticism. Since Philip Rieff spoke of "the triumph of the therapeutic" in 1966, numerous philosophers and sociologists have joined in criticizing "therapeutic values" that promote the welfare of the individual over that of the community. In 1978 Christopher Lasch accused the psychotherapies of promoting a form of narcissism in Western culture through the promotion of selfish motives and ignoring the broader social interest. In his 1971 book, *Against the Self-Images of the Age,* Alasdair MacIntyre specifically criticized the imposition upon society of such goals as personal satisfaction and interpersonal effectiveness. He contended that ethical evaluation of these goals had been bypassed in deference to the general idea of therapy. Whether the goal of self-gratification has gained preeminence as a result of therapy, or whether therapy has grown as part of a larger trend within society to look toward

the individual as the vehicle for fulfillment, is beyond the scope of this entry.

Modes of Therapy

Though there are over 200 psychotherapies and supporting philosophies presently in use by mental health professionals, most of these have not been scientifically tested for effectiveness. Only a few of these therapies can be considered specifically in this entry. Emphasis will be given to recently developed and proven therapies. Although Hans J. Eysenck's claim, from his 1953 book, *Uses and Abuses of Psychology,* that psychotherapy in general offers no better chance for recovery from psychological distress than does spontaneous remission has been repeatedly disproved, it is not clear what aspects of psychotherapeutic technique account for its effectiveness. Responding to the question of whether one form of psychotherapy was better than another, Lester Luborsky and colleagues could only quote the nineteenth-century English writer Lewis Carroll and ask, "Is it true that 'everyone has won and all must have prizes'?" There has been much research since the late 1970s demonstrating therapeutic effects specific to the type of psychotherapy used, but the evidence favoring effects not specific to a particular psychotherapeutic method still predominates.

A number of reasons have been proposed to explain these findings (Beutler and Crago). First, there is strong evidence that a good therapist–patient match is a more powerful predictor of therapy outcome than is treatment method. Second, the measures used to assess efficacy for experimental treatment groups may be insensitive to important differences in outcome between individual patients. Furthermore, the goals sought by different therapies may be so different as to not be adequately captured by a common measure of outcome. Third, differences in the level of psychotherapist experience may have more impact than differences in psychotherapy approach. An attempt has been made to produce therapy manuals for clinical trials that minimize these factors. But these manuals have also come under criticism as retarding the therapist's ability to respond to the individual needs and style of the patient. In summary, it has been difficult to show the advantage of one psychotherapeutic method over another because personal elements of the patient–therapist interaction, not easily tested by current methods, appear to be critical to therapeutic success.

PSYCHODYNAMIC THERAPY. A number of therapies derive their understanding of the patient and the modes of therapeutic action from Freudian psychoanalysis. Almost from the moment that Freud formulated the foundations of psychoanalysis, they were subject to revision by his followers such as Carl Jung, Alfred Adler, and Karen Horney. Elaborations of psychoanalytic theory in the direction of ego psychology by Anna Freud and Erik Erikson, and in the direction of object-relations theory by Melanie Klein and Donald Winnicott, have been especially influential in contemporary psychodynamic psychotherapy. Nevertheless, there are important similarities among these different approaches. They all consider unconscious forces to be important in psychopathology and insight into these forces to be therapeutic. Contemporary psychodynamic therapies derived from these theories continue to use the therapeutic relationship to reveal unconscious determinants of behavior. However, various features of the treatment are modified, such as its frequency and duration (e.g., through brief dynamic therapy); its metapsychology (e.g., through self-psychology); or its understanding of basic conflicts (e.g., through existential psychotherapy).

In brief dynamic therapy, treatment is more focused, short-term, and directive than in classical psychoanalysis. Whereas the latter may involve four to five sessions per week over a period of years in psychoanalysis, brief dynamic therapy may be completed in as few as ten to twenty weekly sessions. The therapist tries to elucidate a *core-conflictual theme* that is then explored. Typical difficulties in one particular area of life, such as assertiveness on the job, are the focus of treatment. Like psychoanalysis, brief dynamic therapy considers the re-creation of important conflicted relationships in the relationship with the therapist—transference—to be an essential therapeutic tool. Lester Luborsky, David Malan, Habib Davanloo, Hans Strupp, Peter Sifneos, and John Mann have articulated different types of brief dynamic therapy. Its effectiveness has been demonstrated in the treatment of stress and bereavement, late-life depression, and adjustment, affective, and personality disorders (Goldfried, Greenberg, and Marmar).

Brief dynamic therapy is not simply a compressed form of psychoanalysis; it holds unique benefits and risks. Exploration of the patient's psyche is focused but intense. Patients must be well motivated, have a circumscribed problem, and be able to tolerate an unsettling and persistent confrontation of their customary psychological defenses. Therefore, appropriate selection of patients is crucial to the success of this mode of therapy.

Self-psychology, another descendant from psychoanalysis, was developed by Heinz Kohut (1913–1981) as an elaboration of the psychoanalytic concepts of narcissism and the self. Kohut conceived psychopathology in terms of deficits in the self rather than conflicts among unconscious drives. Kohut defined "self" as an independent center of initiative. Self-psychology sees the most fundamental psychological need to be the organization of the individual's psyche into a

cohesive configuration, the self. The self must then establish sustaining relationships between itself and its surroundings.

The therapist, through empathic understanding, establishes herself as one of these sustaining relationships for the patient. Once the therapist has been established as a *self-object,* the stage is set for *transmuting internalization,* whereby the self of the patient is gradually able to perform those functions previously provided by the therapist. This occurs through gradual frustration of the patient's need for a perfectly empathic other. The result is the restoration of the self as a center of initiative, compatible with one's ideals and talents and capable of providing a sense of purpose to one's life.

Rather than presenting ethical challenges entirely different from other dynamic therapies, self-psychology highlights the power and peril present in all the transference-based therapies. In order to be effective, the therapist must become a *self-object* for the patient, that is, a source of self-esteem. Thus, the process of developing a cohesive and autonomous self in this therapy will involve periods of intense dependence and vulnerability for the patient.

Existential psychotherapy is heir to the humanist and client-centered approaches that flourished in the 1960s. Existential therapy is a psychodynamic therapy because it is primarily concerned with the interaction of psychological forces within the individual but, compared with psychoanalysis and its near cousins discussed above, "it is based on a radically different view of the specific forces, motives, and fears that interact in the individual" (Yalom, p. 8). Existential dynamics are not developmental in the way that Freudian psychodynamics are. Rather than focusing on how the past is recapitulated in the present, existential therapy focuses upon fundamental intentions or choices that are part of the "future-becoming-present." Irvin D. Yalom has detailed four "ultimate concerns" with which existential therapy deals: death, freedom, isolation, and meaninglessness.

Because existential psychotherapy rests its theory of psychopathology on universal human concerns, it sees a fundamental continuity between the normal and the pathological. Psychological symptoms are seen as a natural part of confronting the dilemmas and paradoxes of human life. This can mean that the patient seeking to *just feel better* or to pass from the pathological to the normal can be at odds with the existential therapist, who considers dread an inescapable part of life. For similar reasons, it has also been difficult to do good empirical research on existential psychotherapy. This form of therapy focuses upon the personal creation of meaning, thus presenting a view of the psyche not especially amenable to causal analysis. Existential and humanistic psychotherapies have generally had more theoretical than practical appeal. They offer a rich image of the psyche, devoid of reductionistic formulas, but have not found wide pragmatic application in reducing the distress of individual patients.

COGNITIVE-BEHAVIORAL THERAPY. Since the 1970s, a "cognitive revolution" has largely overtaken behaviorism in psychology. In psychotherapy, this revolution emerged in the form of cognitive–behavioral therapy. While behaviorism treated the mind as a black box upon which the powers of environmental reinforcement act, cognitivism holds that interpretations by the individual determine what constitutes positive or negative reinforcement in a given situation. Controlled clinical trials have demonstrated the efficacy of cognitive therapy for depression, chronic pain, anxiety, and a variety of other disorders. In cases of mild to moderate severity, its efficacy is similar to that of antidepressant medication, and it may provide a lower rate of relapse in such conditions as panic disorder (Beck, Emery, and Greenberg).

Cognitive–behavioral therapy essentially consists of training in problem solving. Cognitive therapy is based on the assumption that distress originates from ineffective responses to difficult life circumstances. Mediating between life events and emotions, and driving these responses, are spontaneous interpretations or *automatic thoughts* that are subject to a variety of common distortions. Therapy targets these cognitive distortions, such as overgeneralization and arbitrary inference, by helping the patient make a scientific "turn to the evidence" for these thoughts. Cognitive–behavioral therapy usually includes "homework" for the patient both of a cognitive (e.g., recording automatic thoughts) and a behavioral (e.g., completing small mastery-enhancing tasks) nature. The natural focus of cognitive therapy is upon the present situation and interpretations, though it is possible to plumb ever deeper into the personal assumptions and habits that lie behind current automatic thoughts. Because of this focus on the here and now, cognitive–behavioral therapy tends to be much more simple and straightforward than the psychodynamic therapies described above. Cognitive-behavioral therapy is focused on the amelioration of the current episode of depression or anxiety, whereas psychodynamic therapies also strive to address those factors that make a patient predisposed to episodes of depression and anxiety.

Cognitive therapy portrays mental health in terms of an absence of distorting cognitions. This lends a value-free, scientific air to this psychotherapy that may, however, not be entirely accurate. A body of research exists that suggests depressed persons' perceptions and judgments (especially of interpersonal situations) are quite accurate and realistic,

whereas nondepressed persons show systematic optimistic biases and distortions (Taylor and Brown). If cognitive therapists are not bringing their patients back into the light of interpersonal truth, then the therapy can take on the flavor of "brainwashing for better social functioning." As discussed above, there is a tendency among all forms of psychotherapy to adapt patients to their current social milieu.

NONTRADITIONAL THERAPIES. A vast array of practices are marketed to improve well-being. Many are scientifically unproven, and some violate ethical precepts held dear by the more traditional psychotherapies. Massage therapy, Rolfing, bioenergetics, and a host of other techniques use physical methods, including the touching of the patient by the therapist, to relieve psychological as well as physical problems. These therapies function as psychotherapies insofar as they associate the release of muscle tension with the release of emotional tension. One of Freud's disciples, Wilhelm Reich (1897–1957), pioneered the idea of character armor as muscle tension and the incorporation of massage into psychotherapy.

Other therapies use techniques derived from Eastern religions to increase well-being. Meditation and guided imagery, for example, have become standard techniques at stress-management clinics. In the medical setting, they are stripped of their metaphysical elements and presented as secular relaxation training. This training varies in sophistication from deep-breathing exercises to Buddhist mindfulness meditation. The rationales offered for these therapies similarly vary from physiological calming to appreciation of the fundamental emptiness and interdependence of all events. There is mounting evidence of the effectiveness of this kind of treatment for stress-related physical disorders such as headaches or back pain. Certain sectors of society, however, remain suspicious of the religious roots of these treatments. These nontraditional therapies challenge people's sense of the proper boundary between psychotherapy and sexual gratification, on the one hand, and between psychotherapy and religious practices, on the other.

Ethical Issues in the Psychotherapies

Developing a method by which to choose the appropriate psychotherapy is a problem that has only recently received serious attention. Traditionally, the therapy received was determined by the therapist one selected. The appropriateness of the therapy was judged by the intuition of therapist and patient. The attempt to derive a *differential therapeutics* in psychotherapy, comparable with that found in other areas of medicine, is in its infancy. All patients with similar levels of depression do not need the same type or duration of therapy. In psychotherapy, unlike in physical medicine, diagnosis alone is inadequate to select appropriate psychotherapy. For example, more than a diagnosis of major depressive episode must be known about the patient, such as the person's individual history and personality. Researchers are working to specify the "intermediate-level psychological determinants of problems that mediate between diagnostic grouping and type of intervention" (Goldfried, Greenberg, and Marmar, p. 685).

The importance of factors other than technique to psychotherapy outcome has led some to stress the centrality of the therapeutic alliance in the treatment process. Section 1 of the psychiatric annotations to the first edition of the American Psychiatric Association's (APA) *Principles of Medical Ethics* (1973) states, "The doctor–patient relationship is such a vital factor in effective treatment of the patient that the preservation of optimal conditions for development of a sound working relationship should take precedence over all considerations" (p. 1060). Within this relationship, the greatest challenge for the therapist is the appropriate use of power. The *transference relationship* detailed above gives the therapist tremendous influence over the patient's life, which must be balanced by a viable *therapeutic partnership* (Karasu).

Informed consent for psychotherapy has been proposed as one way to address these concerns. In medical practice, informed consent usually means a discussion between patient and doctor about the risks and benefits of an invasive treatment prior to its initiation. The application of informed consent, even in this regard, has lagged in the area of psychotherapy. Informed consent is often thought unnecessary or implicit for something as low-tech as psychotherapy. But Peter S. Jensen and colleagues argued in 1989 that "informed consent is more than just an ethical or legal obligation: inherent in the process of informed consent is the potential for the enhancement of clinical work" (p. 379). That is, informed consent offers an opportunity to establish the treatment alliance on solid ground. Frank discussion of both the limitations and the benefits of therapy diminishes the illusion of therapist omniscience and patient helplessness so commonly present at the initiation of therapy.

Boundaries of Therapy

Psychotherapy has been criticized as *the purchase of friendship.* Because both friendships and therapeutic relationships are ideally honest, intimate, and supportive, the question of their difference is a natural one. The crucial difference is mutuality or reciprocity: friends serve each other's needs. A therapist is paid to serve the patient's needs. The therapist uses professional expertise to fashion a relationship with his

patient that addresses and corrects the patient's psychopathology. The patient is not obligated to entertain, fascinate, or gratify the therapist; responsibilities are limited to regular attendance and payment for sessions. The theory is that a patient concerned with his therapist's well-being cannot give adequate priority to his own recovery.

In practice, this boundary between therapist and friend is more fuzzy. Therapists must find their patients worthy of interest and concern if therapy is to succeed. It is difficult for therapists to develop deep concern for their patients and yet to not need their approval or companionship. Most therapies proscribe social contact between therapist and patient in order to better define the therapist's role and task. Some therapies, such as those that offer *re-parenting,* specifically promote social therapist–patient contacts outside of sessions. Though some find this expansion of the power of the therapeutic relationship helpful, most would consider the lack of clear boundaries dangerous.

The most egregious violation of boundaries in psychotherapy is sexual contact between therapist and patient. Approximately 5 percent of psychiatrists and psychologists admit having sexual contact with their patients (Lakin). Given the intensely intimate atmosphere of therapy, such temptations are understandable. Nevertheless, sexual contact with a psychotherapy patient is considered the worst possible exploitation of the transference relationship. This is because therapists who become involved sexually with a patient are exploiting the trust established for therapeutic purposes for their own sexual gratification. The APA prohibits all sexual contact with current and former patients.

While there is general agreement that sexual gratification of the therapist is always a sign of exploitation and to be avoided, how this avoidance is accomplished is subject to considerable variation. Psychoanalysts allow free expression of all sexual fantasies concerning the therapist but prohibit all touching. Massage therapists and others who do body work rely upon the emotional release prompted by touch but avoid all sexual conversation.

Confidentiality has traditionally been one of the most important ways in which the boundaries of therapy are respected. Frank and open discussion of the patient's deepest hopes and fears is essential to psychodynamic therapy and would be inhibited by the possibility of public disclosure by the therapist. The stigma associated with psychotherapeutic treatment means that disclosure to employers, colleagues, or neighbors can produce actual damage to the patient's social well-being.

Since the 1976 *Tarasoff v. Regents of the University of California* case, which mandated that psychotherapists warn identifiable potential victims of violence, patients' rights to therapist confidentiality have been limited when "disclosure is necessary to avert danger to others." Justice Matthew A. Tobriner's comment in this case, "The protective privilege ends where public peril begins," means that therapists weighing disclosure must consider the public good as well as the good of their patients. Psychotherapy cannot exist in a legal and moral vacuum within society. The *Tarasoff* decision has at times, however, been used to expand the therapist's social responsibility for potentially dangerous patients. This responsibility can include not only warning potential victims of patient violence, on the basis of uncertain evidence, but also testifying against one's patients in court and providing preventive detention in psychiatric units for those considered potentially violent.

Mental Health in the Medical Model

Dynamic psychiatry, which emphasized the role of psychological processes and reactions, dominated mental healthcare for three-fourths of the twentieth century. This psychiatry had blurred the line between normal and pathological psychological processes, claiming that unconscious forces operated in both. Dynamic psychiatry focused on case formulation, a highly individualized, semibiographical account of the important events, relationships, and unconscious forces in a patient's life. Though these formulations could be formulaic or reductive (e.g., jokes about "head shrinking"), their intention was to bring out the unique situation of the individual.

In 1980 the 3rd edition of the APA's *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-III*) appeared, signaling the beginning of a new hegemony for diagnostic psychiatry. Diagnostic psychiatry, in contrast with dynamic psychiatry, sought to find the ways that patients were fundamentally similar to each other. It emulated the central role that diagnosis played in the rest of medicine. While the state of psychiatric science precluded a classification of diseases based on etiology (causes) and tissue pathology, psychiatric diagnosticians were able to provide categories of symptoms called mental disorders that were linked with prognosis, family history, and treatment implications. These categories allowed researchers to reliably document the prevalence of specific disorders, to determine the efficacy of treatments in groups of similar patients, and to explore patterns of inheritance for these disorders.

The overall effect of these changes was to bring psychiatry in much closer alignment with the prevailing medical model. Public mental health shifted away from community-focused efforts to improve overall mental health and toward preventing and treating specific disorders in individuals. Psychiatric research became tightly linked with specific

disorders and much more concerned with the biological causes of these disorders. Aided by improvements in psychopharmacology, the emphasis in treatment also shifted from psychosocial to biological treatments. There are ethical implications of the focus on psychiatric diagnosis as well as ethical concerns about the use of psychopharmacology, and these issues are discussed next.

DSM-III, and its descendants, *DSM-III-R* (1987) and *DSM-IV* (1994), are designed to be symptom-based classifications that do not attempt to determine the causes of the disorders described. Some vestiges of causation remain (e.g., in the adjustment disorders, post-traumatic stress disorder, and the bereavement exclusion for major depression), but they are few. Clinicians used to distinguish between reactive (i.e., externally caused) and endogenous (i.e., internally caused) depressions, but this has fallen out of favor because of a lack of biological treatment implications. Psychiatric diagnosis simply looks at the symptoms displayed by the individual to determine if psychopathology is present. By suspending consideration of causation, psychiatric diagnosis removes the patient from her life. The diagnostic system has no way of encoding whether the symptoms constitute a *reasonable* or *unreasonable* response to the stresses of daily life (Horwitz). Clinicians must still make these determinations (e.g., is the top priority for treatment this woman's depression or her abusive husband?). But the diagnostic system offers little assistance in these essential and difficult determinations. Some have argued that deciding whether the person or the situation is *crazy* is the central ethical dilemma of psychiatric practice. It is claimed that this issue was behind the abuse of psychiatry for political purposes that occurred in the Soviet Union (Fulford, Smirnov, and Snow).

Diagnostic psychiatry has been widely criticized, generally by proponents of dynamic psychiatry, for minimizing the role of psychological processes in mental disorders. But a more serious flaw may be its omission of social factors in these disorders. A purely symptom-based diagnostic system necessarily omits consideration of the social context within which the symptoms arise. This decontextualization of mental disorders makes them appear to be problems of individuals rather than problems of society. Research and treatment becomes focused within individuals and their brains rather than where and how the individuals live. Psychiatric diagnosticians may counter that it is difficult to change the social context through clinical interventions. This is certainly true, but it is not an adequate excuse for a psychiatry that places all responsibility for misery that is manifested as mental disorders within the individual. Some psychiatrists have begun to argue against the claim that psychiatric diagnosis is neutral, objective, and disinterested. They have urged a move to a postmodern focus that emphasizes social and cultural contexts, recognizes the values implicit in definitions of mental health, and works to minimize medical control of coercive interventions (Bracken and Thomas).

Managed Mental Healthcare

Mental health services have never been distributed according to any systematic assessment of population need. Cultural and financial barriers have meant that upper-class patients have greater access to mental health services even though the distress of patients in lower classes may be more severe and disabling. Psychiatrists have historically gravitated toward patients interested in their services, so mental healthcare is among the most geographically and socioeconomically maldistributed of all medical specialties.

Some aspects of this mental health service maldistribution have been changing. Beginning in the 1970s, there was tremendous growth in the number of nonmedical psychotherapists and in clients seeking their services. Following the introduction of Prozac in 1987, there has been great expansion in the prescription of antidepressant medications, especially in primary-care medical settings (Olfson et al.). In the last years of the twentieth century, mental healthcare thus became generally more available to middle-class Americans. During this same period, overall medical costs for society were rising rapidly. In the 1990s, managed care arose as a method to contain these costs. Though mental healthcare comprised only a small percentage of these costs, insurers saw mental healthcare as discretionary and subject to no natural limits. Managed care therefore imposed strict limits on mental healthcare, especially on the number of psychotherapy visits and the number of inpatient psychiatric days. The overall result of these trends is that more people have access to more limited mental healthcare.

Managed care has reduced the average number of psychotherapy visits per patient and increased the proportion of patients who receive medication rather than psychotherapy. This has increased the number of patients who can receive mental health services, but it has left many practitioners feeling that they can no longer deliver adequate services to anyone whose care is covered by medical insurance. Rather than accept the limits imposed by managed care, many of the most skilled psychiatrists and psychologists have simply opted out of the medical insurance system. This is because therapists have traditionally understood that their duties involved providing good care to individual patients. Therapists are primarily concerned with the patient in their office, not with all the potential patients in the community. What responsibility society and individual

therapists have for the mental health of the general community has been neither decided nor seriously debated.

Body, Mind, and Spirit in Psychiatry

Managed care has sharpened the tension between a dynamic psychiatry of the mind and a diagnostic psychiatry of the brain, but it did not create this tension. Its roots lie deep in the difference between the humanities and the natural sciences. Simply put, the former emphasizes a personal, first-person, and subjective perspective on the human situation. The latter emphasizes an impersonal, third-person, and objective perspective on the human situation. The battle for supremacy or synthesis of these perspectives is currently being waged within psychiatry. Anthropologist Tanya Luhrmann summarized this battle in her 2000 book, *Of Two Minds: The Growing Disorder in American Psychiatry,* which takes up a conflict over the nature of competent and compassionate practice in psychiatry. The battle achieved prominence in a lawsuit over the psychodynamic versus psychopharmacologic treatment of severe depression in a physician (Klerman; Stone). Many clinical issues are included in this battle. Perhaps the most central is the relative priority accorded to self-understanding versus symptom relief. Psychodynamic psychiatrists are trained that sometimes symptom relief must wait to allow self-understanding to occur. Psychopharmacologists believe that it is most important to provide relief to the suffering patient and that self-understanding can come later.

This is also a battle about the relation between disease and self in psychiatry, about the nature of empathy and compassion for those with psychiatric disorders, and even about the nature of humanity. Families of patients with serious mental illnesses, such as schizophrenia, are strong advocates of the disease model in psychiatry through organizations such as the National Alliance for the Mentally Ill. They have been successful at raising money for research and clinical care for mental illnesses seen as brain diseases. They see the disease model as the best way to fight the stigma of mental illness that has held back progress in clinical care. This model also takes the focus off the family environment as a cause for mental illness.

Some patients with mental illness, however, take strong exception to the disease model. As one patient with schizophrenia was quoted, "Can you imagine how insulting it would be if you turned to me and said, 'I'm sorry you have a diseased brain.'? When it gets right down to it, the medical model is an insult to me. To say I have a diseased brain does not validate me. I have a complicated thought system, with different behaviors" (Luhrmann, p. 267). This patient does not accept the sharp distinction between his disease and himself. Schizophrenia is too much of who he is. If psychiatry cannot offer him a cure of his disease, why should he accept that he is damaged rather than just different?

Indeed, it has always been difficult to separate disease and self in psychiatry. So many psychiatric symptoms seem like willful misbehavior or self-inflicted suffering, that observers are inclined to make a moral judgment rather than a medical diagnosis. Severe mental illnesses distort a person's intentions as well as the person's behavior, so it is difficult to see the person as distinct from the disease. Diagnostic psychiatry minimizes the role of intentions in misbehavior, explaining that the disease rather than the person is speaking. Psychodynamic psychiatry leaves this misbehavior partially in the realm of intentions by attributing it to unconscious forces. Thus diagnostic psychiatry sees the pain of mental illness as arising outside the self, whereas psychodynamic psychiatry sees it as arising from within the self.

These differences are important because they shape people's attitudes toward some of the most severe forms of human suffering. How people approach the pain of others strongly determines the nature of the human community. That is why mental health therapies have ethical implications beyond the medical setting.

MENTAL ILLNESS

• • •

I. DEFINITION, USE AND MEANING

The concept of mental illness, including its lay counterparts such as madness and insanity, has been subject to widely different interpretations since classical times and between different cultures (Robinson). Models of mental disorder, as they are now called, continue to be hotly contested between different stakeholder groups in mental health right up to the present day (Fulford et al., 2003). Running through these differences and disputes, as outlined later in this entry, is a tension between what may be called moral and scientific models. Mental illness, understood in terms of this tension, is poised between the everyday moral world of free agency, subjectivity and reasons, and a scientific world of determinism, objectivity and causal laws.

How the tension between moral and medical models of mental illness is resolved in a period of unprecedented advances in the neurosciences—in behavioral genetics, in functional brain imaging, and in psychopharmacology—is critical to a range of ethical issues in psychiatry: the insanity defense (Robinson), ethical aspects of diagnosis (Dickenson and Fulford, ch. 4), the nature of autonomy in psychiatry and psychotherapy (Hinshelwood, 1995, 1997), the boundary between medical psychiatric treatment and social control (Bloch and Reddaway; Fulford, Smirnoff and Snow), the growing role of users (or consumers) in the design and delivery of services (Department of Health), and not least, the fight against prejudice and discrimination, that brand of internal racism (Fulford and Radden) to which all those concerned with mental health, whether as users or as providers of services, remain subject.

This entry explores the meaning of the concept of mental illness, not directly, by way of a critique of the very large number of competing definitions available in the literature, but indirectly, by way of the use made of the concept in practice. This approach —examining the use of concepts as a guide to their meanings—is exemplified by the work of the English philosopher J. L. Austin (1911–1960) and others working mainly in Oxford in the middle years of the twentieth century (Warnock, 1923–1995). The approach, called linguistic analysis or ordinary language philosophy, although relatively neglected by subsequent generations of philosophers (Williams, 1929–2003), and certainly very far from being a philosophical panacea (Fann), provides a conduit or bridge between philosophical theory and medical practice (Fulford 1989, 1990, 2001). In psychiatry, linguistic analysis offers a number of helpful insights into: (1) the nature of the problem presented by the concept of mental illness; (2) the methods available for tackling the problem; and (3) the outcomes that can be expected in tackling problems of this kind.

The Problem: Many Definitions

Difficulties in the use of the concept of mental illness have traditionally been assumed to reflect difficulties of definition. This assumption, of a genetic link between difficulties of use and difficulties of definition, was not unreasonable given the successes of psychiatry in the second half of the twentieth century in improving the reliability of its diagnostic categories by clarifying the definitions of many of its key diagnostic terms: The US-UK Diagnostic Project (Cooper et al.), for example, and the International Pilot Study of Schizophrenia (World Health Organization, 1973), showed that difficulties in the use of the concept of schizophrenia were indeed due to difficulties of definition (discrepant rates of diagnosis turned out to reflect discrepant definitions). There are, furthermore, as this entry shall explore, many examples of continuing difficulties both in the use of the concept of mental illness and in its definition. These examples, however, understood linguistic analytically, point, not to the traditional assumption of a genetic link between use and definition, but rather to the need for a reformulation of the problem as one of difficulty in the use of the concept of mental illness *rather than* a difficulty of definition.

CASE EXAMPLE: SIMON. Simon, a forty-year-old African-American lawyer, was threatened with a malpractice action, which he believed to be racially motivated, by a group of colleagues. Although he had never been a particularly religious man, he responded to this situation by setting up a makeshift altar in his front room and praying all night. In the morning he found that wax had run down from a candle on to his bible, marking out certain words and phrases. This is how he described his experience: "I got up and I saw the seal (wax mark) that was in my father's bible and I called (my friend) and I said, you know, something remarkable is going on over here. I think the beauty of it was the specificity by which the sun burned through. It was … in my mind, a clever play on words." Simon continued to have similar experiences for eighteen months. His *seals* meant nothing to anyone else. But for Simon they were direct communications from God, showing that he was "…the living son of David…and captain of the guard of Israel."

TWO CLASSIFICATIONS, TWO DEFINITIONS, TWO DIAGNOSES. Simon's story, which is based on a real person's experiences, comes from a study of the differences between delusion and spiritual experience carried out by a British psychologist Mike Jackson, at the time working as a doctoral student with Gordon Claridge at Magdalen College, Oxford (Jackson, 1997; Jackson and Fulford). The study included blind ratings using one of the first carefully standardized instruments for assessing a person's mental state, the Present State Examination (PSE). Developed by John Wing, John Cooper and Norman Sartorius at the Institute of Psychiatry in London, the PSE includes a glossary of carefully crafted definitions that, together with a standardized interview schedule, allow the identification of over one hundred symptoms and signs of mental disorder with high degrees of reliability (Wing, Cooper, and Sartorius). PSE ratings of Simon's story identified his experience as a delusional perception, a form of primary delusion. The PSE defines this as a delusion which is "based upon sensory experiences (delusional perceptions) in which a patient suddenly becomes convinced that a particular set of events has a special meaning" (Wing, Cooper and Sartorius, p. 172–173).

What then does this delusional perception mean diagnostically? There are currently two major classifications of psychiatric disorders, chapter V of the tenth edition of the *International Classification of Diseases* (ICD-10), produced by the World Health Organization under the direction of Norman Sartorius (World Health Organization (WHO), 1992), and the fourth edition of the *Diagnostic and Statistical Manual* (DSM-IV),, produced by a taskforce of the American Psychiatric Association (APA) chaired by Allen Frances (APA, 1994).

The ICD-10 and the DSM-IV classifications are in many respects similar. In particular both are descriptive in orientation. That is to say, both seek to define mental disorders as far as possible descriptively, by reference to the presence of specific symptoms, like delusional perception, of known reliability. Yet ICD-10 and DSM-IV suggest radically different diagnoses in Simon's case. In ICD-10 delusional perception (as defined in the PSE) is one of a number of symptoms that, if present, are sufficient for a diagnosis of schizophrenia (or of some other psychotic illness—affective, organic, or other—depending on associated features). According to ICD-10, then, Simon had schizophrenia (or some related psychotic disorder). DSM-IV, by contrast, requires for a diagnosis of schizophrenia, not only one or more of the relevant symptoms (summed up in its Criterion A), but also deterioration in social and/or occupational functioning (Criterion B of "social/occupational dysfunction," p. 285). And inquiry about Simon's social and/or occupational functioning, reveals that, far from deteriorating, as required by Criterion B, it actually *improved!* He was empowered and guided by his experiences, idiosyncratic as they were; he won his court case; and his career consequently went from strength to strength. By the lights of ICD-10, then, Simon had a psychotic illness (albeit one with, in this instance, a benign course); but by the lights of DSM-IV, he had a positive (albeit idiosyncratic) spiritual experience.

MANY DEFINITIONS OF MENTAL ILLNESS. On first inspection, it is somewhat disconcerting, at least from psychiatry's point of view, to find that its two major classifications, although closely similar in their scientific orientations, should yield radically different ways of understanding Simon's story. This is the more surprising given that those responsible for the two classifications worked hard to make them compatible. Simon's case, furthermore, is not marginal in these classifications: Karl Jaspers, the founder of modern descriptive psychopathology, placed delusion among the central symptoms of mental disorder (Jaspers, 1913a); and the case for a medical model of mental disorder is regarded by many as being strongest for the psychoses. It was for this reason that Thomas Szasz, notorious for the slogan *mental illness is a myth* (Szasz, 1960), called schizophrenia, in the title of a later paper, the "sacred symbol of psychiatry" (Szasz, 1976).

Disconcerting, though, as this incompatibility between ICD and DSM may be, viewed in its historical context it is but a manifestation of the long-running tension between medical and moral understandings of madness. As noted at the start of this entry, this tension runs across many cultures and back at least as far as classical Greece (Robinson). In the early-twentieth century, the tension surfaced in Jaspers's insistence on the need for both causal (medical) and meaningful (moral) accounts of psychopathology (Jaspers, 1913b). Psychiatry, for much of the twentieth century, ran mainly with the causal side of Jaspers's psychopathology. But the tension continued to be evident in the conflicting scientific and hermeneutic interpretations of psychoanalysis (Ricoeur), in the rediscovery of meanings by psychology, and of causes by phenomenology, in the second half of the twentieth century (Fulford et al., 2003), and, perhaps most transparently of all, in the so-called debate about mental illness in the 1960s and 1970s (Siegler and Osmond; Caplan et al). In this debate the medical (causal-disease) model of mental disorder was directly opposed by a variety of non-medical models—for example, psychological (Eysenck), social role theory (Scheff), labeling theory (Rosenhan), political (Foucault), existential (Laing) and moral (Szasz 1960, 1987). Each of these alternatives to the medical model sought to shift our understanding of mental disorder away from the causal-disease framework of medicine towards frameworks in which, to varying degrees and in different ways, agency and subjectivity are retained. Szasz's model is among the most overtly moral in the sense that he takes mental disorders to be problems of living, defined by psychosocial, ethical, and legal norms, to which we should respond, not passively, by seeking treatment, but actively, by taking responsibility for them.

It has been rightly pointed out, in respect of this debate, that the term medical model in fact covers a number of rather different models (Macklin); and that psychiatry, in particular among medical disciplines, aspires to a balanced biopsychosocial approach in which different models represent no more than perspectives on (McHugh and Slaveney) or levels of (Tyrer and Steinberg) the subject. Modern psychiatric textbooks all emphasize the importance of considering social and psychological aspects of mental disorder alongside the biological. Anecdotal reports, nonetheless, from people who actually use services (Campbell), taken together with both surveys (Rogers, Pilgrim and Lacey), and empirical social science research (Colombo et al.), all suggest that, in practice, mental health professionals, whatever their theoretical commitment to a broad biopsychosocial model,

tend in practice still to be guided by very different implicit models in their approach to their work.

MANY DEFINITIONS OF BODILY ILLNESS. The range and diversity of competing models of mental illness has been subject to different interpretations, none particularly flattering to psychiatry (Phillips). At best, psychiatry is taken to be scientifically primitive (Boorse, 1976), our use of models being assumed to be a temporary expedient reflecting the "limited information" about mental illness currently available (Tyrer and Steinberg, p. 2). Linguistic analysis, by contrast, offers a positive rather than negative interpretation, an interpretation in which the different models represent different aspects of the meaning of mental illness with complementary, rather than competing, roles in clinical work and research. This positive interpretation will be discussed further in the section on Outcomes. But a first linguistic analytic step towards it is to see that, so far as definition is concerned, one is *no more able to define bodily illness than mental illness.*

From the perspective of those wedded to a genetic link between transparency of definition and ease of use, this may seem to be a somewhat surprising claim. For the concept of bodily illness, after all, if not wholly unproblematic in use, is at least considerably less so than that of mental illness: In contrast with even the central cases of mental illness, such as schizophrenia, there is no dispute about whether heart attacks or appendicitis, for example, as central cases of bodily illness, are diseases.

That bodily illness, nonetheless, is no easier to define than mental illness, is shown by three considerations:

1. There is an on-going debate about the meaning of bodily illness, less high profile, certainly, than the debate about the meaning of mental illness, but, if anything, growing in volume and intensity rather than moving towards resolution. As recently as 2002, Richard Smith, the editor of a leading medical journal in the United Kingdom, the British Medical Journal, reignited the debate about the meaning of bodily illness by asking where we should draw the boundary of disease (Smith).
2. The derivations of some of the most contested positions on the meaning of mental illness stand in direct line of descent from equivalent positions on the meaning of bodily illness. Thus current attempts to define mental illness employing criteria derived from evolutionary biology (e.g., Neander, Wakefield) are derivative, through the work of the American philosopher Christopher Boorse (1975, 1976, 1997), on an earlier debate, which started in respiratory medicine, about the definition of bodily illness (e.g., Scadding).
3. Much of the debate about mental illness, although indeed ostensibly a debate about the meaning of mental illness, actually turns on differences of view about the meaning of *bodily* illness. The critical difference between Thomas Szasz (1960), for example, and his British opponent, the psychiatrist R. E. Kendell, the difference that led to their respective moral and medical interpretations of mental illness, was a difference in their understandings of the meaning not of mental illness but of bodily illness: Szasz took genuine illnesses as instantiated by a series of examples of bodily illness to be defined by anatomical and physical norms, which, being absent in putative mental illnesses, made mental illness a myth; Kendell took genuine illnesses as instantiated by (many of the same) examples of bodily illness to be defined by evolutionary norms of reduced life/reproductive expectations, which, being satisfied by (many) putative mental illnesses made mental illness no different in principle from bodily illness (see Fulford, 1989, ch. 1). Similar differences about the meaning of bodily disorder continue to drive current debates about the meaning of mental disorder (Fulford, 2000).

These three points about the concept of bodily illness have been spelled out at some length because they are the lynch pin of the linguistic analytic reformulation of the problem of mental illness. It is a matter of observation that the concept of mental illness is more problematic in *use* than that of bodily illness. But since bodily illness turns out to be no more transparent to *definition* than mental illness, the difficulties associated with the use of mental illness are unlikely to be derived (directly at least) from difficulties of definition. This is the sense in which, as indicated at the start of this section, the problem of mental illness is one of use *rather than* definition. The problem itself, indeed, reformulated linguistic analytically, turns out to be as much a problem of bodily illness as of mental illness. Before spelling out this reformulation of the problem more precisely, though, a brief look at two definitional blind alleys, the causal blind alley, and the dualism blind alley, is necessary.

THE CAUSAL BLIND ALLEY. One of the most widespread misperceptions in so-called biological psychiatry is that our current difficulties in defining mental illness will be resolved by future scientific advances. The origin of this misperception is the success of physical medicine in developing diagnostic tests to detect the *causes* of bodily illness, the employment of these tests diagnostically, and their incorporation into classifications of disease. A disease, so defined, is a change in the structure/function of the body that has a tendency to cause

illness. But causation *as such* does not define pathology (health no less than illness is *caused*). The chain of causation does indeed, on this model, flow from disease (the change in bodily structure/function) to illness (the changes in the patient's experience and/or behavior). But the flow of *meaning* runs the other way, from illness to disease. It is the status of an experience and/or behavior *as* pathology which determines the status of the underlying bodily causes of that experience and/or behavior *as* pathology, not vice versa.

If, therefore, as in the case of many bodily illnesses, an experience and/or behavior is unequivocally pathological, the underlying causes of that experience and/or behavior will be unequivocally pathological as well. Conversely, though, if, as in the case of many mental illnesses, an experience and/or behavior is only *equivocally* pathological, then the underlying causes of that experience and/or behavior will be only *equivocally* pathological as well. Causation, then, or more precisely knowledge of causation, is, for the purposes of conceptual clarification, a blind alley. (See Fulford, 1989, chapter 4, for a more detailed treatment, including the place of "stipulative definition," in Urmson's sense of the term.).

THE DUALISM BLIND ALLEY. A second widespread misperception is that our difficulties with mental illness are derived in some (generally undefined) way from the (supposed) ills of Cartesian dualism, the separation of mind and brain as distinct substances. This misperception is evident in the positions of those both for and against the concept of mental illness (see, e.g., respectively, Roth and Kroll; Szasz, 1998). It can be taken as two rather different claims. As a claim that *solving* the mind body problem will solve the problem of mental illness, it substitutes for our local difficulties with mental illness, some of the deepest and most intransigent problems of general metaphysics—not much of a bargain, conceptually speaking! As a claim, alternatively, that there is no *real* difference between mind and body, and hence no real difference between mental illness and bodily illness, it simply begs the (operative) practical question, namely, just why mental illness (conventionally denotated) is so problematic in use compared with bodily illness. Either way, then, dualism, or more precisely the denial of dualism, is, like causation, a conceptual blind alley.

The distinction between bodily *illness* and mental illness it is worth adding, is, anyway, readily drawn at the relevant level, i.e. of experience and/or behavior (Fulford, 1989, chapters 5, 7 and 8). Thus, bodily illness is concerned (mainly) with movements (e.g. paralysis), perceptions (e.g. blindness) and bodily sensations (e.g. nausea, dizziness, and pain), while mental illness is concerned (mainly) with the higher mental functions, such as emotion, desire, volition, belief and motivation. The distinction between mental illness and bodily illness, drawn in this (ordinary language) way, is entirely neutral, equally to the provenance of different causal theories (biological, social, psychological, etc), and to the many different philosophical propositions on the mind-body problem. It is also, as will be shown below (section on Outcomes), the basis for a positive way of understanding the more problematic *use* of mental illness compared with bodily illness, derived from philosophical value theory.

A LINGUISTIC-ANALYTIC REFORMULATION OF THE PROBLEM OF MENTAL ILLNESS. The problem of mental illness, then, to return to the starting point of this section, really is a problem in use rather than a problem of definition. There *is* a problem of definition, certainly, but it is a problem of definition of the generic concept of *illness* (including related concepts of pathology, such as disease, dysfunction and disorder) whether bodily or mental.

This reformulation of the problem can be further clarified in terms of the linguistic-analytic distinction between lower-level and higher-level concepts. Thus the traditional assumption, that difficulties in the use of the concept of mental illness have their origin in difficulties of definition, was based, as noted above, on twentieth-century successes, as in the US-UK Diagnostic Project, in solving difficulties in the use of psychopathological concepts by clarifying their definitions. The psychopathological concepts in question, however, were all, linguistic-analytically speaking, lower-level concepts—the lower-level delusion of guilt, for example, proved easier to define than the higher-level concepts of delusion and psychosis. From the perspective of the traditional assumption, this was an (unexplained) failure of the definitional program. From the perspective of linguistic analysis, by contrast, it is a reflection of a property common to all concepts, namely, that higher-level concepts in general, although used with often effortless facility, are peculiarly difficult to define.

A standard non-medical example is the concept of time. Most of the time, the concept is used (as in this sentence) seamlessly. Yet, if pressed, one would not be able to define it. Saint Augustine (354–430), the early Christian philosopher and Archbishop of Hippo, in his *Confessions,* said, "So what is (a) time? If no one asks me, I know; if they ask and I try to explain, I do not know" (Bk. II, ch. 14, No. 17). We *can* define lower-level concepts, of course: a watch face is, simply, the display side of a watch; a watch is, almost equally simply, an instrument for measuring time; but time is … here, as with the concept of illness, we get stuck.

We can extend the parallel with the concept of time. For with time, as with the concept of illness, there are

contexts in which the concept *does* run into difficulties in use. In the case of illness, difficulties in use arise in psychological medicine. In the case of time, difficulties in use arise in theoretical physics, for example. In theoretical physics, the difficulties in use arise because the concept of time has to be used in contexts and at scales very different from those in which it developed. Some might argue for a broadly parallel explanation in the case of illness: the French philosopher and historian, Michel Foucault (1926–1984), for example, argued that the concept of mental illness arose by extension from that of bodily illness as a response to the work ethic of the industrial revolution (Foucault); and, as will be discussed in the Conclusions, there is indeed a sense in which the concept of illness is increasingly under pressure through scientific advances in medicine, much as that of time has been in physics. But Foucault's explanation, and others like it, all fail to explain the long history of difficulties about the concept of mental illness, stretching back, as indicated at the start of this entry, at least 2,500 years.

The question, then, that should be asked regarding the concept of illness, is not why it is difficult to define: this is an interesting question, philosophically, that we can indeed ask of higher-level concepts in general. But the question that should be asked is just why the concept of illness is relatively difficult to use in psychological medicine compared with bodily medicine. Reformulated in this way, furthermore, in linguistic-analytic terms, the problem is no longer a problem merely of mental illness at all. The challenge, for analysis, is, indeed, to explain why mental illness is relatively *problematic* in use. But there is an equal and opposite challenge to explain why bodily illness, although no less easy to define, is relatively *un*-problematic in use. So how should we go about this?

The Method: Philosophical Field Work

The method of linguistic analysis, noted above, of focusing on the use of concepts as a guide to their meanings, directly exploits the fact that, with higher-level concepts, people are better at using than defining them. Austin, whose now classic paper, "A Plea for Excuses," illustrates the linguistic-analytic approach, called this philosophical "field work" (Austin, p. 25). As already noted, linguistic analysis is neither unproblematic nor a panacea. There is, furthermore, no *a priori* reason why someone may not still come up with a definition, a neat formula or code, which encapsulates the full meaning of illness, higher-level concept as it is, and explains, even-handedly, its relatively problematic use in psychiatry and its relatively unproblematic use in bodily medicine. There is no *a priori* reason, similarly, why someone may not come up with a simple formulaic definition of some other related higher-level concept, such as health (Nordenfelt) or disorder (Wakefield). Nonetheless, linguistic analysis, as a method, can be used to good effect both negatively, to critique proposed definitions of mental illness and related concepts, and positively, to raise awareness of aspects of the meanings of these concepts which would otherwise tend to remain hidden.

NEGATIVE USE OF LINGUISTIC ANALYSIS: AS A CRITIQUE OF DEFINITIONS. Linguistic analysis, then, involves attending to language use. Normally we attend to the message. Linguistic analysis involves taking a step back, as it were, and attending to the language—to the actual words and phrases—in which the message is delivered.

As applied to proposed definitions, this stepping back and attending to language use can be helpful in its own right. Jerome Wakefield, for example, has argued in a series of impressively detailed articles (e.g., Wakefield, 1999, 2000), that dysfunction, as a component of his proposed definition of disorder (the other component is harm), can be defined value-free by reference to evolutionary norms. In this Wakefield stands in direct line of descent not only from Boorse, Kendell, Scadding and others in the debate about disorder (noted above), but also from a long line of philosophers working on the concept of function in biology (e.g., Neander; Thornton). Wakefield's enthusiasm and his rhetorical style make him a particularly effective current advocate of this approach. If one steps back, though, from his message and considers the words in which his proposed definition of dysfunction is actually expressed, it is possible to see that many of these are, in part, ambiguous as to factual and evaluative meaning. The terms in which Wakefield's definition of dysfunction are expressed, that is to say, can be used (as is required to support his claim to a value-free definition) descriptively; but they can also be used evaluatively. His definition includes the word "failure," for example (Fulford, 1999, p. 412). From a linguistic analytic perspective, then, there has to be a suspicion that while the rhetorical effectiveness of Wakefield's claim to a value-free *definition* of dysfunction is carried by presenting us with the value-free side of the meanings of these terms, the actual *work* (the linguistic work) of the concept of dysfunction as it is actually used (even by Wakefield) nonetheless depends (in part but essentially) on the evaluative side of their meanings (Fulford, 2000).

Others have succeeded in producing unambiguously value-free definitions of relevant terms. Boorse, for example, whose work was also noted above, defined disease stipulatively as a "… deviation from the natural (= statistically typical) functional organization of the species … " (1975, p. 59),

adding, to cover endemic diseases, that disease should be "… mainly due to environmental causes" (1975, p. 59). Boorse's definition of disease, then, unlike Wakefield's definition of dysfunction, is indeed unambiguously value-free. But its persuasiveness, even as a stipulative definition, is undermined by the fact that Boorse himself continues to *use* the term disease with clear evaluative connotations. Thus his value-free criterion of statistical deviation becomes, only four lines later, the value-laden "*deficiencies* in functional efficiency" (1975, p. 59 [emphasis added]) and the value-free "environmental causes" becomes, again only a few lines later, the value-laden "*hostile* environment" (1975, p. 59 [emphasis added]). Boorse has rightly pointed out that this is very far from being a knockdown argument against his definition of disease (Boorse, 1997). But from a linguistic-analytic perspective it is at least suggestive that the *meaning* of disease, and hence the *use* that people (including Boorse himself) make of the term, does include an essential element of evaluation.

The slips that Boorse, and others (Fulford, 2000), make from value-free definition to value-laden use, can be understood in terms of the idea that words are, as Austin put it, "our tools" (p. 24). Based on this then, we can say that Boorse defines say, a hammer, stipulatively in terms only of its handle (equivalent to the fact part of the meaning of disease/dysfunction). But as soon as he has to use a hammer for real, the head (equivalent to the value part) becomes essential. Without the handle, to extend the analogy, the hammer cannot do the job we require of it; but the use that we actually make of a hammer for *real,* shows that the head (the value part) is essential as well.

Further examples of use providing a critique of definition are to be found in psychopathology. As already noted, the reliability of psychiatric diagnosis has been much improved by careful definition at least of lower-level psychopathological terms. The *validity* of psychiatric diagnosis, on the other hand, far from being improved, has in some cases actually been prejudiced by attempts to extend the approach of simple formulaic definition from lower-level to higher-level concepts. Delusion, for example, a term, as noted above, of central importance in descriptive psychopathology, is regularly defined in textbooks by criteria that transparently fail to encompass the full uses of the term in practice (Fulford, 1989, ch. 10).

The concept of psychosis, a step higher up the hierarchy than delusion, provides an even more dramatic example. In ICD-9 (World Health Organization, 1978), mental disorders were divided up (consistently with traditional descriptive psychopathology) primarily into psychotic and non-psychotic varieties. In ICD-10 and DSM-III (American Psychiatric Association, 1980), this primary division was abandoned on the grounds essentially that the concept of psychosis is resistant to operational definition, both classifications adopting instead a larger number of primary divisions (10 for ICD-10; 15 plus Personality Disorders and V codes for DSM-III). Closer inspection, however, shows that these new primary divisions contain, implicitly or explicitly, the traditional subdivisions into psychotic and non-psychotic categories (Fulford, 2003a). In other words ICD-10 and DSM-III are, so far as the psychotic/non-psychotic division is concerned, just ICD-9 and traditional descriptive psychopathology, turned upside down! The implication, linguistic analytically, is that the psychotic/non-psychotic distinction, difficult as the concept of psychosis is to define, continues, like the head of the hammer in the example above, to be essential to the set of conceptual tools that we need in speaking of psychopathology.

POSITIVE USE OF LINGUISTIC ANALYSIS: TO RAISE AWARENESS. The above examples should all be understood, on the linguistic analytic model, as showing, not that this or that proposed definition is wrong, but that it is incomplete. The continued use of a concept with a meaning that is denied or excluded in a proposed definition, shows that the meaning in question is, again like the head of a hammer in our example above, essential to the work that that concept does for us, linguistically speaking. Linguistic analysis, then, as a former Professor of Psychiatry at the Institute of Psychiatry in London, Sir Denis Hill, put it, is in this respect like psychoanalysis, a consciousness-raising exercise (personal communication). Examining the actual use of concepts for real thus helps to raise awareness of aspects of their meanings which, otherwise, would be neglected or ignored.

It is important to be clear that very little is claimed for this positive use of linguistic analysis. In the first place, examining the use of concepts, is, as Austin put it, in the title to an informal talk on the subject, no more than "… one way of possibly doing one part of philosophy" (Warnock, p. 6): or, again, ordinary language, although always the first word, "… is *not* the last word" (Austin, p. 27). Then second, linguistic analysis is no Royal Road to a grand unified theory. Like empirical scientific work, linguistic analysis is piecemeal, tackling doable projects, and satisfied with small increments in understanding. As Austin, again, pointed out, this means that the work of linguistic analysis, like the work of a scientific research program, can be broken down across a team or community of researchers, in contrast to the lone scholar model traditional in philosophy (Warnock, ch. 1). And all this in turn means, finally, that linguistic analysis can

be connected with other methods, philosophical and empirical, with, as will be explored in the next section, outcomes that are well-grounded and directly relevant to policy, practice, training, and research in mental health.

Outcomes: From Meaning to Usefulness

Recent linguistic-analytically oriented work on the concept of mental illness has been focused on raising awareness of the role particularly of evaluation (of judgments of good and bad) alongside description in our psychopathological concepts. The American psychiatrist, John Sadler, for example, has carried out a detailed study of the epistemic values shaping the construction of the diagnostic categories of personality disorder in DSM-IV (Sadler, 1996). Such epistemic values include coherence, comprehensiveness, simplicity, instrumental efficiency, and relevance. Sadler explored the roles of such values in shaping DSM-IV, however, not by general speculation, but by careful analysis of the language of a foundational paper on the classification of these disorders by the man who, as noted above, was later to become chair of the DSM-IV taskforce, Allen Frances published in 1982. Frances, like the DSM taskforce itself (APA, 1994, p. xv), was concerned (rightly) with the evidence base of the classification of personality disorders. Work in the philosophy of science, though, suggests that proposals for classifying these disorders would be likely to be driven, also, by epistemic and other kinds of evaluation (Luntley). Sadler's analysis showed that this was in fact so, and it defined precisely the kind and impact of some of the values actually involved.

THEORY: A MORE COMPLETE VIEW. The significance of Sadler's work, consistently with the consciousness-raising outcomes of linguistic analysis, is not to undermine the scientific basis of psychiatric classification. It is rather to show how the *science* of diagnostic classification (to the extent that this is confined to the evidence-base of our classifications) is combined with (generally unrecognized but nonetheless logically operative) *evaluations.* The importance of this more complete view of what another Oxford philosopher Gilbert Ryle (1900 – 1976) would have called the logical geography of our classifications, is evident in the case history of Simon at the start of this article. DSM, despite its claims to being a descriptively-based classification, is shot through with evaluations (Fulford, 1994). The DSM (like ICD) *is* descriptive, of course; but it is also evaluative. And Criterion B, the criterion of social/occupational dysfunction at the heart of the DSM classification, which, as discussed above, turned out to be crucial to the differential diagnosis in Simon's story, is a case in point. An exclusively factual account of dysfunction requires that Criterion B be understood, like the symptoms in Criterion A, as a matter exclusively of evidence. But when it comes to social and occupational functioning, it is hard to avoid the conclusion that what counts as good or bad functioning is, in part, a matter also of value judgments. In Simon's case, then, the operative diagnostic criterion, as to the differential diagnosis between delusion and spiritual experience, was not a descriptive but an *evaluative* criterion.

This of course raises the question of why evaluation is so much more prominent in psychiatric classification and diagnosis compared with their counterparts in bodily medicine. The answer one gives to this question depends on which model of disorder one accepts. Szasz, at one extreme, argued, as noted above, that psychiatry is value-laden in this way because mental disorders are really moral not medical problems. Kendell, Boorse (1976), and others have argued that psychiatry is value-laden because it is at a primitive stage of its development as a science. Linguistic analysis suggests a third kind of answer, namely that it is because psychiatry is concerned with areas of human experience and behavior, such as emotion, desire, volition, belief, and sexuality, in which human values *differ widely and legitimately.*

Thus, values, according to this linguistic-analytic answer, stand alongside facts in the definition of diagnostic concepts in *all* areas of medicine, bodily as well as mental. But the conditions with which bodily medicine is typically concerned, like heart attacks for example, tend to be painful and life threatening, and, hence, *bad* conditions by anyone's standards. There is no Criterion B for a heart attack, therefore, not because there is no evaluative element in the diagnostic concepts used in cardiology, but because what counts as bad functioning in hearts is widely agreed upon, hence is not problematic diagnostically, and hence can (generally) be safely ignored in practice. Where, however, cardiology, and disciplines like it, are, in this sense, evaluatively *simple,* psychiatry is evaluatively *complex.* Psychiatry *needs* a Criterion B in cases like Simon's, therefore, or some equivalent evaluative criterion, because what counts as bad functioning in areas such as emotion, desire, volition, belief, and sexuality, is *not* widely agreed upon, hence *is* problematic diagnostically, and hence *cannot* be safely ignored in practice.

This linguistic-analytic interpretation of the more value-laden nature of mental illness, which we owe to yet another Oxford philosopher, R. M. Hare, provides at least one reason why, in terms of the linguistic-analytical reformulation of the problem of mental illness developed in the first part of this article, the use of illness is relatively problematic in psychiatry while being relatively unproblematic in physical medicine. It is now clear that this is not because bodily illness

is easier to define than mental illness, still less because psychiatry is less scientific than bodily medicine, but because psychiatric diagnostic concepts are evaluatively more complex than diagnostic concepts employed in (most) areas of bodily medicine.

PHILOSOPHY INTO PRACTICE. The recognition that the concept of mental illness is, in the sense just outlined, evaluatively complex, has been the basis for a number of recent developments taking philosophical theory into the heartland of mental health practice.

In the United Kingdom, for example, new training programs, aimed at giving mental health practitioners the skills for effective decision making where legitimately different values are in play (Fulford, Williamson, and Woodbridge), have been developed within the National Service Framework, a policy document defining the U.K. government's core strategies on mental health (Department of Health). These training initiatives draw in particular on the principles and skills-base of Values-Based Practice (Fulford, 2003b), and on research combining linguistic analysis with empirical social science methods to explore the different models of disorder implicit in multi-disciplinary teams (Colombo et al.). They are also closely linked with recovery-oriented and other innovative user-centered approaches to the development and delivery of services (Allott et al.). On a wider international canvas, these initiatives connect with practically-oriented research employing a growing number of other philosophical methods, including the German philosopher and mathematician Gottlob Frege's (1848–1925) logic of relations (Van Staden and Kruger), the use of discursive methods to reveal the meaning and intentionality implicit in the speech and behavior of Alzheimer's disease sufferers (Sabat), and a whole series of studies in phenomenological psychopathology (e.g., Musalek, Stanghellini).

Linguistic analysis, then, in itself and combined with other methods, empirical and philosophical, can help to clarify the place and roles of the evaluative elements of meaning in the concept of mental illness, adding fine-grained, and hence potentially practically useful, detail to our understanding of the concept.

There is of course a good deal more to the meaning of mental illness (and of our concepts of disorder generally) than just this element of evaluation. Many of the most difficult problems in the use of the concept turn, indeed, not on whether someone is in a *bad* condition (as in Simon's case), but on whether they are in a bad condition of a kind that is properly thought of as an *illness* (the problems associated with the insanity defense, noted at the start of the entry, for example). The DSM, in an important caveat, rightly emphasizes that psychopathology is not defined by negative value judgments alone (DSM-IV refers specifically to social value judgments, APA, p. xxi–xxii). Values, then, as the DSM's caveat makes clear, although indeed necessary (along with facts) to the definitions of psychopathological concepts, are very far from being sufficient.

This brings the argument back to the wider debate about models into which, as noted above, the long-running historical tension between scientific and moral understandings of mental illness has resolved in recent decades. Coming back to this debate, though, within the now more complete view of the conceptual structure of medicine revealed by linguistic analysis, opens up to psychiatry an extensive resource of powerful philosophical methods for exploring the full richness and subtlety of its diagnostic concepts: besides analytic philosophy (e.g., Bolton and Hill), such methods include discursive analyses of the inter-personal creation of meaning (Gillett; Harré), hermeneutics (e.g., Widdershoven and Widdershoven-Heerding), existentialism (e.g., Morris), the phenomenologies of both Martin Heidegger (1889–1976) (e.g., Bracken) and Maurice Merleau-Ponty (1907–1961) (e.g., Matthews), and classical philosophy (Megone). Contrary to the causal blind alley, furthermore, noted above, research in these new areas of philosophical psychopathology (Graham and Stephens), as those most directly concerned have been among the first to recognize (Andreasen), is set to become more, not less, important with future advances in the neurosciences.

The practical impact of such research, it is important to add, understood within a (linguistic-analytically) more complete view of the conceptual structure of medicine, will not be to secure the dominance of any one model, medical, moral or otherwise; still less will it be to create a super model, an unstable oil-and-water amalgam of incompatible elements of meaning. The impact of such research will be, rather, to clarify, piecemeal but progressively, the elements of the different models and thus to endorse their roles as complementary ways of understanding what is, after all, at the center of mental healthcare, the distinct perspectives of individual people with particular experiences of mental distress and disorder. If mental illness is a complex and multifaceted concept, this is because, encompassing as it does such areas of human experience and behavior as emotion, desire, volition, belief and sexuality, it reflects the complex and multifaceted aspects of human nature itself. Psychiatry, above all among medical disciplines, is concerned, not just with bodies or with parts of bodies, nor even just with minds or with parts of minds, but with what the Oxford philosopher Kathleen Wilkes, in the title of her seminal 1998 book on the relationship between philosophy and psychopathology, reminded us are *real people.*

Conclusions: Psychiatry First

This article has explored the problems raised by the concept of mental illness through the lens of linguistic analysis as exemplified particularly by mid-twentieth-century philosophers of the Oxford school, such as J. L. Austin. Although not currently fashionable in philosophy in general, in relation to the concept of mental illness this approach has a number of clear implications, summarized here under problem, method and outcomes.

As to the problem of the concept of mental illness, linguistic analysis shows that this should be reformulated in terms of use rather than definition. The challenge is not, directly, to *define* the concept of mental illness, since the (relatively) unproblematic concept of bodily illness turns out to be no less difficult to define. The challenge, rather, is to explain, even handedly, why mental illness should be relatively *problematic in use* while bodily illness is relatively *unproblematic in use,* despite both concepts being equally difficult to define. The method suggested by linguistic analysis, correspondingly, is to focus on use rather than definition, to step back from the message (proposed definitions) and become more attentive to the language (the actual words and phrases) in which the message is expressed. This approach delivers no simple formulaic definition. Combined with other methods, though, philosophical and empirical, it has a number of outcomes relevant to policy, practice, training, and research in mental health. These outcomes, as illustrated in this entry, amount to one answer to why mental illness is relatively problematic in use compared with bodily illness, namely, because mental illness, in contrast to bodily illness, is concerned, characteristically, with areas of human experience and behavior, such as emotion, desire, volition, belief, and sexuality, in which human values differ widely and legitimately.

II. CULTURAL PERSPECTIVES

In the late 1970s and early 1980s anthropological researchers began to focus on the cross-cultural study of health and illness, both mental and physical, and systems of healthcare. In looking at Western views of mental illness, one finds the imprint of culture on the diseases distinguished and characterized, the symptoms associated with those diseases, and the etiological theories.

Anthropology and Medicine

The critical and reflexive view that leads to the the dissolution of traditional Western categories derives from anthropology's cross-cultural nature and tradition of long-term

research on indigenous languages. That research demonstrates the created nature of those categories and highlights the culturally constructed nature of Western realities, whether popular, medical, or scientific (Carlson; Fausto-Sterling, 1992; Gaines, 1992a, 1992b; Geertz, 1973, 1983; Gould; Kleinman and Good).

Biological and social and cultural anthropologists study health, illness, and medical systems around the world. Biological anthropologists tend to use U.S. biomedical conceptualizations and research strategies in cross-cultural contexts. Although some medical anthropologists utilize biomedical definitions of illness in *ethnomedical* and *ethnopsychiatric* studies of specific cultural or ethnic forms of medicine and psychiatry, usually in non-Western cultures, many have abandoned that practice (Gaines, 1998c).

Those researchers have joined social scientists from all fields who utilize interpretive perspectives. In medical anthropology such scientists initially focused on folk medical traditions. However, since the late 1970s many have reflected on and analyzed the cultures of professional medical systems in the West and elsewhere (Kleinman, 1980; Leslie; Lock) and the sciences on which those systems draw (Gaines, 1979, Gaines, 1998c; Hahn and Gaines; Townsend; Young, 1995). Increasingly, anthropologically trained researchers come from the psychiatric profession (Kleinman, 1977, 1988; Littlewood and Lipsedge).

Interpretive social sciences have replaced Enlightenment science's ideas of cause and effect and use of universal laws to explain human behavior. Explanation has been supplanted by understanding and interpretation derived from idealist forms of social science theory and philosophy. Both popular and scientific realities now are seen as creations or constructions that are locally fabricated. In medical anthropology *cultural constructivism* is a major interpretive perspective that focuses on medical systems (Gaines, 1991, 1998c).

The interpretive constructivist perspectives allow one to see both professional and folk psychiatries equally as ethnopsychiatries, that is, cultural psychiatries. Constructivism suggests that psychiatry is a problematic but locally meaningful experience-near, ongoing historical construction that is constituted by various forms of embodied and disembodied discourse (Gaines, 1991, 1992a).

Constructivist perspectives have affinities to the history and philosophy of science (Foucault; Gilman, 1988; Gould; Hacking, 1983) and to gender studies (Fausto-Sterling, 1992, 2000; Gaines, 1992b). They have made it possible to penetrate the veneer of medical and other sciences to reveal their cultural assumptions and biases concerning madness, nature (human and otherwise), human development, human differences and biologies (gender, "race"), emotion, and identity (Duster; Fausto-Sterling, 1992, 2000; Gaines, 1987, 1992a, 1992b; Gaines and Farmer; Gilman; Kleinman and Good). Medical anthropology has added to these debates with ethnographic studies of healers, researchers, and patients in their cultural contexts (Gaines, 1979, 1992a; Hahn and Gaines; Kleinman, 1980, 1988; Lock; Marsella and White; Townsend; Young, 1995). Although each professional psychiatric tradition embodies culturally specific beliefs and values, they all represent their objects of concern (diseases) as real and universal. Depending on the culture or the cultural variations within a society, those realities are usually in the domain of nature but may have a more spiritual orientation (Gaines, 1998b).

Ethnopsychiatries represent distinct systems rather than versions of a unitary psychiatry. A review of mental illness in the cross-cultural record suggests that in other cultures illnesses often cannot be classified in accordance with Western nosologies such as the Diagnostic and Statistical Manuals (DSMs) of the American Psychiatric Association (APA). Novel disorders in traditional societies are not versions of homegrown disorders. Conversely, many disorders that are assumed to be natural entities in the West cannot be found in other cultures or lack key or even defining symptoms. This suggests that diagnostic criteria are altered to fit unruly entities into Western molds (Gaines, 1991; Gaines and Farmer; Kleinman, 1977, 1988; Kleinman and Good).

The Problem of Western Professional Psychiatry

A cultural focus on professional ethnopsychiatries, particularly that of the United States, shows that they differ in significant ways. This also shows a lack of a universally valid "gold standard" by which all forms of mental illness can be evaluated.

Although ethnopsychiatries can be expected to differ substantially, an advocate of biological causal realism would not expect that to be true of professional (ethno) psychiatries. The distinctiveness of ethnopsychiatries suggests their cultural construction; they are not the same psychiatry focused on *natural* illnesses as it is practiced in different countries.

Cross-Cultural Knowledge of Mental Illness

Research in ethnomedicine and ethnopsychiatry, in the philosophy of science and history, the history of medicine, and gender studies has converged to raise epistemological and ethical concerns for modern psychiatries in multicultural nation-states. Those concerns derive from the fact that

popular and professional psychiatries have been revealed local cultural constructions. Hence, the key question of psychiatric systems—What is normal and what is abnormal?—may be posed in an ethical context: What are the ethical problems generated by one psychiatric theory or nosology applying its notions of normality and abnormality to members of distinct cultures in modern plural societies? A cultural assessment of U.S. professional ethnopsychiatry shows a diversity of opinions and the elusive nature of definitions and diagnoses of mental disorders, suggesting its inadequacy as a standard.

Are Mental Illnesses Natural and Universal? Deconstructing U.S. Ethnopsychiatry

The view that psychiatric illness is universal eschews culture as a formative influence and assumes that disorders have similar natures that are expressed everywhere. That is, each disorder is known by its symptoms, which by definition must be distinct, at least collectively, from those of other disorders. In this view, in studying mental illness cross-culturally, one studies the same things in different cultural settings.

To make that argument one must posit that psychiatric disorders are biologically based (biochemical or genetic) and thus are beyond culture. One also must assume that there is a single human psychology that can be manifested in aberrant forms. If this view is correct, the same disorders should be identified and treated in all professional and popular psychiatries. It is assumed that a professional psychiatry *discovers* those entities and then names and classifies them (e.g., American Psychiatric Association, 1987, 1994); it does not invent them.

Labeled phenomena exist apart from their labels, it is thought. However, psychiatry mistakes its labels for realities rather than models (Geertz, 1973) or representations of reality (Hacking, 1983) that are used for particular purposes. This view expresses an implicit empiricist theory of language, holding that disease labels correspond to independently existing entities in the natural world. However, the empiricist theory is a cultural theory about, not a factual description of, the relationship of language to the world (Hacking, 1983).

When differences in disease entities or in systems of classification (nosologies) across cultures are found, psychiatrists assume that those differences indicate that universal diseases are overlooked, mislabeled, or differently labeled by less sophisticated others. When professional psychiatries disagree, they assert that one is more *advanced* than the others (Kleinman, 1988; Kleinman and Good).

Both views are evolutionist in form and have little scientific merit. It now is known that cultures change historically, not through evolution, because of contact with and borrowing from other cultures as well as innovation. Cultures are distinct because of their unique histories, that are constituted as local culture and passed on through socialization. Cultures do not differ because they represent developmental stages of a single human *culture.*

It is inappropriate to assume that the understandings of U.S. professional ethnopsychiatry are more advanced than those of other countries. For one thing, U.S. psychiatry has borrowed many of its fundamental ideas from other cultures and used them for its own purposes. Also, U.S. psychiatry has changed its views of mental illness radically over time.

The changes have not been in a specific direction, building on past knowledge. Rather, they represent a shift in paradigms. U.S. psychiatry has had dominant etiological paradigms that have been social, hereditarianist biological, psychoanalytic, psychosocial (interpersonal), and biological. The sciences seen as key to psychiatric formulations also have changed over the years. They have included psychology, eugenics, biology, physiology, genetics, and neurology (Dowbiggin; Gaines, 1992b; Hacking, 1995; Kleinman, 1988; Littlewood and Lipsedge; Lurhmann; Young, 1995).

ANOREXIA NERVOSA, CHRONIC FATIGUE SYNDROME, AND MULTIPLE PERSONALITY DISORDER

Anorexia nervosa. The potentially fatal disorder anorexia nervosa is found widely among middle- and upper-income Euro-American women. However, it is seen only rarely outside that narrow sociocultural context even in the United States.

In cross-cultural work key features of the disorder, such as fear of obesity and a distorted body image in the very thin, are not found (Mezzich et al.). Researchers have suggested dropping those symptoms, but in that case how could one find the same disorder with different symptoms when the disorder is defined by its symptoms?

Chronic fatigue syndrome. Chronic fatigue syndrome (CFS) is a disorder for which the search for a biological cause failed, yet it is referred to as if a somatic cause had been isolated as chronic Epstein-Barr virus infection or immune dysfunction syndrome. This disorder, which is fairly common in the United States but confined to specific ethnic and social class levels, is found in few other cultures. Currently, a century-old U.S. term, *neurasthenia,* is being resurrected and applied to CFS, moving it into the province of psychiatry from general medicine, although a somatic cause still is being sought (Kleinman, 1988).

Mutiple personality disorder. Multiple personality disorder is another condition that is found commonly in the

United States. It is invoked in criminal trials as a legal defense and in popular culture. However, it is absent from the classifications and practice of other professional psychiatries (See Hancking, 1995).

PERSONALITY DISORDERS. Several new disorders appeared in an appendix in DSM-III-R (American Psychiatric Association, 1987), including dependent personality disorder and sadistic personality disorder. Those terms appear to be gendered: The former is said to be found among women who "allow" physical abuse over time, and the latter among the men who abuse them. There was considerable political opposition to the tentative formulation of those disorders, which blame female victims of abuse while giving their abusers a legal defense. In English psychiatry the adoption of a premenstrual syndrome made it possible to explain women's injuries: they did it to themselves.

The gender component of those personality disorders recalls the history of U.S. psychiatry, in which traditional notions of women's nature were upheld by psychiatric findings, as were racist notions about minorities (Fausto-Sterling, 1992; Thomas and Sillen). A more explicitly racist psychiatry was that of South Africa, in which a lower psychological and psychiatric evolutionary status was attributed to *nonwhites* (Gaines, 1992a).

Depression and Schizophrenia

Two disorders are considered in biological psychiatry to be models of biogenetic mental diseases: depression and schizophrenia. However, the cross-cultural literature and the most advanced epidemiological studies have challenged that assertion (Gaines, 1992a; Kleinman and Good; Kleinman, 1988; World Health Organization). The formulations of those disorders in the West have been shown to conceal powerful cultural and moral assumptions about emotion, autonomy, sex, and gender as well as human difference (ethnic and so-called racial) (Gaines, 1992a, 1992b; Kleinman and Good).

To examine the epistomology of the formulations of depression and schizophrenia, one first must consider certain key underlying psychological dimensions. Those culturally defined dimensions are constructions of self, will, emotion, and cognition (Gaines, 1992b).

SELF. There are differences in cultural conceptions of self and person with respect to mental illness, its diagnosis, and its treatment. Conceptions of the self vary widely and may include spiritual elements. For example, it is common for people to have spirit siblings in Bali (Marsella and White), but this would be seen as pathological in the United States.

Formulations of the self in India, the Mediterranean countries, and Japan would be seen as incomplete, dependent, and/or unindividuated by U.S. psychiatric standards despite the fact that those familistic, interactionally altering *indexical* selves that maintain interactional harmony and family reputation exist in cultural environments that foster, support, and reward their *sociocentrism* (Marsella and White). Conversely, the *egocentric, referential* Northern European Protestant self (Gaines, 1992b; Marsella and White) with its asocial nature would be seen as antisocial, naïve, and alienated in other contexts. It is the locally conceived self in which psychological disorders occur. Logically, different selves must have different disorders and therefore require different healing strategies. To complicate matters further, many cultures do not exhibit a purely psychological self. Instead, they exhibit social selves (the self is a social psychological, not a psychological, phenomenon), and this is found even in Europe (Gaines, 1992b, 1998b; Marsella and White).

EMOTION AND COGNITION. The distinction between cognition and affect (thinking and feeling) in the West, which is central to the differentiation of psychiatric disease entities, does not exist universally in human nature or biology. The cross-cultural record indicates that these are cultural constructions (Kleinman and Good). Those findings challenge the validity of the construction of depression and schizophrenia as universal diseases grounded in biology, for the psychological domains in which disturbance is said to occur (cognition and affect) are not innate; they are Western cultural constructions.

DEPRESSION. Assessment methods for depression are often ethnocentric even when the approach is said to be entirely *descriptive,* as in DSM-III (1980), DSM-III-R (1987), and DSM-IV (1994). An example is dysphoric affect (an unpleasant, sad feeling), that is a central element of the Western depressive experience.

Dysphoric affect, although disvalued in some Western traditions, is highly valued in others, such as the Mediterranean world with its Latin Catholic, Orthodox, and Islamic traditions (Gaines, 1992a; Kleinman and Good), where suffering is seen as ennobling and indicative of divine interest in the sufferer (Gaines and Farmer). It serves as the basis for interaction in which the self is presented through the *rhetoric of complaint* as beset with problems and as a fellow sufferer (Gaines and Farmer).

In the Buddhist tradition recognition of the worthlessness of the world and the self and the futility of human activity is part of enlightened understanding (Kleinman and Good). Such thoughts therefore have positive personal value

rather than being pathognomic: They are *eudysphoric* (Gaines, 1987).

The complexity of the dysphoric experience can be understood by reference to the interrelation of the cultural context and history, cultural psychology, symbols, and family, status, and gender roles and power relations that collectively contribute to its construction (Kleinman and Good; Gaines and Farmer). Only then is it possible to assess the need for assistance. The intricate patterning of social and cultural forces is complex and requires detailed contextual analysis (Good, 1994).

The patterning of symptoms can vary widely across cultures so that key features of Western-defined disorders such as depression are absent from the experience of members of other cultures even when they are diagnosed as depressed with U.S. psychiatric instruments. For example, there is no psychomotor retardation among *depressives* in France or Morocco, only short periods of dysphoric experience among the Hopi, and feelings of insight and satisfaction in Sri Lanka and India (Gaines and Farmer; Kleinman and Good).

No consistent definitive statement about the prevalence, the incidence, or even the forms of depressive manifestation across cultures can be made, although a variety of assessment techniques have been employed for that purpose (Kleinman and Good). One problem is that false positives appear in the West just as they do in epidemiological studies done in Mediterranean and other countries where there are social and personal values of suffering and social support for its expression.

In attempting to focus on a single disease entity known as depression one is confronted with a semantic problem. The term *depression* is used inconsistently in psychiatric literature. At various times and often in the same study it is used to refer to a mood, a disorder, and/or a symptom of a disorder. Some researchers stress a cognitive explanation of depression, and there are cognitive therapies that may equal or surpass biological/pharmacological interventions in speed and efficacy.

SCHIZOPHRENIA. Research on schizophrenia is hampered by a lack of consistent clarity of definition, particularly in regard to the boundaries of the disorder. Epidemiological, familial, twin, and adoption studies have been interpreted to suggest that a genetic factors is involved in schizophrenia. Although some work has shown a genetic or familial link in a few cases, no genetic link or common abnormality has been demonstrated or implicated in the vast majority of cases. Results involving genetic interpretations often are overstated, and important social/cultural information or explanations are ignored (Duster). Claims implicating various genes as causative of schizophrenia have been withdrawn.

Many findings of central nervous system (CNS) dysfunction appear in the literature, but none is specific or shared by all people who have the diagnosis of schizophrenia. Also, no symptom of schizophrenia is unique to that disorder; all the symptoms associated with or diagnostic of it appear in other disorders described by U.S. psychiatry

The World Health Organization's (WHO) study of schizophrenia (1979) found that schizophrenic patients with similar symptoms on initial evaluation whose disorders met strict diagnostic criteria showed marked variability in the two-year to five-year course and outcome within and across research centers. Patients in developing countries had a much more favorable course and outcome than did those in developed countries.

The disorder is chronic in the West, but this is not the case in the Third World, where the majority people with schizophrenia return to normal functioning (World Health Organization). It has been argued that schizophrenia is a culture-bound, Western *ethnic psychosis,* one specific to a single culture or ethnic group (Devereux). Cultural expectations may play a central role in chronicity; cultures that expect chronicity produce it, and those which expect recovery foster it. WHO data on the prevalence and incidence of schizophrenia in different cultures have been interpreted as establishing *broad* similarities across cultures (World Health Organization), suggesting similar processes, but similarities appear only when contextual evidence is excluded (Kleinman, 1988).

The assertion of the biological nature of psychiatric disorders in certain psychiatries appears to be a result of a patterned misinterpretation of cultural or social phenomena as biological. Those misinterpretations appear to be expressions of a professional *thought model,* a patterned way of thinking (Devereux). This model is a reflection of a folk form of biological essentialism borrowed from German psychiatry as well as a result of narrow biological training (Devereux; Kleinman, 1988).

Challenges to that theory include a resurgent psychoanalytic theory, feminist analytic theories, new psychologies, and cultural psychiatric studies. The biological model has dominated the field in the United States (Luhrman), but some movement away from it can be seen in the inclusion of a "Glossary of Culture-Bound Syndromes and Idioms of Distress" (Mezzich et al.) in DSM-IV (1994). However, cultural thinking has not been centrally present in the text of any edition of the DSM since 1980, when the classifications were intentionally fashioned to promote biological definitions of illness.

The Biological Perspective: Science or Folk Theory?

Researchers believe that the biological emphasis is a result of a long process of scientific advances. Studies of the development of psychiatries in anthropology, philosophy, and the history of medicine and psychiatry suggest otherwise. The biological view in psychiatry has its origins not in science but in the traditional folk culture of Germany and is at least a thousand years old (Gaines, 1992b). That view is an expression of a cultural theory that is a form of biological essentialism. That essentialism holds that the essence of self and other in terms of identity (ethnicity and kinship) and moral worth is determined by biology. *Blut* ("blood") is thought to be inherited and determines a person's identity, character, and moral worth.

The modern versions of this theory are the constructions of *genetic* and other somatic differences that are alleged to exist among people with specific disorders. In this view people who have mental illnesses are *different* kinds of people (Gaines, 1992a).

Some psychiatries, especially U.S., Scandinavian, and Russian, tended to follow in the footsteps of the nineteenth-century dean of German psychiatry, Wilhelm Griesinger, and his follower Emile Kraepelin, the founder of comparative psychiatry. Griesinger and Kraepelin after him in the early twentieth century asserted a biological basis for mental disorders. Kraepelin maintained Griesinger's dictum that "mental diseases are brain diseases," a notion borrowed from German (idealist) philosophy and French racial biology of the late 1700s (Gilman).

In first third of the twentieth century Carl Schneider, in the German materialist (and the Nazi racialist) tradition, advanced the notion of the "first rank symptoms" of schizophrenia. Those symptoms were pathognomic, or definitively diagnostic, of the disorder. Although many were influenced by that formulation in the United States and elsewhere, there was no analysis of the veracity of Schneider's theory until the 1980s when it was discerned that these symptoms were not unique to schizophrenia.

That biological model is dominant in contemporary U.S. psychiatry, although it competed with psychoanalytic and psychosocial perspectives before winning out in 1980 with the publication of DSM-III (Luhrman). Although the biological interpretation of mental illness is said to be based on empirical scientific evidence, its source in a foreign popular culture is apparent.

Social categories from the wider, lay culture—*races*—are construed in science as distinct biological groups, just as they were in German psychiatry and in South Africa. However, U.S. and German notions of race appear in different contexts and are applied to different experiences and thus are not the same folk biological theories. In the United States both the biological psychiatric perspective and the social categories are borrowed and reworked historical cultural constructions, rather than modern advances in psychiatric science.

CULTURE AND THE CLASSIFICATION OF MADNESS. Professional psychiatric classifications of diseases (nosologies), along with the diseases that are classified, change over time. Those changes are seen in psychiatric traditions as improvements and progress that may be viewed in evolutionary terms; that is, Western classifications are different from others because they are more *evolved.*

Changes in classification often represent shifts in assumptions about mental disorders that are products of ideological conflicts, competing explanations for which no data or ambiguous data exist. Rather than pointing in any direction, those changes simply show shifts in dominant theoretical models or political ideologies. They also may represent the imposition of foreign formulations and institutions (Gaines, 1992a).

Terms are deleted or reintroduced, but such actions do not indicate advances. Neurosis appeared in the disease classifications of U.S. psychiatry from 1952 to 1980 but was deleted from the 1980 and later classifications. These classifications are biological in orientation and thus exclude clearly psychogenic illness terms such as neurosis despite ample clinical evidence of their existence. French and other psychiatries continue to use the term and diagnose the illness. There are also "reconstructions" (old terms used for new disorders) in professional psychiatry, such as neurasthenia applied to chronic fatigue syndrome in the United States.

Interpretive analyses of U.S. psychiatric classifications reveal the underlying culture-, gender-, and age-specific viewpoint (Germanic Protestant, male, adult) from which U.S. nosologies are created. Behavioral or ideational differences perceived in others who vary in age, culture, or gender from the ideal are interpreted as a lack of (self-) control expressed as pathology such as depressive illness or psychotic conditions and personality disorders. That deficit is perceived as being caused by differences in group (age, "racial," gender) biology (Gaines, 1992b) i.e., local biology, culturally constituted biologies (Gaines, 1998c). This suggests that classifications are largely a cultural psychological discursive formations, not a classification of naturally appearing diseases (Gaines, 1992b).

Biological essentialism may be seen to act as a psychological defense because it allows one to claim that the afflicted are biogenetically different from *normals.* That is,

members of the psychiatric profession, it is presumed, are normal and thus could not have the same biological defects as does a mental patient (Devereux).

PHARMACOLOGY AND "ETHNIC BIOLOGY." Biological essentialism can be seen in research in U.S. psychiatry that focuses on the study of ethnicity and psychopharmacology (called *ethnic psychobiology,* an oxymoron). Regarded as cutting-edge research, those studies recognize *ethnic differences* in biochemistry. Findings suggest that different doses of particular agents are appropriate for members of different ethnic groups with the same psychiatric disorder. This research takes as its units of research members of *ethnic or racial* groups. Biomedicine assumes that these terms are synonymous and refer to genetically distinct groups. The allegedly distinct biological ("racial") groups that appear commonly in such research are *Hispanics* (a language group), *Asians* (a geographical designation), *blacks* (a color), *Native Americans* (a geographical designation), and *whites* or *Caucasians* (a color or geographical designation, respectively). Those groups are in reality social categories that were created by a particular culture in the last two centuries and adopted by health research. The *racial* designations and the biological theory underlying them are neither universal nor biological.

Research that assumes that members in each category are biologically defined assumes that the members of each category are identical, or nearly so, in genetic composition; what is true of one person belonging to a *race* is generalizable to all members of the putative group. This perspective has several flaws.

The notion of race varies from culture to culture and is absent from most cultures in the present time; it was absent from all cultures in the past. Other modern sciences have different notions of the number and membership of human races. Japanese science considers the Japanese, Koreans, Chinese, and Indians to be members of different *races,* and the Germanic theory separates Germans from all other *white* groups on genetic bases. One may ask with reference to U.S. research, Why is one *racial* theory accepted whereas others are rejected?

This research ignores the substantial variations in doses seen and clinically "proved" to be effective within so-called races, including Europeans, in the practice of different national psychiatries. For example, much larger doses of antipsychotics are needed for *white* U.S. patients than for French, English, and German patients. If those patients all belonged to the same race, that variation would not occur in doses that are predicated on *racial* affiliation.

Biology is assumed to be the basis of physical and genetic distinctiveness and to be stable over time. However, physical anthropology and evolutionary biology have demonstrated that human biology has a common source (Africa) and is extremely plastic. That plasticity is responsible for the great morphological diversification of humankind that has occurred in the last 100,000 years (Gould).

These findings contradict the ideas of biological distinctiveness and constancy over time that the notion of race requires. In contrast, pharmacological work framed in racial/biological terms reflects the biological essentialism noted above. It serves to maintain the cultural construction of race and biological explanations of social and cultural differences. *Racial* biology is thus a form of what has been called local biology (Gaines, 1992a, 1998c).

Professional Ethnopsychiatry around the World

CHINESE PSYCHIATRY. Chinese psychiatry originally was borrowed from the West but also drew from classical Chinese medicine (Kleinman, 1988; Leslie). This suggests that psychiatry can be borrowed and adopted by a culture.

Because it represents China's understandings of Western notions of mental disorders, a number of Chinese disorders are unknown elsewhere. *Qi-gong* reaction is an acute episode that follows overly intense involvement in the *Qi-gong* exercises and breathing practices that are used to promote health and long life. Neither the condition nor the related health practice is known to U.S. psychiatry.

Shenjing shuairuo ("neurasthenia") is the most common psychiatric diagnosis in Chinese psychiatry (Kleinman, 1988; Mezzich et al.) and in areas within the sphere of Chinese influence. The label was borrowed from the United States, where the term was developed over a century ago but fell into disuse, as did the conception of disease it labeled (Kleinman, 1988).

Koro is an acute episodic event characterized by intense concern and anxiety about the withdrawal of the external genitalia into the body; it is related to the Chinese cultural belief that the genitals of the dead recede into the body. *Koro* is found in China and Southeast Asia, where there have been large epidemics. Western psychiatrists, ignorant about Chinese folk beliefs, might see *koro* as a psychosis or panic disorder.

In Chinese psychiatry psychological explanations are not regarded as sensible explanations of suffering (Kleinman, 1980, 1988; Kleinman and Good; Leslie). Patients present somatic (bodily) symptoms such as *koro* almost exclusively. Optimal intervention is somatic as well, often involving herbal medicines to enhance or unblock the passage of vital

energies throughout the body. The physiological conception of mental phenomena is related to notions in India, where in the traditional Ayurvedic psychiatric theory mental phenomena are held to be expressions of bodily states, not psychological dynamics in the Western sense. Indian professional psychiatry is entirely somatopsychic (Leslie; Leslie and Young).

JAPANESE PSYCHIATRY. In Japanese psychiatry two important disorders are widely known in practice and in society: *shinkeishitsu* and *taijin kyofusho.* Both are considered social phobias in the West.

Taijin kyofusho presents as extreme concern over actions or personal hygiene that could be disturbing or disrespectful to others. *Shinkeishitu* is characterized by shyness, tension in social relations, feelings of inferiority, and fear of failure in maintaining appropriate interactions. It is treated successfully by Morita psychotherapy, a blend of Buddhism, German psychiatry, and understandings of Japanese life that is administered on an outpatient basis or in hospitals dedicated to the treatment of *shinkeishitu.* Inpatient treatments for this and most other disorders serious enough to warrant hospitalization are much longer than they are in the United States. This is expected by patients, who see the hospital as a second home and the psychiatrist as a teacher (Lock; Gaines, 1992a). There are a number of psychotherapies in Japan for which there are equivalents of neither the disorders nor the therapies in the West (Reynolds).

Several new disorders in Japanese psychiatry have been recognized by the medical anthropologist Margaret Lock (1980), including housewife syndrome and school refusal syndrome. Both relate to pressures for achievement and success and the relationship of the individual to the group in Japanese society and culture. In the Chinese and Japanese cases the importance of harmony, right role performance, and the social nature of the person is clear.

GERMAN PSYCHIATRY. In Germany research has demonstrated a striking parallel between lay beliefs about mental illness and those of mental health professionals (Townsend). In that country lay and professional segments believe that there are two basic types of mental illness: *Gemütskrankheit* (emotional sickness), which is transient and caused by outside events, and *Geisteskrankheit* (mental sickness), which is said to be inherited, chronic, and not amenable to treatment.

Since the twentieth century German psychiatry has attempted to formulate biological notions of serious mental illness and has influenced many other psychiatric systems, especially that of the United States. Psychiatry makes a sharp distinction between the ill and the well that strongly affects diagnosis and treatment. Mental patients are *different* kinds of people; they are biologically defective. Many family studies focusing on the inheritance of mental disorders have been done in Germany and Scandinavia (Duster; Townsend).

This biological notion was developed in the nineteenth century and was central to the mental hygiene movement of the Third Reich. Because those people were biologically defective, they could not be helped and were a burden to the *normal,* and their lives thus were *not worth living.* That ideology led to the killing of tens of thousands of mentally ill and retarded patients in a process that was the forerunner of the Holocaust.

That ideology also asserted that certain groups of people—so-called races (e.g., Jews, Slavs, Arabs, Gypsies, Celts, Latins, Africans, and people from the East)—although not insane, were nonetheless defective and represented a potential threat. In the German ideology defective and dangerous meant non-German.

SOVIET PSYCHIATRY. Before the dissolution of the Soviet Union Russian psychiatric practice was strongly influenced by German psychiatry and its biological approach. Also influenced by Pavlov, Soviet psychiatry banned psychological and psychoanalytic approaches. Marxist ideology attributed madness and other problems to the evils of nonsocialist economic systems. Because individuals manifested mental disturbances long after the revolution, the causes had to be personal and internal, not social or economic. Hence, dissent was seen as pathology.

Soviet psychiatry described a unique form of schizophrenia—creeping schizophrenia—whose symptoms were usually nonconformity and dislike of expected work duties. Diagnosis could lead to hospitalization and the administration of powerful drugs. The opening of the Soviet Union to the West included a new acceptance of psychoanalytic theory (Mitchell and Black).

FRENCH PSYCHIATRY. French psychiatry identifies and treats several disorders that are not known in the United States or elsewhere. The practice of psychiatry, like the society around it, is hierarchical and authoritarian (Gaines, 1992a). It developed a nonphysical notion of mental disorders in the late 1790s and therefore did not adopt German biological theorizing entirely despite the neurologist Jean-Martin Charcot's organic approach and the rise of hereditarianism. The latter helped the French psychiatric profession gain prominence and authority over the treatment of mental illness (Dowbiggin). French psychiatry historically has been much more intimately connected with the state than have other psychiatric establishments in the West (Dowbiggin; Foucault).

A number of conditions exist in France that have no equivalents in other countries, including *spasmophilie* (literally "prone to spasms" but referring to a variety of vague, nonspecific complaints that include tiredness, loss of appetite, and various somatic complaints) and *triste* (or *fatigué*) *tout le temps* (chronic sadness or tiredness as a result of a great loss or disappointment). In those formulations French ethnopsychiatry expresses its culture's notions of the burden and exquisite sadness of life (Gaines and Farmer; Marsella and White; Gaines, 1991). French psychotherapies aim not at change in but at recognition and acceptance of a historicized self.

French psychiatry has unique historical concerns, such as passion and obsession expressed as monomania (fixed ideas). It was in France that the notion of the toxic nature of the asylum developed.

Culture and Context: Beyond Biological Thinking

Sociologists have long considered social contexts in Western industrial societies as affecting people's psychological status. Classic studies suggested that there is a relationship between social class position, urban dwelling, and an increased incidence of certain forms of mental illness. Although the lower classes have a higher frequency of some illnesses, it was found that the upper classes have a higher frequency of others.

Researchers with anthropological expertise implicated high levels of social disorganization as contributing to increases in the incidence of mental illness. People subject to extreme pressures, such as discrimination and other forms of oppression, that limited their life chances would have less stable environments and therefore would be more vulnerable to psychological afflictions. It also is known that U.S. psychiatry commonly misdiagnoses members of minority groups, attributing serious mental illness to individuals largely on the basis of ethnic group and gender group membership rather than on the basis of symptoms. Thus, the same symptoms in members of different ethnic groups or genders produce different diagnoses and prognoses (Gaines, 1992a, 1992b; Kleinman, 1988; Littlewood and Lipsedge).

Related to social disorganization are the consequences of personal and group traumas such as accidents and criminal victimization (assault, rape, abuse) as well as war, state-sponsored violence and terror, racism, genocide and ethnocide, forced migration, epidemics, poverty, and starvation. Native Americans and African Americans have been the subjects of pogroms, genocide, and terrorism as well as abuse, discrimination, and neglect. It is difficult to deny that those experiences have had a considerable psychological impact.

Stress, a notion derived from World War II and modeled on combat experiences, is relevant in the United States for dispossessed ethnic groups and for veterans, as can be seen in the recent formulation of posttraumatic stress disorder (PTSD) (Young, 1995), which combines trauma and stress with ideas of the unconscious mind that are not found in most other cultures.

The notion of universal biological mental diseases limits the understanding of the known variety of detrimental as well as beneficial sociocultural conditions. It leads observers to see defective persons instead of social inequalities and to seek biological vulnerabilities instead of hopelessness born of despair or the horrors of war. It ignores conditions that are responses to noxious circumstances. As an example, there has been a move to redefine PTSD as a biological defect rather than a reaction to war in veterans and to persecution and torture among Latin American immigrants to the United States.

Biological reductionism cannot explain the appearance of mental disorders across cultures. Although all people are human, they do not have the same ways of living, feeling, thinking, and behaving. To argue that pathology is purely biological is to contradict the fact that normal behavior, although supported by biology, is not determined by it.

Standards of normality vary from culture to culture; what is sane in one culture is insane in another. There is no evidence of a biological basis for the heterogeneity of conceptions of normality and abnormality. The advances offered by biological psychiatry are considerably less than advertised: *Modern* views of the genetics and biology of madness recapitulate theories of eugenics and hereditarianism from the nineteenth century (Carlson; Dowbiggin; Foucault; Gaines, 1992b; Gould) and earlier.

Professional Psychiatries: Ethical Implications

Historical and cross-cultural studies of professional psychiatries suggest that each one is a cultural construction, not a system of dispassionate discernment of natural psychopathologies; there are psychiatries, not one psychiatry. The application of a single theory or practice in a culturally diverse world leads to an ethical question: Are there negative consequences of the application of one culture's psychological medicine as a standard of normality in the evaluation and treatment of cultural others, including immigrants (Gaines, 1998a)?

Bioethics in the United States has grown out of concerns involving personal autonomy (a cultural value), experimentation (including that in the Third Reich), technological change, and informed consent but also out of a

cultural context that gives meaning to those concerns. Bioethicists sometimes excludes social, political, and cultural issues such as "race" and gender, asserting that those things lie outside its domain or that cultural others are "really" the same (Midgley). Such assertions ignore more than a century of cross-cultural research demonstrating the contrary. In much the same way biological psychiatry excludes cross-cultural and historical research that contradicts the current version of psychiatric reality. Thus, it is able to operate in a closed domain that ignores complex historical and cultural realities.

A universalistic bioethics that is beyond culture is illogical. What is ethical in one context is unethical in another. Telling a patient the diagnosis in Japan is unethical, not telling in the United States is (now) unethical; leaving a patient uninformed about a disorder or the rationale for treatment is normal and ethical in Japanese and Italian psychiatry but not in U.S. psychiatry.

Biological distinctions that are reified as *natural,* such as the concept of race in the United States, have negative consequences. Those distinctions produce unequal treatment, disproportionate institutionalization, and higher morbidity and mortality. Adherents of those social views do not address social justice.

Nearly a thousand years ago in Islamic medical ethics physicians were enjoined to be social activists and advocate better living conditions for their community members. That ideology potentially opens the door to change and adaptation as well as social justice. The need to integrate the importance of cultural and social differences into theory and practice while maintaining appropriate levels of care in the face of increasing cultural diversity is the moral dilemma of modern Western and Eastern professional psychiatries in a multicultural, postmodern world.

III. ISSUES IN DIAGNOSIS

Diagnosis of mental or physical illness is the clinician's determination of a clinical state or disease. However, as used in ordinary discourse, *diagnosis* is both a noun, signifying or denoting a particular clinical state, as well as a verb, describing an activity or process of determining diseases and clinical states. Clinicians ask "What is the patient's diagnosis?" as well as "What is your approach to diagnosis?" Considerations of the denotative aspects of diagnosis implicate the general classification and nomenclature of disorders or diseases (nosology), while the notion of diagnosis as a clinical process implicates various normative considerations of diagnostic practice—that is, considerations of fair, valid, and elegant diagnostic procedure. Ethical issues concerning the diagnosis of mental illness concern all of these permutations.

Mental Illness and the Self-Illness Distinction

The ethical issues involved in the diagnosis of mental illness can be considered as closely related to, perhaps even derivatives of, the enigmatic character of mental illness itself. At the core of this enigmatic character is the relation between mental illness and the self. In Western societies, sufferers of *physical* illnesses, diseases, or injuries can almost always distinguish their sense of self (the sense of who they are, the ownership and experiential domain of their unique mental life) from their affliction. For instance, a patient may have cancer, heart disease, a brain tumor, a cold, or a broken leg, but these conditions are over and apart from who the patient is, her holistic identity as a person. Ordinary discourse about physical illnesses often betrays this ego-alien character, where common linguistic metaphors portray disease as a malign force from outside the self: "She was struck down by cancer." "He had a heart attack."

Through their character as afflictions of psychological experience, this phenomenal distinction between self and illness is blurred in the case of mental disorders. Consider a few examples. The experience of depression saturates a patient's perception of herself, where the depth of her sadness and self-doubt overwhelms her sense of competence and worth. A man's schizophrenia wildly transforms his views of and relations with others and the world. Even

amidst recovery from a drug dependency, the addict longs for the pleasure and tranquillity of intoxication. As these examples of mental illness illustrate, the afflicted may be unable to distinguish features of the self from features of illness (e.g., "I am depressed," not "I have depression"). Further, the mentally ill person may even value, or seek to preserve, some features of the illness, as in the case of the addict noted above, or, as another example, the person with bipolar disorder (manic-depressive illness) seeking the euphoria, confidence, and vigor of mania.

This weakening or loss of the self/illness distinction sets the stage for other ambiguities, and with them, a host of actual and potential ethical problems concerning the diagnosis of mental disorders. The intermingling of the personal self and the manifestations of mental illness confound Western cultural assumptions about the sick role. Parsons's notion of the sick role involved a forgiving of the sick individual's usual responsibilities; in Western societies the physically-ill person is thought incapable of the full range of her usual responsibilities, so subsequently, such incapacities are excused. Because of the difficulties in distinguishing aspects of the self from the manifestations of mental illness, this forgiving attitude toward the sick is often absent in the case of mental illness. Moreover, the often incomprehensible, annoying, or bizarre behavior of the severely mentally ill may generate fear in observers. These and other factors conspire to generate the most prominent manifestation of the sick-role confound: stigma, the vilification of "the mad."

Social stigma adds the additional burden of shame, humiliation, and exclusion to the ordinary suffering of mental illness, a burden by and large not shared by individuals with physical illnesses. Stigma subsequently ups the ethical ante in diagnosis, as a mere diagnosis of mental illness often has stigma-driven adverse social consequences, consequences relatively independent of the features of the illness itself. For instance, stigma may manifest itself through insurance or employment discrimination, harsh attitudes toward the homeless mentally ill, unfounded generalizations about the mentally ill individual's capacities, or the avoidance of treatment for mental illness.

Stigmatization of what is today called *mental illness* has been present throughout the recorded history of madness (Porter). At the beginning of the twenty-first century, stigmatizing attitudes toward the mentally ill often are justified by the view that the manifestations of mental disorders are willful and responsible, and the mentally ill fully choose their misery, if indeed they are miserable at all. The most prolific spokesperson for this kind of view is Thomas Szasz, a psychiatrist who since the early 1960s has argued that mental illness is a metaphorical concept that functions to regulate deviant behavior outside the usual sociocultural channels, such as the law, education, and religion (Szasz). For Szasz and like-minded authors, because psychiatric authority regulates deviance outside these usual channels in free societies, psychiatric practice undermines civil liberties on the one hand, and the responsible conduct of citizens, on the other. Psychiatric diagnosis, then, is an instrument of this subverted political authority.

Because of the aforementioned ambiguities concerning responsibility and the self/illness distinction, it is easy to recognize the general moral implications of either accepting or rejecting the Szaszian critique. If one accepts the Szasz position uncritically, one risks building a callous, uncaring society toward what could be catastrophic, with miserable illnesses affecting large numbers of people. If one does not take Szasz seriously, one risks stripping the *mentally ill* of their morality and their autonomy, as well as their unique value as individuals through reducing them to mere expressions of psychopathology or disease states. On the face of it, both these extremes seem unacceptable, so more recent work on the ethics of psychiatric diagnosis has focused on rethinking this problem or seeking a middle ground between conceiving the mentally ill as fully autonomous, responsible actors versus conceiving them as helpless, dependent incompetents.

Scientific Classification and Prudent Practice

Perhaps most influential in the scientific classification of mental illness has been the efforts of the American Psychiatric Association's committees on diagnosis to qualify and stipulate their diagnostic categories in ways that, in the ideal, serve to both constrain mental disorder diagnosis and validate it. This was not always the case. In the early twentieth century, official diagnostic classifications of mental disorders were primarily aimed for hospital registries and the accounting of patient flow. Only with the publication of the first edition of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (DSM) in 1952 was diagnostic classification intended as a tool of science and good clinical treatment. By the third edition (DSM-III) in 1980, and continuing to the present fourth edition (DSM-IV, 1994), the DSM's intentions have broadened even further (Wallace). Since DSM-III, the manuals have resolved to meet a number of objectives or goals:

1. To provide a useful aid to clinical diagnostic practice;
2. To provide a scientifically sound classification of psychopathology for mental health research;
3. To provide an enumerated coding system for record-keeping and billing purposes;

4. To provide a comprehensible nomenclature for education efforts; and, of particular interest for this discussion;
5. To provide an extensive introduction to the manual that specifies prudent diagnostic practice and use of the manual.

The capability of this or any other diagnostic manual to accomplish such an ambitious range of objectives has been a ongoing source of debate. Subsequently, ethics-oriented criticisms of the DSM editions often betray disagreement over the particular balance struck between the various objectives (Sadler). For instance, some critics have noted that enumerated, rigorously-defined and scientifically-tested diagnostic labels oversimplify the complex condition of mental illness and impede the ill from engaging in discussions about themselves and speaking on their own behalf (e.g., Kovel). On the other hand, other critics note that the DSMs are excessively tied to clinical diagnostic traditions and are not scientifically rigorous enough (summarized in Sadler, Hulgus, and Agich). The ethical implication here is that scientifically-compromised diagnostic categories undermine the moral justifications for interventions like involuntary hospitalization or involuntary treatment, or indeed, treatment at all. As a third example, commentators have noted tensions between the values of clinical utility and clinician acceptability in the DSMs versus the efforts to have DSM categories fully reflect rigorous scientific values like validity and reliability (Sadler, Hulgus, and Agich).

Diagnosis and Mental Health Pluralism

As might be expected under the conditions of the blurred self/illness distinction, mental illness has been subject to an extraordinary range of competing and contrasting formulations or understandings. Until the recent ascent of alternative medicine, physical medicine has enjoyed relatively little competition from rival clinical practices based upon non-biomedical explanatory models. This, however, has not been the case for mental illness, as the woes of the psyche have a long history of ministrations from diverse healing and/or helping traditions. What psychiatrists call *mental illness* may be conceived by nonmedical practitioners as spiritual crises, or as secular problems in living, or the result of supernatural forces, or irregularities in various moral, dietary, lifestyle, or other habits. Analogously, ministration to such psychic woes is offered by not just physicians, but pastors or spiritual advisors, hundreds of varieties of lay and professional counselors and psychotherapists, folk healers, alternative clinicians, family, neighbors, and friends. Any effort, then, to provide a common nomenclature for mental distresses is bound to generate disagreement, and the existence of such diverse resources is bound to generate controversy over the relative value of each.

In this sense, then, any mental illness diagnosis (in the broadest sense) under any system of clinical thought, medical or otherwise, can be construed as having an ideological character. Hence, for instance, biomedical psychiatry's predilection for prescribing pharmaceuticals for DSM-diagnosed mental disorders is criticized as the capitalist commodification of everyday life, while interpersonal narrative-based psychotherapies may be praised as more communitarian in their political alliances. Diagnostic practices, if they lend themselves to one or the other ideology, then, are similarly implicated. The DSM approach to this problem has been to develop inclusive and diverse committees in the construction of the DSMs, and invite *outsider* input so that the DSM categories reflect some measure of such pluralistic practices, and hence are open to a range of therapeutic options (Frances, First, and Pincus). The World Health Association's *International Classification of Diseases—ICD-10 Classification of Mental and Behavioural Disorders* (ICD) has sought to provide a common language for mental health practices all over the world, and in developing its classification solicits input from all of its member countries (WHO). As such, its ambitions as a diagnostic manual are necessarily more modest, focusing on providing an enumerated coding for record-keeping and billing, preferring fewer numbers of categories, and adhering more closely to practice conventions than the more innovative, and American-regional, DSM manuals. Nonetheless, the DSM manuals and the ICD manuals have a close relationship, as the DSM is obligated by international treaty to provide compatible diagnostic categories for the ICD manual, and in recent decades the development of each manual has been closely coordinated with the other.

Even within the biomedical paradigm, however, mental health practice (psychiatry, clinical psychology, psychiatric social work, and related fields) has been characterized by a diversity of theoretical formulations, empirical-scientific approaches, and conventions of practice. The approach of the American Psychiatric Association's DSM effort, along with the ICD classification of mental disorders, has been to work toward a diagnostic classification which minimizes, even perhaps eliminates, theoretical assumptions about the causes of mental illness. Moreover, with the DSM-IV effort, the process has included assembling comprehensive scientific literature reviews, a *consensus scholar* approach in interpreting aggregated studies, and extensive and detailed documentation of the developmental procedures and findings used in constructing the manual. With the addition of extensive

field trials (empirical studies) of proposed or revised diagnostic categories, the DSM process aims to continuously improve the scientific validity and reliability of its diagnostic classification. Nevertheless, many non-psychiatric mental health practitioners lament having their own practicable alternatives and may view the DSM/ICD efforts as a *de facto* hegemonic effort by psychiatrists to dominate the mental health field (Beutler and Malik).

Inspired by the problem of adequately circumscribing psychiatric diagnosis (e.g., assuring that people diagnosed are truly ill, and those not so diagnosed are truly well), significant efforts have been made since DSM-III to provide a rigorous definition of mental disorder. This effort is part of the aforementioned goal to recommend good diagnostic practices in the DSM introductory material. Such definitions of mental disorder, and the concepts underlying them, were developed in the introductions to DSM-III and later editions. Since then, such attempts at defining mental illness have been subject to heated debate, as discussed by K. W. M. Fulford in his article "Mental Illness: I. Conceptions of Mental Illness" in this volume.

Preserving the Dignity of the Self

While short of providing explicit moral and aesthetic rules for the proper conduct of psychiatric diagnosis, the introductions to the DSM manuals do prescribe, and proscribe, clinician conduct in significant ways, though these guidelines for use of the DSMs are thought by some to be inconsistently read and heeded. For instance, recent editions of the manuals have included explicit categories and codes indicating diagnostic uncertainty; have used a *multiaxial* diagnostic system that provides for diagnosis of not just mental illness, but other factors like complicating physical illnesses, environmental stressors, and the global adaptive function of the individual; and have provided a *cautionary statement* recommending against the use of DSM categories in forensic or other nonclinical settings. At question is the efficacy of these efforts to facilitate a thoughtful and responsible diagnostic practice; critics claim that despite these efforts, the DSM is still used in a "cookbook" fashion and the individual under diagnostic evaluation is still likely to be labeled narrowly and conceived simplistically (discussed by various contributors in Sadler).

Amidst these clinician-generated efforts to provide fair and scientifically valid diagnoses, the diagnosed and the families of the mentally ill have increasingly organized to protect themselves against what they view often as stigma-generating diagnostic pigeonholing and the diminution of their sense of self (Luhrmann). This movement is most concretely manifested in the terms the mentally ill increasingly use to refer to themselves: no longer *patients,* but now often *clients, consumers, users,* and even *psychiatric survivors* of mental health services. At present the mentally ill have little to no input into how their conditions are classified in systems like the DSM and ICD or how diagnostic criteria are phrased, nor do they have much of a forum for their views about prudent diagnostic practices (Sadler). How much influence this advocacy on behalf of the mentally ill will have on mainstream mental health diagnosis and practice remains to be seen.

The issue of the autonomy of the mentally ill and the ethics of diagnosis have collided in recent controversies over the handling of consent in clinical research settings. The issues were crystallized at the end of the 1990s by a debate in the United States over the National Bioethics Advisory Commission's (NBAC) report addressing the issue of protecting human subjects, as well as protecting research participation, with subjects with impaired decision-making capacity (Roberts and Roberts). Driven by concerns over the allegedly vulnerable but needy mental illness population, the NBAC recommended a series of protections that, from the research community's perspective, would make the clinical research enterprise a burden on researchers and subject-participants: these recommendations would make consent procedures and participation arduous, and create the risk of denying this population access to research participation, subsequently reducing the social benefits of the research. A significant component to this debate was the degree to which any diagnosis of mental disorder qualifies the potential subject as having an *impaired decision-making capacity.*

Cross-Cultural Validity

In the context of economic globalization and increasing cultural interchange, recent thought about the validity of mental disorder diagnosis has addressed the question of the validity of mental disorder diagnosis across cultures. Does the DSM-IV diagnosis of Schizophrenia apply equally to a white Anglo-Saxon Protestant from Normal, Illinois as to a Bantu African tribesman? What about Obsessive-Compulsive Personality Disorder or Anorexia Nervosa?

The issue of cross-cultural validity of mental disorder diagnosis has three general ethical ramifications. The first ramification concerns cultural assumptions of normality. The second concerns the practical matter of accurate detection of psychopathology in multicultural settings. The third ramification concerns which values should prevail in judgments concerning health or psychopathology.

As Dona Davis has noted, the sexual performance norms assumed by, for instance, DSM-IV sexual disorders

do not apply to cultures where *sexual performance* as a cultural construct does not exist. For instance, how can someone have *anorgasmia* or *premature ejaculation* where there is no expectation of female orgasm? (Davis). The normative assumptions (taken-for granted beliefs about what is normal, adaptive, or acceptable) underlying diagnostic systems like the DSM or ICD classifications can pose dilemmas for clinicians working in diverse settings, where, for instance, couples of mixed ethnic origin may have clashes over acceptable and unacceptable behaviors. Normative assumptions underlying mental disorder diagnoses push the clinician into taking culturally-relative moral stands related to cultural assumptions, and more subtly, may mask the very cultural assumptions and beliefs that effective treatment must make explicit.

As a second example, mental disorders (like anorexia nervosa) that are closely conceived within cultural normative assumptions and expectations may not occur or may manifest themselves differently in other cultures. Diagnostic conceptions or criteria that are skewed toward the assumptions and values of Western industrialized cultures may have false-negative and false-positive diagnostic implications in practice. If Third World clinicians are not looking for anorexia nervosa, if indeed it occurs, they will likely miss an authentic disorder (false negative diagnosis). If Western clinicians are looking for anorexia nervosa in Third World populations where it is not endemic, they may nevertheless find cases who are not truly ill (false-positive diagnosis). Culturally invalid mental disorder diagnosis is then an ethical problem because of harms posed by the systematic potential for false-negative and false-positive diagnosis.

A third ethical ramification of cross-cultural validity concerns how mental phenomena are valued. Michael Jackson and K.W.M. Fulford present a case of a man who meets standard examination criteria for psychosis with the exception that his experiences are adaptive, and have enhanced his functioning and life satisfaction. M. Fakhr El-Islam notes that psychosis can be interpreted in fundamentalist Islamic cultures as a prophet's response to spiritual or religious stagnation, and the psychotic symptoms can confer positively valued mystical insights. How mental *symptoms* are valued have important implications on whether such phenomena are truly pathological.

Conclusion

Because of the ambiguity between mental illness and the self, mental illness poses a complex range of ethical challenges, whether one is a scientist engaged in the study of these conditions, a person afflicted with mental illness, or a clinician helping an ill individual. Ethical concerns arise from numerous directions, from the mere act of making a diagnosis, to considering the social impact of diagnosis, to the applicability of diagnosis across cultures.

MENTAL INSTITUTIONS, COMMITMENT TO

• • •

Throughout the world there are legal mechanisms by which mentally ill persons can be sent to psychiatric hospitals even when they do not wish to go (Appelbaum). In the United States this sometimes is done through the criminal justice system: A person may be judged incompetent to stand trial for a crime because of mental illness or may be tried for a crime and found not guilty by reason of insanity and then committed to an institution for mentally ill criminal offenders. The more common type of commitment is civil, and usually no criminal offense is involved: A person is judged to require hospitalization because of his or her mental condition but does not consent to it, but if certain legal criteria are fulfilled, that person may be hospitalized against his or her will. Commitment is a legal process and often is discussed mainly in terms of its case and statutory legal history (Wexler). This entry discusses important ethical issues that underlie the process of civil commitment.

Commitment raises serious ethical concerns. It involves depriving persons of their freedom for days, weeks, or longer, usually by incarcerating them in a locked psychiatric facility. Commitment is one of the ethically most serious actions in which psychiatrists engage. However, neither the process of commitment nor its ethical justification (or the related issue of forced treatment) is mentioned in the American Psychiatric Association's extensive handbook on psychiatric ethics (American Psychiatric Association, 2001b).

In most states this violation of a person's civil liberties can be carried out initially on an *emergency* basis on the strength of one physician's signature on the appropriate form. Most people agree that it is preferable that a psychiatrist be the initial committing physician, but there are too few psychiatrists in many rural areas for this usually to be mandated by law.

After the emergency commitment form is signed, the person who is to be committed is taken to the nearest locked psychiatric facility authorized to receive committed persons. Medical personnel there usually have the authority to question the appropriateness of the commitment and even to refuse to detain the person. In most states, under modern law, a probable-cause judicial hearing is held within two to three working days in an appropriate local court to determine the justifiability of continued detainment.

The vast majority of admissions to psychiatric hospitals, however, are voluntary and do not involve the commitment process. A small minority of voluntary admissions, however, result from persons being told that they will be committed if they do not enter the hospital "voluntarily." There seems to be nothing inherently unethical about giving a person who otherwise would be committed the opportunity to avoid the commitment process in that way, assuming that the planned commitment is ethically justified. It seems clear, however, that these persons have not entered the hospital entirely voluntarily. In addition, it would be prima facie unethical for a physician to use this process deceptively by manipulating a person into entering a hospital by threatening a commitment that in fact would not be carried out.

Legal Criteria for Commitment

Both within and outside psychiatry there is dispute about the commitment criteria that should be written into state statutes. Statutory language varies from state to state (Arthur et al.). All U.S. state statutes stipulate that to be committed a person must be mentally ill, although this concept is defined variously. The existing continuum of positions is based on the width or narrowness of the additional statutory commitment criteria. (For an excellent discussion of one state's commitment laws see Behnke, Winick, and Perez.)

The broadest additional criteria are advocated by those who think that physicians should be able to commit anyone whom they sincerely believe would profit from commitment. At one time many states had statutes with this breadth. Arizona law, for example, as recently as 1981 allowed persons to be detained if they were "mentally ill and in need of supervision, care or treatment" (Wexler, p. 74). Criteria with this breadth seem unsupportable to most

commentators. For example, many persons with a moderate degree of depression are mentally ill in that they satisfy the criteria in the *Diagnostic and Statistical Manual, Fourth Edition* (DSM- IV) (American Psychiatric Association, 1994) for having a psychiatric disorder, and treatment almost certainly would make them feel better. No one, however, thinks that in most cases they should be forced into a psychiatric hospital if they do not wish to go. Thus, more than *mental illness* is necessary to justify commitment.

A narrower position is taken by many psychiatrists (see Chodoff for a classic description of this position and Buchanan and Brock for clear arguments supporting it). In addition to requiring that a person be mentally ill, supporters of this position advocate a criterion stipulating that that person be *gravely disabled* or manifest a *serious disruption of functioning* as a result of the mental illness. Being physically dangerous to oneself (suicidal) or to others (homicidal or physically threatening) represents one type of serious disruption of functioning but not the only one. The behavioral and social disorganization shown by many manic persons, for example, although often not immediately physically threatening to themselves or to others, may in the long run cause those persons serious social and financial harm. Under a *serious disruption* criterion many of those individuals could be committed.

A narrower position still is that advocated by many civil libertarians and some psychiatrists (American Bar Association). A diagnosis of mental illness is required, and there must be a high probability that because of the mental illness a person is a serious physical threat to himself or herself or to others. A minority in this group would restrict the criterion further and require that there be good evidence of recent behavior toward oneself or others that was in fact physically harmful, but most believe that evidence of strong threats of physical harm is sufficient. Most also believe that dangerousness toward oneself can be evidenced not only by threats of suicide but also by extreme self-neglect so that, for example, starvation or untreated serious disease can constitute an immediate threat. However, without the threat of imminent dangerousness of some kind, commitment would not be allowed.

The position at the far end of the continuum is taken by those who believe that psychiatric commitment is never ethically justified and thus that there should be no commitment criteria. Thomas Szasz, a psychiatrist, has been the foremost spokesperson for this position. Szasz believes that the concept of mental illness is mythical and argues that those who manifest what others regard as the symptoms of mental illness should be judged only by the standards of criminal law: If they have broken a law, they may be arrested or otherwise constrained; if they have not, their freedom should be preserved. Szasz believes that commitment is based on a false theory that "medicalizes" deviant behavior into illness and that psychiatrists who commit persons become unwitting arms of the criminal justice system.

For several reasons Szasz's position has not been persuasive to many people inside or outside psychiatry, including most civil libertarians. First, most scholars feel that some psychological conditions satisfy the criteria of a definition of *illness* (Gert, Culver, and Clouser, Margolis) and that Szasz's position has serious theoretical problems (Moore, Culver, and Gert) that he has not addressed. Second and more important, most believe that paternalistic interventions of the type that commitment usually represents are at least sometimes ethically justified.

The principal and enduring tension is between those who hold the two middle positions described above. Some states have commitment statutes closer to one, and some have statutes closer to the other. Those who advocate a broader criterion believe that dangerousness to oneself and others is only one of many manifestations of severe mental illness and that it is cruel and theoretically unjustifiable to ignore the needs of disordered or disabled persons, often homeless and wandering the streets, who clearly would benefit from treatment (Treffert, Peele, and Chodoff; American Psychiatric Association, 2001a). References are made to people "dying with their rights on" and to Janis Joplin's song line "Freedom's just another word for nothin' left to lose."

Those who advocate the narrower grounds fear that relaxing the criterion in the direction of *disruption of functioning* leaves the door open too wide to psychiatric paternalism and represents a threat to civil liberties. Images of forced psychiatric internment of political dissidents in the Soviet Union (Bloch and Reddaway) are invoked as a frightening example of giving psychiatrists the power to confine individuals who are not physically dangerous but only *disrupted* in their functioning. One of the necessary and willing prices of having a free society, they argue, is that people are free to make self-defeating choices and sometimes irrationally reject opportunities for help.

A cohort of persons are committable under a broader but not under a narrower set of criteria. An example is a person with a history of bipolar disorder who becomes increasingly hypomanic and is squandering his carefully accumulated savings in what are almost certainly hopeless financial schemes. He refuses all treatment. Everyone who knows him believes that his spending spree is due to his hypomania, that it would not be unethical to curtail his actions, and that if his behavior were curtailed, he almost certainly would be grateful later. However, although his current behavior is harmful to his long-term interests, he is

not *dangerous to himself or others* as that criterion is explicated in many states.

Many persons, like this man, whose behavior meets broader but not narrower commitment criteria suffer from cyclical disorders: Their aberrant behavior occurs only episodically. Some authors have suggested that such persons might be offered during nonsymptomatic times the opportunity to create a contract stating that if their future behavior deviates from their usual behavior in certain specified ways, they will accept the use of appropriate interventions (confiscation of funds or forced hospitalization, *voluntary commitment*) that otherwise might not be legally permissible (Howell et al., Culver and Gert).

An important empirical issue discussed by Peele and Chodoff is the extent to which statutory criteria for commitment influence the behavior of psychiatrists. Are there patients who are not committed in states with narrow criteria who would be committed in states with broader criteria? Peele and Chodoff, after surveying the scanty evidence that exists on this point, conclude, "It appears that judges and juries base decisions about commitment on what they think is best for the person, regardless of formal criteria" (Peele and Chodoff, p. 436). This would be a useful issue to explore further.

Conceptual Issues Underlying Commitment

ETHICAL JUSTIFICATION. In discussing the ethical justification of commitment a distinction must be made between whether a commitment is intended primarily to help the person who is committed or to help others whom that person may be putting at risk (Gert, Culver, and Clouser; Buchanan and Brock). This distinction sometimes is not clear-cut because it is usually to the advantage of mentally ill persons to be prevented from harming others. The harm they might cause often would be serious and thus would constitute a crime. Committing the crime frequently would be a clear result of the mental illness—for example, obeying a voice commanding that someone be killed—and it is highly likely that the mentally ill offender would be apprehended, incarcerated, and then punished or at least hospitalized for a long time. Nonetheless, there is a distinction between paternalistic and nonpaternalistic commitments, and there is no doubt that the protection of others is the predominant reason for some commitments.

Paternalistic commitment. To the extent that commitment is intended to help the person who is committed, it essentially always qualifies as a paternalistic action. That is, the commitment is intended to benefit the committed person, it violates at least one moral rule (deprivation of freedom) and usually several, it is done without the consent of the person, and the person is at least minimally competent to give consent (Gert, Culver, and Clouser). Whether paternalistic commitment is ethically justified therefore depends on whether a particular commitment meets whatever theoretical criteria for justified paternalism are thought to be adequate.

Various sets of criteria, partly overlapping, have been proposed by Beauchamp and Childress, Buchanan and Brock, Childress, and Gert, Culver, and Clouser. Those criteria depend on theoretical concepts such as the degree of irrationality and voluntariness of the person's behavior and the balancing of physician beneficence and patient autonomy. None of those authors seems to believe that as a species of paternalism, there is anything qualitatively unique about committing mentally ill individuals. Thus, particular acts of commitment are measured directly against the theoretical criteria of the particular justification procedure that is proposed.

However, in the judgment of many authors (Culver and Gert; Buchanan and Brock), the presence of mental illness does play an indirect role in the justification of paternalistic commitment by sometimes affecting concepts that those authors believe are centrally important in the justification process. Thus, some suicidal desires may be regarded as not truly expressing an individual's autonomous wishes (Beauchamp and Childress), or some conditions of mental illness may be thought to affect a person's competence to make decisions (Buchanan and Brock).

Nonpaternalistic commitment. When commitment is not paternalistic, it must be ethically justified on other grounds. To commit persons in an attempt to prevent them from harming others represents a kind of preventive detention that ordinarily is not legally permitted in the United States. In the presence of some kinds of mental illness, however, it is argued by some that nonpaternalistic commitment may be ethically justified.

For example, two men are brought separately to the emergency room by the police. In each instance the police have been called because the man has just threatened to kill his wife. Each man admits to the emergency room psychiatrist that this is true. The first man has a history of paranoid psychotic episodes and in recent days has heard voices instructing him to kill his wife. The second man has no symptoms or history of major mental illness, but he and his wife have a history of chronic marital discord. In both cases the psychiatrist feels that there is a reasonably high probability that the man will harm his wife if he returns home.

On the basis of the fact that in some kinds of mental illnesses persons are not held responsible for their actions, it

may be argued that it is ethically justified to commit the first man but not the second. The second man, for example, presumably has the volitional ability to will or to refrain from willing to harm his wife, whereas the first may not have the volitional ability to will not to harm her (Culver and Gert). Dangerous mentally ill persons sometimes are not considered capable of guiding their behavior in accordance with promulgated social rules (Brock).

PREDICTING POSSIBLE FUTURE HARM. Civil commitment always involves a doctor's appraising a person's physical and mental status and deciding whether commitment is warranted. Sometimes individuals may be committed because they are in such a disabled condition that even more serious future harm seems all but inevitable. A woman may, for example, be hallucinating continuously, be unresponsive to the questions or actions of others, and be significantly malnourished because of a lack of interest in food. Much more often, however, serious future harm is only a possibility: For example, a person has threatened suicide or is hearing voices urging her to harm someone, and the physician must try to predict how likely it is that the harm actually will occur.

The process of predicting possible future harm in the commitment setting has the following components (Grisso): The criterion is what is being predicted (for example, the person's suicide), the cues are discrete pieces of available information about a particular case at a particular point in time (for example, the person's age, sex, state of intoxication, and history of impulsivity), and the judgment is the physician's conclusion after assessing the case (for example, to commit or not to commit). These are three separate elements. Empirical research has focused separately on the correlations among them. The judgment-criterion correlation shows how well physicians do in predicting that particular persons will kill themselves. The cues-criterion correlation shows the extent to which suicides can be predicted from whatever facts about cases can be isolated and measured independently of physicians' judgments. The cues-judgment correlation shows which data about cases lead physicians to make one judgment or another.

A critically important issue with respect to prediction is the extent to which commitment does prevent future serious harm. There are few data addressing this issue. If it were known, for example, that 90 percent of the persons committed would have harmed themselves or others seriously if they had not been committed, most people probably would feel that commitment was ethically justified. Committing one hundred persons would avoid ninety instances of serious harm, although at the *cost* of committing ten persons who would not have caused harm if they had not been committed. By contrast, if only one in a hundred persons would have harmed themselves or others, few would feel commitment was justified because ninety-nine persons would have suffered the evils of detainment to prevent one bad future outcome.

This kind of utilitarian calculus seems central to most writers who discuss the ethical justifiability of commitment. Commitment essentially always inflicts significant harm, but only sometimes does it prevent significant harm. Almost everyone acknowledges that even among those at relatively high risk of causing harm—for example, suicidal persons brought to an emergency room—only a minority would, if left alone, subsequently harm themselves. An emergency room physician thus faces a difficult task. To commit every person would be to commit too many, but which persons should be committed? Certain characteristics of persons (cues) are known to increase the likelihood of future harmful acts—for example, a history of impulsive or suicidal behavior, being inebriated, having access to lethal weapons, being male—but a physician must make a binary, yes-no decision about commitment, not a probability estimate.

Research (Monahan) suggests that physicians are poor predictors of whether harmful behavior will occur (judgment-criterion correlations). There is reason to believe that basing predictions on discrete, measurable pieces of information about a case (cues-criterion correlations) will yield greater accuracy (Monahan). There is, however, probably an upper limit to predictive accuracy; one reason for this is that whether a person commits a harmful act in the hours or days after a physician's assessment may depend at least as much on later fortuitous situational factors such as whether a friend returns a telephone call as on factors that can be measured during the assessment.

A very important statistical feature of prediction plays a key role in understanding the commitment process and making ethical judgements about it. In predicting relatively rare events such as the occurrence of a future suicide through the use of predictive signs of less than extremely high predictive accuracy (for example, a physician's judgment or whether a person has access to a lethal weapon), one inevitably will make a high proportion of false-positive predictions; that is, one frequently will predict future harm when in fact none will occur. This actuarial problem, which is an example of the application of Bayes' theorem, was described by Meehl and Rosen and later applied to the issue of commitment by Livermore, Malmquist, and Meehl.

Suppose that 10 percent of suicidal persons who are brought to an emergency room but are unwilling to be hospitalized would kill or harm themselves seriously if they

were not committed. Suppose further that, using the available cues, physicians' predictions of who will and will not commit suicide have a sensitivity of 70 percent (*sensitivity* refers to the percentage of persons who will commit suicide whom physicians accurately predict will commit suicide) and a specificity of 70 percent (*specificity* refers to the percentage of patients who will not commit suicide whom physicians accurately predict will not commit suicide). It follows that physicians will commit and thus *save* seven of the ten persons destined for suicide but also will commit twenty-seven persons of every ninety persons (30% of ninety) who would not have killed themselves. These latter persons constitute false positives.

The ratio between the number of true positives (seven) and false positives (twenty-seven) shows that nearly four persons will be committed needlessly in order to save one. (These are hypothetical figures. Many would argue that subsequent suicide is rarer than 10 percent in the general psychiatric suicidal population and that 70 percent is too high an estimate of sensitivity (and of specificity); thus, the actual proportion of false positives would be much higher.) The physician would be correct a higher percentage of the time (90%) if he or she simply predicted that no one would commit suicide, but then none of the ten suicidal persons would be saved.

Is it ethically justified to commit four unwilling persons needlessly to save one life? Suppose empirical data existed (they do not) that enabled the construction of actuarial tables that would correlate the nature and number of signs and symptoms shown by mentally ill persons in emergency rooms with their subsequent likelihood of harming themselves or others if they were not committed (cue-criterion correlations). Each person thus could be assigned to a cohort: Some would have a one in five chance of harming themselves or others, some a one in ten chance, some one in twenty, some one in forty, and so forth.

Where should the line be drawn? What is the appropriate trade-off between saving one life and needlessly depriving many persons of their freedom? Reasonable people might disagree about where the line should be drawn, but this is a matter that could be opened to public debate. Psychiatrists probably have no special expertise in deciding where the threshold for commitment should be placed.

When confronted with the inevitable large numbers of false-positive commitments, some people recall the injunction often cited in connection with the U.S. criminal justice system—"Better that ten guilty persons go free than one innocent person suffer"—and conclude that civil commitment is ethically unjustified (Sartorius). Others, however, although concerned about the false-positive problem, believe that there are sufficient differences between the underlying conceptual justifications of the criminal justice system and the civil commitment system that some number of false positives can be tolerated in the civil system (Brock).

Conclusion

Although debates about involuntary hospitalization sometimes are framed in legal rather than ethical terms, it is important to be clear about the underlying ethical issues. Civil commitment involves incarcerating an unwilling person who has committed no crime for days, weeks, or longer. This type of prima facie unethical action requires clear justification in terms of a general moral theory. Current theoretical discussions of commitment emphasize concepts such as the degree of irrationality and the extent of voluntariness of a person's behavior. In applying theoretical concepts to the process of commitment it is critical to describe the components of the process clearly and take into account certain statistical features that are inherent in making predictions about a person's future behavior.

MENTALLY DISABLED AND MENTALLY ILL PERSONS

• • •

I. HEALTHCARE ISSUES

Primary healthcare providers for patients with mental illnesses bear the same ethical obligations as providers who serve patients with physical illnesses, yet they face special challenges in upholding those obligations. When mental illness causes a patient to be violent or suicidal, clinicians may confront situations in which their duties to the patient conflict with other ethical duties. At times, the decision about which duty to obey involves careful moral consideration. Additionally, because mentally ill persons are particularly vulnerable to abuse, the clinician has a special obligation to protect such patients against abuses.

For example, in the case of a patient who has attempted suicide, the duty to respect the patient's autonomy may conflict with the duty to protect the patient from harm. The patient may wish to go home, yet the clinician—who may be a physician in a hospital emergency room, a psychiatrist, or the patient's therapist—may decide to hospitalize the patient. At this point, the patient's fundamental right to refuse care has been denied. The moral justification may seem clear: The patient is not thinking rationally, so he or she should not be permitted to function autonomously. The patient deserves an explanation about why he or she is being hospitalized and has a right to information about the legal routes for challenging the decision.

It's true that in some cases, suicide may be a carefully reasoned choice. Far more often, though, planning or attempting to harm oneself results from a clinical depression or other psychiatric disorder. Discerning whether a patient's suicide reflects a rational decision is typically not possible in an emergency room setting. It would be ethical to hospitalize a patient to prevent suicide until a more thorough assessment could take place, including discussions with family members and or with healthcare providers who have known the patient over a long period of time.

Even when the clinician's overriding moral duties are clear, actual situations are complicated. There is often disagreement among patients, clinicians, families, and the courts about whether a patient's rights may be denied. This article explores common moral dilemmas in the medical and psychiatric care of individuals who are experiencing a major mental illness, such as schizophrenia or clinical depression, and those who suffer from the serious deficits in memory and intellectual functioning seen in dementia or mental retardation. Health professionals caring for such patients are likely to face one or more of the following questions and ethical concerns:

1. Does the person with mental illness have the capacity to decide about suggested treatments (informed consent for treatment)?
2. When is it ethical to hospitalize mentally ill persons against their will (commitment)?
3. Is it ethical to treat mentally ill persons against their will with psychiatric medications (coerced treatment)?
4. Is it ethical to use coercive methods to encourage a mentally ill person to comply with prescribed treatments (coerced compliance)?
5. When is it ethical to withhold information from a person because that person has a history of serious mental illness (truth-telling)?
6. When is it ethical to breach the confidentiality of a mentally ill patient (confidentiality)?
7. Under what circumstances is it ethical to withhold scarce health resources from a person because that person is seriously mentally ill (allocation of scarce resources)?

Informed Consent for Treatment

No patient should be treated by a doctor without first being informed about the nature of the treatment and then consenting to have the treatment. When a person with a history of serious mental illness is being treated for a medical condition, his or her doctors may consult a psychiatrist about the patient's capacity to make medical decisions.

Assessing the capacity to make medical decisions need not involve a comprehensive evaluation of intellectual functioning. A straightforward discussion regarding a patient's understanding of a specific medical decision is usually sufficient. The psychiatrist asks questions about the nature of the illness and possible treatments and determines from the responses if the patient understands the problem, the treatment choices, and the likely consequences of a given decision. A formal judgment of medical competence can only be made in court (Appelbaum and Grisso). However, the psychiatrist's informal evaluation can guide treatment in most clinical situations.

A person whose mental abilities are partly impaired may be competent to make certain decisions about medical care. This situation can arise with an elderly person who suffers from mild dementia or a younger person affected by mild mental retardation (Kaplan, Strang, and Ahmed). For this reason, decision-making capacity must be assessed on a case-by-case basis.

Also, a person who is incompetent at one time may be competent at another. Delirium and depression, conditions seen frequently among patients hospitalized for medical reasons, are examples of conditions that temporarily disrupt clear thinking. A person who is delirious or depressed may be found incompetent to refuse treatment, yet when the delirium clears or the depression lifts, that person is considered competent.

Consider the case of a thirty-five-year-old man with kidney failure (Shuchman and Wilkes). Doctors told him that he required dialysis to take over the function of his kidneys. The man refused dialysis, saying he would rather die. A psychiatrist determined that the man suffered from a severe depression that was interfering with his ability to think rationally, and the man was deemed lacking in the capacity to make medical decisions. Over time, and with treatment, including antidepressant medication, the depression resolved. Eventually, the man's doctors judged him capable of making treatment decisions. However, the man's uplifted spirits did not alter his desire to stop dialysis. The lifesaving technology was discontinued and he died within a few days. Though the outcome may be death, respect for patient autonomy requires that competent patients be allowed to refuse therapies (Angell; Hebert and Weingarten).

Commitment

Though involuntary confinement of mental patients decreased markedly over the last three decades of the twentieth century, it is still an essential tool used to protect patients who are potentially dangerous due to a mental illness. Since

hospitalizing a patient against his or her will necessarily denies the patient's autonomy, it is essential that the act be morally justified. Yet, what qualifies as such justification is controversial.

During the 1960s, a person *in need of treatment due to mental disorder* met the criteria for involuntary admission to a psychiatric hospital in most states and provinces; in the 2000s, the criteria are significantly narrower. Individuals may be involuntarily hospitalized if they are deemed a danger to themselves (for example, if they are about to attempt suicide), a danger to others, or are unable to care for themselves due to mental illness. Typically, the assessment leading to involuntary hospitalization is done by a mental health professional, though such requirements vary in different states and provinces. Once confined, the person may be hospitalized for up to a few days. If commitment extends beyond a specified brief period, a court hearing generally must be held to determine whether further involuntary confinement is appropriate. The courts have also encouraged treatment of psychiatric patients in less restrictive settings than inpatient hospital wards when possible. Other treatment options include "day hospital" programs that allow patients to return home at night, and case management programs that ensure daily checks on outpatients.

In practical terms, the decision to hospitalize someone involuntarily is often a difficult one. Consider a woman who is depressed and has attempted suicide. She might be safest in a hospital, since there is a risk of her making a second suicide attempt while she remains depressed. But safety alone cannot be a reason for hospitalization, as very few of those who attempt suicide will go on to successfully complete suicides in the future. This woman might be safe outside a hospital if she is engaged in frequent outpatient counseling. Commonly, psychiatrists making a decision about committing a patient consider factors known to raise the risk that the person will be harmed or will harm themselves. For example, an individual who has made a serious suicide attempt in the past is at higher risk.

During the late 1980s, psychiatrists and patients' families began objecting to the narrowed commitment criteria, arguing that the rights of people with mental illness were being protected at the expense of their mental health (Appelbaum). These objections resulted in the grounds for commitment being broadened in some areas. The *outpatient commitment* system, in which outpatients are given court-ordered treatment or returned to the hospital in certain situations, is an example of the broadening of commitment laws to include individuals who are not clearly dangerous to themselves or others (Geller). This system, also referred to as *supervised discharge* or *community treatment orders* has been introduced in Australia, Canada, the United Kingdom, and Europe as well as the United States. Though not problem-free, it appears to be an effective means of offering mental patients increased care with greater freedom than inpatient commitment provides (Swanson, Swartz, and Borum, et al. and Swartz, Swanson, and Wagner et al.).

Coerced Treatment

Ethics demands that a competent mental patient's refusal of treatment must be respected. Even a patient confined to a mental institution cannot be treated against his or her will, unless the patient poses an imminent threat of harm to others. This concept received extensive legal backing from court rulings during the 1980s. Courts in Massachusetts, New York, and California ruled that unless a patient was found incapable of making treatment decisions, he or she could not be treated involuntarily with antipsychotic medications. The rulings were motivated by reports that psychiatric medications were overused at mental hospitals and staff were often indifferent to patients' risks of drug side effects.

In many states and provinces, psychiatric medications have since evolved into a special legal category of treatment. Forcibly giving a patient psychiatric medication is only permissible if the patient is behaving in a violent manner or is actively threatening to do so. As a result, clinicians treating mental patients typically cannot medicate a refusing patient without involving the courts. By contrast, physicians do not need to consult a judge in order to commit mental patients to involuntary hospitalization. The result is that mentally ill and psychotic patients may be hospitalized against their will but cannot be medicated against their will (Appelbaum). In these situations, psychiatrists often seek permission from the courts to medicate the patient, arguing that the patient has benefited from medication before or is judged highly likely to benefit from medication.

The courts often grant the permission and treatment proceeds in a practice sometimes known as *medication over objection.* Studies suggest that once a court ruling in favor of treatment is issued, patients often accept oral antipsychotic medications under duress, thereby avoiding forced injections of medication (Greenberg, Moore-Duncan and Herron).

The more stringent criteria for involuntary medication became a focus of controversy on similar grounds as the controversy over narrower commitment criteria. Psychiatrists described mental patients who refuse medication as 'rotting with their rights on,' conveying the image of a person who is not thinking rationally and whose condition is steadily worsening, yet who cannot be treated appropriately or faces delays in treatment because of judicial restraints (Appelbaum and Gutheil).

The mid- to late 1990s saw the start of a movement towards the use of psychiatric *advance directives.* These are treatment guides prepared by chronically mentally ill patients who are capable of making decisions about their psychiatric treatment when they are functioning well but experience repeated episodes of impaired decision-making during relapses. Most states accept advance psychiatric directives in some form but a survey suggests that psychiatric *advance directives* are easily ignored in crisis situations (Backlar, McFarland, Bentson, Swanson and Mahler).

Another area of care in which doctors may seek legal opinions regarding involuntary medication involves severely mentally ill female patients who decline birth-control treatments. Some authors suggest that there are situations in which it would be ethical to act to prevent pregnancy in patients who are incompetent to make medical decisions (McCullough, Coverdale, Bayer, et al.). The courts have held that when a mentally incompetent woman is pregnant, decisions about her obstetric care should involve a determination about what the woman would want if she were competent (Curran). In practice, when a severely mentally ill woman becomes a mother, child-welfare agencies are asked to evaluate the woman's ability to care for her child. In extreme cases, this evaluation may lead to court proceedings that can result in the woman's losing custody of her child.

Coerced Compliance

The idea that a patient's decisions must be voluntary is central to the concepts of patient autonomy and informed consent. Exceptions to the idea of voluntariness, such as commitment and involuntary medication, have been viewed as last resorts for patients considered incapable of making rational decisions. Occasionally, however, coercive methods are used to encourage mentally ill individuals to comply with treatments, even when these individuals' decision-making capacities are not in question. Substance-abusing pregnant women comprise one group that is increasingly coerced into treatment, either via incarceration or via compulsory addiction treatment programs (Abel and Kruger). This use of coerced compliance has been supported by state courts as a means of protecting the woman's future child. Yet the practice is controversial because the potential protection it affords the fetus requires overriding a competent adult's treatment decisions (Chavkin and Paltrow).

The coercive methods used with chronic mental patients are more subtle. An example is a man with a chronic mental illness who received disability payments from the government because of his mental condition. The man's government check was sent to the mental-health clinic where he was treated. To receive his check, the man was required to show up for his therapy session. The therapist believed this was a useful technique for encouraging adherence to treatment in a patient with disorganized thinking.

Mental-health practitioners justify such paternalistic strategies as a means of preventing deterioration in a patient's condition but such clinical justifications may not stand up to moral scrutiny. Yet these kinds of practices would be ethical if they were discussed openly with the patient and the patient consented.

Truth-Telling

A physician or therapist who shields a patient from the truth about his or her illness may unwittingly cause mistrust of care providers and of the medical system in a patient who needs to depend on that system (Sheldon). Yet clinicians caring for seriously mentally ill individuals sometimes do withhold information.

In one example, a physician withheld a diagnosis of cancer from a patient with a history of depression and suicide attempts (Lo). The physician feared that disclosing to the patient that she had a terminal illness could precipitate a suicide attempt. His intention was to protect the patient from harm, but the patient probably should have been informed about her diagnosis.

Though patients in general are likely to be told their diagnoses, studies of patients in psychiatric hospitals from the 1980s found that important information was frequently withheld from such patients. For example, psychiatric patients were prescribed medicines without being informed about potentially serious risks of the medicines (Lidz, Meisel, Zerubavel, et al.; Beck). More recent studies suggest that patients continue to be underinformed about their medications (Schachter and Kleinman). For informed decision making, a patient needs to understand the benefits and risks of prescribed medications and why the doctor believes that the benefits outweigh the risks.

Patients, even those with mental illnesses and disabilities, expect and deserve to be told the truth. This does not mean that the truth should be disclosed insensitively. Health professionals should consider how to convey difficult information in a manner most appropriate to a particular patient, but the information should be provided. Psychiatric patients, like all medical patients, need to feel they can trust their healthcare providers.

Confidentiality

All doctor-patient relationships demand confidentiality. In the special setting of psychotherapy the need to protect a

patient's privacy can be paramount. The special importance of confidentiality in psychotherapy was underscored by a 1996 Supreme Court ruling that protects a patient's statements to a psychotherapist from compelled disclosure (*Jaffee v. Redmond*).

But a patient's need for privacy must be balanced against the rights and needs of others. Suppose a man in treatment for alcohol abuse reveals that he has been aggressive toward his child while intoxicated. State laws mandate the reporting of incidents of child abuse, yet a physician or counselor who reported this man would breach the patient's confidentiality. Here, the clinician must consider whether the man's actions towards his child constitute an offense that must be reported in order to protect this child or others in the future. The decision is made all the more difficult because the man's treatment could help to keep his child safe from harm yet the man may leave treatment if he feels the clinician has betrayed him to state authorities.

Situations other than child abuse pose similar dilemmas. Rules about a physician's duty to warn and protect a person who is threatened by a patient now apply in most states and provinces. Such rules do not dictate a therapist's decision, however. Since the majority of threats made by patients do not represent serious danger to others, clinical judgment is required to decide whether a threat, that a patient utters during the course of a psychotherapy session or merits a breach in confidentiality (Weinstock).

Allocation of Scarce Resources

It would be unjust to withhold healthcare resources from a mental patient strictly due to her mental illness. Yet an exception is sometimes made in the case of extremely scarce resources, such as organ transplants. A patient who is chronically mentally ill and also has severe liver or kidney disease might benefit from a transplant. But persons who receive transplants require drug-induced immunosuppression for the rest of their lives to prevent graft rejection, and it can be difficult for mental patients to comply with such extensive follow-up care (Bunzel and Laederach). Reasoning that transplanted organs should go to patients who will reap the most benefit from them, transplant programs may withhold organs from individuals who are seriously mentally ill (Wolcott). In a survey of heart-transplant programs, most programs considered certain psychiatric conditions to be an absolute contraindication to transplant: A person who has schizophrenia with active psychotic symptoms, or a person with a history of multiple suicide attempts will be automatically denied a transplant (Olbrisch and Levenson).

Such automatic denials are not clearly ethical. In the event that a transplant candidate has a serious mental illness, it is important that the potential for treating the mental illness be considered before the patient is refused a transplant (Council on Ethical and Judicial Affairs). The patient's desire to commit suicide, for example, may be caused by a treatable depression. For transplant programs, the question of how to respond to evidence of a patient's psychological instability is difficult. Case-by-case evaluations of individual patients may yield greater fairness in these sorts of situations than systematically applying formal guidelines. Some patients with mental illness may benefit from early intervention and psychosocial support, while other patients may be unable to adhere to post-transplantation treatment regimens even with help.

Conclusion

In a number of key areas, a mentally ill person may lose certain rights with regard to medical and psychiatric treatment due to the effects of mental illness. As a result, healthcare providers who care for such patients can face difficult ethical dilemmas. The decision to hospitalize a mentally ill person involuntarily is often easily justified on moral grounds. However, decisions to breach a patient's confidentiality, or to withhold scarce resources such as organ transplants, are generally not as clear. Finally, it is probably rare that a physician or therapist who withholds the truth from the patient, or coerces the patient into complying with a recommended treatment, will be acting in an ethical manner.

II. RESEARCH ISSUES

Protecting the interests of mentally ill and disabled people entails a delicate balance between two aims: a rigorous program of research into their medical problems and attention to the difficulties involved in using those people as subjects of research in ethically appropriate ways. Although the hope of understanding mental illnesses and disabilities depends on the results of medical research, persons who have those conditions are especially vulnerable to exploitation and abuse.

Research Guidelines

There are two major problems in conducting research on mentally ill and disabled persons. The first is competence, or decision-making capacity: Because of the nature of their problems some mentally ill and disabled subjects may not be able to make informed decisions about whether to participate in a research protocol. Issues surrounding informed consent are made even more problematic by the fact that mentally ill or disabled subjects may be living in institutions for patients with special mental disorders, and institutionalization can exert pressures that compromise a person's ability to make a free choice about participating in research. The second problem involves risk and the design of research studies. Under what circumstances, if any, can a mentally ill

or disabled person be exposed to the risk of harm in a research study?

Some mentally ill or disabled persons may be incapable of giving valid informed consent to participate in a research study. However, prohibiting those potential subjects from participating would rule out much medical research that could benefit the subjects and others with similar disorders, in the long run harming the populations the studies are intended to protect. For that reason, since the last two decades of the twentieth century there has been a consensus that research on mentally ill and disabled persons can be justified in some cases, subject to certain conditions (National Bioethics Advisory Commission [NBAC]; Royal College of Psychiatrists [RCP]; Royal College of Physicians of London [RCPL], 1990; U.S. National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, 1978, 1979; Wing; World Medical Association; National Institutes of Health; Medical Research Council of Canada [MRCC]).

Perhaps the most important of those conditions is the stipulation that research on incompetent mentally ill or disabled persons should be allowed only if that research cannot be done on competent persons (National Bioethics Advisory Commission; Wing; U.S. National Commission for the Protection of Human Subjects, 1979). The guidelines for biomedical research proposed by the World Health Organization (WHO) and the Council for International Organizations of Medical Sciences (CIOMS) make that requirement explicit, arguing that because of the risks and burdens involved, medical research should not be done on individuals who are unable to choose to participate if it can equally well be done on competent adult volunteers (World Health Organization).

A second condition concerns the amount of risk to research subjects that may be allowed. Many professional and regulatory bodies state that research on incompetent subjects such as children and the mentally ill or disabled ordinarily is approvable only when the research involves a minimal risk or a minor increment over minimal risk to the subject ("Federal Policy for the Protection of Human Subjects"; Royal College of Physicians of London, 1996). According to this reasoning, some research on mentally ill or disabled persons may be ethically justifiable, subject to specific additional conditions, even if it is nontherapeutic (Wing; National Institutes of Health).

Of course, there is considerable room for controversy in defining minimal risk. U.S. federal policy compares minimal risk to the risks of the everyday life of a potential subject or those of a routine physical or psychological examination ("Federal Policy for the Protection of Human Subjects"). The Royal College of Physicians of London (1996) defines minimal risk as covering two types of situations: those that might involve negligible psychological distress, including other trivial reactions such as a mild headache or a feeling of lethargy, and those that involve very remote risks of serious injury or death, comparable with the risk of flying in a scheduled passenger aircraft.

It is widely agreed that research proposals involving mentally ill or disabled persons should be approved by an ethics committee charged with reviewing research proposals, such as an institutional review board. Research should not proceed if a competent subject objects. When a subject is unable to give properly informed consent, consent should be sought from an appropriate surrogate decision maker, such as a relative (World Medical Association).

Competence and Informed Consent

A fundamental ethical requirement for most medical research is the informed consent of the subject. For consent to be valid the subject must be capable of understanding the relevant implications of his or her decision to participate: the purpose, nature, and duration of the research; its possible risks and benefits; and so on. Because of the nature of some mental disorders, it is often unclear whether a mentally ill or handicapped person is capable of giving proper informed consent. Although many mental illnesses and disabilities do not affect those capabilities, it is the duty of a medical researcher to ensure that a potential subject of research is capable of making an informed decision whether to participate.

The ability to make that decision often is termed competence or decision-making capacity. A competent person should be capable of making a decision for which he or she legitimately can be considered accountable (Elliott). Competence ordinarily is defined in relation to a particular activity; a person can be competent to make some types of decisions but not others. For that reason assessments of competence ordinarily should focus on the task at hand, in this case understanding the implications of participating in a particular research protocol.

Most proposed standards for assessing competence focus on the process of reasoning involved in making a decision rather than on the outcome of the decision (U.S. President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research, 1982; Buchanan and Brock; National Bioethics Advisory Commission). Because each person has different needs and values, often there is no single decision that can be judged correct for everyone. However, focusing primarily on a person's reasoning processes also can be problematic. A

competent person sometimes may use faulty reasoning or make irrational decisions yet still be considered accountable for his or her choices (Elliott).

Probably the most influential tests of competence have dealt with consent to treatment rather than to research. A U.S. President's Commission report (1982) relates competence to three aspects of a person's mental abilities: (1) the possession of a set of values and goals, (2) the ability to communicate and understand information, and (3) the ability to reason and deliberate about one's choices.

However, competence criteria that focus primarily on rationality and reasonable deliberation may not be very helpful when the person making the choice has an affective disorder. For example, patients with depressive delusions may consent to hazardous research because they think they deserve to be punished (Elliott; Kopelman).

Furthermore, a mentally ill or disabled person may be able to satisfy a criterion partially but not fully or may be able to satisfy only some criteria. In cases like these it is a matter for debate how high the standards for competence should be set. For this reason some writers and professional bodies, including the U.S. President's Commission (1982), have endorsed a sliding-scale approach to assessing competence (National Bioethics Advisory Commission).

With this approach standards of competence are set higher for interventions with a risk-benefit ratio that is relatively worse and lower for interventions with a risk-benefit ratio that is relatively better. For example, to participate in a research protocol whose risks are great and whose benefits are small a subject might have to show not only that he or she understands the facts and issues but also that he or she *appreciates* the nature of the situation. This may be a very high standard of understanding: an affective as well as a cognitive recognition of the nature of the research, an awareness of how others view the decision, and an understanding that he or she has a mental disorder that is appropriate for study. In contrast, if the risk-benefit ratio is much better, the standard for competence might be set very low, for example, merely showing evidence of a choice to participate.

Even when a subject is clearly incompetent to give informed consent, many writers believe that research should not be done without the subject's assent; that is, researchers should ensure that the subject, to the degree that he or she is mentally capable, agrees to or expresses a positive interest in participating in the research. Research is much more difficult to justify when it is done in spite of a subject's verbal or behavioral objections (Wing). However, it is arguable that research without a patient's assent is justifiable if the patient is clearly incompetent and the research is therapeutic, involves minimal risk, has been consented to by an appropriate surrogate, and is clearly in the best interests of the patient.

Issues of competence and informed consent can be especially problematic in certain mentally ill patients whose competence may change over time. In the case of therapeutic research, for example, on antipsychotic medication, a research protocol may restore to competence a patient who previously was incompetent. In these situations the possible value of restoring the patient to competence should be part of the decision whether to enroll the patient in a research protocol. In cases in which a patient's competence fluctuates over time researchers should try to obtain consent at a time when the patient is best able to give it.

Further provisions may be needed to protect the interests of mentally ill and disabled patients who are incompetent or whose competence is questionable. The Belmont Report recommended that researchers seek the permission of third parties who are most likely to understand a subject's situation and act in that person's best interest (U.S. National Commission for the Protection of Human Subjects, 1979; National Bioethics Advisory Commission). Two standards have been employed widely in making decisions for incompetent patients: the best interests standard, in which third parties make decisions that are based on the interests of patients through the use of socially shared values, and in the case of previously competent patients the substituted judgment standard, by which third parties make decisions that are based on values and preferences the patient may have expressed in the past. The Belmont Report made the additional recommendation that those third parties be allowed to observe the research as it proceeds, with the option of withdrawing the subject from the research at any time (U.S. National Commission for the Protection of Human Subjects, 1979; National Bioethics Advisory Commission).

Institutionalized patients are often especially attractive as research subjects because their medication, diet, and compliance with a study can be monitored and controlled easily. Nevertheless, many writers have argued that institutionalized populations deserve special protection, pointing out the examples of the Willowbrook State School in New York, where mentally retarded children were injected with the hepatitis virus in 1956, and the Jewish Chronic Disease Hospital in Brooklyn, where nineteen chronically ill patients were injected with cancer cells in 1962 (U.S. National Commission for the Protection of Human Subjects, 1978; Kopelman). Some observers have argued that the fact of institutionalization invalidates informed consent and that research on mentally ill or handicapped persons in institutions should be ruled out entirely.

There are several grounds for the argument that institutionalization invalidates informed consent. One that has been rejected widely is that any person who has a mental illness or disability severe enough to warrant institutionalization is mentally incompetent to give informed consent. However, many people have illnesses or disabilities that impair them in ways that require institutional treatment but do not impair their ability to make competent judgments about participating in research. A second argument is that institutionalization itself deprives people of the ability to make their own decisions, for example, by placing them in a situation of constant subordination to authority (Annas et al.). A third argument is that institutions severely limit the choices available to their patients, thus placing constraints on their freedom of choice. Research on institutionalized patients also can be difficult for impartial external observers or regulatory bodies to monitor effectively. For these reasons many agencies and professional bodies require that researchers take special measures to guard against the manipulation of institutionalized subjects.

Risk and Study Design

At the turn of the twenty-first century a number of studies of mental illness attracted considerable criticism because their designs exposed subjects to an unacceptably high ratio of risk to benefit. The most controversial of those studies were placebo-controlled trials, symptom-provocation studies, and relapse studies.

PLACEBO-CONTROLLED TRIALS. The ethical controversy over certain placebo-controlled trials begins from the principle of clinical equipoise, according to which, before a randomized clinical trial can be started there must be genuine disagreement in the community of expert practitioners about which treatment is preferable (Freedman, 1987). If there is disagreement about whether a new psychiatric drug is superior to placebo, clinical equipoise would permit a trial to settle the question. However, would it be ethical to begin a trial comparing a new drug to placebo if there already was an effective standard treatment for the illness in question? According to the requirement for clinical equipoise, the answer is no.

Clinical equipoise is rooted in standards of sound clinical practice. The treatments offered to patients in a clinical trial must be in equipoise with the prevailing standard of care for the subject population in question so that the clinical care of those patients will not suffer as a result of enrollment in the trial. The Declaration of Helsinki states, "The benefits, risks, burdens and effectiveness of a new method should be tested against those of the best current prophylactic, diagnostic, and therapeutic methods" (World Medical Association).

In light of the proven efficacy of many psychiatric agents, it might be expected that placebo-controlled trials in psychiatry would be rare. However, new psychiatric agents are tested routinely against placebo even when failure to treat the illness in question adequately could cause serious harm to the subjects enrolled in the trial, such as patients with schizophrenia or major depression. Indeed, representatives of regulatory agencies such as the U.S. Food and Drug Administration and the Canadian Health Protection Branch have encouraged the use of placebo-controlled trials, especially in psychiatry, arguing that those trials are the only way to determine whether a new drug is effective (Addington). Defenders of placebo-controlled trials also argue that subjects are protected by the requirement for informed consent and that even if a subject's mental illness worsens during a trial, the symptoms of such illnesses are temporary, reversible, and not sufficiently harmful to warrant a prohibition against placebos.

It is difficult to see how major depression and psychosis can be considered insufficiently harmful to subjects, especially when both conditions are associated with a higher risk of suicide. It is also doubtful that informed consent will protect research subjects from enrolling in potentially harmful studies. Many investigators do not conduct an adequate discussion with patients about the risks and disadvantages of taking part in a study, and even when investigators disclose those risks, many patients do not understand them fully (Appelbaum et al.).

The requirement for clinical equipoise does not mean that all or even most placebo controls are unethical. As Benjamin Freedman (1990) has noted, placebo controls are justified in testing treatments for conditions:

1. that have no standard therapy,
2. whose standard therapy has been shown to be no better than placebo,
3. whose standard therapy is placebo,
4. whose standard therapy has been called into question by new evidence warranting doubt about its net therapeutic advantage, and
5. whose validated optimal treatment is not made freely available to patients.

Charles Weijer points out two additional situations in which placebo controls are permissible. If a particular population has failed to respond to first-line treatments for a condition and no proven second-line treatment exists, that population may be enrolled in a placebo-controlled trial. Also, if a new treatment simply is added onto a standard treatment, that

treatment may be tested against placebo as long as all the subjects in the trial get the standard treatment either with the add-on or with placebo.

SYMPTOM-PROVOCATION STUDIES. Another controversial psychiatric study is the symptom-provocation study or challenge study. The purpose of those studies is to learn more about the pathophysiology of mental illnesses by provoking their symptoms in mentally ill subjects. For example, in a number of different studies published in the 1990s researchers gave schizophrenic subjects a variety of psychoactive drugs to exacerbate the symptoms of psychosis. Symptom-provocation studies have generated far more outrage in the popular press and among patient advocacy groups than in the bioethics and medical literature, in which they have been defended for their scientific merit (Whitaker; Miller and Rosenstein). However, in those studies, unlike most clinical trials, mentally ill subjects often are exposed to risks without any expectation of therapeutic benefit. Also, unlike many Phase I clinical trials, symptom-provocation studies are performed not on healthy volunteers but on ill patients. Indeed, the very purpose of those studies is to induce harmful symptoms in patients who already have mental disorders.

RELAPSE STUDIES. A third source of controversy in psychiatry involves relapse studies or washout studies. In relapse studies mentally ill subjects are taken off their regular medications to determine whether they will relapse into their illnesses, how long it will take them to relapse, or whether their health can be maintained without medication. In a widely reported study at the University of California at Los Angeles that began in the 1980s, researchers required that subjects with schizophrenia who had recovered from their symptoms be taken off their medication. After the study was concluded, a subject committed suicide (Katz; National Bioethics Advisory Commission).

Defenders of relapse studies have argued that many mentally ill patients, particularly those with schizophrenia, are maintained on medications that can cause serious and irreversible side effects and that "drug holidays" are often an accepted part of standard therapy. Critics point out that it is in the interests of most patients to be maintained on the therapeutic regimen that has worked for them, that such patients are not informed of the risks of relapse studies, and that a relapse may increase the risk of future relapses (Katz; Shamoo and Keay).

MERGERS AND ACQUISITIONS

• • •

Between 1980 and 2002 there were an unprecedented number of healthcare mergers and acquisitions in the United States, affecting hospitals and hospital systems, nursing facilities, clinics, physician group practices, pharmaceutical manufacturers, and managed-care and other health insurance providers. Predictably, this headlong rush toward consolidation and concentration has triggered increased scrutiny of such transactions by those state and federal agencies responsible for antitrust and tax regulation. It has also spurred increased reflection on the ethical issues at stake in these merger and acquisition decisions. Such issues include concerns about fidelity to organizational mission; effects of organizational restructuring upon community access to services and other benefits; impact upon the welfare, working environment, and overall culture of affected employees; and the prevention and resolution of conflicts of interest among involved parties.

The number and frequency of hospital mergers and acquisitions increased dramatically during the 1980s and early 1990s. The trend peaked in the period 1994–1997, according to data from Irving Levin Associates, with 163 deals completed in 1996 and a record 197 deals in 1997. During that period the number of hospitals belonging to health networks or systems also increased significantly, from 56.2 percent in 1994 to 70.9 percent in 1998. By the beginning of the new century, the frequency of deals had declined somewhat, to 86 in 2000 and 83 in 2001, yet these numbers remain much higher than pre-1990 levels. Among the factors apparently driving this high rate of merger and acquisition activity are reduced Medicare reimbursement rates, significantly increased managed-care pressures to provide more services at lower prices, and a declining market for inpatient hospital services.

Benefits and Burdens of Consolidation

Hospital mergers and acquisitions can provide substantial benefits for institutions, their employees, and the communities they serve. They can bring needed capital into a healthcare organization, providing economic vigor and repositioning in a difficult marketplace; offering opportunities for new or expanded service lines; and even ensuring survival and the capacity to provide services to those in need. They can strengthen an organization's bargaining power and provide economies of scale and increased efficiency, all of which could lead to decreased costs to consumers. And they can bring standardization to, and better assessment of, the quality of care delivered.

A 2002 study by Bazzoli and colleagues examined the self-reported reasons for merger cited by involved hospitals during the periods 1983–1988 and 1989–1996. For both groups, the top three reasons for merger were identical: to

strengthen the institution's financial position, to achieve operating economies, and to consolidate services. Expansion of market share was another reason cited by a majority of respondents. Yet there were also certain changes in emphasis between the two study periods. Those citing expansion of visibility and service availability across the hospital's service area as a significant reason for merger increased from 33.3 percent in 1983–1988 to 53.2 percent in 1989–1996, while those citing expansion of provided service areas as a reason for merger decreased from 63.9 percent to 44.3 percent. In addition, respondents in the more recent period indicated an increasing emphasis upon nursing-staff downsizing as an intended cost-saving outcome of merger activity.

While the potential benefits of hospital consolidations via merger and acquisition can be manifold, these transactions can also create concerns about potential burdens for various stakeholders. One such concern has to do with the consequences of giving up local hospital control. When a community-based hospital merges with or is acquired by an organization or system headquartered elsewhere, especially out of state, what will the loss of local control mean in terms of the new organization's responses to the local community's specific needs? And what will be the postconsolidation status and level of service at the community-based hospital? Many consolidations, especially those involving a for-profit organization, include plans to increase profitability and market position by phasing out unprofitable service lines in favor of more profitable specializations. This can create hardships for communities—access to much-needed yet unprofitable services becomes more difficult, or the burden of providing these services is shifted to others. Another potential service limitation emerges when a merging or acquiring organization takes a strong religious or other principled position against providing certain services. Such consolidations raise understandable public concerns about whether reasonable access to those services will remain available within the community after consolidation.

Further, an increase in the price of services can be another potential community burden resulting from hospital merger or acquisition transactions. While consolidation-related efficiencies may allow for price reductions, or at least a hold on price increases, the newly consolidated and concentrated hospital organization will also have stronger market positioning and greater market power, and that power may be expressed through price increases. A 2000 study by Young and colleagues examined the relationship between market concentration and pricing patterns for three types of nonprofit hospitals: independent hospitals under local control, members of local hospital systems, and members of nonlocal hospital systems. The study showed that, in more concentrated markets, all three types of nonprofit hospitals exercised market power in the form of higher prices—and that hospitals that are a part of nonlocal systems were more aggressive in exercising this market power than either of the other hospital types.

Yet another community concern regarding hospital consolidations is their effect on the provision of charity care. According to American Hospital Association data, overall U.S. hospital expenses for uncompensated care (bad debt and charity care) were $18.5 billion in 1997, up from $6 billion in 1980 (Hall). Yet access to needed care remains difficult for many of the more than 42 million uninsured Americans who cannot afford that care. Thus, communities are often concerned about the effect of consolidation upon a local hospital's willingness to continue providing charity care, especially when a nonprofit community hospital is merging with or acquired by a for-profit hospital or system. There is evidence that for-profit hospitals are less likely to be accessible to the medically indigent and uninsured than nonprofit hospitals are, and that they tend to carry a smaller indigent-care load (Darr). One study of California nonprofit hospitals that were consolidated into for-profit organizations found that charity care declined in almost all cases analyzed. Moreover, in none of the deals did the sale proceeds, usually set aside in a foundation to provide charity care and other community benefits, sufficiently replace the community benefits provided by the former nonprofit hospitals (Mateo and Rossi).

One final area of community concern has to do with how consolidation might affect particular groups of internal stakeholders, namely hospital staff, trustees, and executives. Merger and acquisition activity can, and often does, involve downsizing and the loss of employment for some staff members. It can also lead to negatively perceived changes in working conditions, mission loyalty, and overall organizational culture. On the other hand, hospital executives and trustees, who are responsible for negotiating any possible consolidation, may be subject to various positive inducements, financial and otherwise, for their support of a transaction. Such a possibility appears all the more threatening to a community in which the actual details of a proposed consolidation have not been made public during the planning process.

Moral Obligations of Hospital Leaders

Community concerns have led to some significant changes in legal oversight of hospital consolidations at both state and federal levels, including transactions among nonprofit hospitals and between nonprofit and for-profit hospitals

(Peregrine). Yet it is clear that legal regulation cannot and will not ensure the fulfillment of healthcare leaders' moral obligations to the community as hospital consolidations are contemplated, planned, and executed. Nonprofit hospital trustees and executives, who are accountable for more than 80 percent of U.S. hospital beds, have particular fiduciary responsibilities to the communities served by their institutions, and there are specific moral obligations that should govern their participation in merger and acquisition activities.

MISSION PROTECTION. First, trustees and executives are responsible for upholding and protecting the mission and values of the institution they are already serving. According to the American Hospital Association Board of Trustees, a hospital's mission includes both caring for the sick and injured and improving community health, and any decisions regarding consolidation should thus emphasize the community's future health needs and the best overall organizational arrangements for meeting those needs. Trustees and executives, therefore, bear the moral obligation of participating in any proposed merger or acquisition as representatives of the community and its interests (Wilkins and Jacobson). They must ask how any proposed transaction would affect access to and delivery of health care in the community, seek independent assistance in assessing the impact of the transaction on the community, and work to avoid any unnecessary harmful effects upon quality of life in the community.

A critical aspect of a hospital's mission that should be protected, of course, is the provision of uncompensated care. Trustees and executives must consider the community's future health needs by ensuring that access to charity care will not be diminished or eroded by a merger or acquisition transaction, particularly when a nonprofit hospital is contemplating consolidation with a for-profit hospital or system. Further, as Leonard Weber points out, if a generally beneficial consolidation will also entail certain new community burdens, such as less-convenient location of services, then those segments of the community already experiencing greater social ills (such as poverty and environmental degradation) have a greater claim to be spared new social burdens than do better-off segments of the community.

In some instances a hospital's mission and values will involve specific principle-based exclusions from certain practices, as in the case of most Catholic hospitals' refusals to provide various reproductive services. When such an institution seeks a merger with or acquisition of another community hospital whose mission and values do not entail these service exclusions, then the obligation to consider the community's overall future health needs becomes somewhat more complex. Certainly the conscientious refusals of hospital leaders and sponsors to engage in certain practices should be respected. Yet the general obligation of hospitals to ensure adequate community access to those services normally and legally available in other communities places a potential limit upon the moral right of hospitals to restrict permissible practices (Weber). This becomes an especially strong concern where the postconsolidation institution would be the community's sole provider. In such circumstances, the costs of consolidation may simply be too high.

AVOIDING CONFLICT OF INTEREST. Second, trustees and executives have a moral obligation to disclose any potential conflict of interest and to avoid any private benefit in a proposed consolidation. They should not receive money during a consolidation process—nor should they accept any other incentive offered as a means of securing support for the transaction, such as promises of a job or board membership after consolidation. Any such offers should be disclosed to all involved parties, and negotiation practices should be utilized that will fully separate decisions about the transaction from decisions about positions in the post-transaction institution (Weber). Trustees and executives must be able to assure the community, which they serve as fiduciaries, that personal gain incentives have been removed from the negotiating table, and that the community's best interests are represented there.

PUBLIC DISCLOSURE AND HEARINGS. Third, hospital leadership should make the consolidation process fully public. Trustees should ensure that all objectives and processes of the transaction are made available to the general public and the state attorney general, and they should require public hearings and suitable waiting periods so as to hear and respond to community concerns about the transaction. Community-based consumer organizations should also be consulted in order to assess implications of the proposed consolidation that may not be immediately apparent to trustees and executives (Wilkins and Jacobson).

FAIR MARKET VALUE. Fourth, nonprofit trustees and executives are responsible for ensuring fair market value for their institution in the transaction, particularly when a nonprofit hospital is being acquired by a for-profit hospital or system. This requires, among other things, ensuring independent valuation by a third-party firm with experience in the healthcare field. In addition, the methodology used in determining fair market value should be made a part of public disclosure of the negotiations. A significant portion of a nonprofit hospital's value that must be included in any assessment of fair market value is the community benefit it provides: the hospital's value to community members (as

owners of it), the value it provides in uncompensated care, and the value it holds from past publicly funded investment are all part of its value.

Trustees and executives, as fiduciaries of the community, must ensure that community-benefit value is not lost in consolidation transactions and that community benefit in the form of charity care and other community health initiatives is guaranteed into the future. In the sale of a nonprofit hospital to a for-profit, this usually involves using that portion of the sale price designated as the community-benefit value to establish a nonprofit charitable foundation or trust whose assets will be used to fund charity care and community health ventures. Nonprofit executives and trustees should require that the terms of the foundation—particularly regarding who will control its assets and the specific purposes for which they may be expended—be detailed and clear before consolidation can be completed, and that the foundation will provide regular public reports on its efforts to promote community health (Wilkins and Jacobson).

STAFF AND EMPLOYEE INTERESTS. Fifth, in addition to their community-oriented fiduciary responsibilities, hospital trustees and executives also have responsibilities to their institutional and medical staffs. When any consolidation is considered, staff and employees must be fully informed and educated about its perceived need and its intended goals and processes—and their responses and concerns must be heard. Just as a community assessment is necessary to determine the community interests that are at stake in any proposed transaction, an organizational assessment is necessary to recognize specific organizational cultures and how they may or may not fit with the cultures of other merging or acquiring facilities. The employees and staff in each facility should be oriented to the culture, history, and mission of the other facility or system.

Further, employees of institutions facing consolidation may have concerns not only about postconsolidation culture and working conditions, but also about the prospect of staff downsizing and loss of employment. Quite often these concerns are well founded. If the organization's ability to continue serving the needs of the community will necessarily require staff downsizing, then the trustees and executives have an obligation to ensure, among other things, that: (1) all employees to be laid off will be given advance notice that includes detailed explanation of the necessity of and criteria for their selection; (2) employees to be laid off will have opportunity to appeal their selection if they have reason to believe the criteria were inappropriately applied; and (3) laid-off employees will be provided with significant outplacement services and interim benefits (Weber).

Exit Provisions

Perhaps predictably, the large number of hospital mergers and acquisitions have produced not only many successes, but also quite a few organizational and financial failures. As Michael Peregrine has noted, this reality may suggest a final obligation of nonprofit hospital trustees negotiating a consolidation—namely to incorporate termination provisions (known as *exit* or *unwind* provisions) within the transaction terms. These terms might specify what particular events would indicate a failure of the consolidation's objectives and thus trigger an unwinding, any required mediation or arbitration related to the implementation of the unwinding, the time period during which the trigger would remain effective, and the actual mechanisms for implementing the unwinding if the consolidation fails to achieve its objectives.

Hospitals are, as Kurt Darr notes, "social organizations with an economic dimension, rather than economic organizations with a social dimension." The recent history of U.S. healthcare offers many examples of how the economic dimension of hospitals may be enhanced through mergers and acquisitions. Yet a recognition of the primary social dimension of hospitals illuminates a variety of community-oriented moral responsibilities and obligations that must not be ignored in such transactions, even for the sake of economic enhancement.

METAPHOR AND ANALOGY

• • •

Many of our practices and much of our discourse in healthcare hinge on metaphor and analogy, whose significance is sometimes overlooked because they are considered merely decorative or escape notice altogether. Despite their relative neglect, they significantly shape our interpretations of what is happening as well as what should happen. This entry will examine metaphor before considering analogy, particularly analogical reasoning, noting their overlap where appropriate.

Metaphors in Bioethics

NATURE AND FUNCTION OF METAPHORS. Perhaps because medicine and healthcare involve fundamental matters of life and death for practically everyone, and in often mysterious ways, they are often described in metaphors. For instance, physicians may be viewed as playing God, or acting as parents, and nurses seen as advocates for patients, while medicine itself may be interpreted as warfare against disease. Metaphors involve imagining something as something else, for example, viewing human beings as wolves or life as a journey. "The essence of metaphor," according to George Lakoff and Mark Johnson, "is understanding and experiencing one thing through another" (p. 5). More precisely, metaphors are figurative expressions that interpret one thing in terms of something else (Soskice).

In contemporary philosophical literature on metaphor, critics have challenged some traditional conceptions, contending that metaphors are more than merely ornamental or affective ways to state what could be stated in a more literal or comparative way, and that they can be and often are cognitively significant (see, e.g., Black, 1962, 1979; Ricoeur; Soskice). According to the traditional substitution view, a metaphorical expression is merely a substitute for some equivalent literal expression. For example, the metaphorical expression "John is a fox" substitutes for the literal expression "John is sly and cunning." One common version of the substitution view, what philosopher Max Black (1962) calls a comparison view (elements of which can be found in Aristotle), construes metaphor as the presentation of an underlying analogy or similarity. Hence, metaphor is "a condensed or elliptical simile" (Black, 1962), or it is a "comparison statement with parts left out" (Miller). "John is a fox," for example, indicates that "John is like a fox in that he is sly and cunning." According to such views, metaphors are dispensable ways to express what could be expressed differently, but they often appeal to the emotions more effectively than their equivalent literal expressions or comparisons would do.

By contrast, many recent theories of metaphor stress its cognitive significance. In an early and very influential essay, Black (1962) defended an interaction view of metaphor, in which two juxtaposed thoughts interact to produce new meanings, through the metaphor's "system of associated commonplaces" or "associated implications." The metaphor—for instance, "wolf" in "man is a wolf"—serves as a "filter" for a set of associated implications that are

transferred from the secondary subject (*wolf*) to the principal subject (*man*) in the sentence. In a full interaction or interanimation view of metaphor, the transfer of meaning occurs both ways, not merely from the secondary subject to the principal subject (Soskice).

Metaphors highlight and hide features of the principal subject, such as the physician who is viewed as a parent or as a friend, by their systematically related implications (Black, 1962; Lakoff and Johnson). When argument is conceived as warfare, for example, the metaphor highlights the conflict involved in argument, while it hides the cooperation and collaboration, involving shared rules, that are also indispensable to argument. Our metaphors thus shape how we think, what we experience, and what we do by what they highlight and obscure.

Metaphors are often associated with models. For instance, we have both metaphors and models of the doctor-patient relationship. The physician may be viewed through the metaphor of father and the patient through the metaphor of child, and their relationship may be interpreted through the model of paternalism. Models, for our purposes, state the network of associated commonplaces and implications in more systematic and comprehensive ways—according to Black, "every metaphor is the tip of a submerged model" (1979, p. 31).

Metaphors and models may be good or bad, living or dead. Both metaphors and models can be assessed by how well they illuminate what is going on and what should go on. We can distinguish descriptive and normative uses of metaphors and models, without admitting a sharp separation between fact and value. For instance, the metaphor of physician as father (or parent), and the model of paternalism (or parentalism), may accurately describe some relationships in medicine, or they may suggest ideal relationships in the light of some important principles and values.

MEDICINE AS WAR. The metaphor of warfare illuminates much of our conception of what is, and should be, done in healthcare. This metaphor emerges in the day-to-day language of medicine: The physician as the captain leads the battle against disease; orders a battery of tests; develops a plan of attack; calls on the armamentarium or arsenal of medicine; directs allied health personnel; treats aggressively; and expects compliance. Good patients are those who fight vigorously and refuse to give up. Victory is sought; defeat is feared. Sometimes there is even hope for a "magic bullet" or a "silver bullet." Only professionals who stand on the firing line or in the trenches can really appreciate the moral problems of medicine. And they frequently have "war stories" to relate. Medical organization, particularly in the hospital, resembles military hierarchy; and medical training, particularly with its long, sleepless shifts in residencies, approximates military training more than any other professional education in our society (Childress).

As medicine wages war against germs that invade the body and threaten its defenses, so the society itself may also declare war on cancer or on AIDS under the leadership of its chief medical officer, who in the United States is the surgeon general. Articles and books even herald the "Medical-Industrial Complex: Our National Defense." As Susan Sontag notes, "Where once it was the physician who waged bellum contra morbum, the war against disease, now it's the whole society" (p. 72).

The military metaphor first became prominent in the 1880s, when bacteria were identified as agents of disease that threaten the body and its defenses. The metaphor both illuminates and distorts healthcare. Its positive implications are widely recognized—for instance, in supporting a patient's courageous and hopeful struggle against illness and in galvanizing societal support to fight against disease. But the metaphor is also problematic. Sontag, who was diagnosed with cancer in the late 1970s, reports that her suffering was intensified by the dominance of the metaphor of warfare against cancer. Cancer cells do not just multiply; they are *invasive.* They *colonize.* The body's *defenses* are rarely strong enough. But since the body is under attack (*invasion*) by *alien* invaders, counterattack is justified. Treatments are also often described in military language:

> Radiotherapy uses the metaphors of aerial warfare; patients are "bombarded" with toxic rays. And chemotherapy is chemical warfare, using poisons. Treatment aims to "kill" cancer cells (without, it is hoped, killing the patient). Unpleasant side effects of treatment are advertised, indeed overadvertised. ("The agony of chemotherapy" is a standard phrase.) It is impossible to avoid damaging or destroying healthy cells (indeed, some methods used to treat cancer can cause cancer), but it is thought that nearly any damage to the body is justified if it saves the patient's life. Often, of course, it doesn't work. (As in: "We had to destroy Ben Suc in order to save it.") There is everything but the body count. (Sontag, p. 65)

Such "military metaphors," Sontag suggests, "contribute to the stigmatizing of certain illnesses and, by extension, of those who are ill" (p. 99). Other ill individuals have found the military metaphor unsatisfactory for other reasons. For instance, as a teenager, Lawrence Pray originally tried to conquer his diabetes, but his struggles and battles were futile and even counterproductive. Then over time he came to

view his diabetes not as an *enemy* to be *conquered,* but as a *teacher*. Only then did he find a personally satisfactory way of living (Pray and Evans).

Still others with illness, by contrast, have found the military metaphor to be empowering and enabling. In her wide-ranging study of pathographies, that is, autobiographical descriptions of personal experiences of illness, treatment, and dying, Anne Hunsaker Hawkins identifies several "metaphorical paradigms" that offer themes of "an archetypal, mythic nature." In addition to illness as a battle, she notes illness as a game or sport (a subset of the military metaphor), illness as a journey into a distant country, illness as rebirth or regeneration— and, on a somewhat different level, healthy-mindedness as an alternative to contemporary medicine. While pathographies are individualized statements, they provide "an immensely rich reservoir of the metaphors and models that surround illness in contemporary culture" (p. 25). These various metaphorical paradigms structure individuals' interpretations of their experiences of illness. Patterns emerge in individuals' selection of metaphors. They vary in part according to the illness involved—for example, the military metaphor is more common in descriptions of experiences with cancer and AIDS, while the rebirth metaphor is more common in descriptions of a critical life-threatening event, such as a heart attack. Furthermore, the military metaphor is more prevalent than the journey metaphor because it better fits the experience of modern medicine—for instance, it is easier to construe the physician as a *general* in a war than as a *guide* on a journey. Nevertheless, these various metaphors are often mixed and complementary. They can be evaluated, Hawkins suggests, according to their capacity to enable and empower ill persons, for instance, by restoring a sense of personal dignity and worth. And, while expressing larger sociocultural patterns, the individual's choice of a particular metaphor is a creative act of assigning meaning to his or her illness.

The metaphor of warfare has been further challenged in modern medicine because of its apparent support for overtreatment, particularly of terminally ill patients, because death is the ultimate enemy, just as trauma, disease, or illness is the immediate enemy. Physicians and families under the spell of this metaphor frequently find it difficult to let patients die. *Heroic* actions, with the best available weapons, befit the military effort that must always be undertaken against the ultimate enemy. Death signals defeat and forgoing treatment signals surrender. Some clinicians even feel more comfortable withholding (i.e., not starting) a treatment for cancer, for instance, than they do withdrawing (i.e., stopping) the same treatment, in part because withdrawing treatment implies retreat.

According to its critics, the invocation of the military metaphor often fails to recognize moral constraints on waging war. "Modern medicine," William May writes, "has tended to interpret itself not only through the prism of war but through the medium of its modern practice, that is, unlimited, unconditional war," in contrast to the just-war tradition (1983, p. 66). In the spirit of modern total war, "hospitals and the physician-fighter wage unconditional battle against death" (1983, p. 66). One result is that many patients seek assisted suicide or active euthanasia in order to escape from this warfare's terrorist bombardment. Traditional moral limits in the conduct of war include the principle of discrimination, which authorizes direct attacks on combatants but not on noncombatants. In medical care, the opposing combatant is the disease or death, not the patient. However, the patient is regularly the battleground and sometimes even becomes the enemy. Furthermore, in accord with the just-war tradition's requirement of reasonable prospect of success and proportionality, the treatment should offer the patient a reasonable chance of success; his or her suffering must be balanced against the probable benefits of prolongation of life.

Other problematic or ambiguous implications of the war metaphor appear in the allocation of resources for and within healthcare. First, under the military metaphor, society's healthcare budget tends to be converted into a defense budget to prepare for and conduct war against disease, trauma, and death. As a consequence, the society may put more resources into healthcare in relation to other goods than it could justify, especially under a different metaphor, such as nursing or business (see below). Indeed, the society may overutilize healthcare, especially because technological care may contribute less to the national defense of health itself—through the reduction of morbidity and premature mortality—than other factors, such as the reduction of poverty.

Second, within the healthcare budget, the military metaphor tends to assign priority to critical care over preventive and chronic care. It tends to concentrate on critical interventions to cure disease, perhaps in part because it tends to view health as the absence of disease rather than a positive state. It tends to neglect care when cure is impossible. A third point is closely connected: In setting priorities for research and treatment, the military metaphor tends to assign priority to terminal diseases, such as cancer and AIDS, over chronic diseases. Fourth, medicine as war concentrates on technological interventions, such as intensive-care units, while downplaying less technological modes of care.

In short, the military metaphor has some negative or ambiguous implications for a moral approach to healthcare

decisions: It tends to assign priority to healthcare (especially medical care) over other goods, and, within healthcare, to critical interventions over chronic care, killer diseases over disabling ones, technological interventions over care, and heroic treatment of dying patients rather than allowing them to die in peace.

Some of the negative or ambiguous implications of the war metaphor for healthcare can be avoided if, as noted earlier, the metaphor is interpreted in accord with the limits set by the just-war tradition. However, the war metaphor may require supplementation as well as limitation. It is not the only prominent metaphor for healthcare; since the early 1980s its dominance has been threatened by the language of economics and business, as reflected in the language of a healthcare industry. Providers deliver care to consumers, seek or are forced to seek productivity in light of cost-effectiveness or cost-benefit analyses, and may be concerned with "resource management, managed-care systems, and market strategies" (Stein, p. 172). This metaphor also highlights and hides various features of contemporary healthcare. Many critics of this metaphor worry that the language of efficiency will replace the language of care and compassion for the sick and equity in distribution of healthcare. Nevertheless, this metaphor has become more and more pervasive and persuasive as the structure of medicine and healthcare has changed, and as concerns about costs have become more central in societal discussions. Patients often fear undertreatment as hospitals and professionals seek to reduce costs, in contrast to their earlier fears of overtreatment under the war metaphor.

Both military and economics metaphors illuminate contemporary healthcare. But they may not be adequate, even together, to guide and direct healthcare. Whether any particular metaphor is adequate or not will depend in part on the principles and values it highlights and hides. Others have proposed nursing, a subset of healthcare, as a supplementary metaphor for the whole of healthcare, because of its attention to caring more than curing and to hands-on rather than technological care. Even though this metaphor of nursing is also inadequate by itself, it could direct the society to alternative priorities in the allocation of resources for and within healthcare, particularly for chronic care.

THE WAR AGAINST AIDS. Even as the military metaphor has been partially displaced by business and economics metaphors in the changing structure of healthcare, it has gained favor as a way to describe and direct society's response to the major epidemic of the acquired immunodeficiency syndrome (AIDS). Societies often resort to the metaphor of war when a serious threat to a large number of human lives requires the mobilization of vast societal resources, especially when that threat comes from biological organisms, such as viruses, that invade the human body. And AIDS activists have appealed to the military metaphor in an effort to galvanize society and to marshal its resources for an effective counterattack against the human immunodeficiency virus (HIV) that causes AIDS. However, critics charge that the war on AIDS has diverted important resources away from other important wars, such as the war against cancer.

Other controversies have emerged. From the beginning of the war against AIDS, identification of the enemy has been a major goal. Once the virus was identified as the primary enemy, it also became possible to identify human beings who carry or harbor the virus. This technology then led to efforts to identify HIV-infected individuals, even through mandatory screening and testing, as potential enemies of the society. In social discourse and practice, the carrier tends to become an enemy as much as the virus he or she carries, especially since society views many actions that expose individuals to the risk of HIV infection as blameworthy. Thus, the metaphor of war often coexists with metaphors of AIDS as punishment and as otherness (Ross, 1989a, 1989b; Sontag). In this specific case of war against AIDS, just as in the general war against disease, the military metaphor would be less dangerous if society adhered to the constraints of the just-war tradition, rather than being tempted by a crusade.

RELATIONSHIPS BETWEEN HEALTHCARE PROFESSIONALS AND RECIPIENTS OF CARE. Relationships between physicians and other healthcare professionals, on one hand, and patients, on the other, have been described and directed by a wide variety of metaphors and models (Childress and Siegler). For example, William May (1983) has identified images of the physician as fighter, technician, parent, covenanter, and teacher; Robert Veatch has identified several major competing models of physician-patient relationships: engineering, priestly (which includes the paternalistic model), collegial, and contractual models. Other metaphors such as friend and captain of the ship have also been used (King et al.).

Some critics contend that such models are *whimsical gestalts,* that many other arbitrary models could be invented—for example, bus driver or back-seat driver—and that moral points can and should be made more directly (Clouser). Such criticisms overlook how metaphors and models function in the interpretation and evaluation of interactions between physicians and patients. They miss the role of imagination, which can be defined as "reasoning in metaphors" (Eerdman). For example, opponents of paternalistic

medical relationships usually do not eschew all use of metaphor; instead they offer alternative metaphors, such as partnership or contracts. And these various metaphors may be more or less adequate to describe what occurs and to direct what should occur in health care.

Metaphors and models highlight and hide features of the roles of physicians and other healthcare professionals by their various associated implications. For example, viewing the physician as a parent—or specifically as a father, based on the nineteenth-century model of the family—highlights some features of medical relationships, such as care and control, while hiding others, such as the payment of fees. In their use to describe, interpret, and explain relationships, such metaphors are subject to criticism if they distort more than they illuminate. And when they are offered to guide relationships and actions, they are subject to criticism if they highlight only one moral consideration, such as the physician's duty to benefit the patient or to respect patient autonomy, while hiding or obscuring other relevant moral considerations. It is also appropriate to consider the feasibility of various ideal relationships in light of significant personal, professional, and institutional constraints.

Several metaphors may be necessary to interpret healthcare as it is currently structured and to guide and direct actions, practices, and policies in healthcare. Some metaphors may fit some relationships better than others; for example, relations in clinical research, family practice, and surgery may be illuminated respectively by the metaphors of partner, teacher-student, and technician-consumer. Furthermore, not all of these metaphors conflict with each other; some may even be mutually supportive as well as compatible, for example, contractor and technician.

NURSING AS ADVOCACY. Major changes in the conception of nursing correlate with alterations in its primary metaphors. Whether situated within the military effort against disease or viewed as physicians' handmaidens and servants, nurses have traditionally been expected to cultivate passive virtues, such as loyalty and obedience. Their moral responsibility was primarily directed toward physicians and institutions, such as hospitals, and only secondarily toward patients. This interpretation of responsibility was shaped in part by nursing's military origins in the nineteenth century, as well as by societal conceptions of gender (Winslow; Bernal). Then in the 1970s, nursing was reconceived through the metaphor of advocacy. Nurses became advocates for *clients* and *consumers* (the term *patient* was often rejected as too passive). This legal metaphor, drawn from the advocate as one who pleads another's cause, especially before a tribunal of justice, highlights active virtues such as courage, persistence, and perseverance, and views the nurse as primarily responsible to the patient or client. This metaphor is explicit or implicit in formal nursing codes, and it is also featured in a large number of nurses' stories of advocacy and conflict in healthcare (Winslow; Bernal).

Critics note that the metaphor of advocacy reduces the range of services traditionally offered by nurses; it is thus insufficiently comprehensive (Bernal). In addition to distorting the human experience of illness, it distorts nursing by focusing almost exclusively on patients' or clients' rights, construed mainly in terms of autonomy, and it neglects positive social relationships in healthcare (Bernal). It highlights conflict among healthcare professionals because it implies that some of them do not adequately protect the rights of patients. Thus, the metaphor frequently supports a call for increased nursing autonomy as a way to protect patient autonomy. Because of its adversarial nature, many question whether the metaphor of advocacy can adequately guide relationships among healthcare professionals in the long run, even if it is useful in the short run. The metaphor may also assume that the nurse's responsibility to the patient/client is always clear-cut and overriding, even though nurses may face serious conflicts of responsibility involving patients, other individuals, associates, and institutions (Winslow). At the very least, sympathetic commentators call for further clarification of the metaphor of advocacy (Winslow); while critics seek alternative metaphors and models, such as covenant (Bernal), partnership, teamwork, or collegiality, that appear to offer more inclusive, cooperative ideals.

PLAYING GOD AND OTHER METAPHORS OF LIMITS. "Playing God" has been a common metaphor for both describing and directing the activities of scientists, physicians, and other healthcare professionals. They have been criticized for usurping God's power—for instance, the power over life and death—by letting patients die or by using new reproductive technologies.

There are theological warrants for playing God in the Jewish and Christian traditions, which affirm the creation of human beings in God's image and likeness. Thus, Paul Ramsey calls on those who allocate healthcare to play God in a fitting way: We should emulate God's indiscriminate care by distributing scarce lifesaving medical technologies randomly or by a lottery rather than on the basis of judgments of social worth.

Despite a few such positive uses of the metaphor of "playing God," the metaphor is generally used to identify two aspects of divine activity that should not be imitated by humans: God's unlimited power to decide and unlimited power to act. On one hand, users of this metaphor demand

scientific and medical accountability over unilateral decision making. On the other hand, critics call for respect for substantive limits—for example, not creating new forms of life (U.S. President's Commission, 1982).

Edmund Erde contends that statements such as "doctors should not play god" are so unclear that they cannot function as commands and do not articulate a principle; thus, they cannot be followed because agents do not know how to conform their actions to them. Nor do they explain why certain actions should not be undertaken. Such phrases are, Erde argues, "metaphoric in that they tuck powerful feelings and images into descriptive language that cannot be understood literally" (p. 606). Any activity, such as mercy killing, that is "labeled `playing god' carries the implication that it is clearly wrong" (p. 607). These phrases are used for situations in which agents face choices, but one option is considered immoral and is rejected as arrogantly and presumptuously playing God. The background of intelligibility of this metaphor, according to Erde, is found in the Western idea of the great chain of being, which identifies appropriate responsibilities at each level and opposes the usurpation of power and the failure to respect limits.

Other important and widespread metaphors of limits include the "thin edge of the wedge" and the "slippery slope," both of which warn against undertaking certain actions because other unacceptable actions will inevitably follow. Examples regularly appear in debates about euthanasia. Even though such metaphors are often misused, they are appropriate in some contexts. In each use of these metaphors, important moral questions require attention—the evaluation of the first action and subsequent actions—and important conceptual and empirical questions must be addressed in order to determine whether the putatively bad consequences will inevitably follow what might be innocuous first steps. (Similar questions emerge for some analogies, such as the Nazi analogy, which is also widely invoked to oppose such practices as mercy killing.)

METAPHORS FOR BIOETHICS AND BIOETHICISTS. The role and function of the bioethicist have often been construed in metaphorical terms. The common language of *applied ethics* invokes the metaphor of engineering as an application of basic science that does not contribute to basic science. The expertise of applied ethicists resides in their ability to apply general theories and principles to specific arenas of human activity. The metaphor of application has been widely challenged on the grounds that it is too narrow and distorts much that is important in bioethics. The term *applied* suggests that ethicists are problem solvers rather than problem setters, that they solve puzzles rather than provide perspectives, that they answer rather than raise questions, and that they begin from theory rather than from lived experience. It implies a limited technical or mechanical model of ethics.

The term *applied* distorts the numerous theoretical controversies in bioethics, and neglects the way bioethics may help to resolve or recast some theoretical controversies. At the very least, the metaphor of application may need to be supplemented by various other metaphors for the task of practical ethics and the role of the practical ethicist: "Theoretician, diagnostician, educator, coach, conceptual policeman, and skeptic are also supplemental or alternative roles to that of the technician" (Caplan, p. 30).

Some other metaphors are drawn from ancient religious roles, such as prophet or scribe. Yet another metaphor is *conversation,* which is prominent in approaches to bioethics that emphasize interpretation, hermeneutics, and narrative. And the *stranger* has been proposed as the best metaphor for the ethicist in professional education because his or her outside perspective can challenge ordinary assumptions (Churchill).

Suggestions emerge at various times to retire all metaphors, not merely some metaphors in some realm of discourse—for instance, Sontag proposes retiring all metaphors for illness. However, it is not possible to strip our discourse in science, medicine, and healthcare, or in biomedical ethics, of all metaphors. Instead, we must use metaphors with care and must carefully assess their adequacy in descriptive and normative functions.

Analogies in Bioethics

ANALOGIES AND ANALOGICAL REASONING. Often metaphors and analogies are presented in ways that indicate their substantial overlap. Indeed, for the comparison view of metaphor, there is little difference between them, because metaphors are compressed analogies. Some recent theories of metaphor have stressed, by contrast, that metaphors create similarities rather than merely expressing previously established and recognized similarities or analogies. According to Black, comparison views of metaphor fail because they reduce the ground for shifts of meaning (from the secondary subject to the primary subject) to similarity or analogy (1962). Nevertheless, there is a strong consensus that metaphorical statements presuppose some resemblance, even when they also create resemblance (Ricoeur). Black later conceded that metaphors "mediate an analogy or structural correspondence." Metaphor is, roughly speaking, "an instrument for drawing implications grounded in perceived

analogies of structure between two subjects belonging to different domains" (1979, p. 32). And yet metaphor does not merely compare two things that are similar, but rather enables us to see similarities in what would be regarded as dissimilar.

Metaphors and analogies are thus closely related, with metaphors both expressing and creating similarities. In general, good metaphors function cognitively to generate new meaning and insight, by providing new perspectives; while good analogies extend our knowledge by moving from the familiar to the unfamiliar, from the established to the novel. In stretching language and concepts for new situations, analogy does not involve the imaginative strain often evident in the use of metaphors (Soskice). Nevertheless, the differences in function between metaphors and analogies should not be exaggerated.

The term analogy derives from the Greek *analogia,* which referred to mathematical proportion. "An analogy in its original root meaning," Dorothy Emmet observes, "is a proportion, and primarily a mathematical ratio, e.g., 2: 4: : 4: X. In such a ratio, given knowledge of three terms, and the nature of the proportionate relation, the value of the fourth term can be determined. Thus analogy is the repetition of the same fundamental pattern in two different contexts" (p. 6).

Analogical reasoning proceeds inductively, moving from the known to the unknown. It appears prominently in problem solving and thus is featured in research in cognitive science and artificial intelligence (Helman; Keane). For instance, computer problem-solving programs must search for analogous problems that have been successfully solved to generate solutions to new problems whether in highly structured domains such as law or in less structured domains.

Analogical reasoning has an important place in moral discourse, not only because of its importance in problem solving, but also because of the widely recognized moral requirement to treat similar cases in a similar way. Often stated as a principle of universalizability or of formal justice or formal equality, dating back at least to Aristotle, the requirement to treat similar cases in a similar way also appears in the common law's doctrine of precedent. The basic idea is that one does not make an acceptable moral or a legal judgment—perhaps not even a moral or legal judgment at all—if one judges that X is wrong, but that a similar X is right, without adducing any relevant moral or legal difference between them. In general, analogical reasoning illuminates features of morally or legally problematic cases by appealing to relevantly similar cases that reflect a moral or legal consensus (precedent). Of course, much of the moral (or legal) debate hinges on determining which similarities and differences are both relevant and significant.

Since the early 1980s ethicists have directed new attention to the role of analogical reasoning in case-oriented or casuistical judgments in bioethics and elsewhere. In *The Abuse of Casuistry,* Albert Jonsen and Stephen Toulmin identify "the first feature of the casuistic method" in its classical formulations as "the ordering of cases under a principle by paradigm and analogy" (p. 252). For instance, the rule prohibiting killing is set out in *paradigm cases* that illustrate its most manifest breaches according to its most obvious meaning. Moving from simple and clear cases to complex and uncertain ones, casuists examine various alternative circumstances and motives to determine whether those other cases violate the rule against killing. They seek analogies that permit the comparison of "problematic new cases and circumstances with earlier exemplary ones," that is, the similar cases that constitute presumptions (Jonsen and Toulmin, p. 316).

Despite the claims of some modern casuists, it is not clear that analogical reasoning distinguishes casuistical from principlist approaches. For instance, in analyzing the novel microallocation problems of modern medicine, Paul Ramsey appealed to the analogous "lifeboat" cases—when some passengers have to be thrown overboard in order to prevent the lifeboat from sinking—as a way to interpret the requirements of the principle of equality of opportunity in distributing scarce lifesaving medical technologies such as kidney dialysis. Because principles and rules are indeterminate, and because they sometimes conflict, analogical reasoning can be expected in case judgments—mere application cannot be sufficient.

Analogies are often divided into two main types: analogies of attribution and analogies of proportion (Cahill). The analogy of attribution involves a comparison of two terms or analogates, both of which have a common property, the analogon, that appears primarily in one and secondarily in the other. As Thomas Aquinas noted, *healthy* is used primarily for a person in a state of health (a *healthy* person) and secondarily for those medicines and practices that help to maintain or restore health (e.g., a *healthy* diet) or specimens that provide evidence of the body's health (e.g., *healthy* blood). By contrast, in the analogy of proportion, the analogates lack a direct relationship, but each of them involves a relationship that can be compared to a relationship in the other (Cahill). This second type is most common in analogical reasoning in biomedical ethics, as is evident in debates about maternal-fetal relations and abortion, where analogies of attribution also appear, particularly with reference to the fetus.

Analogical reasoning in debates about maternal-fetal relations. Debates about maternal-fetal relations, including

pregnant women's decisions to abort and to decline cesarean sections, illustrate the pervasiveness and importance of analogical reasoning. Traditionally, abortion has been construed as directly killing the fetus, an innocent human being, in violation of the duty of nonmaleficence. Hence, in traditional Roman Catholic moral theology, direct abortions are tantamount to homicide. Sometimes the analogy of the *unjust aggressor* appears in situations where the pregnancy threatens the pregnant woman's life or health; but it has not been accepted in official Catholic thought the way the similar analogy of the *pursuer* has been accepted in some Jewish thought to justify abortions when there is such a threat.

Some feminists and others have attempted to recast the debate about abortion to focus on the basis and extent of the pregnant woman's obligation to provide bodily life support to the fetus. Often accepting, at least for purposes of argument, the premise that the fetus is a human being from the moment of conception (or at some time during the pregnancy), they argue that this premise does not entail that the pregnant woman always has a duty to sustain the fetus's life regardless of the circumstances of pregnancy, the risks and inconveniences to the pregnant woman, and so forth. Their arguments often proceed through analogies to other hypothetical or real practices or cases, on the assumption that a judgment about those practices or cases will entail a similar judgment about abortion.

The fantastic abortion analogies introduced by Judith Jarvis Thomson (1971) have been particularly influential and controversial. In one of her artificial cases, an individual with a rare blood type is kidnapped by the Society of Music Lovers and attached to a famous violinist who needs to purify his system because of his renal failure. Part of the debate concerns whether relevant analogies can be found in such fantastic, artificial cases, in contrast to actual real-life cases. For example, against Thomson, John Noonan opposes abortion in part by appeal to a U.S. tort-law case, in which the court held liable the hosts who had invited a guest for dinner but then put him out of their house into the cold night even though he had become sick and fainted and requested permission to stay (Noonan).

Some feminists and others contend that other analogous real-life legal and moral cases support the pregnant woman's free decision to continue or to discontinue her pregnancy. For many the relevant analogous cases concern living organ and tissue donation. Such donations are conceived as voluntary, altruistic acts that should not be forced by others even to save the potential recipient's life. They are *gifts of life.* Requiring a pregnant woman to continue the pregnancy until birth imposes on her a heavier burden than others are expected to bear in analogous circumstances, such as a parent who could save a child's life by donating a kidney. Thus, the provision of bodily life support, whether through donating an organ or allowing the fetus to use the uterus, has been conceived as a gift of life that should not be legally enforced (Mattingly; Jung).

According to Lisa Sowle Cahill, much analogical reasoning about pregnancy overlooks what is unique about maternal-fetal relations and thus obscures the morally relevant features of pregnancy or makes some relevant features more significant than they are. Many analogies problematically narrow our moral perspective on abortion by portraying the inception of pregnancy as accidental and the fetus as strange, alien, and even hostile. Furthermore, they often rely on the connotative meanings of their terms, particularly as embedded in a story, such as Thomson's case of kidnapping the unwilling blood donor. Examples also appear in the rhetoric of abortion opponents who, for instance, speak of the fetus as a *child,* and thereby distort the unique dependence of the fetus on the pregnant woman (Cahill). Finally, Cahill contends, justifications of abortion based on analogy often rest on liberal convictions that special responsibilities derive only from free choice.

For all these reasons, Cahill holds that analogical reasoning needs supplementation through direct examination of the unique features of maternal-fetal relations, particularly total fetal dependence, and of the ways these unique features qualify maternal, professional, and societal obligations. She argues that, as a category or class of moral relations, pregnancy "is unique among human relations at least because in it one individual is totally and exclusively dependent on a particular other within a relation which represents in its physical and social aspects what is *prima facie* to be valued positively" (p. 283). Hence, she argues, most analogies hide what is distinctive and unique about pregnancy, even though they identify some morally relevant features of maternal-fetal relations.

With the emergence of other maternal-fetal conflicts, particularly regarding cesarean sections to benefit the fetus, similar debates have emerged about the appropriateness of the analogy with living organ and tissue donation. For instance, in the case of A.C. (1990), the majority of the court held that, just as courts do not compel people to *donate* organs or tissue to benefit others, so they should not compel cesarean sections against the will of pregnant women to benefit potentially viable fetuses. The dissenting opinion rejected the analogy with organ and tissue donation, insisting that the pregnant woman "has undertaken to bear another human being, and has carried an unborn child to viability," that the "unborn child's" dependence upon the

mother is unique and singular, and that the "viable unborn child is literally captive within the mother's body" (A.C., *In re,*).

Even though analogies with organ and tissue donation are now widely invoked to oppose state control of pregnant women's decisions regarding both abortion and cesarean sections, there are important differences between these two contexts. In the abortion debate, pregnancy is viewed as the provision of bodily life support and is itself analogous to the donated organ. In the debate about cesarean sections, the surgical procedure is analogous to organ donation—the potentially viable fetus is removed for its own benefit rather than to benefit some other party as in organ or tissue donation. In the abortion debate, the pregnancy is viewed as invasive; in the debate about cesarean sections, the surgical procedure is invasive. The central issue is whether state coercion in these cases to benefit the fetus is morally and legally acceptable. The debate hinges in part on the appropriateness of the living organ and tissue donation as an analogy. Even the critics of the analogy engage in analogical reasoning, but they deny that the similarities are more morally or legally relevant and significant than the dissimilarities. Defenders of governmental coercion could also hold that the moral or legal precedent is mistaken and that organs and tissues should sometimes be conscripted or expropriated from living persons.

Similar disputes appear in other areas of contemporary bioethics—for instance, in debates about whether mandatory testing or screening for antibodies to the human immunodeficiency virus, which causes AIDS, can be justified by analogy to accepted practices of mandatory testing or screening; and in debates about whether transplantation experiments using human fetal tissue, following deliberate abortions, are analogous to the complicitous use of materials or data from the morally heinous Nazi experiments. In these cases, as in many others, the debates focus to a great extent on the relevance and significance of the proposed analogies.

Conclusions

Debates in biomedical ethics are often debates about which metaphors and analogies illuminate more than they distort. Far from being merely decorative or affective, metaphors and analogies are central to both discourse and practice. They must be evaluated specifically according to how well they function to describe and/or direct actions and relationships. Even though in recent bioethics metaphors and analogies have sometimes been offered as ways to circumvent or transcend principles and rules, particularly through attention to cases, narratives, and aesthetic dimensions of experience, they are not necessarily incompatible with principles and rules. Analogical reasoning is important within frameworks of principles and rules, as well as in casuistry, and metaphors and models often succeed or fail depending on how well they express the full range of relevant moral considerations.

MILITARY PERSONNEL AS RESEARCH SUBJECTS

• • •

A key ethical issue in the use of military personnel as research subjects is whether individuals in the armed services are free to accept or decline participation in research. Voluntary participation has been recognized as an essential requirement for ethical human experimentation; it is the cornerstone of the Nuremberg Code, issued in 1947 as part of the prosecution of Nazi physicians. Some bioethicists have expressed concerns that military discipline, with its emphasis on following orders and the chain of command, may constrain an individual's ability to make uncoerced decisions about participation in research. It is not clear, for example, how participation in a research study differs significantly from other hazardous duties expected of military personnel.

Negotiating the balance between respect for individual autonomy and the needs of the military is more problematic when nations are at war. During World War II, the medical needs of the military were invoked to justify the experimental use of vaccines and drugs in military populations, as well as nontherapeutic research on conscientious objectors, orphans, prisoners, and the mentally ill. Nearly 60,000 American military personnel were recruited through "lies and half-truths" into secret tests of mustard agents (sulfur and nitrogen mustard) and Lewisite (an arsenic compound) (Pechura and Rall). In the Persian Gulf War of 1991, the military's decision to seek a waiver of its own regulations about informed consent for the administration of investigational drugs and vaccines to American servicemen and servicewomen prompted controversy between critics who condemned this deviation from the Nuremberg Code and supporters who argued that the principle of preventing unnecessary harm to military personnel made the decision

necessary (Howe and Martin; Annas and Grodin). These issues, which have received little sustained analysis, require greater attention from bioethicists.

Historical Use of Military Subjects

Historically, the armed forces have provided both unique opportunities and special needs for the study of human health and disease. "He who would become a surgeon," observed the Greek physician Hippocrates, "should join the army and follow it" (Hume, p. 78). Early efforts in disease prevention and treatment reflected the practical concerns of maintaining military personnel in good condition. One of the earliest clinical trials involving human subjects was conducted by the Scottish naval surgeon James Lind (1716–1794), who administered six different treatments to twelve sailors suffering from scurvy, and observed the beneficial effect of oranges and lemons in recovery from the disease (Carpenter).

Traumatic injuries from guns and other weapons have provided distinctive opportunities for military physicians to study human anatomy and physiology. In the 1820s, American army surgeon William Beaumont investigated the process of human digestion in a live subject after his repeated efforts failed to close the gunshot wound to French–Canadian trapper Alexis St. Martin's stomach. Beaumont developed an employment contract with his research subject, who agreed to allow physiological experiments in exchange for room, board, and wages. Beaumont also persuaded the trapper to enlist in the U.S. Army, giving the physician more complete control of his subject and rendering St. Martin's "faithless absconding" subject to military law (Numbers).

The rise of experimental science and the germ theory of disease in the late nineteenth century increased experimentation involving human beings. The Medical Department of the U.S. Army expanded its efforts to control infectious diseases, the major cause of mortality in the military before World War II. All U.S. Army commanders were directed to cooperate with the Medical Department to secure volunteers for experimental inoculations or other medical investigations approved by the War Department (Dow). Both the British and the American armed forces conducted experiments with newly developed vaccines for typhoid fever and other diseases (Tigertt). The introduction of aviation and its rapid development after World War I accelerated military research with human subjects (Pitts).

Introduction of Participant Consent

The shift from therapeutic experiments to nontherapeutic research in the early twentieth century fostered more formal arrangements with research subjects. In 1900 Major Walter Reed and members of the U.S. Army's Yellow Fever Board adopted the first written agreements between research subjects and experimenters. The Spanish immigrants who participated signed contracts that described compensation for subjects (civilians received $100 in gold and an additional $100 if they contracted the disease) and identified some of the risks of participation (Lederer). American physicians working in the Philippines followed Reed's example; prisoners in Manila's Bilibid Prison signed agreements written in their own dialect for medical research studies (Chernin; Lederer). During World War I, some physicians continued the policy of having written agreements with American soldiers who participated in infectious disease research (Sellards).

The success of the yellow fever research gained public approval for human experimentation. Public reaction to the research-related deaths of Army nurse Clara Maas and two Cuban volunteers, however, led the surgeon general to suspend the Army's work on a yellow fever vaccine in 1902. Most published reports of military medical research emphasized the voluntary nature of participation. References to cash payments and better duty assignments raised questions about the pressures to volunteer. In principle, American military personnel, although required to undergo standard medical procedures to enhance their military fitness, retained the right to refuse participation in medical experiments (Johnson).

The advent of World War II spurred massive changes in the organization and funding of medical research. The Committee on Medical Research, part of the Office of Scientific Research and Development, sponsored clinical research projects on an unprecedented scale. Pressures to find solutions for military medical problems encouraged investigators to conduct numerous trials with human subjects. As historian David J. Rothman has observed, the arguments that were used to justify sending men into combat were also invoked to sanction the use of conscientious objectors and civilians—prisoners, orphans, the retarded, and the mentally ill—in nontherapeutic research for military needs.

The wartime research ethos continued into the Cold War era. Both military and civilian researchers increasingly used human beings in experiments with little regard for the principles of consent and voluntary participation elaborated in the Nuremberg Code, or in the regulations governing research adopted by the secretary of defense in 1953 but classified as top secret until 1975 (Annas, Glantz, and Katz). During the Cold War, some 250,000 men and women were exposed to radiation as part of state-sponsored nuclear

testing in Nevada and the South Pacific. In the early 1950s the American military conducted indoctrination and panic studies on troops at atom bomb tests (Moreno). Between 1955 and 1967, the U.S. Army and the Air Force supported more than eighteen research projects on the effects of hallucinogenic drugs on human performance in the United States and Canada (Annas and Grodin). Many of the nearly seven thousand servicemen who participated in drug tests at the Army Chemical Center at Edgewood Arsenal, Maryland, apparently received little information about the risks they incurred as a result of their participation in lysergic acid diethylamide (LSD) studies. Army investigators similarly failed to inform the more than one thousand participants about risks they incurred in tests of various nerve gases (Downey).

Amid the public condemnation of the LSD studies and the exposure of large numbers of servicemen to harmful radiation in the race to develop an atomic arsenal, the U.S. Army, Navy, and Air Force revised policies for research involving military personnel. In 1972 the American military banned all tests of nerve gases involving human subjects, and in 1974 issued new regulations for research on military personnel. In 1983, U.S. Department of Defense Directive 3216.2, "Protection of Human Subjects in DoD-Supported Research," established a uniform policy for research involving human subjects throughout the Department of Defense. In addition to adhering to the regulations for the protection of human subjects of the Department of Health and Human Services, the guidelines charged the military chain of command to ensure that the fundamental rights, welfare, and dignity of human subjects be protected to the maximum extent possible (Winter). Research involving American military personnel received greater scrutiny in the 1980s (Howe, Kark, and Wright; Maningas). Some military research subjects have received compensation for injuries they sustained in tests conducted without their knowledge.

New Complications in Military Research

Biological and chemical weapons pose some special problems for military personnel. Nations have approached the search for effective protections against these weapons in different ways. Whereas the American military discontinued the testing of toxic chemicals on human beings, the British Ministry of Defense continued to test antidotes for nerve gases on volunteer soldiers. Critics of the experimental exposure of soldier volunteers to nerve gases have cited safety concerns, as well as doubts that soldiers were "capable of giving full and informed consent to participate in complex toxicological experiments" (Mason, p. 30). Other North Atlantic Treaty Organization (NATO) countries have conducted similar testing of protective gear and drugs against nerve gas and a wide variety of other chemical weapons.

The threat of chemical and biological weapons in the Persian Gulf War in 1991 led the U.S. Food and Drug Administration (FDA) to grant the Department of Defense's request for a waiver of federal informed-consent regulations for administering investigational drugs and vaccines to troops stationed in Kuwait. Although the threat of chemical weapons did not materialize, the successful waiver of informed consent raised distinctive issues for military physicians. In the absence of informed consent, should a military physician follow orders and administer an investigational drug? Another related question for the military physician is whether his or her primary responsibility is the welfare of an individual patient or the success of a military mission (Howe; Annas).

Issues posed by research on military personnel are complex. As bioethicist George Annas has argued, these issues require critical attention in peacetime, since they are "not susceptible to rational analysis in wartime" (Annas, p. 773).

MINORITIES AS RESEARCH SUBJECTS

• • •

In 1984 Margaret Heckler, secretary of the U.S. Department of Health and Human Services (HHS), established the Task Force on Black and Minority Health to investigate the health status and health needs of minority groups in the nation. A year later, that panel presented its report, noting the lack of data about many aspects of minority health and the need for greater inclusion of minorities (defined as blacks, Hispanics, Asian/Pacific Islanders, and Native Americans) in medical research projects (U.S. Department of Health and Human Services, 1985). In response, the National Institutes of Health (NIH), the largest financial supporter of medical research in the United States, began to urge that grant applicants include African-Americans and other minorities as research subjects in their projects. Applicants not incorporating minorities in proposed studies were expected to provide "a clear rationale for their exclusion" (U.S. Department of Health and Human Services, 1988, p. 3). The NIH Revitalization Act of 1993 turned those suggestions into requirements that minorities (categorized as American Indian or Alaskan Native, Asian or Pacific Islander, Black-Not of Hispanic Origin, and Hispanic) must be included in all NIH-supported biomedical and behavioral clinical research projects involving human subjects, except where clear and compelling rationale and justification existed for their exclusion from such studies (U.S. Department of Health and Human Services, 2000, 2002).

The HHS task force's rationale for promoting data-gathering and research studies on minorities was both practical and humanitarian: to "understand … the reasons underlying the longstanding disparity of health status in the United States" between minorities and the majority population, in order "to prevent or reduce much of the illness and death experienced by minorities in disproportion to their representation in the American population." Those reasons, according to the report, included "physiological, cultural and societal factors" (U.S. Department of Health and Human Services, 1985, vol. 1, p. 37). Therefore, Americans needed to conduct research and gather information about the health, health environment, and healthcare practices of all citizens in order to improve everyone's health.

The African-American Experience

Historically, U.S. medical researchers included—even preferred to use—minorities (for example, immigrants from Ireland, Germany, eastern Europe, and Africa) in their research studies; not until recently, however, did they select members of these groups for the humanitarian reasons delineated in the HHS task force report. In general, researchers used minorities as experimental subjects because they were easily exploited; they studied minority health when minority health threatened the majority population (for example, in times of epidemics). The African-American health experience provides a good historical example of these research practices. While examples of the use of other racial and ethnic minorities for human experimentation in the United States may be cited individually or during certain time periods, white employment of blacks for such purposes was a consistent practice that, sadly, encompasses the entire sweep of U.S. history.

Almost from the time of white settlement of the American continent, whites noted differences between themselves and blacks in health matters such as disease immunities and susceptibilities, and reactions to medications. Self-interest was an important factor in whites' use of blacks as objects of research and study in antebellum times. The following examples illustrate that self-interest. Blacks were unwilling immigrants to the New World—they were enslaved—and were, for their white owners, an economic investment. White physicians thus needed to know as much as possible about caring for their black patients when illness struck. Furthermore, blacks, especially house servants or laborers in small businesses or farms, often worked in close physical proximity to whites. It was important for whites to recognize and study the medical differences between themselves and blacks in order to understand the risk of contracting diseases brought into their homes or workplaces by ailing slaves (Savitt, 1978). Antebellum southern physicians like Josiah Clark Nott of Mobile and Samuel Cartwright of New Orleans spent parts of their careers noting and writing about black medical distinctiveness (Breeden). They and slaveholders did mostly observational and statistical studies, occasionally engaged in physical human experiments on African-Americans, and published their ideas in agricultural and medical journals (Savitt, 1982).

After Emancipation in 1865, concern about the spread of diseases prevalent among blacks to the entire population continued to motivate whites to study black illness. They noted a steep rise in such lethal diseases as tuberculosis among the newly freed population, and predicted the decline and disappearance of blacks from the United States by the turn of the twentieth century. Morbidity and mortality studies conducted by insurance companies confirmed these dire predictions and made it difficult for blacks to obtain life insurance (Haller, 1970b; Torchia, 1977). Further, African-Americans became the object of numerous medical studies and articles (Haller, 1970a; Torchia, 1977). Physicians in the late nineteenth century reported on the state of black health in their regions or in the South as a whole. Some prominent African-Americans, W. E. B. Du Bois in particular, engaged in research on the health status of blacks and published their findings to refute the misleading conclusions whites had drawn. In particular, Du Bois pointed out the inaccuracies and unscientific approach of those researchers who purportedly found blacks' brains smaller and less developed than whites' brains; reminded readers that whites also suffered greatly from consumption (tuberculosis), alcoholism, and syphilis; and pointed out that other factors besides race, especially living conditions and economic status, influenced people's health or susceptibility to disease.

Beginning in the 1890s, a significant population shift of African-Americans from the rural South to northern cities (termed the Great Migration) increased white awareness of black health problems and encouraged physicians all over the country to study diseases that affected both groups, such as tuberculosis and syphilis (Torchia, 1975, 1977; Jones). Diseases that primarily afflicted blacks, however, such as sickle-cell anemia, discovered in 1910, were not widely studied or publicized even in the black medical and lay communities. That disinterest in sickle-cell anemia did not change until the 1950s, when it was recognized as a molecular genetic disease, the first of its kind (Savitt, 1981; Scott; Wailoo). The civil rights movement of the 1950s and 1960s further raised the consciousness of white Americans about the exclusion of blacks from many aspects of American life, including healthcare and medicine. The HHS task force report of 1985 made explicit the need to include blacks in the mainstream of U.S. biomedical research.

Use of Other Minority Groups

African-Americans have a unique history as research subjects in the United States. They were not the only voiceless minority in American history, however, and not the only group used as research subjects. In the South most of the experimental subjects were black; in the North they were usually poor, recent ethnic immigrants, like the Irish, Germans, and eastern Europeans. Many of their graves were robbed by medical students or professional body snatchers known as *resurrectionists,* and their bodies were dissected. The segregated blacks and the poor white minorities who

used the public hospitals and clinics run by U.S. medical schools became the objects of experiments and of surgical or medical demonstrations by teachers on behalf of their students (Bynum; Humphrey; Lederer; Bowman). As historian of medical research Stanley J. Reiser stated about the nineteenth and especially the early twentieth centuries: "[S]ome physicians viewed hospital patients as an experimental population from whom knowledge could be gained, and on whom students could also learn" (p. 11). This was the cost to the poor of obtaining free or low-cost medical care.

Investigators felt little need to ask these voiceless people for consent to perform experiments (Lederer). Until the 1947 Nuremberg Code—the result of blatant misuse of a minority population (Jews in Nazi Germany) for unregulated medical experimentation—there was no uniform requirement for gaining consent from research subjects in medical experiments. Even after 1947, minority groups were exploited in the United States. In one often-cited example, researchers in San Antonio, Texas, studied a group of Mexican-American women visiting a clinic to obtain birth-control assistance. Wishing to discover whether the reported side effects of birth-control pills were physiological or psychological, the researchers gave one group of women a placebo and instructed them to use a vaginal cream in addition. The patients in the study did not know they might receive a placebo or that using the vaginal cream alone put them at substantially greater risk for becoming pregnant. Seven women involved in the study became pregnant (Veatch).

The Tuskegee Syphilis Experiment

The most notorious example in American history of experimentation on members of a minority group without their consent was the Tuskegee Syphilis Experiment. Between 1932 and 1972 the U.S. Public Health Service (PHS) conducted an investigation into the natural history of untreated syphilis on four hundred unsuspecting black men from Macon County, Alabama. Building their research on an 1890s study of untreated syphilis among white males in Oslo, Norway, PHS officials wished to determine if racial differences existed in the natural course of the disease. The African-American men selected for the Tuskegee experiment thought that they were part of a select group receiving special medical care. In fact, they were receiving no care at all for their syphilis.

Physicians and officials from the Alabama State Board of Health, the Macon County Health Department, and the Tuskegee Institute, as well as local physicians, cooperated with the PHS in establishing the project, shunting the unwitting subjects to government physicians for their medical care, or providing the PHS with medical facilities for physical examinations and autopsies. The experiment continued even after the Nuremberg Code went into effect in 1947, after penicillin became available for the treatment of syphilis in the 1950s, and after the PHS had instituted strict guidelines on the use of human subjects in experiments funded by the NIH and other of its agencies in 1966 (Brandt; Jones; U.S. Department of Health, Education, and Welfare; Reverby). Those guidelines were reemphasized when the Tuskegee story became public in 1972, bringing home to the medical research community the importance of obtaining informed consent from research subjects, and of avoiding bias and using caution and sensitivity when considering the need for racial and ethnic medical studies.

Current Humanitarian Approach to Research Using Minority Participants

Since the 1985 HSS task force report, numerous articles have appeared discussing results of research that included minority population groups. The dilemma researchers face in reporting and interpreting their results has now become separating innate biological factors from cultural ones as determinants of the phenomena under study (e.g., disease incidence, drug efficacy, behavioral differences). There is general agreement among researchers that race is a social construct which becomes less and less meaningful in multicultural/multiethnic societies where interbreeding over decades or centuries has occurred. Definitions of white and black, for example, differ within and among countries and often are also tied to social and economic status. Diseases and behaviors express themselves for reasons that can relate to such non-biological factors as stress, diet, and living conditions. Minorities, having once served as the misused objects of research and human experimentation because it was convenient and in the self-interest of the majority population, have again been singled out to serve as research subjects for U.S. medicine—though for different and more humanitarian reasons. Interpreting and understanding the results of medical research that includes minority groups and sub-groups has now become the challenge (Benowitz; King; Osborne and Feit; Schwartz; Witzig; Wood).

MISTAKES, MEDICAL

• • •

With its report, *To Err is Human: Building a Safer Health System,* The Institute of Medicine (IOM) Committee on the Quality of Health Care in America performed a commendable public service. The report dramatized the extent of a hitherto under-appreciated public problem, harm to patients because of medical error. The report estimates that between 44,000 and 98,000 deaths occur each year due to adverse medical events, that one-half of these *adverse events* are preventable, that the total cost of these medical misadventures is between 17 and 29 billion dollars, and that the events rank eighth in causes of deaths in the United States.

The report does more than locate a problem largely unrecognized by the public. It points to faulty systems, rather than individual's performance flaws, as the source of the majority of adverse events. The report also sets forward policy recommendations to meliorate the problem. The IOM recommended a triad familiar to those who study safety and post-hoc accounts of accidents: 1) training to improve the performance of personnel, 2) developing new technologies to improve the performance of fallible human operators, and 3) implementing new procedures to improve the over-all functioning of the healthcare delivery system. These changes will bring to medicine the philosophies and work routines of *total quality improvement.*. The IOM report sets for itself the laudable operational goal of halving medical errors over five years. Success depends in large part on the providers of medical care accepting the IOM's diagnosis and implementing its treatment plan. There will be resistance on both fronts. No change will occur without a re-thinking of how healthcare providers define their obligation to provide quality care.

Error as a Systems Problem

The IOM report defines error in a way most involved in patient care would find unfamiliar: "the failure of a planned action to be completed as intended (i.e. error of execution) or the use of the wrong plan to achieve an aim (i e., error of planning)" (p. 28). This definition seems to ignore uncertainty inherent in medical practice. "An adverse event is an injury caused by the medical management rather than underlying condition of the patient. An adverse event attributable to error is a *preventable adverse event*" (IOM, p.28). The IOM's definitions presuppose that what should be done is clear, that outcomes are unproblematically attributable to treatment alone, and that what constitutes an *error* is not subject to debate. Notably, Troyen Brennan, one of the researchers involved in the Harvard Medical Practice Study (HMPS) questioned whether error or preventable adverse events are easily distinguishable from more innocent treatment failures (Brennan).

While the IOM report uncritically accepts the HMPS and subsequent replications and extensions of it and uses the HMPS to shape the basis of the IOM's recommendations, researchers have raised multiple questions about the HMPS findings and their interpretation. The HMPS bases its estimates of adverse events and preventable adverse events on retrospective chart reviews. Death was among the criteria used to select charts for reviews. This raises the strong suspicion that both *outcome* and *hindsight* bias influenced reviewers's judgments of the appropriateness of care. Researchers looked at physicians's responses to patient vignettes describing identical diagnoses and treatments but varying with respect to positive and negative outcomes. In these studies, doctors are more likely to find medical error in cases with negative outcomes. Even when raters are asked to pay no attention to outcomes, they still judge the treatment with poor outcomes more negatively than when identical treatment has a positive outcome. The HMPS does not establish a direct link between specific errors and outcomes nor does it address the possibility of attribution error or spurious causality. Finally, McDonald, Weiner, and Hui, have suggested that counting deaths attributable to error, as in the IOM report, is too gross a measure. Many of those who died from the identified errors had terminal diagnoses and complex multi-system problems. A more precise measure of the burden of error may be *days of life lost* (McDonald, Weiner, and Hui). None of these criticisms suggest that medical error does not constitute a serious problem or that there is not substantial room for improving medical care systems. However, reservations about the methods and assumptions of the HMPS and the IOM report suggest that reducing medical error is more complex and may leave more room for debate than the IOM report acknowledges.

One goal of the IOM report is to shift attention away from individual professionals's performance and to focus on system performance. The report embraces *normal accident theory,* a blend of organizational and management theory, cognitive psychology, and human factors engineering to understand and explain the occurrence of preventable adverse events (Perrow). The theory holds that modern technological systems are *error prone* (Paget) and that we should

think of certain mishaps as *normal accidents.* Errors and mistakes, with all their baleful consequences seldom result solely from individual failings—what Charles Perrow a leading proponent of this approach, calls *ubiquitous operator error.* Rather, errors and mistakes are embedded in the organization of complex technological work like medicine. The two structural features most important to the production of normal accidents (in medicine, preventable adverse events) are interactive complexity and tight coupling. That is, each component of the system is intrinsically complicated and each component's performance affects the functioning of other system parts. Small deviations from expected performance ramify through the system in unpredictable ways through unanticipated feedback loops creating large consequences. For a complex technological undertaking such as medicine, this is an unpleasant fact.

The IOM report focuses on a rejoinder to normal accident theory, *highly reliable organizational theory,* to remedy the problem. This approach acknowledges that errors can never be eliminated and concentrates on what organizational features allow workers to operate risky and complex technological systems, such as nuclear-powered aircraft carriers, with a minimum of untoward incidents. The theory relies on work structures that have redundancy and overlap; teams that encourage constant communication among and between the ranks; constant surveillance and monitoring for even the smallest deviation from expectations; flexible authority systems that permit even low-ranking workers to question those with the highest authority; a rich oral culture that constantly uses stories to remind workers of behavior that can create trouble; a reporting system that takes note of *near-misses* and is constantly self-correcting and non-punitive when trouble arises; and technology designed to be user-friendly and cue workers to avoid the most common errors (Roberts; Rochlin, Laporte, and Roberts; Weick; Weick and Roberts).

Error in Professional Culture

Through its pleas to end inaction regarding adverse events and its call to break the pattern of *naming, blaming and shaming* engaged in by professionals, the IOM report acknowledges the need to change the shopfloor culture of medicine. Curiously, the IOM report neglects workplace studies of physician attitudes, beliefs, and behavior. As a result, the report ignores leverage points for and barriers to change in physician culture. Worksite studies of physicians concentrate on how doctors negotiate and understand the meaning of such terms as adverse event, preventable adverse event, and *negligent error.* Their meanings are not fixed but are fluid and flexible, highly dependent on context.

One of the earliest discussions of medical mistakes, by Everett C. Hughes, suggests a rough calculus for the frequency of mistakes, based on the skill and experience of the worker and the complexity of the task. Because academic hospitals involve front-line workers (students, residents, and fellows) who may have little experience and because many of the clinical problems encountered often deviate far from the routine, one might expect to find a fair number of mistakes and errors in such institutions. However, says Hughes, hospital work is organized to control and limit the occurrence of mistakes. The organization of physician work in teaching environments also reduces the recognition of error and makes responsibility and accountability difficult to pinpoint. Hughes describes a set of *risk-sharing* and *guilt-shifting* devices that obscure exactly where in a chain of events the error or mistake occurred. These work practices include supervision, cross-coverage, consultation, and case conferences. These practices make it harder to see and correct individual mistakes, or for that matter, system errors. Errors are a feature of the workplace, and an elaborate division of social and moral labor prevents mistakes and errors from coming plainly into view.

Eliot Freidson describes the social processes used in a group of physicians to bury mistakes and to sustain a *structured silence* about mistakes. Freidson's results are striking given that the group that he observed was designed self-consciously to maintain the highest imaginable professional standards. In a setting designed to maximize surveillance by colleagues of each other's behavior, Freidson found that peer monitoring and surveillance were unsystematic at best. Referral relations structured colleagues's knowledge of one another's performance. Knowledge gathered in this way was haphazard; the two main sources for information were patient gossip and colleague complaints. Regular procedures or mechanisms for evaluating colleague performance and sharing the results of such evaluations did not exist. Once an individual physician's knowledge and dissatisfaction with the poor performance with another group member had crossed some threshold for action, few options for action were open. Freidson labeled the most immediately available informal action employed by group members *the talking to.* Colleagues confront the offender, who either clears the air with a non-defensive response or increases distrust with defensive one. If the results of a talking to were unsatisfactory, a physician could engage in a private boycott by refusing to refer additional patients to the offending colleague. The possibility of formally making a complaint and having a physician removed from the group existed but was so administratively cumbersome as not to be a realistic option. In Freidson's work we see that that notions of error, mistake, and competence are conceived within the work

group at the level of the individual and that there is a general reluctance to deal with these issues through formal organizational measures.

Charles L. Bosk's *Forgive and Remember: Managing Medical Failure* examines how surgical residents learn to separate blameless errors from blameworthy mistakes in the course of their training. Errors appear blameless, largely, if they are seen as part of the normal learning process. Attending faculty anticipate that inexperienced residents will make some technical or judgmental mistakes. These errors are considered a normal consequence of providing opportunities to the unpracticed. Errors are blameworthy when, in the eyes of senior surgeons, it is difficult to sustain a claim that a resident acted in good faith. Bosk identified two types of blameworthy errors: (1) normative errors, which breach universal rules concerning physician behavior and (2) quasi-normative errors, which mark a resident's failure to conform to an attending surgeon's cherished, but often idiosyncratic, way of doing things. A source of great confusion for residents is the fact that attending surgeons treat breaches of personal preferences as seriously as breaches of universal rules. Technical and judgmental errors, so long as they are not repeated, especially on a single rotation, are forgiven. Not so with normative and quasi-normative error; residents who commit these breaches are often dismissed from training programs. This public punishment, just as Émile Durkheim (1933) long ago suggested, works: (1) as a general deterrence for the not yet corrupted; (2) as reinforcement to the norms of the group; and (3) as a device to increase solidarity among those that share a commitment to the community.

Each of the studies reviewed above has a different focus and emphasis. However, when they, and other similar research that concentrates on the dynamics of the work group, are assessed together, a number of themes to which the recommendations of the IOM Report do not give sufficient weight emerge. These themes include the following:

1. The inherent uncertainty of medical action—diagnosis and treatment are assessed in prospect, probabilistically. After action is taken results are known and uncertainty evaporates. The relation between a treatment and outcome once so cloudy now appears over-determined.
2. The essentially contestable nature of error itself—everyone knows errors are untoward events whose occurrence needs to be minimized. What medical workers do not agree on is what happened and why. In each instance, we can agree that errors, in general, are to be avoided, while disagreeing, in each instance, that this action was an error.
3. The medical profession tolerates *normal error.* Workers in the same occupation share the same difficulties and have an artful appreciation of all the factors that can create negative outcomes in the face of what otherwise looks like flawless technical performance. What medical workers have in common is an understanding of the ever present possibility for the unexpected negative outcome and a set of beliefs about work that allow such outcomes to be neutralized.

These themes underscore how, on the one hand, the IOM Report is an attempt to encourage the medical profession to take more responsibility for its obligation to the larger society and, on the other, just how difficult that task is.

Perhaps these difficulties are seen most clearly in the recommendations to increase reporting of near misses. For such reporting to be effective, however, the participants in the current system have to possess the ability to recognize the events that they need to report. Workplace studies of error demonstrate, however, that workers's ability and/or willingness to do this should not be taken for granted. Inherent uncertainty, the essentially contested nature of error, and the normal tolerance for the risks of the workplace, when combined with the intense production pressure of hospital practice all create barriers to seeing near misses. What is not seen cannot be reported. What is not reported cannot be learned from. Successful implementation of the IOM recommendation requires that the context of the workplace be taken into account.

Ethics and Medical Error

Two issues dominate the ethical concerns associated with mistakes in medicine: disclosure and accountability. However, as the preceding discussion reveals, a third matter deserves moral scrutiny: definitions of terms. We need to know what counts as error before we can conclude who has a duty to reveal what information, who has the right to receive information, and how professional and legal systems should respond to misadventure.

Classic thinking about mistakes has focused on process and outcome. People may proceed erroneously (begin the wrong operation, administer the wrong medication, fail to do something prescribed or indicated) and, through care or good luck prevent or escape harm. On the other hand, things may expectedly work out poorly for the patient (e.g., they may die, as in the previous discussion) even though, upon close examination, no one omitted appropriate actions, committed inappropriate acts, or otherwise behaved *wrongly.* In many cases of adverse outcome, one simply finds a great deal of uncertainty about what happened and why. Medicine's lack of complete understanding of disease and physiology leaves a much unexplained or even inexplicable.

At the very least, despite human desire to eliminate doubt and fix blame, the world of human medicine leaves a great deal up in the air when one wishes to say a doctor, nurse, pharmacist, or other healthcare worker erred or that a system failed. Finding egregious behavior is easy; the problems arise when an observer does not like what has happened but cannot readily point a finger at the cause.

Starting in the last quarter of the twentieth century, attitudes and practices towards disclosure of clear-cut medical error changed from guild-like self-protectionism to more forthright, perhaps preemptive truth-telling. That is, both medical ethicists and risk managers now counsel practitioners to tell patients or their legally authorized representatives (parents, guardians, among others) when an obvious error occurs. Few now suggest hiding an overdose, administration of a mismatched blood product, or some clearly preventable difficulty in the operative field. Philosophers and lawyers take a pragmatic approach here. Not only do people want to know when something has gone wrong, not only do some argue wronged individuals have a right to know, the consequences of failed cover-ups include overwhelming anger and much larger jury awards. As Sissela Bok pointed out in *Lying: Moral Choice in Public and Private Life,* in a socially complex world, including that of modern medicine, lying just does not succeed.

Note, however, that the generally accepted admonition to tell the truth often fails to provide practical help. Did the surgical assistant pull *too hard* on the retractor, resulting in a lacerated artery and a much-prolonged operation for microvascular repair? Was this negligence or something about the patient's fragile tissues? If the patient's recovery is unimpeded, does it matter? Do patients and surrogates want to know every detail of what happened? Might *full disclosure* inappropriately undermine trust? While there might be objective agreement that the degree of disclosure should somehow follow the desires or psychological needs of patients, loved ones, and legal surrogates, it is not at all clear how one determines, in advance, how much an individual or family member wants to know in a given situation.

Regarding accountability, many problems remain. If the assistant in the hypothetical operation was a surgical intern scrubbing in on this kind of operation for the first time, how does that fact influence an assessment of whether she made a culpable mistake or made an excusable error? The legal system usually acknowledges that trainees do not bear the same level of responsibility as their supervisors—much of the time lawsuits drop involved students and residents from being named defendants in malpractice actions. However, there are no reliable systems for determining how professionals or society should factor (in)experience into judgments about moral responsibility for things going awry. Bosk, in his book on surgical training, *Forgive and Remember: Managing Medical Failure,* distinguishes between technical and normative error. This distinction assists in understanding that surgeons use social and behavioral standards to assess residents's ethics, but it is not clear how the law or patients can or ought to use such an approach.

How best to respond to ethically suspect or clearly wrong behavior must also be considered. Answers here might also take into account context as well as the specific acts or omissions. How might sleep deprivation play a role in evaluating someone's mistake? Would it or should it matter if the individual's lack of sleep were a result of staying on duty in the middle of a snow storm that precluded replacement staff from reaching the hospital? Should reactions to first offenses be limited, especially for those in training? Focused (re)education may suffice for the cognitive components of error. However, whether reviews of professional standards and obligations can effectively ethically rehabilitate those who seem morally indifferent or disinclined to take their duties as professionals seriously is not really known. Finally, relatively little attention has been paid to the affective consequences of mistakes on those who make them. As Joel Frader notes in "Mistakes in Medicine: Personal and Moral Responses," routine reactions to error should include counseling and support for those involved, especially regarding the guilt and fear common following errors that have produced or nearly resulted in serious harm.
