These justifications also constitute arguments against the criterion. Rationales that are medical in nature actually support medical criteria rather than a psychological ability criterion per se. When psychological ability per se is invoked, the convenience of the staff or the presumed social value of the patient is problematically allowed to override the patient's claim to equal access. Moreover, caregivers' judgments about the coping abilities and cooperativeness of patients are much more subjective than the physical assessments they conduct and are therefore vulnerable to personal bias. Like everyone else, caregivers find that they can work best with those most like themselves, and many observers question the appropriateness of ranking human lives based on how well-matched patients are to caregivers.

Supportive environment. A supportive environment criterion is one that favors those patients who will have the most supportive living environment during and following treatment. Considered potentially valid by 61 percent of the participants in the U.S. Study, this criterion favors patients with the best access to personal and professional caregivers as well as facilities and other material resources relevant to effective treatment. Without sufficient postoperative care, for example, not only may scarce resources be wasted, but a

treatment such as a heart transplant may result in a worse death than if the patient had received no treatment at all. Alternatively, the absence of a supportive environment may indicate that the patient warrants low priority on social value grounds.

A supportive environment criterion per se, however, is unnecessary if the concerns it addresses are already accounted for by medical benefit or social value criteria. Even as a form of another criterion, supportive environment is a problematic consideration, because the connection between people's environment and their medical outcomes or social value is far from precise. Helpful supports are not always necessary for a satisfactory medical outcome, and personal bias easily intrudes when assessing lifestyles or home situations quite different from one's own. In fact, this criterion by its very nature can be unjust when it denies treatment to patients (e.g., children with an inadequate home environment) on the basis of the irresponsibility of others (e.g., parents) or society at large. Arguably, the special needs of such situations call for extra care, not less.

MEDICAL CRITERIA. The third cluster of criteria are explicitly medical in nature, having to do with health-related outcomes of treatment. There are five of these criteria: medical benefit, imminent death, likelihood of benefit, length of benefit, and quality of benefit.

Medical benefit. The most basic of the medical criteria is a medical benefit criterion, acknowledged as a legitimate allocation criterion by 95 percent of the participants in the U.S. Study. Unlike many other medical criteria that compare and rank candidates for treatment, this criterion includes for further consideration everyone with a reasonable likelihood of receiving from treatment significant medical benefit in terms of length and quality. This criterion casts a wide net: any degree of likelihood, length, and quality that can reasonably be considered minimally significant is sufficient. Treatments not offering such benefit are commonly excluded as futile, though futility itself is a concept that requires careful definition (Jecker and Schneiderman).

The requirement that patients benefit medically from scarce medical resources is rooted in ethical standards of efficiency and justice. Without this requirement, precious resources would be wasted on patients who would receive no benefit from them. Moreover, according to many theological and philosophical traditions, need constitutes the major exception to the egalitarian presumption generally built into concepts of justice. The notion of need includes the ideas that some disease or injury condition is present (or will be, where the need for preventive care is in view), and that a person's life is thereby undesirably altered. A need for a lifesaving resource, for example, implies that a person's life is in jeopardy without it; no preferable alternatives remain.

The major difficulty with this criterion is the way in which standards of need can be manipulated. A classic illustration is the provision of kidney dialysis in Great Britain (Aaron and Schwartz). Resources allocated for dialysis by the government-run healthcare system have been insufficient to treat all who could benefit medically from dialysis, according to normal standards of need. Yet many have claimed that all who need treatment receive it. Matching of available resources and need has been achieved by tightening standards of need in sections of the country where resources are particularly scarce. Also, general practitioners do not even refer certain patients to kidney specialists for dialysis when practitioners know that sufficient resources are not available.

Imminent death. The second medical criterion, imminent death, takes the standard of need a step further. Sometimes called an *urgency* criterion, it accords special priority to patients who will die soon without treatment (support for it was not measured by the U.S. study). While the term *imminent* is not precise—generally ranging from a few days to a few weeks—it has been found workable by many in clinical and legal contexts alike (Kilner, 1990).

Not only does this criterion recognize situations of special need, it also results in more lives saved. (A necessary stipulation, though, is that it be applied together with the medical benefit criterion, so that priority will not be accorded to patients for whom treatment is futile.) Because patients whose death is not imminent can survive for a period of time while imminently dying patients receive priority care, a new treatment may become available in the interim, enabling patients in both categories to live. Alternatively (and more likely), additional resources may be made available at any point as the life-threatening situation becomes better known. In fact, the scarcity itself may be only intermittent, as is often the case with intensive care space.

An imminent death criterion, though, is more problematic in practice than it may appear to be in theory. In many situations it is impossible to determine with precision whether or not a patient's death is imminent. In others, caregivers can overstate the urgency of their patients' conditions in order to give them priority access to lifesaving resources. While doing so may be unfair, it may represent an understandable attempt to avoid another problem with the criterion. By making patients wait until they have deteriorated almost to the point of death before they receive priority access to treatment, the criterion ensures that resources will be devoted to the sickest patients. Worse medical outcomes

for those treated and greater suffering for those who might wait are bound to result. Moreover, additional resources may never become available for those not prioritized by the criterion.

Likelihood of benefit. Each of the three remaining medical criteria addresses a particular aspect of medical effectiveness. The first of these, likelihood of benefit, was affirmed by 96 percent of the participants in the U.S. Study. This criterion assumes that more than a minimal likelihood of medical benefit is a necessary prerequisite for receiving scarce medical resources. Those with the greatest likelihood should be favored to ensure the most productive use of available resources. While this justification resembles the rationale underlying a social value criterion, the benefits in view here are limited to medical benefits experienced by the persons receiving the scarce resources. Moreover, more lives may ultimately be saved if this criterion is applied, although such will not be the case in every situation in which the criterion is applied.

Several obstacles attend this criterion. Precisely quantifying the probabilities of every patient's benefiting from a particular treatment so that all can be comparatively ranked is quite difficult. Furthermore, while a productive use of resources may be applauded, the cost of achieving it is arguably too great. Many patients have significant (albeit lesser) likelihoods of benefiting from treatment; yet the criterion leaves them with no realistic prospect of receiving lifesaving care if enough patients with better prospects are waiting for the same treatment. Patients can no longer trust caregivers with essential information that suggests their cases may be complicated, because caregivers must steer resources to the patient with the best prospects rather than simply attending to the needs of each patient. Ultimately, this criterion tends to discriminate against whichever groups in society have the poorest health in general and thus the lowest likelihood of having optimal outcomes from any treatment. Poor persons, disabled persons, and members of racial minorities are particularly vulnerable on this score.

Length of benefit. With a length of benefit criterion, all patients are ranked according to the length of time, rather than the likelihood, that they will benefit medically from treatment. As in the case of other comparative medical criteria, the underlying concern is to achieve as much medical benefit as possible from the available limited resources. Specifically in this case, the criterion helps to maximize the success of treatment by maximizing the length of time patients live following treatment. Of the participants in the U.S. Study, 96 percent indicated that a length of benefit criterion should have some place in microallocation decisions.

Several of the difficulties with this criterion parallel those of a likelihood of benefit criterion. Accurately predicting the length of time patients will survive following treatment is extremely hard. The criterion also tends to discriminate against the same groups of people disadvantaged by a likelihood of benefit criterion, because these typically less-healthy groups on average do not live as long as others following various types of treatments. This discriminatory effect extends to elderly patients as well, because they tend to have fewer years of life remaining regardless of the treatment in view. The significance of this concern, however, is as debatable as the age criterion itself. The most fundamental problem with a length of benefit criterion may be its presumption that length of life rather than persons per se is the appropriate focus of allocation decisions. Each person's life is uniquely important to that person. Those who argue that all people have a right to life (including life-sustaining resources) add that rights do not diminish the sicker one gets.

Quality of benefit. The final medical criterion, quality of benefit, shares the wide support expressed for other medical criteria, including acknowledgment by 97 percent of the U.S. Study participants. Like the two previous criteria, it ranks patients on a scale, in this case a scale of quality of life following treatment. This criterion rejects the common preoccupation with merely keeping patients alive and insists that healthcare is also responsible for producing lives with as high a quality as possible. Good quality of life is important to patients because it contributes substantially to their happiness as well as to their autonomy (their ability to make uncoerced decisions concerning their own lives). From a social standpoint, higher quality lives have a tendency to be more socially productive lives.

Quantifying all qualitative considerations in order to compare patients on the same scale, however, may be impossible. Even if it were possible, predicting the quality of life that will follow treatment sufficiently precisely to distinguish most patients remains problematic. So does achieving agreement as to what factors characterize a good quality of life and how these factors should be ranked. While such measures as QALYs (quality-adjusted life years) have been developed to assist macroallocation decision making, they have not proven as helpful in distinguishing individual patients at the microallocation level. Another difficulty arises when some people (usually caregivers) must assess the quality of others' lives. People judge others' quality of life on the basis of objective, observable quality of life indicators. Unfortunately, evidence has long suggested that such objective indicators do not correlate well with patients' subjective experience of their own lives (U.S. Congress). In fact, what is unacceptable to the well may be quite acceptable to the sick.

When some people impose their standards of quality on others, moreover, biases against such groups as disabled, poor, and elderly persons can easily intrude.

PERSONAL CRITERIA. The final four criteria may be designated as *personal* because their justifications are rooted in personal values such as liberty and the worth of the individual. These four are: willingness, responsibility, ability to pay, and impartial selection.

Willingness. Supported to some degree by 89 percent of the participants in the U.S. Study, a willingness criterion ensures that only patients who genuinely want treatment receive it. This criterion respects patients' rights to bodily integrity, as well as their autonomy, or freedom, to make vital decisions that primarily concern their own lives. People have unique life plans and values, and only they can accurately assess the balance between the benefits and burdens of their own treatment. For many, a right to the free exercise of religion is at stake. When resources are allocated to willing recipients, the recipients themselves are happier and the resources are less likely to be ineffective or rejected midcourse. Even if people choose to forgo treatment because other qualified patients need the same treatment, the choice can be applauded as an act of giving rather than simply branded as a typical suicide.

Nevertheless, a willingness criterion can also be problematic. For it to be employed ethically, patients must have complete information concerning the healthcare treatment in question, including the costs and benefits of receiving it; they must understand this information; they must be free from the (sometimes subtle) coercion of family, professional, or other caregivers who might want them to accept or reject treatment; and they must have the mental capacity, despite their current health predicament, to make and communicate decisions that reflect their values. A willingness criterion can also easily become a cover for patients' selfish behavior—for example, suicidal rejection of life-sustaining treatment with no regard for others who in some way depend on them.

Responsibility. Responsibility is actually a willingness criterion of a different sort. It steers resources away from people who willingly engage in unhealthy lifestyles or risky activities that result in the need for treatments (support for it was not measured by the U.S. study). Most commonly invoked as a macroallocation criterion, this criterion has provoked significant debate. Proving responsibility in specific cases is particularly controversial (Wikler).

Ability to pay. As a criterion for microallocation of healthcare resources, ability to pay received support from 43 percent of the participants in the U.S. Study. People with insufficient funds or other necessary resources are explicitly excluded by this criterion from access to certain forms of healthcare. The criterion functions in many indirect ways as well. The uninsured, in fact, use health services only about half as much as the insured and are more likely to die from treatable conditions as a result (Evans; Institute of Medicine). The inability of some patients to pay for the support services that necessarily accompany certain treatments—such as travel expenses and postoperative care—has also in effect excluded some patients from treatment. When transplantable organs have been the scarce resource, those with the ability to mobilize the media or key politicians have occasionally gained special access to the necessary organs. The ethical considerations here are essentially those attending a market approach to macroallocation.

Impartial selection. When all other ethically justifiable criteria have been applied, and there remain more eligible candidates for resources than there are resources to provide, caregivers sometimes invoke an impartial selection criterion. Affirmed by 31 percent of the participants in the U.S. Study, this criterion mandates a random selection from among eligible candidates. Its rationale is that each person who has an equal moral claim on a scarce resource should have an equal opportunity to receive it. The apparent arbitrariness of the selection helps to keep the tragedy of the situation clearly in view. It focuses more attention on the need for additional resources to be made available at the macroallocation level, if possible. There is no comforting illusion that the "best" candidates are being treated.

Some forms of impartial selection, though, may be better than others. One option is a first-come, first-served approach. Because the time that each person is stricken with a medical condition and seeks treatment is more or less random, this approach functions as a sort of natural lottery. Its appeal stems from the familiarity of waiting lines inside and outside the realms of healthcare and from the way that this approach does not seem as starkly random as an explicit lottery. True randomness, however, is the whole point of an impartial selection criterion. First-come, first-served is inferior to a genuine lottery on this score. Patients with the greater power, mobility, information, and confidence associated with the relatively wealthy have better access to healthcare generally and to referral networks in particular. Accordingly, they tend to get on the waiting lists for scarce resources sooner than those who are less wealthy and empowered.

Some weaknesses of an impartial selection criterion, though, are not unique to a particular form of the criterion but are inherent in the criterion itself. For instance, many of

the social benefits that other criteria generate are lost when an impartial selection criterion is applied. Socially destructive persons such as dangerous criminals are sometimes selected instead of people who have made great positive contributions to society. Rather than respecting human dignity, impartial selection may demean it by not considering the unique features of each person. Admittedly, people cannot make infallible decisions. In the eyes of some, however, human judgments are arguably better than blind chance.

Allocation Approaches

Allocation criteria, the building blocks of microallocation, must be prioritized and arranged into some sort of basic approach if microallocation decisions are to be ethically consistent. This approach can then serve as a framework for designing specific allocation procedures tailored to particular resources and settings. Approaches tend to be justified ethically by appeals to norms such as productivity, equality, and freedom, but relatively little grounding is typically provided for these norms in the context of allocation discussions. Such norms have long had broad intuitive appeal in Western culture. Nevertheless, increasing ethical pluralism together with the tensions among the norms themselves underscore the need for a larger frame of reference (religious, rationalistic, or otherwise) within which such norms can be justified (Palazzani).

The many approaches to microallocation that have been advocated sort ethically into two groups. One group of approaches is oriented primarily toward making the most productive use of resources; the other, toward ensuring that suitable candidates have equal access to treatment through some form of impartial, or random, selection. Impartial selection may play a minor role in productivity-oriented approaches, but usually only to break ties. Furthermore, all approaches generally affirm or assume some sort of willingness criterion because of the importance of respecting people's freedom.

PRODUCTIVITY. Three forms of productivity-oriented approach can be distinguished. One form focuses exclusively on medical considerations (e.g., Leenen). Employing only medical criteria, along with sociomedical criteria whenever they are essential to good medical outcomes, this approach seeks to allocate resources to those most likely to benefit medically. Medical criteria, particularly when rooted in the notion of meeting needs, can be defended on the basis of ethical concerns other than productivity: for example, a principle of justice. But when all (or virtually all) decision making depends on comparative medical judgments among patients, a more utilitarian concern to maximize productivity is typically at work. The strengths and weaknesses of such approaches will vary depending on which of the three comparative medical criteria (likelihood, length, and quality of benefit) are employed.

A second, related form of productivity-oriented approach attempts to enhance the productivity of an exclusively medical orientation by allowing special exceptions on the basis of value to society. The concern may be to ensure treatment for particularly valuable individuals (e.g., Langford) or to exclude particularly unworthy candidates (e.g., Bayles). In the former case, the relevant rationales are those supporting social value and/or vital responsibilities criteria; in the latter, rationales undergirding a responsibility criterion also apply.

The third form of productivity-oriented approach takes this concern about social value one step further. It makes social considerations primary, combining whatever criteria are necessary to yield the most productive use of scarce resources. The ethical justifications and weaknesses of this form of approach are fundamentally those of the social value criterion itself—most obviously when such approaches affirm social value per se as the overarching consideration (e.g., Basson). When social criteria such as social value and progress of science are combined with comparative medical criteria and/or sociomedical criteria (e.g., Rescher), the additional justifications and weaknesses of those criteria come into play secondarily.

IMPARTIALITY. The major alternative to productivity-oriented approaches seeks to give suitable candidates equal access to treatment through some form of impartial selection. The pool of suitable candidates typically includes all who meet the medical benefit criterion. Priority groups within this pool are identified on the basis of nonutilitarian criteria: vital responsibilities alone (e.g., Childress), vital responsibilities plus resources required (e.g., Winslow), or both of these criteria plus imminent death (e.g., Kilner, 1990). (A priority may also be given to any group of people whose likelihood of benefit is substantially higher than that of all others, though the productivity-oriented nature of this priority creates ethical tension within an impartiality-oriented approach.) Finally, candidates are ordered within each priority group through impartial (usually random) selection.

In contrast to the explicit or implicit utilitarian bent of productivity-oriented approaches, in which benefit to society is the primary goal, the justification of this last type of approach is more egalitarian in nature. Within certain limitations designed to save as many lives as possible, all potential recipients of scarce resources are ensured an equal opportunity to receive them. This commitment to life and

equality may simply be intuitive or reflect popular sentiment. Alternatively, respect for life and equality may be grounded in a philosophical or religious understanding of ethics. One philosophical example would be social contract theory, in which such respect may be seen as something to which all people would agree, if they had to decide upon ethical standards to govern society under certain ideal conditions (Winslow; Rawls). A religious example would be the biblical accounts of God's exemplary commitment to even the poorest, which is foundational to Christianity and Judaism (Mitchell; Ramsey; Zoloth; Mackler).

PARTICULAR SETTINGS. Implementing any approach requires tailoring it to particular settings. For instance, medical assessments are handled differently when allocating intensive care (Zoloth-Dorfman and Carney; Lantos, Mokalla, and Meadow) as opposed to transplantable organs (Caplan; Schmidt) or kidney dialysis (Cummings; Rutecki and Kilner). In the intensive care setting, a tool often used has been the APACHE (Acute Physiology and Chronic Health Evaluation) System. Through laboratory tests and bodily measurements, the APACHE System is able to predict patient death rates and length of intensive care stay when patients are first admitted to intensive care (Knaus et al. 1993; "Medical Algorithms Project"). A different quantitative system has been developed for assessing both medical and nonmedical considerations in organ transplantation. The United Network for Organ Sharing (UNOS) has developed a national point system to prioritize patients needing transplants. In the case of kidney transplants, for instance, candidates whose blood type is compatible with that of the donated organ are ranked according to point totals. These totals represent the sum of points given for medical considerations such as antigen matching and for nonmedical considerations such as time on the waiting list (OPTN). Methods of quantifying social value rankings in particular geographic settings have also been developed (Charny, Lewis, and Farrow).

Numerical systems are helpful in facilitating consistent comparisons among potential recipients of healthcare. Nevertheless, the need for judgment in microallocation is unavoidable (AMA, 1993). Caregivers must help identify medically appropriate courses of action, assess the likely outcomes of those courses, and assist potential recipients in their decision making. Potential recipients must evaluate the benefits and burdens of all available courses of action in light of their own sets of values and beliefs. Interdisciplinary committees and healthcare teams in public-policy and institutional settings must not only craft ethically sound allocation criteria into workable allocation approaches; they must also determine what shape such approaches take in specific settings and discern how they apply to particular people. Microallocation, like healthcare itself, remains an art as well as a science.

HEALTHCARE SYSTEMS

• • •

A healthcare system can be defined as the method by which healthcare is financed, organized, and delivered to a population. It includes issues of access (for whom and to which

services), expenditures, and resources (healthcare workers and facilities). The goal of a healthcare system is to enhance the health of the population in the most effective manner possible in light of a society's available resources and competing needs. By the beginning of the twenty-first century access to healthcare had come to be regarded by most countries and the United Nations as a special good that is necessary either as a matter of or pursuant to basic human rights. An examination of healthcare systems therefore includes consideration of the ways in which a particular system addresses commonly held values.

The extent and form of a specific system are influenced by a variety of factors, including the unique culture and history of a population or country. What is considered healthcare can vary markedly in accordance with a country's level of development, culture, and social values. Some populations put emphasis on the prevention of disease, whereas others emphasize only the care for or cure of particular illnesses. Definitions of health and disease and of *appropriate* healthcare providers also are subject to cultural variability.

A second major influence derives from the priorities given to various ethical values: "There is no way to adjudicate disputes among the Holy Trinity of cost, quality and access unless a court of values is available to dispense its wisdom" (Reinhard, pg. 1). Those values include respect for the autonomy of both patients and providers, the maximization of benefit, and the promotion of justice or fairness, understood as equality or liberty.

Balancing those values has posed a dilemma in the United States. Public opinion polls have revealed that most Americans see access to healthcare as a fundamental right. However, Americans' equally strong belief in individual autonomy and responsibility, the use of the market as a means for distributing goods and services, and fears about government interference create conflict and have led to a fragmented healthcare system.

A third influence on the structure of a healthcare system is the level of economic resources available. There is a strong positive correlation between economic resources as measured by the per capita gross domestic product (GDP) and both healthcare expenditures and the proportion of a nation's GDP that is spent on healthcare (Gerdtham and Jonsson). This indicates that although healthcare generally is valued, countries and individuals may consider food, shelter, and in some instances spending for the military more important. However, although the economic resources available to a country have a great effect on that country's overall expenditures on healthcare, there is nearly as much variation in the forms of the healthcare systems in countries that are economically poor as there is in wealthy countries.

Public versus Private Control

All governments have some degree of involvement in healthcare because essentially all countries have a centrally funded agency that is concerned with public health issues. The proportion of healthcare expenditures spent on public health tends to be higher in low-income countries, although the level of effort varies greatly from country to country. Government involvement usually includes surveillance of communicable diseases and interventions to prevent or curtail epidemics. Some countries have more extensive government involvement through direct delivery of services (e.g., immunizations, well-child care, screening for developmental disabilities, and treatment of communicable diseases) and programs of health promotion. Public health efforts in the United States are fragmented but have begun to receive more attention as the costs of personal, disease-oriented healthcare and concerns about bioterrorism have increased.

Beyond public health measures, healthcare systems vary dramatically with regard to the degree of public versus private control (Anderson et al.). In fact, the extent of government control is probably the most distinguishing characteristic among systems. In most member countries of the Organization for Economic Cooperation and Development (OECD) the healthcare system is dominated by the public sector. The OECD countries with a high percentage of revenues from the public sector in 2000 included Luxembourg (93%), the Czech Republic (91%), and the Slovak Republic (90%) (OECD). In a few countries the majority of revenues come from the private sector. In the United States the private sector accounts for about 56 percent of healthcare expenditures. The only other OECD countries that receive a majority of funds (more than 50%) from the private sector are South Korea (56%) and Mexico (54%).

The public side of healthcare systems in industrialized countries can be placed into two categories: countries with comprehensive programs and strong government control of virtually all aspects (financing, delivery, quality monitoring) of the system, such as Great Britain, the Scandinavian countries, and the countries of the former Soviet Union, and countries in which the government's role is limited to financing or guaranteeing enrollment for all citizens in a health insurance plan, such as Germany, Belgium, France, and Canada. Both types of systems are characterized by

public financing or mandates that guarantee universal coverage, payment that is negotiated between the public sector and providers, and policies regarding facilities and healthcare workers that are modulated predominantly by the public sector.

In countries in which the private sector is the dominant payer for healthcare universal coverage is less common, payment varies from provider to provider and insurance company to insurance company, and policies regarding healthcare workers are negotiated in the marketplace. In the United States, for example, patient and professional autonomy are dominant (Reinhard). Most individuals or employers are free to choose from among multiple insurers and providers, and most provider groups have the freedom to choose whom to serve, how much to charge, and what credentials are required to join the group.

Especially notable has been the strong distrust of government interventions except when they are deemed necessary to guarantee access to a group that is seen as *entitled* because of a special service it has rendered (retirees, veterans) or special need (disability, poverty). However, even in the United States there have been a number of occasions (as in 1910, 1935, 1948, 1965, 1972, and 1994) when a reasonably strong attempt was made to provide a substantial increase in government involvement in the healthcare system. Except in 1965 those attempts failed because of a combination of factors, including provider opposition, lack of public consensus, fears of increased government involvement, and relatively comprehensive healthcare benefits that most working Americans receive from employment-based private insurance.

Financing

The means of financing healthcare, perhaps more than any other aspect of a healthcare system, mirror the values and priorities of a society. As was noted above, unlike the case in the majority of the OECD countries, healthcare financing in the United States is mostly private. There is also little public financing of healthcare in most low-income countries. Because of the high cost of many interventions and the unequal distribution of healthcare costs among individuals, lack of a broad-based system of public financing creates a system in which healthcare is rationed on the basis of the ability to pay.

Beginning with Germany in 1883, most industrialized nations have implemented a government-coordinated or government-controlled system of financing for personal healthcare services. This varies from the systems in countries such as Great Britain and the former Soviet Union, in which virtually all healthcare is financed through general tax revenues collected by the national government, to systems, such as Canada's, that are financed from both state and national revenues, to those of Germany, France, Belgium, and the Netherlands, in which financing is mandated by the national government through required participation in a community- or employment-based insurance funds.

In the third type of system most funds are obtained through required contributions based on wages. All countries with strong central control have at least a small market of privately financed healthcare that is used predominantly by the rich and the politically connected. For example, in Germany and the Netherlands the most affluent people are not required to purchase health insurance, and most choose to purchase private health insurance, which gives them better access to medical services. Some countries with mixed systems (e.g., Japan and Australia) have a small market for private health insurance that complements the public-sector benefits.

The proportion of public financing of healthcare in the United States has been increasing steadily, rising from about 23.3 percent in 1960 to nearly 44.3 percent in 2000 (OECD). In spite of these increases, there is no universal government-guaranteed or compulsory health insurance. Employer-based or individually purchased private insurance is the most common way people obtain health insurance coverage. A variety of publicly financed programs (e.g., Medicare and Medicaid) provide insurance to persons over age sixty-five and some poor people. They are financed by a spectrum of public financing mechanisms, including federal and local government revenues, the use of income and employment-based taxes, and in some states the revenues from a lottery.

Financing for active-duty military personnel, veterans, and Native Americans mirrors the centrally controlled healthcare systems of Great Britain and the former Soviet Union. Revenues come from the federal income tax, and services are provided by public-sector employees. The Medicare program is financed primarily from a wage tax, whereas Medicaid (for certain categories of disabled and low-income persons) is financed from a combination of state and federal general tax revenues. Financing for some care for the poor who are not eligible for Medicaid comes from general tax revenues at the state or local level that are paid to city and county public hospitals and state mental hospitals.

The dominance of a private system of financing in the United States is a reflection of not only that nation's values but also of a number of historical events. The Blue Cross program began in Texas when Baylor Hospital enrolled

schoolteachers in an insurance system during the Great Depression as a method to guarantee that hospitalized patients could pay their health bills. Private health insurance grew slowly during the 1930s.

The real spread of private health insurance occurred during World War II, when wages but not fringe benefits were frozen as a wartime price-control measure. As more firms began to offer health insurance as a benefit, private insurance companies saw the potential for expanding their markets and encouraging those enrolled in health-insurance plans to buy their other insurance products. Another impetus to the market was the decision by the federal government to exempt healthcare benefits from federal income tax. The large number of insurance plans in the United States, each with its own marketing, benefit packages, premiums, deductibles or copayments, billing, and payment requirements, together with the thousands of private physicians, clinics, and hospitals, has created an immense administrative bureaucracy with aggregate administrative spending of $89.7 billion in 2001 (Center for Medicare and Medicaid Services; Levit et al.).

Access and Delivery

A second major characteristic of a healthcare system is access, which has multiple definitions, including the following:

1. The ability to obtain needed care
2. The potential and actual entry of a given population into the health system
3. The timely use of personal health services to achieve the best possible outcome
4. The timely use of needed, affordable, convenient, acceptable, and effective personal health services

Different countries approach the issue of access in various ways and define the term differently. Health systems with strong central control, such as those in Great Britain, the Scandinavian countries, and the countries of the former Soviet Union, emphasize equal access to care for all their citizens. Those countries have a single-payment system, with most healthcare providers working as salaried government employees and a single government-defined set of benefits. There tends to be strong emphasis on primary care by general practitioners and relatively tight control of the number and distribution of providers and facilities that provide highly technical services. In some countries this degree of government control results in substantial waiting times for some services and limited access to advanced technologies. Thus, whereas this approach produces an apparently high level of equal opportunity to obtain needed health services, it may deny some individuals access to lifesaving technologies and restrict both provider and patient choices. This depends on the level of spending a country is willing to commit to healthcare.

Countries with less centralized systems vary more in regard to the level of access. In some countries access to healthcare for the poor is restricted by the ability to pay. Moreover, providers' freedom to choose their patients can restrict access to medical services among insured low-income individuals. For example, many providers in the United States refuse to serve Medicaid recipients because of the low payment rates. In countries with less centralized health systems working individuals employed in low-paying jobs often face financial barriers (high out-of-pocket expenses for copayments, deductibles, or premiums) to receive needed care (Lee and Tollen). Similarly, the limited control of healthcare workers and facility location tends to result in geographic maldistribution of providers and healthcare facilities.

The degree of access varies widely in the United States. Financial barriers to access are substantial for more than 41 million Americans without health insurance coverage and about the fifth of insured individuals who have inadequate insurance (Mills; Hadley and Holahan; Kaiser Commission on Medicaid and the Uninsured). Studies have shown that those who are poor and have no health insurance have a markedly lower use of almost all forms of healthcare despite their tendency to have a lower baseline health status. This lack is especially great in terms of primary care and preventive services (Bayer and Fiscella). Although the uninsured have some access to high-technology care, especially in urban areas, through use of the emergency rooms and outpatient clinics of public hospitals, research has shown that they have poorer outcomes of hospitalization (controlling for severity) and a markedly lower use of high technology compared with those who have insurance. There is also growing evidence that limited access to primary care results in not only poorer health outcomes but also higher overall costs through delayed treatment, reduced patient adherence to therapeutic regimens, and increased emergency room and hospital admissions.

Payment

The level and means by which providers of healthcare are paid has a substantial effect on access, costs, and the quality of care. In countries that rely on a private healthcare delivery system (the United States, Canada, France, and Belgium) the predominant mode of payment for physicians who

provide ambulatory care is fee-for-service. In most instances physicians bargain with insurers or the government over a fee schedule. In some countries there is a provision that physicians can charge patients more than the allowed fees in certain circumstances. There is concern that the financial incentives inherent in a fee-for-service system result in over utilization of services, especially those reimbursed at higher levels relative to other services. However, the autonomy of providers is preserved, and there is an incentive for increased productivity. Additionally, there is no conflict between the financial interests of providers and their duty to provide all services that are of benefit to patients. Cost- or charge-based reimbursement for institutions (hospitals, nursing homes, etc.) has similar risks and benefits.

Some insurers in the United States and the Netherlands use capitation (a set payment per person per year) or a set payment per case to pay providers. Capitation payments provide an incentive for healthcare workers and facilities to limit the volume of provided services and allow providers to determine precisely which services to provide. At the same time, case-based payment and capitation create a conflict between the financial incentive of the provider and the interest of the individual patient in receiving all services that are of possible benefit. This can be a problem for people with multiple chronic conditions, who are often the most expensive to treat.

In many countries, hospitals are paid on prospectively negotiated global budgets and hospital-based providers, including physicians, are paid on a salaried basis. These methods of payment have little apparent effect on the provision of services to individuals. However, the level of payment may have a profound effect on which technology is acquired and on whether providers expend the time and effort required to provide a given service in general.

Expenditures and Cost Controls

Since 1960 in virtually every country expenditures for personal healthcare services have been rising in absolute terms and in relation to GDP (Anderson et al.). Health expenditures have been increasing at a rate nearly double that of other major sectors of some national economies. In some countries concerns are being raised that spending on medical care is occurring at the expense of other socially desirable goods and services. This is especially true in the United States, where despite the highest per capita and GDP-adjusted healthcare spending in the world, healthcare is still not accessible to all, and there is growing concern about other social problems such as deteriorating schools, homelessness, poverty, and crime.

One reason for controlling health spending is that there is strong evidence that more healthcare spending does not necessarily buy better health (Newhouse). Even more compelling is the growing evidence that a substantial number of medical-care services may provide only small marginal benefits. Although small benefits and high cost are the norm in industrialized countries, many developing and economically disadvantaged countries cannot provide their populations with even basic public health measures such as immunization and sanitation.

In many industrialized countries cost controls have created the potentially unpopular phenomenon of waiting lists. Some countries, notably the United Kingdom and the Scandinavian countries, have implemented a policy of increasing health spending to eliminate waiting lists.

The response of different healthcare systems to the growing problem of cost has in general reflected the basic organization and values of each country. In countries with strong central control there has been increasing pressure to create fixed budgets and establish tight control over the acquisition of advanced technologies (supply-side control). Access to basic health services for everyone has been maintained at the expense of not providing expensive services that are potentially lifesaving for a few individuals.

By contrast, in the United States there are relatively fewer advocates for global budgeting. Efforts to reduce costs have focused primarily on enhanced competition (demand-side control). These cost-control mechanisms appear to have produced some one-time reductions in healthcare spending but have had a very modest effect on the rate of growth of expenditures.

Because of the seemingly inexorable rise in costs in the United States, employers have been shifting more of the cost of healthcare to employees by increasing employee-paid premiums, eliminating coverage for dependents, increasing copayments and deductibles, or eliminating coverage altogether. The response of private insurance companies to growing cost concerns has been to refuse to insure high-risk employees (medical underwriting) or to tie premiums directly to the previous year's expenditures by a particular group (experience rating). Employers became more aggressive in eliminating benefits such as health insurance for retirees when the labor market became looser and profits decreased. All these factors, along with a rise in the number of part-time workers and employment in small, nonunion service industries that lack medical benefits, have been primary determinants in the increase in the number of working-age individuals in the United States who are without health insurance.

Resources

The most visible aspects of any healthcare system are the facilities and personnel involved in the delivery of healthcare. Centralized systems have attempted to provide greater equality in the distribution of facilities and healthcare workers by focusing on the needs of a community rather than on the autonomy of providers and patients. In some centralized systems the national government may determine how many and which types of physicians, nurses, and other healthcare workers are produced; the location of hospitals and the technology they may purchase; and the location of hospital-based and outpatient-care providers. Care is strongly regionalized, with easily accessible primary care for most common healthcare problems, some specialty care available in regional hospitals, and subspecialty and tertiary care confined to a few large teaching centers.

In contrast to most other countries, the healthcare system in the United States provides little central control. There has been almost complete autonomy for providers, starting with a system of health-professional education with a substantial number of private schools and little or no restriction on specialty choice, practice, or hospital location or on the availability of technology. Because of the prestige and generous payments for new technology nearly all hospitals provide a full array of high-technology services. This complements a strong trend toward subspecialization among health professionals. In the case of physicians the percentage of generalists versus specialists declined from nearly 50 percent in 1961 to the current 28 percent; if OB/GYN and emergency medicine physicians are included in the generalist category, the figures are 32 percent primary care physicians and 68 percent specialists (Bureau of Health Professionals; Council on Graduate Medical Education). The abundance of specialists, especially those who are trained to perform high-technology procedures, is thought to exacerbate the over utilization of some healthcare services. Conversely, the decline in the number of generalists is believed to be a contributing factor in the poor access to healthcare experienced by persons in rural areas and those with low incomes in urban areas.

Choices for the Future

All countries are continuing to search for better cost-containment and cost-effectiveness mechanisms, including the difficult task of placing limits on the healthcare technologies that provide small marginal benefits to a few individuals at a great cost to the community.

Tension will grow between the values of individual autonomy (reflected in the assumption by patients that the *right* to healthcare includes all interventions that are of possible benefit and the assumption by providers that they have the *right* to set prices and choose where and whom to serve) and concern for the good of the community and other societal needs. Attempts to achieve equality in the systems of financing, payment, cost control, and delivery will have to take into account increasing competition for limited resources and the perceived infringement on personal freedom. Balancing these competing claims will be especially difficult in the United States with its multiple systems and distrust of government involvement in human services.

A renewal of a sense of community and a careful balancing of values will be necessary in achieving a reasonable solution. Although the future is unclear, the United States probably will reconsider policies for rational allocation between healthcare and other sectors of the economy, government regulation to require universal and equitable access to defined *basic* insurance policies, mandated employer-based insurance with a publicly financed safety net, payment based on capitation with some adjustment for the severity of illness in a specific group of patients, and incentives (including scholarships and loan forgiveness) for providers who choose to provide primary care in shortage areas.

HEALTH INSURANCE

• • •

The social and economic vulnerability of wage laborers gave rise to nineteenth-century reforms that are the forerunners of modern health insurance. When the flow of resources to a household depends on wage labor, sickness for any prolonged period threatens the family's ability to secure food and shelter. The practice of organizing workers to contribute a portion of their wages to health (or sickness) insurance funds was a response to this vulnerability, and set a social pattern in industrialized nations that has continued for more than a century. The two principal ethical concepts associated with health insurance are social solidarity and social justice.

Health Insurance and Social Solidarity

As was evident in the European sickness funds, the insurance compact expresses an underlying solidarity among insurance pool subscribers. Persons facing a common vulnerability organize into a group whose shared resources, built up from relatively small individual contributions, will assist members who suffer financial loss as a result of illness or injury. Since the anticipated harm is a matter of probability, the group that pools its resources must be large enough and composed of persons with sufficiently variable risk levels so that, in a given period of time covered by the contributions (or premiums), only a minority of those at risk will actually experience illness or injury. The majority will contribute without needing to draw on the pooled resources. Those who do not encounter harm stand in a relationship of fiscal solidarity with those who do. The smaller the group, the more vulnerable it is to being overwhelmed by a small number of very large claims. If the group includes a large number of persons with high probability of need (the elderly, for example), a high level of member contributions will be required to guarantee adequate resources to cover every claim.

In addition to the purely fiscal relationship among contributors, reigning social and political ideas affect the conscious feelings of solidarity they experience as members of an insured group. Compulsory sickness insurance for workers, providing for both lost wages and the cost of medical care, was first organized at a national level in 1883 in Germany by the conservative chancellor Otto von Bismarck

as a defensive maneuver against the rising influence of the German Social Democratic Party. As Paul Starr noted in his 1982 work, Bismarck believed workers were less likely to demand more radical reforms if certain harsh realities of the industrial revolution could be tempered with benevolence flowing from the monarchy.

In the closing decades of the nineteenth century, several other European nations took similar actions to protect workers' vulnerability, but the United States showed little interest in the idea until the Progressive reformers began to press the issue in the early years of the twentieth century (Hirshfield). They promoted compulsory health insurance as a form of enlightened self-interest on the part of the middle class: The survival of individual freedoms essential to capitalism required taming the tendency of free enterprise to pursue profit without concern for the precarious circumstance of wage laborers. Robert N. Bellah, et al. (1985) noted that the vocabulary of individualism typical of the culture of private consumption has shaped public discourse about health insurance in the United States, and the concept of social solidarity is only faintly evident in the debate that has evolved since the early twentieth century (Churchill).

In some societies, social consciousness about health insurance sees it as a component of the nation's system of social insurance—that is, a public guarantee that certain basic human needs will be met at some minimum level for all members of the community. This has typically been the meaning of health insurance in Western Europe. Conversely, health insurance may be seen as a marketable service properly residing in the private sector, which has been the dominant, though not unanimous, social understanding in the United States (Greenlick, 1988).

The Progressives' compulsory insurance campaign had failed prior to 1920, and by the late 1930s, the idea of voluntary health insurance for workers as a fringe benefit of employment had taken over as the prevailing rationale for social change. The appeal of voluntary insurance, supported by tax subsidies for employers and workers, was fully compatible with the Progressives' individual freedoms argument. Indeed, the voluntary approach seemed capable of solving the solidarity problem, as the percentage of the whole population with voluntary hospital insurance shot up from less than 10 percent in 1940 to 57 percent in 1950 and to nearly 90 percent by the early 1970s (Anderson). With health insurance spreading widely through the working community, yet systematically leaving those not in the workforce outside the fold, the idea of national health insurance based on explicit appeals to solidarity and social justice emerged periodically but each time failed to pass into law (Hirshfield; Starr).

Health Insurance, Social Justice, and Rights

The concept of justice is the second major ethical theme associated with health insurance. Concerns about justice and health insurance derive from the question whether it is fair for some, but not all, citizens to have insured access to healthcare. Originally, health insurance was viewed as required by social justice not for everyone, but only for those made vulnerable by the conditions of wage labor. Compulsory insurance schemes were designed to help capitalism by making the working class more secure. The U.S. middle class broadly committed itself to the voluntary purchase of health insurance when, as a means of winning better fringe benefits through collective bargaining (intensified under wage and price controls during World War II), getting health insurance as a benefit became a normative expectation of workers.

Once the idea of health insurance takes hold in a society and is widely believed to give access to a fundamental benefit of social existence, it comes to be seen as the way members of the society purchase their healthcare, not merely the way they protect themselves from potential financial loss. Having insurance and getting needed healthcare become closely linked in the logic of justice. (For an account of how social expectations give rise to the perception of entitlement and societal obligation, see the work of Michael Walzer.)

The idea of a right to healthcare as a requirement of social justice is intimately connected to the practice of collectively financed healthcare. The notion that healthcare might count among positive human rights derives from the widespread belief that healthcare successfully meets fundamental human needs, such as security, relief from suffering, prevention of premature death, and maintenance of functional capacity. (For a philosophical argument about the grounds and limits of universal entitlement, see Norman Daniels's work and Charles J. Dougherty's publication.) Creating legal protections for that right becomes a problem of political will.

The injection of rights language into political arguments about health insurance is itself evidence of the evolution of the concept and expansion of its original limited goal of protecting wage laborers from the effects of major illness. In the absence of a constitutional or statutory declaration of a right to healthcare, opinion leaders use human rights language to motivate members of society and to provoke legislative action aimed at helping persons whose needs are being ignored. While specific contractual rights to healthcare exist between insured persons and their insurance carriers, that is not what advocates of a right to healthcare have in mind. When reformers argue for a right to healthcare, they

mean that basic relationships of solidarity and interdependence among all members of society create a societal obligation to ensure access to healthcare for all. (For a discussion of issues raised by rights discourse in relation to health insurance and access to healthcare, see the U.S. President's Commission Report, and the 1994 work edited by Audrey Chapman.)

During the second half of the twentieth century, aggregate expenditures for healthcare rose at such a dramatic rate that by the 1980s, cost control in healthcare became a central issue for reformers. However, the question of setting limits makes debate about a right to healthcare politically difficult. Unlike rights to liberty or the pursuit of happiness, which entail noninterference by others, a right to healthcare entails paying someone to provide costly services. By 1990, the need to speak of a limited right was clear to many leaders, although negative reaction to the idea of rationing healthcare led many to deny its necessity, and how to define limits was hotly debated (Strosberg). In 1989, the state of Oregon intensified the debate when it organized a unique social experiment to guarantee coverage to uninsured persons while setting limits on what would be covered based on a prioritized list of healthcare services (Garland, 1992, 1994, 2001).

Organization and Financing of Health Insurance

The fundamental concept of any form of insurance is risk sharing: A large number of people who face a common threat of harm (auto accident, fire damage, costs of treatment for illness or injury) share their risks by paying premiums to an insurer who promises to finance payments to those who in the future actually suffer misfortune. All members of the risk-sharing group get a sense of security in return for their contributions even if they do not receive specific insurance payments (as a result of being personally harmed).

Ethical issues in risk sharing through health insurance are shaped by the insurer's decisions about how to organize and finance the common fund that members of a group rely on for protection against potential financial loss. For example, insurers may organize risk-sharing pools among individual subscribers, various age groups, business firms, or labor organizations. Financing might be done through a single, community-wide premium or through variable premiums tied to past utilization, health-risk or ethnic group or age or gender. The European approach was to develop social insurance mechanisms, or sick funds, initiated by the public sector. In the United States, the free market casualty insurance model was adapted in a unique form to fulfill the social insurance function. The resulting hybrid fails to satisfy either free market norms or social insurance ideals.

The major development in U.S. health insurance in the 1930s and 1940s was led not by government or business but by nonprofit corporations such as Blue Cross (hospital insurance service corporations), Blue Shield (physician insurance service corporations), and a variety of consumer and producer cooperatives that provided coverage for hospital and medical services. The corporate missions and characteristics of these organizations gave U.S. health insurance a strong social insurance tendency without fully incorporating the European approach.

Because they believed that the nonprofit organizations' approach to health insurance violated the basic tenets of casualty insurance, commercial insurers initially showed no interest in this market (Iglehart). Casualty insurance assumes that a hazard insured against is measurable and not something the insured person wants (such as checkups or preventive services), or can control (such as pregnancy).

From the beginning in the United States strict casualty insurance principles were ignored. While health insurance protects subscribers from the financial impact of relatively rare high-cost medical services, plans commonly also cover many low-cost services used every year by most members of the insured group. The typical health insurance plan provided to employees of large corporations includes coverage for some ambulatory care costs (office visits, X-rays, and laboratory services) and the major portion of emergency room and hospital charges. About 80 percent of the population will use some ambulatory care services, while only 10 percent of the population will need hospital care in any given year.

By the time the commercial insurers overcame their suspicion of the field, the nonprofit insurers had already brought much social insurance philosophy into the market. Consequently, while the health insurance language includes many standard insurance terms ("adverse selection," "moral hazard," "product lines," "lives covered by plans"), leading the casual observer to conclude that the field is a traditional casualty insurance market, it is, in reality, a form of social insurance peculiar to the United States. However, the competitive practices of commercial insurers have led to widespread use of experience rating, which undermines the social insurance spirit by making health insurance more expensive for those in greatest need. Health insurance plans use three basic methods to protect subscribers: indemnity benefits, service benefits, or direct provision of service. Indemnity insurance, typical of commercial insurers, reimburses a patient for a portion of incurred medical expenditures. Service benefits, typical of nonprofit insurers, pay

physicians and hospitals directly on behalf of subscribers. Health maintenance organizations, by contrast, actually organize and deliver services directly to their members at clinics and hospitals that the plans usually own and operate, paying for professional services by salary or contract, not on a fee-for-service basis.

In a widespread effort to control medical care costs in the 1990s, managed care systems, especially those who were not associated with organized delivery systems, used various discounting and risk-sharing reimbursement mechanisms to pay medical service providers. By 2000, providers and patients had grown increasingly unhappy with the restrictions imposed by managed care strategies and the organizations could claim little success in controlling medical costs (Levit, Smith, and Cowen). New strategies relied on shifting costs to patients and members of insurance plans (Draper, Hurley, and Lesser; Christianson, Parente, and Taylor; Trude, Christianson, and Lesser). Six major tendencies characterize the way U.S. health insurance adapted casualty insurance concepts to serve a social insurance function: leadership by nonprofit corporations; a gradual shift from financing based on equal shares (community-rated premiums) to financing based on unequal shares (experience-rated premiums); consumer preference for comprehensive benefits; use of service and indemnity methods of benefit definition; carriers' preference for group rather than individual marketing of plans; and persistent ambivalence in the general public about the role of government in health insurance.

NONPROFIT STATUS OF HEALTH INSURANCE PIONEERS. Because the pioneers in U.S. health insurance were nonprofit, charitable organizations, they were developed to provide a social function beyond creating a profit for shareholders or syndicate owners. However, the social objective was not always to benefit consumers. Blue Cross was first organized to provide for the financial survival of the American voluntary, nonprofit hospital system during the period of the Great Depression. Although organized medicine initially opposed the new insurance schemes as unwanted intrusions into the privacy of the patient-physician relationship, Blue Shield was eventually formed as a preventive measure to keep mechanisms for paying physicians under the direct control of organized medicine. Provider cooperative prepaid group practices, such as Kaiser Permanente, were formed because some reform-minded physicians believed that prepaid group practice was a more satisfying and socially responsible way to practice medicine.

These nonprofit institutions were chartered in the public domain and were guided by boards of directors who were reminded that they represented society at large, rather than a group of stockholders. The corporate cultures that emerged under this influence generally produced organizational behavior different from that found in commercial insurance companies (Greenlick, 1988). The nonprofit corporations possessed a sense of mission to the community, a sense nurtured by their close ties to community hospitals and physicians' organizations. In the 1970s, pressured by their large corporate customers to contain costs, the nonprofit insurers began to behave like their competitors, the commercial insurance companies, and moved from community rating of premiums to experience-rating practices. Consequently, premiums increased for high-risk groups, making it difficult for the most needy to maintain health insurance coverage.

COMMUNITY-RATED VERSUS EXPERIENCE-RATED PREMIUMS. In an institutionalization of the concept of solidarity, the pioneer U.S. health insurance organizations originally used community-rating principles to fund their programs. In pure community rating, the premium is set by estimating the required budget for the covered population for the next year and dividing the total budget by the number of people expected to be covered. The result is the premium charged to each member of the population for the coming year. Thus, all employers in an insurer's service area would be charged the same per capita premium for their employees.

By contrast, in an experience-rated system, the approach favored by commercial carriers, the most recent available claims experience is analyzed to define a risk profile for specific groups. These risk profiles are applied to the next year's expected total budget to calculate group-specific premiums. Experience rating increases the premiums for groups that include high-use subscribers and reduces premiums for groups that include infrequent users. Consequently, people with serious and chronic health problems, who most need the risk-sharing of health insurance, are forced to pay higher and higher premiums, until they can no longer afford the cost of coverage (Greenlick, 1989).

As experience rating became more common, people with preexisting health conditions were frequently excluded from insurance coverage. This led many states during the 1980s to create special high-risk pools for "uninsurables." The practice also made health insurance too expensive for thousands of firms with small numbers of workers, especially those where even one worker had recently experienced a high-cost illness episode. The shift toward experience rating by nonprofit insurers has led to a disturbing incongruity between a social policy that favors free market practices in U.S. health insurance and a prevailing public expectation that private health insurance should fulfill a social insurance function.

COMPREHENSIVE BENEFIT PACKAGES. Because pioneer health insurance organizations had among their objectives supporting the providers of care, they designed insurance plans based on comprehensive benefits that would cover not only infrequently needed high-cost services but also many low-cost services that might be used regularly by most subscribers. The idea of comprehensive benefits was very popular with the employees whose employers were paying most, or all, of the premiums for health insurance. This popularity was supported by the post-World War II belief that economic growth could permanently keep pace with new demands. During the 1960s and 1970s, most Blue Cross Blue Shield and prepaid group practice plans covered, with little deductible or coinsurance cost to the insured, most of the costs of physician, laboratory, X-ray, emergency room, and hospital medical and surgical services. During the 1970s, insurers increasingly added coverage for prescription drugs. To keep pace, commercial insurance companies increased the breadth and depth of their coverage, particularly for low-risk groups.

The preference for comprehensive benefits contributed to the explosive rate of growth in the health services industry during the postwar era. In 1940 healthcare accounted for 4.1 percent of the gross national product (GNP). It had expanded to 7.2 percent by 1970, reaching 10.7 percent in 1985 (Eastaugh). By the late 1970s, a chronic sense of crisis afflicted business and government administrators of health insurance budgets. Cost-containment strategies that used deductibles and coinsurance to reduce the use of health services by insured persons achieved only modest success. However, these typical casualty insurance mechanisms conflicted with the social insurance function of health insurance and were hotly debated among health insurance reformers in the early 1990s.

SERVICE BENEFITS VERSUS INDEMNITY BENEFITS. A distinguishing characteristic of the Blue Cross/Blue Shield programs and the prepaid group practices is that they sell their customers a promise to provide medical care services (service benefits) rather than a promise to reimburse incurred expenses (indemnity benefits). Service benefit organizations concern themselves with issues of delivery of care more than indemnity insurers, who cover only a specified portion of medical care expenses.

Preferred provider organizations (PPOs) and multiple forms of health maintenance organizations (HMOs) emerged from the cost-controlling strategies of the 1970s and 1980s. These service-delivery reforms sought cost savings through peer group review of practice patterns, favoring those that produced effective care while reducing frequency and length of hospitalizations, using fewer repeat visits, and increasing the use of outpatient care in place of costly hospital services. U.S. insurers took a hand in designing and administering these delivery system reforms, giving them a significant role in healthcare that went far beyond merely paying the bills.

GROUP ENROLLMENT VERSUS INDIVIDUAL MARKETING. Like the European social insurance movement, the development of health insurance in the United States was based on enrollment through employment groups. As more Americans left rural occupations and moved to the cities during and after the Great Depression of the 1930s, they found work in large industrial companies that increasingly offered comprehensive health insurance coverage as a fringe benefit of employment. The health insurance industry focused on enrolling members through work groups. As long as employment in these industries grew, so did the proportion of U.S. citizens covered by health insurance. Labor market forces seemed to be producing social insurance goals without the need of centralized decisions.

Employment-based group enrollment ultimately comes up short from the social insurance perspective, however, since many persons with significant healthcare needs are not in the work force and will not have access to health insurance. This way of distributing health insurance leaves workers doubly vulnerable to fluctuations in the labor market: Low-wage jobs frequently do not include health insurance benefits, and business cycles or industry competition may cause work force reductions leading to loss of health insurance for employees and their dependents (homemakers and children).

Inequities in the labor market carry over to health insurance when employment is the basis for its distribution (Jecker). Women's groups argue that healthcare services important to women, such as mammography, have tended not to be covered. Women who work are less likely than men who work to have employer or union contributions to their insurance. Women are also more likely to work part-time and receive no fringe benefits. Women are less likely to belong to a labor union and they change jobs more frequently than men, making them more vulnerable to preexisting condition exclusions from insurance. Women predominate in low-paying jobs where insurance is usually not offered as a benefit. Many of these distribution inequities also affect minorities, leading some reformers to argue for uncoupling health insurance from employment.

After vigorous growth between 1940 and 1960, the employment-based system had generated health insurance coverage for nearly 70 percent of the population under sixty-five, while only slightly more than 40 percent of the elderly were covered, leading to the establishment of Medicare and Medicaid in 1965 (Anderson). These two programs brought

health insurance protection to virtually all of the elderly, and to a significant proportion of those living in poverty, as well. They did not, however, provide coverage for everyone, so that the United States entered the 1990s with more than thirty million citizens having no health insurance. This fueled a vigorous revival of interest in a national health insurance program capable of guaranteeing coverage for every citizen.

During the 1980s, self-insurance emerged as a cost-control strategy among large corporations. These firms stopped buying health insurance for their workers and set themselves up as the at-risk entity for healthcare costs incurred by their employees. The practice put these corporations beyond the reach of state insurance regulations because of a 1974 federal law, the Employee Retirement Income Security Act (ERISA). The intent of ERISA was to protect pension trust funds in companies with employees in several states from inconsistent and burdensome state regulations. The effect on health insurance, while not a primary goal of ERISA, so complicated health-insurance reform that, by the late 1980s, it became a critical element in all proposals that relied on employee benefits as the primary vehicle for distributing health insurance to citizens.

At the beginning of the twenty-first century, the concept of *defined contribution* to employee benefit packages (rather than defined benefits) became popular among free market reformers (Christianson et al.). This concept responded to employers' desire to be less involved in insurance purchasing and shift decision making to their employees. The strategy combined a set amount of employer contribution with a responsibility on employees to purchase their own health insurance. Employees could use a portion of the defined contribution for direct purchase of services. In the final analysis, employees in such a plan would be individually responsible to cover the costs of their care with a combination of out-of-pocket spending, insurance protection, and limited access to the defined contribution pool created by the employer. This approach can be understood as an effort to deemphasize the social insurance model by insisting on increased consumer responsibility for non-catastrophic healthcare needs.

The Government Role in U.S. Health Insurance

The U.S. government has had a role in health insurance since the eighteenth century, when it accepted the responsibility to provide medical care for the U.S. Merchant Marine. During the growth period of private health insurance in the United States prior to Medicare and Medicaid (1940–1965), the federal government let the private market work, limiting itself to indirect involvement through tax incentives for employers and employees who favored the purchase of health insurance as a fringe benefit. State and local governments were expected to provide care to the indigent and to the mentally ill. As a large employer, the federal government became a major purchaser of health insurance for its employees.

Finally, the federal government is a major supplier of social insurance for medical care for Native Americans, active-duty military personnel and their dependents, and veterans. The total public expenditure for medical care services in 2000 was $590 billion, 45 percent of the $1.3 trillion total national expenditure for health services and supplies during the year.

Government involvement in U.S. health insurance differs distinctly from paths followed by most other industrial nations. In Europe, several nations have made the direct delivery of healthcare a national government responsibility (e.g., the United Kingdom and the Scandinavian countries); others have taken up the role of coordination in mixed public-private systems (e.g., Germany, the Netherlands, Switzerland); others have assumed the role of providing health insurance to the citizenry, allowing hospitals and physicians to operate in a fee-for-service environment (France).

In the late 1960s, Canada adopted an approach similar to France's: Each province has a monopoly on health insurance for basic services, while the federal government plays a coordinating role. Canadian Medicare rests on five essential principles: universal entitlement, accessibility of services, comprehensive benefits, portability of benefits across provincial boundaries, and public administration of the system within each province.

Questions about the proper role of government in health insurance continue to be central issues in debates among U.S. health insurance reformers. Proposals put forward in the first decade of the twenty-first century will succeed or fail on the basis of their ability to make the case that they have found an acceptable balance point on the public-private continuum where private markets (insurance carriers, providers, suppliers) come together under public policy constraints to produce an acknowledged common good.

Conclusion

As the twenty-first century dawned, the evolution of health insurance in the United States and elsewhere had reached a point where significant new public policy decisions were increasingly demanded by the consumer groups, business, politicians, and health professionals (see Rashi Fein's work).

In all industrial nations, the rates of growth in total expenditures for healthcare were creating economic strains and social concern (see the report of the Government Committee on Choices in Healthcare). Particularly in the United States—with the highest percentage of its GNP devoted to healthcare—business, government, and consumer groups insisted on effective control of total healthcare expenditures. Some argued that the solution had to come from submitting healthcare to a competitive market. Others preferred government regulation through global budgets, delivery system reforms, and limitations on services that qualify for collective financing. Most reformers insisted that health insurance had to stop fueling uncontrolled growth in healthcare spending.

Expenditure control has major consequences for the social insurance aspect of health insurance schemes. Many European nations and Canada have sought to control total expenditures without sacrificing the healthcare component of their social insurance commitments. In the United States, many providers, social reformers, and the general public have demanded explicit commitment to the social insurance dimension of health insurance: a universal system that would guarantee a decent minimum of healthcare to every citizen. Reformers were particularly concerned to have the nation address the equity issue. During a thirty-two-month period in 1990–1992, one-fourth of the entire population outside of institutions were without health insurance for at least one month; more than one-third of the African-American population and nearly one-half of the Hispanic population found themselves excluded from coverage (Pear).

Growing public awareness of the size of the uninsured population and the vulnerability of the middle class to loss of job-related health insurance have led to growing dissatisfaction with the system and sparked a renewed interest in health insurance reform. Dozens of proposals emerged in the late 1980s and 1990s driven by several key questions. Should America continue its multiple payer, public-private system, or embark on a new path with a streamlined single-payer system? Should the single payer be the federal government or each state? If there were to be multiple payers, who would conduct the negotiations needed to coordinate their practices so that universal coverage would be achieved and maintained?

The multiple-payer approach continues the path of adapting casualty insurance and free-market forces to serve the social insurance function. In the mid-1990s, President Bill Clinton proposed a market-structuring, multiple-payer solution (White House Domestic Policy Council; Zelman), and was immediately criticized by sponsors of competing market proposals for interfering too much with market forces and not trusting them to achieve efficient allocations (Enthoven and Singer). Single-payer advocates, arguing that Clinton was fundamentally mistaken and that the private health insurance market was simply the wrong vehicle for achieving universal coverage and cost control, invoked the social insurance model, abandoning market pluralism in favor of uncomplicated universality and administrative efficiency achievable through centralized financing.

Finally, the Clinton proposal failed politically. Backing away from universal coverage, the Clinton Administration launched a special program to increase children's access to coverage in 1997 (Title XXI of the Social Security Act, the State Children's Health Insurance Program). By 1999, all fifty states had approved programs that either created a special program for children, an expansion of Medicaid, or some combination of the two. Despite success in reaching children, the percentage of Americans without health insurance has grown, costs have not come under control, and the critics of the status quo remain unable to attract sufficient political consensus to bring about universal coverage.

Health insurance in the United States continues to evolve. The tension between the casualty insurance practices and social insurance ideals frustrate reformers in both camps. The enduring challenge is to formulate policies that can control total expenditures while allocating resources fairly and promoting the common good.

HEALTH POLICY IN INTERNATIONAL PERSPECTIVE

• • •

Health polices of international agencies and individual countries reflect choices involving diverse ethical issues, including rights and responsibilities of individuals versus society, choices over who benefits and who pays for healthcare services, trade-offs between saving identifiable lives and

statistical lives, and choices involving interpersonal and intergenerational equity. This entry begins by examining the role of international agencies in providing public health services, ethical issues raised by testing and use of new drugs, and government involvement in purchasing and providing healthcare. It then outlines four generic models for healthcare financing and delivery that many countries have adapted to their unique circumstances. These four healthcare financing and delivery models reflect different choices about an individual's right to basic healthcare services, and views about whether an individual's ability to pay should influence access to certain services.

Public Health and Preventive Services

International agencies play a critical role in health policy, first by setting public health and health-status goals, and then by monitoring an individual country's progress toward these goals. For example, over the past twenty years the World Health Organization (WHO) has established goals and specific targets for the *Health-for-All* initiative. Two fundamental objectives of this initiative are: (1) making health central to human development and (2) building sustainable health systems (Antezana, et al.). In order to monitor these objectives, Health-for-All in the 21st Century has identified global health targets that each country should meet, such as eliminating certain infectious diseases through childhood immunization and improving access to water, sanitation, food and shelter (Visschedijk and Simeant). In 2000 the WHO began ranking and assessing health systems's performance in 191 countries based on five composite indicators. The WHO hopes to make this assessment a regular activity, which will help policy-makers to monitor their performance in comparison to other countries (WHO, 2000a).

In most countries, public health agencies have the primary responsibility for creating programs that will achieve specific health objectives. International agencies like the World Bank and the United Nations and some affluent countries have programs to assist developing countries. The U.S. Agency for International Development (USAID), for example, operates programs that help developing countries to establish and operate a variety of public health activities.

While there is generally a consensus that government agencies should finance and provide public health and disease-prevention services, policy differences and financial commitments affect the success of specific programs. For example, the childhood immunization rates for six major infectious diseases (diphtheria, pertussis, tetanus, measles, poliomyelitis, and tuberculosis) vary greatly from country to country. In 2000 the immunization rates for diphtheria, pertussis, measles, and poliomyelitis ranged from 55 percent of infants in Africa to over 90 percent of infants in Europe (WHO, 2001). In most countries the WHO's target rate of 90 percent coverage for the year 2000 was not achieved (WHO, 2001).

Another public health activity, the testing and approval of drugs, highlights conflicting ethical values. Beneficence, in terms of concern for public welfare, is reflected when nations employ comprehensive but time-consuming approval processes in order to ensure a safe and efficacious drug supply. The U.S. Food and Drug Administration, for example, has adopted strict regulatory standards that prevent the domestic adoption of new drugs and devices until their safety and efficacy are established beyond reasonable doubt (Sheinin and Williams). In contrast, a respect for autonomy, in terms of individual access to healthcare, is obstructed when the length of the drug approval process delays access to potentially lifesaving treatments—particularly for patients who have exhausted current treatment options and are willing to take experimental drugs.

Since the early 1990s, people with acquired immunodeficiency syndrome (AIDS) have been the most vocal proponents of allowing individuals unrestricted access to unproven medical treatments. Advocates of placing greater weight on beneficence, on the other hand, point to the approval of thalidomide by the United Kingdom in the 1960s, while it was still in testing stages in other countries. The drug was never approved in other countries and was pulled from the British market after it became apparent that severe congenital deformations resulted from maternal use of the drug (Burger).

The principle of justice can be jeopardized when drug trials are carried out in developing countries by investigators and sponsored by agencies from developed countries (Beyrer and Kass; Council for International Organization of Medical Sciences [CIOMS]). Some developing nations have used drugs not approved in industrialized countries. Lower costs of unapproved drugs make them a relatively affordable medical treatment option for poorer nations. In some cases, individuals in low-income nations benefit from access to various drugs, while in other cases individuals are harmed by access to unsafe or inefficacious therapies. For example, HIV/AIDS accounts for about 20 percent of all deaths in Africa, which creates urgent need for new drugs and effective vaccines for HIV infection (Creese, et al.). This urgency is being used to lower the ethical standards of international research and result in ethically controversial actions (e.g., not providing drugs after the conclusion of the clinical trial or make the drugs available at unaffordable prices) (Greco,

Stolberg, Okie). In order to assist the efficient purchase of safe and efficacious drugs by developing nations, the WHO and other international agencies have established *essential drug lists* that identify drugs satisfying the healthcare needs of the majority of the population, and are revised every two years (WHO, 2000b).

Medical Services

Particular attention should be paid to ethical choices in the financing and delivery of medical services, since these services account for a large portion of most countries's total healthcare spending (Organization for the Economic Cooperation and Development [OECD]). The provision of medical-care services requires policymakers to debate myriad ethical values and conflicts, and each country's medical-care system reflects its choices about underlying ethical matters.

Unlike public health activities, which are considered to benefit all members of society, medical-care services are generally considered as private goods, since it is the individual who benefits directly from them. Some countries consider access to medical care a merit good—a good that, although private, benefits society as well. Health insurance is a major determinant of access to care. In most industrialized countries health insurance coverage is universal. In the United States, however, 14 percent of Americans did not have health insurance in 2000 (Mills).

Similar value choices are exemplified by the benefits package that countries's health systems offer. Some countries's health systems cover only hospital and physician care, while others include such items as long-term care, drugs, dental care, home health services, and eyeglasses (Healy). In addition, many European countries incorporate housekeeping, spa vacations and social services into their provision of healthcare services. Cultural norms also affect countries's health systems. Japan, for example, did not establish a formal system of long-term care until recently, in part because of the tradition that the eldest son and his wife have had responsibility for the son's parents (Campbell and Ikegami).

Countries's decisions about government involvement in provider issues can highlight conflicts between the individual liberty of providers and patients's access to care. Some countries, such as Israel, have adopted policies that restrict providers's ability to practice in areas that exceed a certain physician-population ratio and have developed policies that encourage them to operate in underserved locations (Anderson and Antebi). Other policies may limit the total income that can be generated by health professionals, either through restrictions on the salaries that physicians can earn or by limiting the volume of services the physicians may provide (White). In addition, some countries, such as the United Kingdom, permit providers to operate publicly (through a national health service) and have a private practice (Healy). Other countries, like most of the provinces in Canada, require a provider to work completely in the publicly financed plan or completely in the privately financed sector (Flood and Archibald).

Countries use three basic mechanisms, in addition to out-of-pocket payments, to finance medical-care services. One option is to use general tax revenues. With this method, citizens pay for medical services based on the structure of the overall tax system. This option is considered by economists to be the most progressive. For economists, progressive means that the income tax rate increases as the taxpayer's income rises. A second basic method to generate funds for medical-care services is through a payroll tax earmarked for the health system. This is referred to as a proportional or flat tax since the tax rate does not vary with income. The third basic method to finance medical-care services is through health-insurance premiums. This method is considered to be regressive by economists because the rate falls as income rises.

A related financing and access issue is that of the cost sharing by individuals. Cost sharing, such as coinsurance, copayments, and deductibles, is introduced when health insurance systems want to give patients a financial incentive not to use certain health services—especially services they believe to be only marginally beneficial. However, the patients' ability to make appropriate choices is debatable especially when they are poor (Fuchs). Poor patients's demand for care depends more on whether they have money at the time than on their own judgment of the seriousness of the condition (White). Some countries, such as the United Kingdom, Canada, and Germany, operate with no or nominal deductibles and coinsurance (Glaser, U.S. General Accounting Office 1991a, 1991b). Other countries have substantial cost-sharing requirements. For example, 10 to 20 percent coinsurance requirements are typical in the United States and France, and 20 to 30 percent coinsurance requirements are typical in Japan and Korea (U.S. General Accounting Office 1991b, Anderson).

Four Healthcare Financing and Delivery Models

As individual countries design their own healthcare financing and delivery systems, they make a number of policy decisions that are based upon ethical considerations. These

decisions involve choices regarding who is covered, the method of financing the medical-care delivery system, and whether the delivery system is public or private. These healthcare financing and delivery systems are categorized below into four models and specific countries are identified that exemplify each type of model. It is important to recognize, however, that no country fits any model precisely, and that healthcare systems are dynamic. The four generic models are national health service, national health insurance, social insurance, and private voluntary health insurance.

NATIONAL HEALTH SERVICE. National health service systems usually collect revenues from general taxation, mandate the use of public facilities, and have limited cost sharing. As a result, countries with national health service generally offer the greatest equality in access to care and employ the most progressive financing methods. However, some critics have expressed concern that national health services may be relatively inefficient and unresponsive to individuals's healthcare service preferences (Enthoven).

The United Kingdom's National Health Service (NHS) is the archetypal example of this model. Since its creation in 1948, the guiding principal of the NHS has been equity—equal access to healthcare services for all inhabitants. The NHS offers a comprehensive array of government-provided services, a national benefits package, and is financed by general tax revenues. During the early 1990's, the concerns about inefficiencies and customer service led to introducing some market incentives and development of a system of competition within the NHS (Enthoven). However, subsequent reforms initiated by the Labor government largely abolished the quasi-market and emphasized the idea of collaboration with a return to strong elements of command and control (Le Grand).

NATIONAL HEALTH-INSURANCE PROGRAM. National health-insurance systems usually generate revenues from general taxation, have private providers and facilities, allow the government to set payment rates for healthcare providers, and may have limited cost sharing. The major difference between national health insurance and national health service is the ownership of the facilities.

The Canadian health system is an example of a national health-insurance system. Revenues are generated from general taxation, the government sets payment rates for the providers who participate in the system, and there is no cost sharing. Healthcare professionals must choose between participating in the national health-insurance system and opting out of the system entirely to work in the privately financed sector (Flood and Archibald).

SOCIAL INSURANCE. In social insurance systems, revenues are generated from payroll taxes, the private sector provides health insurance, private facilities are common, and the government sometimes sets payment rates for providers. Although insurance is compulsory, and thus accessible to all, the scope of healthcare benefits may vary by plan.

Social insurance, the first type of health insurance to be developed, was introduced in Germany by Otto van Bismarck [1815–1898] in 1883. Germany has continued to use the social insurance system, and several European nations and other countries like Japan and Korea have modified the basic social insurance model to meet their own needs (Glaser, Powell and Anesaki, Anderson).

PRIVATE VOLUNTARY HEALTH INSURANCE. In the private voluntary health insurance system revenues are generated by a variety of sources including premiums, payroll taxes, and general taxation, private facilities are the norm, the government may or may not set provider payment rates, and coinsurance is common (Maxwell, Storeygard and Moon). This system is likely to have the greatest disparity in access to healthcare services, since access is based upon ability to pay. In addition, it is common for a proportion of the population to be uninsured. In theory, this system should be more efficient than government-run health systems, because free-market competition should result in greater efficiency (Enthoven and Kronick). However, it is believed by many that free-market principles, such as a free flow of product information and price sensitivity among consumers, do not fully apply to the healthcare sector, and consequently competition and greater efficiency do not always occur (Rice et al.). The United States and many low and middle-income countries use a system of voluntary private health insurance.

Summary

Health financing and delivery systems are influenced by divergent views on a number of ethical issues. Countries must resolve ethical dilemmas such as (1) whether access to basic healthcare services is one of the fundamental rights of every human being, and (2) how scarce resources should be allocated between the old and the young, between medical and preventive care, and between healthcare and other social needs, as they develop their healthcare systems.

HEALTH POLICY IN THE UNITED STATES

• • •

Issues of health and healthcare are rather similar across countries, and there are many commonalities in the ways that governments deal with them through health policies. All industrialized nations, for instance, have public health programs and license and regulate healthcare providers to some extent. But there are many differences among their health policies as well—policies that both address and raise issues of justice. Much of the variation in approaches can be traced to the histories, ideologies, and institutions of respective political systems. The relatively unique character of the American political tradition is an essential context for understanding the distinctive aspects of health policies in the United States and their bioethical implications.

Impact of Liberal Ideology

Compared with other industrialized nations, the political ethos of the United States emphasizes the importance of the individual rather than the collectivity (see Gøsta Esping-Andersen). U.S. political ideas, institutions, and behavior uniquely reflect a virtually unanimous acceptance of the tenets of seventeenth-century English political philosopher John Locke, whose liberal philosophy was in harmony with the laissez-faire economics subsequently propounded by Adam Smith in *The Wealth of Nations* (2000 [1776]). As Locke propounded in *Of Civil Government, Two Treatises* (1924 [1690]), the individual should be much more important than the collective, and one of the few important functions of a limited state is to ensure that the wealth that individuals accumulate through the free market is protected. The framers of the U.S. constitution, strongly influenced by the atomistic individualism of Locke's philosophy and his views on the sanctity of private property, took pains to limit the power of government. The constitutional rights they established for American citizens are largely protections for the individual and his property from governmental actions.

This ongoing ideological tradition helps to explain an important distinctive feature of the American political system's approach to health policy. Although U.S. governments intervene a great deal in the health arena, on some matters they are more inclined to rely on the individual and the free market than most other industrialized nations.

Unequal distribution of access to healthcare is a prime example of the effects of this approach. Most industrialized nations, for instance, use the power of government to assure health insurance coverage for virtually 100 percent of their citizens. The rate of government-assured health insurance in the United States, however, is only 33 percent, by far the lowest among industrialized nations (Anderson and Poullier), because the expectation is that most financing of personal healthcare is the responsibility of individuals and their employers (some exceptions are discussed below). Consequently, in 2000, 14 percent of Americans, nearly forty million persons, had no health insurance (U.S. Census Bureau). Lack of insurance, of course, limits access to care, and has been documented by researchers such as David W. Baker, Joseph J. Sudano, Jeffrey M. Albert, et al., (2001) as increasing the risk of poor health.

Impact of Power Fragmentation

Even as the framers of the Constitution were enamored of Locke's political philosophy, they and many other early Americans were heavily influenced by French philosopher Baron de Montesquieu's *The Spirit of the Laws* (1949 [1748]), in which he urged that the powers of governments should be separated in order to thwart the development of tyrannical states. Accordingly, the framers divided the very limited powers of the national government they established into executive, legislative, and judicial branches—each with the power to check the actions of the others. This structure, of course, made it difficult for government to act and thereby interfere with individuals and their property.

The separation of powers exacerbated what was already a characteristic of the American political system, the endemic fragmentation of power in a federal form of government. Not only did the state governments retain most of their power in the federal system but, reflecting the influence of Montesquieu, the powers in each of them were also separated. The fragmentation of governmental power in the United States is astounding: Altogether, there are some 80,000 governments—including counties, municipalities, special district governments, and independent school districts, as well as the state and national governments—and the powers of each of these are usually separated, and even further fragmented. Therefore, generally speaking, government intervention of a sweeping nature is difficult in the American political system. Health policies and other policies tend to be incremental rather than systemic or comprehensive.

One consequence in the health arena, for example, is that various American presidents since the 1920s have failed

in their efforts to secure national health insurance, including President Bill Clinton who declared it the prime legislative goal of his first term (1992–1996). One of them may well have succeeded if he had been the head of a disciplined ruling party in a parliamentary system of government, with no separation of powers. Another consequence is that many important health policies are carried out in disparate and uneven fashions throughout the nation because they are primarily the responsibility of state and local governments. These responsibilities include: public health; regulation of hospitals, nursing homes, home health agencies, hospices, and other healthcare provider organizations; licensing of healthcare professionals; and regulation of private health insurance plans. Still another and related consequence is that it is difficult to establish national standards for healthcare.

Government Health Insurance and Direct Care

Despite a political culture that emphasizes individualism and the free market, about three-fifths of all U.S. spending on personal healthcare is financed, directly or indirectly, by governments (Woolhandler and Himmelstein). About 25 percent of this amount is used to support the employer-sponsored system of private health insurance through tax subsidies and public employee benefits. About 20 percent of it is spent on direct government provision of healthcare to veterans and members of the armed forces (and their dependents), and to Native Americans (under treaty obligations). Almost all of the remaining 55 percent is spent on Medicare and Medicaid, two government health insurance programs for selected groups of Americans that have been politically legitimized as especially deserving of collective help. A central rationale for the establishment of these two programs has been "market failure"—the fact that employer-sponsored private insurance does not tend to reach these particular groups.

Medicare, enacted by Congress in 1965, provides national health insurance for about forty million persons. One group covered by the program is all persons aged sixty-five and older who are eligible for Social Security benefits (or Railroad Retirement Benefits)—over 99 percent of Americans in this age range—about thirty-five million people at the turn of the twenty-first century. The political threshold for legitimating older people as a special deserving group worthy of collective assistance had already been crossed during the Great Depression when the Social Security Act of 1935 created government-funded old-age retirement benefits at the age of sixty-five. The rationale for establishing Medicare was that older persons, retired from employment, had no way to obtain group health insurance. Comparatively few had employer-sponsored retiree health insurance. Moreover, most older people could not afford the comparatively steep premiums charged for individual insurance policies, and many could not obtain them because of pre-existing medical conditions.

Medicare coverage was extended in 1973 to another select group, younger individuals who become eligible after they have received Disability Insurance (DI) benefits from the federal government for at least two years; about five million such persons were covered at the turn of the century. These are persons who, due to a medically certified physical or mental impairment (but not other circumstances), are unable to engage in any kind of *substantial employment* (earning $500 monthly or more) for at least a year. They have been politically legitimized as deserving of Medicare coverage because without employment they cannot obtain group health insurance or afford it on their own. Until the year 2000, DI recipients who were able to return to substantial employment lost their Medicare coverage after two years. However, in recognition of the fact that many employers of former DI recipients do not provide health insurance, this disincentive to work was attenuated by the Ticket to Work and Work Incentives Improvement Act of 1999. It enables DI recipients who become substantially employed to participate in the Medicare Program for an additional four and one-half years.

The Medicaid program, established by the federal government along with Medicare in 1965, is a jointly-funded cooperative venture between the national and state governments that provides healthcare insurance coverage for some poor Americans. But Medicaid policy does not fully equate poverty with *deservingness.* Federal law only requires states to provide coverage for specific categories of deserving groups among the poor that, in their nature, are unlikely to be able to obtain employer-sponsored insurance through the market. Although the list of these requirement categories is long and detailed, the principal eligible groups are children, adults with dependent children, disabled persons (who are not eligible for federal DI benefits), blind persons, and older people (to cover their long-term care costs and certain other expenses not covered by Medicare). Persons within these categories are eligible for Medicaid if their income and financial assets fall below thresholds determined by each state (within minimum federal guidelines). Poor working age men generally do not qualify for Medicaid; the vast majority of those who are eligible in the "adults with dependent children" category are single women. Altogether, the program covers over forty million persons.

Because state governments have considerable latitude in setting income and asset thresholds for Medicaid eligibility,

there are substantial interstate inequalities in program participation by persons within the categorical groups designated in federal legislation. An example is the range of low-income thresholds used by states to determine whether infants are eligible for Medicaid. At the most generous end of the range of low-income thresholds used by states in 1999 was Tennessee's 400 percent of the federally-established poverty line; at the other extreme were eight other states with a threshold of 133 percent (Ku, Ullman, and Almeida).

Federal Regulation

The federal government's Food and Drug Administration has long played a role in protecting consumers through regulation. The agency is responsible for ensuring that medicines, medical devices, blood supplies, and certain experimental medical treatments (e.g., gene therapy) are safe and effective, and that foods and cosmetics are truthfully labeled and not harmful. It is only since the late 1980s, however, that the federal government has entered the broader arena of regulating healthcare providers and health insurers, traditionally the bailiwick of state and local governments. It has done so principally to address bioethical issues.

Some policies have been enacted to compensate for perceived inadequacies in state regulation, such as measures in the Omnibus Budget Reconciliation Act of 1987 established to reform the quality of nursing home care. Others have responded to new developments in thinking about ethical patient care. For instance, in the context of growing concerns about protecting patient autonomy, the federal Patient Self-Determination Act was enacted in 1990. It requires healthcare organizations to immediately inform new patients of their rights to refuse medical and surgical treatment and to execute written legal documents, called *advance directives,* regarding their preferences in this regard.

In 1996 alone, the federal government enacted three regulatory laws intended to protect consumers by addressing ethical issues. The Mental Health Parity Act of 1996 responded to inequities in coverage for mental healthcare by requiring that if a group insurance plan covers mental health, the annual and lifetime benefits available must be equivalent to those available for medical and surgical services. The Newborns' and Mothers' Health Protection Act of 1996 addressed perceived issues in quality of care by mandating minimum inpatient stays for mothers and their newborns following deliveries and caesarean sections. And the Health Insurance Portability and Accountability Act of 1996 made obtaining group health insurance easier for individuals with pre-existing health problems and disabilities or previous illnesses, and for those who lost their coverage because of changing jobs or job termination.

The role of the federal government in addressing ethical issues through regulatory policy is likely to expand continually. Technological and biomedical discoveries and innovations inevitably generate questions of fairness and equity that lend themselves to the possibility of government intervention, such as whether genetic tests should be used as screens to exclude applicants for private insurance, whether or in what circumstances stem cell research should be allowed, or how scarce societal resources (e.g., organs for transplantation) should be distributed.

Major Ongoing Issues

The agenda for government policy action grows larger and larger because new issues do not obliterate ongoing concerns. Perhaps the two broadest and most important ongoing issues from a bioethical perspective are: (1) how government will deal with issues of increased longevity; and (2) whether government will remedy the unequal distribution of access to care by securing insurance for the uninsured.

INCREASED LONGEVITY. One set of issues involving increased longevity is generated by the aging of the baby boom, a cohort of 76 million Americans born between 1946 and 1964. During the early decades of the twenty-first century the ranks of older Americans will swell enormously. By 2030, the population of Americans aged sixty-five and older will double, from about 35 million in 2002 to 70 million, and make up 20 percent of the population. Because of this population aging, and ongoing developments in medical technology, the nation will need to greatly increase its financial commitment to the Medicare program if it is to be sustained.

Various commentators are alarmed by this prospect. Bioethicist Daniel Callahan, for example, has described future healthcare costs of older persons as "one of the great fiscal black holes" (p. 216) and argues that these costs will pose an enormous and unsustainable economic burden for the nation and drain resources that could be used for other worthy social causes—an issue of so-called intergenerational equity. Thus, he and others maintain that rationing healthcare on the basis of old age is essential from an economic point of view. Moreover, from a philosophical perspective, Callahan regards it as inappropriate for older people to live beyond what he terms a "natural life span." Accordingly, for both economic and philosophical reasons he has urged that the Medicare program should not pay for life-saving care for anyone aged about 80 or older, and he hopes that this practice will extend to the private sector. Others (e.g., Binstock and Post) have sharply critiqued the arguments of Callahan and other proponents of old-age-based rationing

on both economic and ethical grounds. It is not clear that such rationing at the age range suggested would save a great deal of money. And among the ethical arguments against it is the specter raised by the notion that a demographically-defined group might be singled out as unworthy of life-saving care, and be the first of many groups to which such a designation might be applied.

Another dimension of longevity that raises important bioethical policy questions is the quest to slow, arrest, or reverse processes of aging. The U.S. National Institutes of Health (NIH) not only support research to understand the basic biological processes of aging, but promote efforts to substantially increase average life expectancy or the human life span. In 1999, for example, two NIH institutes convened a clinical advisory group of more than fifty scientists to set a research agenda for slowing the fundamental processes of aging and extending maximum life span (Masoro). The desirability of such a policy has been questioned from a number of quarters.

Among bioethicists, Leon Kass, appointed in 2001 as chairman of the U.S. President's Council on Bioethics, opposes such efforts. He believes that even if the human life span were increased by only 20 years, we would lose the benefits that finitude confers:

1. interest and engagement in life;
2. seriousness and aspiration;
3. beauty and love; and
4. virtue and moral excellence (Kass).

Even one of the premier biological researchers in the field of aging, Leonard Hayflick (1994), rejects the goals of substantially extending life expectancy and life span because of distributional justice issues that would arise regarding access to longevity technologies and because of various other social and economic consequences. Other biologists, however, particularly those who are engaged in efforts to slow or reverse the processes of aging, acknowledge such concerns but do not feel that they warrant a halt to their quest to achieve increased longevity (e.g., de Grey, Ames, and Anderson; Miller). And bioethicist John Harris argues that it is doubtful that coherent ethical objections can be generated against the achievement of immortality and urges that we "start thinking now about how we can live decently and creatively with the prospect" (p. 59).

INSURING THE UNINSURED. Finally, as noted above, about forty million Americans have no health insurance in the early years of the twenty-first century. Trends in the labor market suggest that the outlook for expansion of health insurance coverage through the private sector is dim for the foreseeable future. Although the percentage of employed Americans grew to its highest level in many decades during the economic expansion that took place in the 1990s, employer-sponsored healthcare benefits did not grow apace. When the economy began to flag in the early years of this century, the ranks of the uninsured grew. In the absence of a new government health insurance initiative that reaches beyond the present selected, politically legitimated groups, it is unlikely that many of the uninsured will be covered; indeed, their number could grow.

Since 1994, when Congress rejected President Clinton's initiative for national health insurance, no such policy has been on the political agenda. When and how might such an effort be renewed, and how might it have a chance of success?

The proportion of voters who are poor and members of racial and ethnic minority groups will grow sharply over the next several decades, and these groups are disproportionately represented among the uninsured. Perhaps they will be mobilized effectively in a demand for access to the healthcare that their fellow citizens are receiving.

Another possible scenario is that the swiftly changing dynamics of American healthcare will threaten profits in the healthcare industry. Government insurance for an additional forty million persons (and perhaps a larger number in the future) would be a bountiful source of revenue. Unlike the American Medical Association, which vigorously opposed initiatives to secure universal insurance during the twentieth century, the contemporary healthcare industry might appreciate what government can do for it. As Bruce Vladeck observed in 1999, Medicare financing has largely built and sustained the modern medical industrial complex. The political power of the healthcare industry, although fragmented into various interests, is substantial; it might very well carry the day for universal coverage if united by a vision of what further governmental largesse could do for it. If so, despite a political tradition that has been dominated by emphasis on individualism and the free market, the United States will be able to eliminate major inequalities in access to healthcare.

HEALTH SERVICES MANAGEMENT ETHICS

• • •

Health services management ethics encompass the myriad ethical issues, virtually all of which directly or indirectly affect clinical services, faced by the managers of organizations that deliver health services and the moral context in which these decisions are made. Health services managers plan, organize, control, direct, and staff health services organizations (HSOs) and lead, coordinate, and integrate their activities so that clinical care can be provided. In essence, by managing the HSO, managers provide the workshop and wherewithal that enable clients and patients to receive health services. These preventive, acute, restorative, and supportive services may be provided in and through a variety of organizational settings that include inpatient services, outpatient (clinic) care, and home health services. The most intensive or acute services are provided to hospitalized inpatients; the least acute are provided in the home and in hospice, where the emphasis is comfort care and pain control. The types of health services management ethical issues that arise in the various settings are similar and run a gamut that includes macro-level resource allocation, conflicts of interest, staffing levels, and providing the structure and support for patients and families as they decide whether to withhold or withdraw life-saving treatment.

Health services managers are commonly educated in professional masters degree programs where there is emphasis on the skills of business and the ethics of medicine. In other words, these programs socialize health service managers to understand that they are entering a field in which they manage a social enterprise with business dimensions, rather than a business enterprise with social dimensions. This fact in itself makes the HSO and those working in it unique and unlike any other type of service organization. The persons served by the HSO have a unique relationship with it. This relationship is expressed through a level of trust in the organization and implicitly in its management that is rarely found in the service industry.

Health Services Management as a Profession

Health services management was recognized as a distinct academic discipline in the early 1930s. This makes it a

relative late-comer to a field including the long-established professions of medicine and nursing. In seeking professional status, health services managers have established and joined professional associations that, in turn, have developed and adopted codes of ethics. These vary in their level of proscription and prescription and the methods of enforcement, but all have the common thread of doing what is in the patient's best interest—usually as defined by the patient. The codes tend to emphasize beneficence, nonmaleficence, respect for persons (autonomy, truth-telling, fidelity, and confidentiality), and justice. Applying the ethical principles often used in clinical ethical decision making is sometimes strained, nevertheless they provide a useful starting point that is supplemented as needed by other principles.

A few states flirted with licensure of hospital administrators, but this appears to be a dead issue. In response to federal regulation that was stimulated by scandals in nursing homes, however, nursing home administrators are licensed in all states. Future scandals and abuses in the health services field likely will stimulate new government regulatory forays. As with state licensing of health professions such as medicine and nursing, regulation of HSO managers probably will include codification of ethical expectations.

It is noteworthy that managers in the health services field are often held to a higher standard than managers in business and other sectors of the economy. This may result in part from their association with the healing professions of medicine and nursing. It may also be a function of the not-for-profit tradition that is so dominant in the health services field. The higher standard also may arise from the expectation that none of those served by such an organization should have their trust breached—the trust inherent in the intimate, emotional, and vital relationship established in the process of delivering health services.

Personal Ethic

In addition to the guidance provided by the codes of ethics of professional associations, health services managers should develop a personal code of professional moral conduct—a personal ethic. Formal academic instruction in ethics is an expected part of graduate-level health services management education. Students enter health services management education with a moral framework developed from life experience, family environment, religious values, introspection, and self-study. The academic preparation in their professional education sensitizes them to the managerial and clinical ethical issues that they are likely to encounter and provides a framework for analysis and problem-solving ethical issues. Because of the pragmatic and applied nature of their work, health services management ethics tend to be normative and ask the question "What ought I (we) to do in this situation?"

Even with additional academic preparation, however, health services managers are likely to understate the importance of having a prospectively-developed, coherent, comprehensive, and consistent personal ethic. Their academic preparation is likely to give them a mind set that they can reason through and solve almost any problem that arises. While partially true, such an approach will not aid managers in anticipating ethical issues and prospectively working to prevent them or minimizing their effect when they arise. Lack of a personal ethic is likely to result in a relativistic approach to ethical problem solving, which is generally undesirable and certainly inconsistent with the value frameworks so ubiquitous in HSOs. It is difficult to overstate the importance of a well-developed personal value system.

Organizational Culture and Values

HSOs have mission and vision statements framed within the context of stated organizational values. The values identified reflect the culture of the organization; this implies that the organization's culture has been *discovered.* All organizations have a culture—the shared values that make each HSO unique. Rather than having *discovered* the culture and organized these discoveries into a mission statement, however, it is more typical that senior management developed a statement of values that they hold themselves or that they think should be the HSO's. The resulting organizational values statement may or may not reflect the culture of the HSO. Culture (and values) can be affected over time, but it is a slow, almost glacial process. Managers must beware of the trap of failing to model the organization's stated (desired) values, but asking of staff that which they are unwilling to do themselves. This will do naught but lead to cynical, noninvolved staff. Leading by example is essential.

The organization's values should be key to and provide the context for all HSO activities. These values must be the context in which staff are recruited, screened, and hired. Failure to measure candidates against the framework in which they will work invariably lead to mismatches of context and staff. The result will be higher costs and unnecessary and counterproductive levels of dissatisfaction, or worse. In terms of the HSO's services and how they are provided, its values should be inviolate. This is to say that, despite the demands of users, the organization can maintain its integrity only if it refuses to act in ways inconsistent with its values. It must be true to itself.

Questions arise as to the need for congruence between the organization's values and the personal ethic of staff,

especially staff in management positions. Sectarian HSOs are likely to demand that senior leadership be adherents to their faith, a decision within the prerogatives of private organizations. It is more important, however, and often forgotten, that the values (personal ethic) of staff at all levels be congruent with the HSO's. Only by achieving a high level of congruence is the HSO able to live its values by developing a strong, pervasive culture. Managers may assume staff members have a *tabula rasa* or a generally compatible value system, and then must teach the HSO's culture tothem; the HSO's values must be reinforced by the actions of all, especially those in leadership positions. A strong culture, with clearly defined and shared values, will drive from it those whose interests and actions are contrary and this in itself is a worthy goal. High levels of cultural conformity do tend to stifle innovation, but this risk can be overcome in other ways, such as including innovation as an identified, important value in the culture.

Addressing Ethical Issues in the HSO

Health services managers have a multi-faceted role in preventing, identifying, and solving ethical problems. The importance of a personal ethic has been discussed. As a resource allocator, the health services manager is obligated to provide the support needed by the organization and its staff so that they are educated about ethics issues, have learned a methodology for addressing the ethical dimensions of management problems, and have the systems and procedures to support these efforts. Education about the HSO's values is an essential first step toward these goals; celebrating heroes of the culture and providing case examples are very useful. In addition, the manager is the driving force in ascertaining that the policies and procedures of the HSO address all of the areas where it is likely ethical problems will arise. For example, a comprehensive policy about accepting gratuities that is communicated to staff will go far to prevent conflicts of interest.

Ethics committees are required by institutional and programmatic accreditors and, thus, are ubiquitous in HSOs. Most commonly these committees are involved in clinical ethical issues and in this regard are charged with clinical case consultation, developing and reviewing clinical policies, and educating staff. Clinical staff tend to predominate on ethics committees, although social workers, clerics, and managers usually participate. Ethics committees are less likely to be involved in management ethics problems. Managers seem reluctant to allow ethics committee involvement in reviewing ethical implications of macro-resource allocation, for example. Support for ethics committees by management should include a modest budget, some staff assistance, and the prestige of recognizing their importance to the organization. Ethics committees commonly use ethicists as consultants.

Key Issues in Managerial Ethics

CONFLICTS OF INTEREST. Conflicts of interest arise when someone has two sets of duties or obligations and meeting one set makes it impossible to meet the other. They embody the biblical admonition against serving two masters. Whether a conflict of interest is present is fact-dependent, and accurate determination requires careful scrutiny. The potential for a conflict of interest does not necessarily mean that there is a conflict of interest. It is useful to distinguish differing interests that might lead to conflicts of interest from actual conflicts of interest. Even when differing interests are present it is possible to avoid actual conflicts of interest, but the slope is slippery.

Differing interests are present, for example, when an HSO manager has an ownership interest in a supplier that could service the HSO. If the manager approves purchases from that supplier at higher-than-market prices, a conflict of interest has occurred. However, if the price is lower than available elsewhere the differing interests continue, but no conflict of interest has occurred. In fact, the better pricing is an advantage to the HSO. However, if the manager uses the position of authority to cover up inadequacies in the supplies being provided, the differing interest has produced a conflict of interest.

All HSOs should have a policy defining conflicts of interest. Conflicts of interest can be avoided by disclosing the conflicting interest and recusing oneself from the decision. Using competitive bids also reduces the probability of conflicts of interest. Managers must avoid even the appearance of a conflict of interest. Few revelations are as devastating to one's moral leadership as the suggestion of improper gain from a position of authority. Health services managers, generally, are held to a higher standard than managers in the business sector, and the mere appearance of impropriety is considered more stringently than would be the same activity if performed in another enterprise.

CONSENT. Although it is commonly considered a purely clinical ethics issue, consent is an issue that should concern the HSO manager. If it is to operationalize the patient's autonomy, the HSO must assure itself that the patient has been adequately informed as to the services that are to be rendered under its auspices. The legal requirement is that the physician obtain the patient's consent after explaining benefits, risks, and alternatives to the services that are to be

rendered. However, the HSO should have policies and procedures that involve nursing or other appropriate clinical staff in ascertaining that the patient adequately understands what is happening. The manager is obliged to recognize that assuring the adequacy of consent is important; establishing the means by which it can be done and providing the staffing will make it a reality.

RESOURCE ALLOCATION. Resource allocation in HSOs occurs at the macro and micro level. The macro level includes new plant, capital equipment, and services. These decisions have major resource implications for the HSO. In turn, macroallocation decisions have major implications on the microallocation decisions made by clinicians. For example, a decision not to expand the intensive care unit (ICU) (macroallocation) means that decisions about individual patients (microallocation) will be constrained by the number of ICU beds. This, in turn, may mean that patients who might benefit from ICU services may be unable to readily receive them. Macroallocation decisions invariably have clinical implications, whether direct or indirect, and successful managers involve physicians in making these decisions. Nevertheless, resource constraints mean that not all that is clinically desirable is available.

RESOURCE CONSTRAINTS. Concomitant with ethical issues of macroallocation is the problem of resource constraints. Reimbursement from all funding sources is increasingly sparse. Most HSOs are barely achieving a modest surplus; many are running deficits. This change has occurred because of the dramatic funding reductions that began in the 1980s, after the halcyon days of the 1960s and 1970s. It is likely that the problem of inadequate reimbursement will continue unabated as patients demand more from HSOs and third-party payers are increasingly unwilling to pay at adequate levels and in a timely manner.

STAFFING. Severe shortages of several health professions plague HSOs. Registered nurses have received the most attention, although other health professions such as pharmacists and imaging technologists have also attracted too few. In addition, it has been projected that the emphasis on primary care in the 1980s and 1990s will result in too few physicians in some procedure-based specialties in the twenty-first century. HSOs have responded to nursing shortages by reducing the ratio of registered nurses to other types of staff who provide direct care to patients and instituting tuition benefits programs to encourage staff to enter nursing. Although health services managers and HSO trade associations assert that these shortages have not led to a diminution in quality of care, it stands to reason that doing more with less will eventually affect quality negatively, thus raising questions of beneficence and nonmaleficence.

COSTS. As the costs of providing health services continue to climb at double the rate of inflation in the general economy, and as the rate of reimbursement declines, the health services manager is caught in a double squeeze. Higher costs mean that more resources must go into providing basic services, and there is less capital for new equipment, programs, services, and innovation. This further exacerbates the resource allocation issue discussed above.

QUALITY OF CARE. It is estimated by researchers and quality improvement experts that 30 percent of the costs of providing a good or service occurs because of waste, delay, and rework. Such costs in the HSO setting are even more significant because to them must be added the discomfort, pain, morbidity, and mortality that can occur. The HSO manager has an ethical obligation to undertake quality improvement throughout the organization in all of the many clinical and administrative processes.

CLINICAL ETHICS ISSUES. Managers must assure that clinical staff have the support needed to prevent, minimize, and solve clinical ethical issues that arise. In addition, managers must be aware of clinical ethics issues that arise and make changes and improvement in the support available. Managers are expected to participate in ethics committees and institute and participate in ethics grand rounds in the HSO. Only by such hands-on involvement can the manager be aware of failings and issues that arise in the HSO.

The Future

The future promises to be even more challenging to health services managers than the past has been. The types of problems noted above are likely to continue, both in their present forms and in new permutations. New or exacerbated problem areas include terminal illness and futility care, advance directives, serving the underserved, marginal practitioners, multiculturalism (especially the differing meanings of life, death, disease, and treatment held by American subcultures), corporate compliance, employment practices, and whistleblowing. Three of these areas are noteworthy.

FUTILITY CARE. Futility care has been discussed since the early 1990s, but remains inadequately addressed. Acute care hospitals face families (and, less often, patients) who demand that care offering no hope of benefit be continued.

Fear of legal action and bad publicity have prevented hospitals from acting to withhold or withdraw services in such situations.

MULTICULTURALISM. Effectiveness in a multicultural society requires that the HSO's values are clearly communicated to patients, lest the HSO be pulled in many directions with inconsistent demands. Patient interests must be accommodated when possible, but not in contravention of the organization's values.

CORPORATE COMPLIANCE. Corporate compliance is the hot button issue of the new millennium. An organization whose culture and values include honesty, respect, and fair dealing will require little attention to corporate compliance, even though compliance officers are mandated by law. Its values already encourage staff to act honestly. Managers must assure that the organization's culture has no incentives for staff to do otherwise.

Conclusion

Health services managers face a future paradoxically marked by a bleak economic outlook and a challenging, hopeful outlook for providing services. Even as they endeavor to bring high quality health services to all who need them, health services managers will have to do so with fewer resources and under heavier constraints then ever in the profession's history.

HINDUISM, BIOETHICS IN

• • •

The following is a revision and update of the first-edition entry "Hinduism" by A. L. Basham. Portions of the first-edition entry appear in the revised version.

Hinduism is a religious system that has grown and developed from the Vedic religion identified with Aryans who invaded the Indian subcontinent over a period of centuries in the second millennium B.C.E. It is rooted in an oral tradition that gave rise to four groups of sacred texts during a period that is difficult to pinpoint more precisely than 1500 to 900 B.C.E. Based on this informal collection of traditions, beliefs, and practices and the corpus of formal written treatises, which together provided a context for development of the medical system known as *Ayurveda,* Hinduism encompasses a range of values and codes of conduct highly relevant to a study of Indian bioethics.

Hinduism as we might recognize it today took shape in the Gupta Period (c. 300–500 C.E.), often regarded as the classical age of Hindu India. This entry will identify and briefly discuss basic concepts, which clarify the setting for analysis of bioethics in Hindu India, before focusing on medical ethics in *Ayurveda.* Just as they do now, social and cultural values defined standards of medical education and practice, ideas about ethical behavior as a determinant of health and disease, the balance of commercial and altruistic motives of clinicians, access to care and humane treatment, and the rights and responsibilities of patients and physicians.

Hindu Worldview

The doctrine of transmigration is a definitive concept for Hinduism. It postulates the existence of an innermost self (*ātman*) for all beings, ranging from the highest god to the meanest insect, that is essentially immutable. By becoming incarnate, this self becomes further involved with matter, which some philosophical systems hold to be fundamentally illusory and others regard as the primordial source of intellect, ego, elements, and the material world. According to the conduct of the embodied being, the soul or self is carried at death to another body, in which it flourishes or suffers according to previous behavior (the law of *karma*). This process is called *samsāra.* From an outsider's perspective, the force of *karma* operates as a tangible manifestation of an

ethical system associated with principles of righteous conduct and moral values inherent in the concept of *dharma,* a difficult-to-translate term that embodies cosmic order, sacred law, and religious duty. Within the system, however, the effects of *karma* are typically conceived more as the operation of natural law governing the effects of behavior than a statement of moral and ethical values.

Transmigration links all living beings in a single system. Unlike the Judaeo-Christian and Islamic religious systems, Hinduism makes no sharp distinction between human and animal. *Dharma* as a guide to proper behavior is relative, not the same for different people or different beings. The ideas of *karma* and *saṃsāra* motivate values of nonviolence (*ahimsā*) and vegetarianism. Nonviolence, which was never so prominent a value in Hinduism as it was in Jainism and Buddhism, has less stringent implications for laypersons than for ascetics, and it does not interfere with righteous warfare, punishment of criminals, or self-defense.

The process of transmigration is considered painful, and the main quest of classical Hinduism has been to find "release" (*mokṣa*) from the cycle of birth and death and thereby enter a state of timeless bliss. For the orthodox schools of Hindu philosophy and systems of Buddhism and Jainism that sprang from them, knowledge provides a means of escaping this repetitive cycle of birth, death, and rebirth. Each of these schools has a somewhat different interpretation of the problem and the solution. Both the *Sāṃkhya* school, identified with yoga practice and once very influential, and the heterodox sect of Jainism, define release as the complete separation of the individual soul from matter. The *Advaita* Vedanta system, which exerts the greatest influence on intellectual Hinduism, interprets it as a full realization of the illusory character of the material world, the speciousness of individual personality, and the recognition of the soul's identity with an underlying impersonal world spirit, often called *Brahman.* Theistic Hinduism of the *ViśIṣtādvaita* school, which has had the greatest influence on popular ideas, interprets release as union with the personal God not through knowledge but through devotion to *Viṣṇu,* who is identified with *Brahman,* the ultimate reality of the universe and out of whom the world repeatedly emerges in the course of cosmic cycles.

Ideally, release is the aim of all striving, but Hinduism recognizes the validity of other aims, which for laypersons are fully legitimate. The ascetic (*sannyāsī*), on the other hand, "who has given up the world," should pursue only release. Ordinary people approach this goal through gradual stages over many lives. For them there are three legitimate aims: *dharma,* adherence to religious and ethical norms in order to ensure a happier rebirth; *artha,* amassing wealth for the benefit of oneself and one's family; and *kāma,* seeking pleasure and the satisfaction of personal desires. These three aims are valued in descending hierarchical order, but each is fully acceptable for different persons at a particular stage of life and for caste-based communities, which may emphasize one of them.

The Hindu pantheon begins with one primeval being, or God, and innumerable supernatural beings, all of whom are endowed with individual volition. Some of these beings adhere to the will of the higher gods, but others oppose the work of creation. Battles between gods and demons, light and darkness, and good and evil were important features of the earliest Hindu literature, and these themes are widely represented in popular beliefs and practices. Complementing more intellectual naturalistic explanations that are also a prominent feature of Hinduism, some look upon the world as a place full of demons, which are normally at war with gods, and which can be potent factors in causing misfortune and disease.

Hindu cosmology refers to four ages (*yuga*) over the period of a great cycle (4,320,000 years). The current cycle, the *Kali yuga,* is the worst, but fortunately the shortest, lasting 432,000 years, about 5,100 of which have elapsed. Looking backward to better times provides a guide in this troubled age. Neither the doctrine of *karma* nor that of cosmic decline, however, implies fatalism. Human effort may influence the process, and it holds potential for gaining release from the personal cycles of birth and rebirth. Hindu texts emphasize the virtue of human effort (*puruṣakāra*), rather than passive acceptance of adversity that may follow from destiny or chance.

Social Norms

The four great classes (*varṇa*), constituting an eternal hierarchical social order, were believed to have emerged at the beginning of time from the body of the Creator as the fundamental basis of society. The *Brahman* (priest), the *Kṣatriya* (warrior and ruler), the *Vaiśya* (merchant), and the *Sūdra* (worker) formed these four classes, each with different roles, responsibility, and status. Maintaining differences that distinguish each of them was a prerequisite of the social order, and any effort to violate the boundaries of social organization and behavior was an affront to nature and the gods, degrading for those at the top and punishable for those at the bottom. Below the four great classes were the untouchables, theoretically outside, but operating at the bottom of the social order. They performed important social functions that others considered polluting, such as removing garbage, cremating corpses, working in leather, and so forth. Contact between them and the other classes was strictly limited.

Although aspects of this class structure persist in Hindu society today, social conditions rarely operated according to textbook norms. More important and more complex in everyday life was the caste (*jāti*), a group of families generally following the same profession and theoretically contained within one of the four classes, though not always recognizably so in practice, especially in South India. Castes were also hierarchically graded and normally endogamous. Local councils of elders exerted great power over their members.

Family

Social research in recent years has emphasized the primacy of the family over the individual in Hindu and other societies outside North America and western Europe. Hindu individuals were more likely to define themselves with reference to the extended family (*kula*) as a corporate unit. Social responsibilities, which constitute underpinnings for the concept of *dharma,* rather than individual rights, were clearly the priority among ethical concerns. Except in some parts of South India, primarily Kerala, the family was patrilinear, patriarchal, and patrilocal, though the authority of the patriarch was limited by traditional law. He did not have the right to dispose of family property arbitrarily, nor did he have complete control over the lives of family members.

The ritual of *śrāddha,* whereby dead ancestors retained a presence, sustained by the living, was a powerful force in shaping the character of Hindu family life. A male descendant to perform the *śrāddha,* a ritual offering of rice balls (*piṇḍa*), was needed not only to sustain the ancestral lineage but also to avoid one's own suffering in the afterlife. In view of heavy child mortality, it was incumbent upon families to produce as many children as possible, in the hope that at least one surviving son would maintain the lineage, attend to the spiritual needs of the ancestors, and contribute to the economic well-being of the family.

A Hindu wife was integrated into her husband's family, and theoretically (though not always in practice) completely subordinate to him. In many communities it was considered indecent to leave a girl unmarried after her first menstruation, and marriage normally required the payment of a heavy dowry. Thus, the birth of a daughter was often looked on as a misfortune. Although female infanticide has been practiced and persists in some parts of India, the practice is completely without foundation in the Hindu scriptures, which look upon abortion and infanticide as grave forms of murder.

Prospective parents employed various techniques to increase their chances of bearing a male, rather than female, child. Diet and activities of a pregnant woman were believed to influence the sex, physical features, and character of the offspring. Treatises of *Ayurveda* advise that intercourse on even days after the onset of menstruation produces sons, and on odd days it produces daughters (Caraka, iv. 8. 5). *Pumsavana* rites to alter the sex of a recently conceived embryo and ensure the birth of a male child are discussed in the texts of *Ayurveda.* They are also discussed in religious treatises of the Veda and other texts that detail proper Hindu codes of conduct (*dharmaśāstra*) (Kane).

In recent years profitable ultrasound clinics have proliferated in India, in some states illegally, to make use of modern technology to identify and abort female fetuses. Responding to a culturally based gender bias and a persisting dowry system that taints perceptions of female children as economic liabilities, this ultrasound technology challenges the viability of *pumsavana* clinics previously established in some *Ayurvedic* hospitals and employing traditional Hindu medical methods for assuring the birth of male children.

Individual Conduct

Within the framework of the three aims of life (*purusārtha*) acceptable for the high-caste individual were a series of ritual observances and taboos throughout life. Sacraments beginning before birth and continuing after death marked the progress of life. The Brahman was expected to devote a considerable amount of time each day to prayer and ritual, and members of other castes were encouraged to imitate him.

The aim of many of these sacraments and taboos was to maintain ritual purity. Although conceived with reference to another conceptual framework, many practices also maintained a hygienic standard contributing to health in a tropical climate. Notable examples include insistence on a daily bath, the custom of eating with the right hand and washing the anus and sexual organs with the left, the ban on eating cooked food left overnight, and a strict taboo against contact with human corpses and animal carcasses. The bodily fluids of others, such as saliva and mucus, are considered polluting, and contact with anything contaminated by them, such as used dishes or drinking glasses, was to be avoided.

Social values and a conflicting emphasis in various texts of classical Hinduism portray an ambivalent attitude that both exalts and denies sexuality. *Vedic* texts regard sexuality as a metaphor for a ritual sacrifice. The *Bṛhadāraṇyika Upaniṣad* (vi. 2. 13), among the best known of this speculative genre of Hindu scriptures (*Upaniṣad*), identified woman as a sacrificial fire fueled both by her own and her male partner's genital organs in the act of sexual intercourse.

Semen is an offering to this fire, which may generate a person.

In later texts, however, sex is affirmed as a valid source of gratification, a legitimate pursuit among the three aims of life: righteousness, wealth, and pleasure. Erotic temple art and texts devoted to the details of enhancing sexual gratification, such as the *Kāma Sutra,* document a cultural sanction of pleasure seeking for men. These texts acknowledge female sexuality but consider it primarily from a male perspective—how to attract and please a man. Hindu texts concerned with moral codes of conduct (*Dharmaśástra*) emphasize chastity and procreation more from the classical period onward than previously (Bhattacharyya).

Even for men, classical Hinduism confines sexual activity to one stage of a man's life. An initiation ceremony (upanayana) that preceded a long period of celibate studentship was a milestone for upper-caste boys. Afterwards, a young man was married, normally to a bride chosen by his parents, and raised a family. According to the ideal, he was expected to give up family cares in late middle age to devote the rest of his life to religion and to strive for liberation. Ascetic values discouraged sexual activity, which not only distracts the individual from a quest for release from the cycle of rebirth but also results in the loss of physical and spiritual power.

In addition to the emphasis on a moral code of religious practices, Hinduism also emphasizes ethical principles of social relations. The principle of nonviolence has often been interpreted in a positive sense, as actively benefiting others. Though subject to the constraints of conflicting values in a comprehensive social order, Hindu texts and practices encourage virtues of honesty, hospitality, and generosity. Explicit codes detailing how guests are to be received, fed, and looked after emphasize hospitality as a social value (see chap. 21 on receiving guests in Kane). The *Taittirīya Upanisad* (i. 11. 2) admonishes students to treat parents, teachers, and guests as gods.

Hindu Medicine

A complex medical system, known as *Ayurveda,* "the science of (living to a ripe old) age," developed in India over the first millennium B.C.E. The theory of health and disease according to *Ayurveda* refers to a humoral physiology based on the balance of three substances (*dosas*): wind (*vāta*), bile (*pitta*), and phlegm (*kapha*). They are recognizable indirectly by their impact on health and illness. The excess of one or another and their locus in the body or among bodily elements (*dhātu*) determines the nature of specific physical and mental diseases, their manifestations, and subtypes. Although *karma,* demons, and deities may also play a role in producing ill health, it is a relatively minor role in the medical texts and more of a concern in other settings. The role of a physician practicing *Ayurveda* is to restore the harmony of humoral balance with medicines, purification, massage, diet, and directives for appropriate lifestyle. Experience with an exceptionally wide pharmacopoeia and careful observations of the symptomatology, clinical course, and treatment response of various diseases—especially chronic conditions for which Western medicine does not provide a clearly superior alternative—have enabled practitioners of the system to maintain the respect of a large number of South Asians who continue to use it.

Health, Disease, and Morality

Ayurveda, despite its emphasis on the humoral basis of health and disease, also recognized external (*āgantu*) causes that provided a better account than endogenous (*nija*) causes—that is, humoral imbalance—to explain some medical conditions. *Karma* referred to the impact of misdeeds in a previous life. Irreverent, unethical behavior and other violations of codes of conduct (*prajñā-aparadha*) in one's current life were not limited to effects on that individual; they could also affect offspring (Caraka, iv. 8. 21, 30). Serious transgressions of the king might also produce epidemic disease and disasters (*janapadoddvamsana*) in his kingdom (Caraka, iii. 3). Moral conduct, affecting individuals, distinct from epidemics affecting populations, operated through the all-embracing doctrine of karma; in some instances, *karma* explained health or disease if the humoral theory or demonic possession could not, and in other instances, it provided a complementary explanation.

Illnesses might be caused by the sins or shortcomings of a previous existence; longevity was also explained by this idea of *karma.* The doctrine encouraged inner acceptance of disease and gave a ready-made explanation of its cause, but nowhere is a person advised to submit to illness without attempting its cure. *Karma* could explain otherwise mysterious congenital defects. Someone born with a deformed hand, for example, could be said to have incurred this misfortune as a result of an evil deed (for instance, striking a *Brahman*) committed by the same hand in a previous life. This did not necessarily discourage efforts to improve the condition by surgery, since the duration of the punishment through *karma* was not known, and the trouble might be only temporary. Since the evil brought about by *karma* cannot be estimated with certainty, and the bad effects of sins can be offset by the merit gained by good deeds, there was every reason why a sick person should seek all available medical help to achieve health.

Other factors besides *karma* were believed to promote health or disease. Devotion (*bhakti*) to God, who might set aside the law of *karma* for the faithful, promoted longevity and health. Neglect of religious duties and lack of faith, on the other hand, might lead to the withdrawal of divine protection, increasing the risk that demons might exert their influence, leading to disease or madness.

More closely linked with ethics was the general view in the medical treatises that equanimity and kindness are therapeutic in their effects. Excess in every respect is looked on with disfavor by the medical texts. An impressive emphasis on the values of moderation, altruism, and love to promote health and longevity is found in the seventh-century text of the Buddhist physician Vāgbhata, the *Aṣṭāṅgahṛdayasaṃhitā* (1965, i. 2). This work, along with the *Caraka Samhitā* and the *Suśruta Samhitā*, is among the so-called great-three (*brhattrayī*) texts of classical *Ayurveda.* After reviewing the benefits of exercise and symptoms resulting from overexercise, it enjoins the physician to support those who are sick, poor, or needy and to treat them with respect.

Mental and spiritual training in concentration and meditation, commonly known as yoga, was also believed to promote health and longevity. Yoga is still widely practiced both as treatment for clinical problems in yoga clinics of some Indian hospitals and more generally to promote health and well-being. Different forms of yoga practice involve physical postures and exercises (*hatha-yoga*), meditation (*rāja-yoga*), or both. These produce not merely health and longevity; they also provide a way for the most advanced adepts to attain liberation from the cycle of rebirth, and hence immortality.

Ethics of Medical Practice

The activities of the physician (*vaidya*) were closely linked with the doctrine of the three aims of Hindu life (Caraka, i. 30. 29; Vāgbhaṭa, i. 2. 29). Viewed as complementary, rather than contradictory, they guide appropriate behavior. By relieving suffering and adding to the sum of human happiness, a physician (assumed in the texts to be a man) fulfills the first aim, carrying out his religious duty; from the generous fees of his wealthy patients he achieves the second aim, riches; while the third aim, pleasure, is achieved by the satisfaction he obtains, first, from a high reputation as a healer and, second, from the knowledge that he has cured many people whom he loves and respects.

The last two aims were not to be disparaged. The few famous physicians described in story and tradition were not selfless servants of humanity but very wealthy men—in that regard resembling successful practitioners of modern times. There appears to have been no ban to keep a physician from advertising his skill. As the example of Vāgbhata indicates, Hindu and Buddhist medical traditions were closely linked. A Buddhist text, the *Mahāvagga,* provides more biographical detail than the Hindu sources about medical practice in the same society. It refers to the material interests of a renowned doctor in his youth, *Jīvaka,* recently qualified and in search of patients. As he entered an ancient Indian city, to earn money for his onward journey, he walked through the streets inquiring, "Who is ill here? Who wants to be cured?" (Mahāvagga, viii. i. 8–13).

Although Jīvaka's concern for his fees was matched by qualifications and skill, it appears that quackery was also rampant in ancient India; charlatans would come canvassing as soon as they heard that a well-to-do person was sick (Caraka, i. 29. 8–12). Recognizing such problems, Suśruta (i. 10. 3) referred to a system of licensing qualified medical practitioners. Texts on politics and statecraft suggested punishments for doctors whose ineffective treatment resulted in injury or death (*Kauṭilya,* iv. 1; Kane). Caraka also advocated a high moral standard for a proper physician, based on religious duty (*dharma*). At the outset, a physician's training began with a solemn initiation, at which his teacher (*guru*) instructed him that he was to live a frugal and ascetic life, celibate and vegetarian, while undergoing training. He must obey his teacher implicitly "unless instructed to commit a mortal sin." The prescribed instruction continues:

> When you have finished your studies, if you want to have a successful, wealthy, and famous practice, and to go to heaven when you die, you must pray every day, when you get up and go to sleep, for the welfare of all beings, especially cattle and brahmans, and you must strive with all your power to heal the sick. You must not betray your patients, even at the risk of your own life.… You must always be pleasant of speech … and always strive to improve your knowledge.… Having entered a patient's home, a physician's speech, mind, intellect, and senses should be devoted to nothing other than caring for the patient. Any peculiarities of the household you may learn about should not be disclosed outside. (Caraka, iii. 8. 13. 4–5, 7)

This well-known passage has been compared with the Hippocratic oath. The text also addressed other persisting dilemmas of medical practice. If it becomes clear that a patient in treatment has a fatal condition, the matter of whether or not a doctor should disclose this information was left largely to the doctor's discretion. Caraka advised that if a physician concludes that the condition of the patient is hopeless and if he believes that it might shock the patient or others, he should keep this knowledge to himself.

The same chapter of the Caraka Saṃhitā also contains advice about when a physician should refuse to provide treatment. He should not treat the king's enemies, women unattended by a husband or guardian, or patients for whom a request for treatment comes as they are about to die (Caraka, iii. 8. 13.6). Accepting a terminal case might damage his reputation.

The Hindu medical tradition is based on a relatively stable theory of health and illness, but it advocates a policy of openness to new ideas about treatments. Although the theoretical basis rooted in the doctrine of the three humors has always guided *Ayurveda* and undergone little modification over the course of time, the *vaidya* was advised to be constantly on the lookout for new drugs and treatment methods. Compared chronologically, the texts show a steady increase in the number of items in the pharmacopoeia. Even after his long apprenticeship was over, the physician was counseled to continue to improve his knowledge by studying his patients and inquiring about unusual but potentially useful remedies from hermits, cowherds, and hillmen (Suśruta, i. 36. 10).

Professional gatherings of physicians were regarded as valuable opportunities for the exchange of knowledge that could enhance a clinician's skills. The descriptions of these colloquiums distinguish friendly discussions from hostile debates, and the exchange of information was not necessarily free and open. Many physicians guarded proprietary knowledge not recorded in professional textbooks, knowledge they might reveal to prove a point in the heat of impassioned debate. Entering into professional discussions, the clinician is advised not to boast, embarrass others, or fear discomfort. In the company of knowledgeable colleagues, he is advised to listen attentively and speak freely. The text also advises how to handle hostile discussions with superiors, inferiors, and equals. "The wise never applaud a person engaging in hostile discussion with a superior … but the following methods help in quickly overpowering an inferior disputant.…" (Caraka, iii. 8. 15–21; see also the remainder of chap. iii. 8).

The texts encouraged the physician, though he might be wealthy and unfettered by any rules of an ascetic character, to consider himself a sort of secular priest with a special, almost supernatural charisma bestowed on him by the initiation ceremony at the beginning of his studies. The high-caste man who had undergone the normal Hindu initiation (*upanayana*) was "twice-born" (*dvija*), and thus superior to the Śudra or woman, who had only one birth. The *vaidya* was even a step beyond, "thrice-born" (*trija*). As the prescribed words of his teacher show, this exalted status required a high standard of fortitude and conduct. The student was taught that as a physician he should always be "of calm mind, pleasant speech, … the friend of all beings" (Suśruta, i. 10. 3). To some extent professional identity relieved him of the burden of caste taboos. He could enter the homes of people of a lower caste than his, handle their bodies, and even taste their urine when making a diagnosis.

Notwithstanding vegetarian cultural values, treatment employed animal products to compound drugs, and they appear to have been prescribed freely. The taboo that proscribed handling a corpse, however, may have applied to most physicians. Most medical texts do not advocate the actual dissection of a cadaver; *Suśruta Saṃhitā* (iii. 5), however, is an exception. It advises that for a surgeon to study the position of internal organs, a carefully selected dead body should be placed in a cage after removing excrement from the entrails, positioned in a stream with a swift current, and examined after seven days as it begins to decompose. In that way the body might be studied in each anatomical layer, beginning with the skin.

Although concerns about ritual pollution and principles of nonviolence inhibited anatomical study and surgery in *Ayurveda,* in recent years they appear to have had surprisingly little influence on modern medicine in India, known as allopathy, with respect to the burgeoning surgical practice of organ transplantation. Concern about the adverse impact on the transmigration of souls has had a negligible effect on the transmigration of vital organs from one person to another. Bombay has acquired a dubious distinction as a world center for transplants from unrelated live donors, spawned by a profitable private-practice medical industry, an impoverished subpopulation willing to donate organs for a fee, and enterprising brokers whose activities reflect little concern for the ethics of these practices.

Access to Healthcare

The provision of free medical care to the poor was looked on as part of a king's duty to protect his subjects, which was generally interpreted in a positive sense (Caraka, i. 30.29; see also the background essay in vol. 1, pp. 254–264 of P. M. Mehta's translation). From the days of the benevolent Buddhist emperor Aśoka in the third century B.C.E., the better rulers of India responded in some measure to this responsibility. Medical clinics of one kind or another, where professional doctors provided free services to the poor, existed in many cities. These were sometimes supported by the states, but others were often financed by private charity. In South India especially, hospitals and dispensaries were often attached to the great temples. Medical services might have been subsidized by doctors themselves, for they were encouraged to treat the poor, learned Brahmans, and ascetics without charge (Suśruta, i. 2. 8; vi. 11. 12–13). Free medical

services in South and Southeast Asia, however, were more extensive in Buddhist Sri Lanka and Cambodia.

Reasoned Suicide and Mental Health

The aim of the idealized ascetic to attain release and end the cycle of rebirth provided an acceptable rationale for suicide in highly selected circumstances. *Sallekhaná* is a Jain practice sanctioned for elderly mendicants involving ritual fasting that ends in death; its aim is for the individual to meet the final moment with utmost tranquillity (Settar). The *Dharmaśāstra* literature, which outlines Hindu codes of conduct, also refers to another form of religious suicide, the "great journey," justified by incurable disease or great misfortune (Kane). Those who undertake this ultimate renunciation in the final stage of life proceed in a northeasterly direction, "subsisting on water and air, until his body sinks to rest" (*The Laws of Manu,* 6. 31). Other means of accomplishing religiously motivated suicides include jumping from a height (*bhrgupāta*), often associated with pilgrimage sites where these suicides were most frequent, such as Śravana Belgola, west of Bangalore in South India, and Prayaga (modern Allahabad) in the North.

Questions about these carefully reasoned suicides, usually sanctioned only for the elderly, were framed in religious rather than medical contexts, unlike current debates about euthanasia and assisted suicide in the West. Nevertheless, issues identified as appropriate justification by those who advocate these practices in both settings are comparable, especially the role of terminal illness and functional disability. Whether one regards these socially sanctioned self-willed deaths as suicide or something else is a debatable matter. Some scholars avoid the stigmatized English term (Settar), although more commonly suicide is used descriptively, regardless of whether it is proscribed.

Although Hindu texts were very much concerned about ethical questions that ultimately lead to sanctioning or condemning suicides, based on their circumstances, the context of the discourse was strikingly different from that of present-day debates about physician-assisted suicides. Suicide in the West typically raises questions about deviance and mental disorder. Concerns for victims are framed in clinical terms with a focus on prevention and cure of psychopathology associated with suicidal impulses. Hindu traditions that consider suicide are concerned with a different set of questions, which focus not on deviance but on cultural values. Religious suicides of ascetics and pilgrims and the self-immolation of a widow on the funeral pyre of her husband (*anumarana*)—an act that has come to be known as *sati,* after the Sanskrit term for the "righteous woman" who undertakes it—were not discussed in medical contexts. Modern criticism of *sati* proceeds from social, economic, and feminist perspectives; it focuses on questions about the deviance and disorder not of the victims but of societies that disvalue women, especially widows.

Suicide was regarded neither as a defining feature nor an important symptom of mental disorder. Mental disorders (*unmāda*), however, were recognized and classified according to threatening, disorganized, and disordered behaviors, and by disturbing emotional states. The classification of some of these mental disorders fit the characteristic humoral framework, but others did not. Like some childhood diseases discussed in the texts (but few other health problems), they were explained by the influence of demons and deities. The texts prescribe a mix of gentle, humane treatment, as well as not-so-gentle efforts to restrain and shock patients into normalcy with threats of harm and false reports of the death of loved ones. Offerings to demons and deities (*bali*) and medicines to correct a humoral imbalance of excessive wind, bile, or phlegm were also prescribed for mental illnesses attributed to these respective causes.

Conclusion

Many issues that remain concerns in modern medical practice were recognized and addressed by Hindu religious texts, codes of conduct, and Sanskrit treatises of *Ayurveda.* The medical texts discussed responsibilities of the physician to society, patients, and colleagues in terms that recognized the professional nature of these interactions, distinctive social values, and political forces. Medical theory, which was primarily humoral, incorporated a moral basis for explaining health and illness of individuals. Some questions that have become major concerns for medical ethics in the West, such as the status of rational suicide, were considered in the context of Hindu traditions other than medicine.

Recent developments in biotechnology have placed controversial questions about bioethics and cultural values near the top of an agenda for equitable social policy in South Asia. The ongoing debate that follows from the impact of new technologies should be informed by an appreciation of the cultural and historical contexts in which these questions emerge.

HOLOCAUST

• • •

Bioethics is a type of *discourse,* defined as "any collective activity that orders its concerns through language" (Zito). As members of a discourse community, bioethicists use rhetorical strategies to make arguments, define terms, and influence the direction of the discourse as a whole. One of those strategies is to invoke the Holocaust as a way to warn, cajole, criticize, or silence those who have opposing or divergent views. The use of the Holocaust as a rhetorical instrument raises important ethical and strategic questions for bioethics.

The Holocaust

The Holocaust lies like a specter behind modern bioethics. Contemporary bioethical discourse derives much of its moral legitimacy from the legacy of the Holocaust. The unfathomable cruelty of the Holocaust is paradigmatic of

the degree to which the unfettered power of the majority over despised minorities can distort human relationships. The eugenic philosophy that undergirded social engineering and extermination campaigns informs all current debate about genetic engineering and population genetics. The genocidal strategy of the Nazis, coupled with the complicity of large segments of the German public, including medical professionals, showed the depths to which human beings could go in the pursuit of misguided philosophies of science and in-group politics. The atrocities committed in the name of medical research revealed individual subject vulnerability in the hands of investigators so starkly that virtually all modern standards for protecting human research subjects originated in the aftermath of the Holocaust.

The events that occurred in Germany under National Socialism have come to represent evil in pure form, without caveat or ambiguity. The Holocaust thus has come to signify the ultimately evil act; the Nazi enterprise, the ultimately evil political and social movement; and Hitler, the ultimately evil leader. By extension, those who were inactive in the face of evil are invoked as the paradigm of complicity and those who did not speak out are emblems of culpable silence. It thus is not surprising that evoking the Holocaust as a rhetorical strategy has enormous symbolic power.

However, such power cannot be wielded without risk. Drawing on symbols of ultimate evil to buttress arguments about the undesirability of lesser evils may be emotionally satisfying, but it is rarely a persuasive rhetorical strategy. If the analogy is seen as inapt, it tends to weaken rather than strengthen the case being made. Still, the temptation to employ the Holocaust is strong, and it has become a central metaphor for a variety of social movements (Stein), special interests (Novick), and political actors (Lin and Gur-Ze'ev) as well as in popular culture (Hungerford, Mintz, Zelizer).

The use of the Holocaust in bioethics has taken on a particular character. Bioethics is a normative discourse, and the Holocaust is a signifier with great normative power. The Holocaust frequently is invoked in bioethical discourse to draw analogies, suggest threats to vulnerable groups, or warn against perceived slippery slopes. After a brief historical summary, some of those strategies will be examined in this entry to explore their impact on bioethical discourse.

Rhetoric and the Holocaust

The term *holocaust* is derived from the Greek *holokauston,* meaning "burnt whole," which was a derivation of the Greek translation of the Hebrew *olah,* a biblical term for a burnt sacrifice. Historically, the term was used to denote great destruction of human life, especially through conflagration. For that reason it was employed often by journalists in World War II to refer not only to the destruction perpetrated by the Nazis on Jews and others but also to Allied acts such as the bombing firestorms that destroyed much of Hamburg and Dresden. It is ironic that the German press used the term first to refer to the bombing of German cities.

The use of *holocaust* in reference to the destruction of the European Jewish community at the hands of the Nazis gained currency by being the preferred English translation of the Hebrew word *shoah.* The 1948 Israeli Declaration of Independence, for example, makes reference to the *shoah,* which is rendered as "the Nazi holocaust" in official English translations (Novick). However, in the decades after World War II the destruction of European Jewry was rarely part of American public discourse. It was only during the 1960s, particularly with the advent of the trial of the Nazi official Adolf Eichmann, that the term *holocaust* began to be used in common discourse to refer to World War II. At first the term often was used to refer to the death of all the millions of people who were killed by the Nazis. By the late 1960s, however, *the Holocaust* (capitalized and usually preceded with the word *the*) was defined in dictionaries as the genocidal killing of millions of Jews by the Nazis during World War II.

The lowercased term *holocaust,* however, still is used commonly to describe great loss of human life at the hands of others, as occurred in Biafra in the 1960s, Cambodia in the late 1970s, Afghanistan in the 1980s, and Rwanda and Serbia/Bosnia in the 1990s. Over 2,000 books in print include the word *holocaust* in their titles, many of which do not refer to World War II: *The Real Holocaust* depicts the African slave trade, *The Silent Holocaust* describes victims of famine, and two books titled *The Forgotten Holocaust* discuss South American Indians and the rape of Nanking; *Holocaust Island* is a book of poetry about Australia by an aboriginal poet.

Despite the widespread and diverse use of the term, controversy over its proper usage outside the Nazi context remains. The *American Heritage Book of English Usage* reports that 99 percent of its Usage Panel, composed of over 180 experts who determine the correct employment of terms, accept the term *nuclear holocaust.* However, only 60 percent accept its use for the 1 million to 2 million victims of the Khmer Rouge, only 31 percent for the millions of victims of drought in Africa, and a mere 11 percent in reference to the AIDS epidemic.

The use of the term *holocaust* in other contexts is confounded by the fact that the rhetorical power of the word largely has been taken over by its single exemplar; every use of the term, even in lowercase or in other contexts, inevitably becomes a referent. Another complication is that the penetration of the term into the American consciousness has been

astonishing. Ninety-seven percent of the public in one poll knew what the Holocaust was, a higher percentage than could identify Pearl Harbor or knew that the United States had dropped an atomic bomb on Japan. The majority in a second poll said that the Holocaust "was the worst tragedy in history" (Novick, p. 232). The casual use of the term outside the Nazi experience can provoke the sensitivities and strong voice of the Jewish community, which was affected singularly by the Nazi campaign of eugenic eradication and for which the Holocaust remains a powerful and personalized event. Such factors complicate the term's use in contexts other than the Nazis' actions in World War II.

The Uniqueness of the Holocaust

The controversy surrounding the use of the Holocaust as a metaphor revolves in part on claims of the Holocaust's *uniqueness.* The targeting of one ethnic group said to be singularly evil; the use of medical and public health justification for the destruction of that group; the relentless and single-minded searching out and destruction of all men, women, and children in that group as an end in itself; the widespread collaboration of the public in each new country conquered; the dedication of enormous economic, military, and social resources to that end; and the systematic technological extermination of the group are said to set the Holocaust apart from all other cases of genocide in human history.

Lucy Dawidowicz (*Hastings Center Report*) has argued that the Nazi experience cannot be used to gain insight or help resolve the conflicts of other eras. If the Holocaust is *unique* and thus is a singular, exceptional, disjunctive moment in the course of human history, it lies outside the flow of normal events and cannot serve as a historical lesson. It therefore cannot be used to understand *normal* evil or even the periodic emergence of extraordinary evil. Conversely, if the Holocaust is just one, however singularly tragic, example of many historical examples of genocide or hatred, what is to keep its particularities intact when it is used constantly as the referent for the killing of the Armenians, African slaves, or embryos? The Nobel Prize winner Elie Wiesel, who is known for his advocacy of the uniqueness of the Holocaust, has tried to resolve the dilemma by arguing that the Holocaust was "a unique Jewish tragedy with universal implications" (quoted in Novick, p. 239). However, it is difficult to maintain that an event is both absolutely unique and universally applicable.

Arguments against the use of the Holocaust as an analogy to other cases of suffering take two major forms. One suggests that the Holocaust had a uniquely Jewish context and that to use the term as a referent cheapens and discounts the Jewish experience of suffering and loss. Edward Alexander in an article titled "Stealing the Holocaust" indicts those who use the Holocaust to call attention to other instances of injustice, arguing that they *use up* something accumulated by Jews through their suffering. A second argument suggests that use of the referent blunts the true horror and extremism of the event. Discussing the related use of the label *Nazi* in a Hastings Center Report Conference on bioethics and the Holocaust, Milton Himmelfarb lamented the "overly hasty invocation of 'Nazism' and the rather free and easy use of Nazism to brand practices with which we disagree.… By universalizing Nazism, one makes it shallow, and one removes the actual reality of Nazism. If everything is Nazi, then nothing is Nazi, and even Nazism wasn't Nazi" (*Hastings Center Report,* p. 7).

Insisting that the Holocaust lies outside history and has no role in creating an understanding of other cases of mass killing is also problematic. The argument for the incomparability of the Holocaust trivializes other crimes and can lead to discussions such as the reported argument about whether the Bosnian slaughter was "truly holocaustal or merely genocidal" (Novick, p. 14). Some analogies are clearly apt. The discussion of the *Rwandan holocaust* in a medical journal, indicating with the lowercase *h* that the term is used as a noun and not explicitly as a reference to the Jewish Holocaust, seems a proper usage (Decosas). The tragic events in Rwanda are well described as a holocaust.

The Holocaust in Bioethical Discourse

In bioethical contexts the Holocaust often is invoked as a form of moral approbation. The development of the Nuremberg Code in the wake of the Holocaust was the clear precursor to the emergence of modern protection measures for human subjects and therefore often is referenced legitimately (Caplan). However, the Holocaust-Nazi analogy also is invoked regularly to condemn a wide range of practices (e.g., abortion, physician-assisted suicide), healthcare strategies (e.g., managed care, age rationing), and even people (e.g., by opponents of the work of philosopher Peter Singer). Sometimes the analogies are so overblown as to be easily dismissed, for example, when the breast implant controversy was referred to at an Institute of Medicine meeting as the "silicone holocaust" (Ault). However, it is instructive to look at a number of cases in which the use of Holocaust metaphor or imagery is employed to make a bioethical argument in a professional or public forum.

ANIMAL RIGHTS. Animal rights activists have called fur farms *Buchenwalds for animals* and have likened animal experimentation to the human medical experiments of the

Nazi doctor Josef Mengele. A best-selling book in the animal rights movement called *Eternal Treblinka* (Patterson) argues that there are many parallels between animal exploitation and the Nazi exploitation of people and points out that the slaughterhouse was the model for the death camps. In 2003 People for the Ethical Treatment of Animals (PETA) mounted a graphic campaign and exhibit called *Holocaust on Your Plate,* which placed 60-square-foot panels displaying gruesome scenes from Nazi death camps side by side with disturbing photographs from factory farms and slaughterhouses. One exhibit shows a starving man in a concentration camp next to a starving cow. The campaign, which highlighted medical research using animals along with other forms of animal exploitation, used the slogan "To animals, all people are Nazis" (Specter). Jewish leaders, as well as many others, objected strongly to the exhibition.

AIDS. AIDS activists often use the slogan "silence equals death" to liken the purported indifference among bystanders in the face of the epidemic to the inaction of those who let the Holocaust occur. It also has become common for activists to refer to AIDS as the "Gay Holocaust" (Bamforth). At the 2000 AIDS summit in South Africa delegates accused drug companies of a "holocaust against the poor" for refusing to provide Africans with inexpensive AIDS drugs (Smith). Used in tandem with the slogan about silence, that phrase is an implicit rebuke of the claimed unwillingness of the drug companies and others to dedicate the resources and attention to its eradication that the activists believe AIDS deserves.

ABORTION AND EMBRYONIC STEM CELLS. In the abortion debate and more recently in the human embryonic stem cell (hES) debate both sides have made use of Holocaust metaphors to defend their positions. The pro-life and anti-hES movements commonly refer to the destruction of embryos as "the American Holocaust" and use symbols and images from the Holocaust as a primary metaphor in their literature (Neustadter). When he was surgeon general of the United States C. Everett Koop warned of a progression "from liberalized abortion … to active euthanasia … to the very beginnings of the political climate that led to Auschwitz, Dachau, and Belsen" (quoted in Novick, p. 241). At a Senate Labor and Health and Human Services Appropriations Subcommittee meeting in April 2003 Senator Sam Brownback of Kansas likened embryo research to Nazi research on Holocaust victims.

Conversely, the pro-choice side often argues that state control of women's bodies is the first step toward state ownership of people and ultimately toward genocide. The Holocaust thus is also used to argue against state involvement in reproductive freedom. Pro-choice advocates point out that abortion was illegal in Nazi Germany and that the state prominently expressed an interest in controlling women's reproduction through antimiscegenation and compulsory sterilization laws.

END-OF-LIFE ISSUES. Public discussions about end-of-life options, from disconnecting life supports to physician-assisted suicide, inevitably raise comparisons to the *euthanasia* campaign in World War II, especially in Germany (Kottow, Spannaus et al.). In a *Hastings Center Report* commentary, the *Village Voice* columnist Nat Hentoff compared Dan Callahan's argument in *Setting Limits* (in which Callahan argued that some categories of people, notably the elderly, should not be entitled to the same access to healthcare as others) to the Nazi policy of *lebensunwertes leben,* "life unworthy of life." Hentoff also stated that the Hastings Center's 1987 Guidelines on the Termination of Life-Sustaining Treatment and the Care of the Dying would have been welcomed by defense attorneys for Nazi doctors. Although the respondents, including Callahan, addressed some of Hentoff's arguments against Callahan's points, the responses focused predominantly on the appropriateness of the Nazi analogy. Ironically, the epithet also was hurled from the other side of the issue as Jack Kevorkian assailed doctors who were not willing to help patients die as Nazis (*New York Times*).

THE HOLOCAUST AS AN IMPEDIMENT TO PROGRESS. Some people argue that the focus on the Holocaust has become an impediment to medical progress. In a keynote speech to molecular biologists in Berlin in 2002 the Nobel laureate James D. Watson, the codiscoverer of the structure of DNA and the first director of the Human Genome Project, told his German audience that the time had come to "put Hitler behind us" and embrace the good that genetic science can do (Koenig).

Rhetorical Strategies

The uses of the Holocaust in bioethical argumentation tend to follow a number of rhetorical strategies. The Holocaust may be used comparatively to suggest that a targeted act or position is morally equivalent: "What is happening here is no different from (or no better than) what was done during the Holocaust." Others use the Holocaust as a referent for a slippery slope argument: "Actions like these, if they continue, will lead to a Holocaust." Some use the term to chastise their colleagues or adversaries: "Your actions are no different from those of the Nazis or those who stood silent in the face of the Nazis." Conversely, the Holocaust can be used to justify an action by arguing that a criticism is misplaced: "After all, this is not like the Holocaust."

Conclusion

The cautions enumerated above are not meant to suggest that there are not appropriate and thoughtful attempts to use the Holocaust in bioethical argumentation. The Holocaust stands as a signal moment in the human encounter with euthanasia, unconscionable medical experimentation, victimization of the marginalized and powerless, relentless bureaucracy, eugenic extremism, and other acts and philosophies that bioethics forgets at its peril. Clearly, the considered use of the Holocaust can illuminate and strengthen a moral position. For example, many antiabortion and anti–embryo research scholars have tried to use the Holocaust as a thoughtful and nonsensational analogy to explore issues of vulnerability and medical justification (Neuhaus).

Bioethics is most effective when it pursues reasoned moral discourse, and the use of hyperbole and rhetorical strategies that depend on shock and insult cheapens the enterprise as a whole. In such cases the Holocaust does not inform bioethical debate but instead erodes it. The lessons of the Holocaust have profound meaning for modern bioethics, and the atrocities committed must stand as a bellwether against moral recidivism. Invoking the Holocaust to score rhetorical points, however, fails as a rhetorical strategy and degrades the genuine lessons that the Holocaust offers to bioethical discourse.

HOMICIDE

• • •

Homicide has been defined as "the killing of one human being by the act, procurement, or omission of another"

(Black, p. 867). However, federal homicide statistics reflect the police classification of homicide deaths as either murder or nonnegligent manslaughter, with deaths caused by negligence, suicide, or accident excluded. Some deaths that are not included in these federal statistics may ultimately be ruled homicides by a coroner or a court. Reported statistical data derive from various sources, including the FBI's Uniform Crime Reporting (UCR) Program and the FBI's Supplementary Homicide Report (SHR). Homicide figures reported from these databases are estimates, rather than exact numbers, because: (1) the classification is based on police investigation rather than coroner findings or judicial determinations; (2) many homicides are unsolved, resulting in the omission of data related to offender, and sometimes victim, characteristics; and (3) state agencies may fail to report details relating to homicides. These omissions in the available data may result in biased conclusions. For instance, the SHR does not include details related to approximately 8 percent of the homicides reported in the UCR, so conclusions from the SHR may be biased.

Despite these limitations, it is believed that homicide is the least underreported of any serious crime in the United States. Available data underscore the increasing frequency with which homicide occurs in U.S. society. As an example, the nation's murder rate in 1997 was 6.8 per 100,000 persons, compared to a rate of 4.6 per 100,000 in 1950.

Once considered to be an issue for law enforcement only, homicide is now recognized as a major public health problem (Novello, Shosky, and Froehlke). Because of disparities in the risk of homicide across subgroups, homicide must be considered as an issue of ethical, as well as public health, concern.

Epidemiology

Homicide data for the years 1976 to 1999 indicate that, compared to whites, blacks are six times more likely to be homicide victims and eight times more likely to commit homicide. Males represent nearly 75 percent of all homicide victims and almost 90 percent of all offenders. Compared to females, males are three times more likely to be killed and eight times more likely to commit homicide. Younger individuals are also at greater risk; almost one-third of victims and nearly one-half of offenders are under the age of twenty-five (Fox and Zawitz).

Homicide among intimate partners and family members remains a major concern, despite decreases in the rates of such events. In comparison with males, females are more likely to be killed by their intimate partners (defined as current or former spouses and current or former boyfriends and girlfriends, including those of the same sex). Women in the United States are at higher risk of homicide victimization than women in any other high-income society (Hemenway, Shinoda-Tagawa, and Miller). In 1998 the deaths of almost three-quarters of all women murdered were attributable to their intimate partners (Rennison and Welchans). For the period from 1993 through 1999, intimate partners killed 32 percent of all female murder victims ages twenty to twenty-four (Rennison, 2001). Analysis of homicide data for the years 1981 through 1998 indicate that the highest rates of intimate partner homicide during these years were among black and white females in the southern and western states (Paulozzi, Saltzman, Thompson, et al.), and most female victims were killed by an unarmed partner. Additionally, homicide is a major contributor to deaths occurring during pregnancy (Dannenberg, Carter, Lawson, et al.).

Women who kill their intimate partners often do so in response to repeated batterings. These beatings may result in the development of trauma symptoms, such as anxiety and psychic numbing, as well as lowered self-esteem and the development of self-destructive coping responses to the violence. The victimization may also lead to a total loss of the woman's social self. In general, a battered woman does not attack her abuser when harm is imminent but, instead, during a hiatus in the assaults. The incidence of female-perpetrated partner homicide appears to be lower in states that have strong domestic-violence legislation and greater access to supportive services such as shelters, crisis lines, and support groups (Dutton).

Disparities also exist in the disposition of cases involving intimate partner homicide. Of the 156 wives and 256 husbands convicted in 1988 in the United States for murdering their partners, wives received prison sentences that, on average, were twenty years shorter than those received by convicted husbands, even when comparing only those husbands and wives who were not provoked prior to the homicide (Langan and Dawson).

The United States has the highest rate of childhood homicide of any industrialized nation in the world (CDC). In fact, homicide represents the leading cause of infant deaths due to injury in the United States (Overpeck, Brenner, Trumble, et al.). An estimated 37,000 children were killed in the United States between 1976 and 1994, and one-fifth of these murders were committed by a family member (Greenfield). Of all children under the age of five who were murdered from 1976 to 1999, 61 percent were killed by parents or stepparents, and an additional 29 percent were killed by other relatives or by a male acquaintance. Most of the children killed were male and most of the offenders were male (Fox and Zawitz). Children under the age of eighteen

accounted for nearly 11 percent of all murder victims in the United States in 1994, and nearly half of these children were between the ages of fifteen and seventeen. Among those killed in this age group, nearly 70 percent were killed with a handgun, while almost 20 percent were killed by another child. In addition, infants born to very young mothers have an increased risk of homicide (Overpeck, Brenner, Trumble, et al.).

The number of homicides involving adult or juvenile gang violence has increased fourfold since 1976 (Fox and Zawitz), and an increasing proportion of these homicides are now associated with firearm use. In Los Angeles County, for example, firearms were used in 94.5 percent of homicides in 1994, compared to 71.4 percent in 1979. Homicides committed with semiautomatic weapons also increased substantially during this period (Hutson, Anglin, and Kyriacou).

As of 2000, firearm use accounted for approximately 70 percent of all murders in the United States (Rennison, 2001). From 1973 to 1999, more than 80 percent of all workplace homicides were committed with a firearm (Duhart). The rate of homicides involving firearms has historically been higher in the southern states than in other regions (USDOJ, Homicide Trends). This regional variation has been attributed to both sociocultural factors and to the ease of access to firearms in the South.

Despite the increase in gun-related homicides, numerous state legislatures eased restrictions on the availability and use of firearms during the closing decades of the twentieth century, allowing citizens to carry concealed weapons even into churches and some government buildings. Public surveys indicate, however, that such increased gun-carrying actually reduces, rather than increases, public perceptions of safety (Hemenway, Azrael, and Miller).

The risk of homicide is also associated with the use of alcohol or illicit substances by the perpetrator and/or the victim immediately prior to the killing (Pernanen). Chronic alcohol use has been found to increase by up to tenfold an individual's risk of being a homicide victim (Rivara, Mueller, Somes, et al.). It is believed that the use of alcohol and illicit substances may adversely affect an individual's ability to process and interpret information correctly, thereby increasing the likelihood of miscommunication, which may lead to violence. Additionally, because alcohol use may impair an individual's judgment, intoxicated persons may be more likely to place themselves in situations that entail a high risk of violence. Chronic alcohol use may also indicate that an individual has an antisocial personality disorder, which is associated with increased rates of violence and victimization (Rivara, Mueller, Somes, et al.).

Prevention

Prevention efforts may focus on one or more of three levels. Primary prevention efforts attempt to prevent the onset of a condition—such as preventing violent behavior. These efforts often utilize a broad-based approach aimed at the general public, including messages urging the use of nonviolent means to resolve disputes and problems. Secondary prevention efforts target populations considered to be at high risk, such as individuals who have already committed some act of violence. Tertiary prevention is analogous to damage control after an event has already occurred, and most frequently consists of arrest and incarceration following the commission of a homicide.

Various primary prevention strategies have been utilized in an attempt to reduce the relatively high rates of homicide in the United States. Numerous jurisdictions have adopted *child access prevention laws,* which hold adults criminally liable for the unsafe storage of firearms in environments where children live or are present (Webster and Starnes). Such laws remain controversial, however, due to the ease with which children can obtain firearms outside of the household (Hardy). Pediatric-based counseling of parents to increase their safety-related behavior has also been recommended, but the effectiveness of this approach is questionable due to physicians' lack of time, their inability to accurately assess actual gun ownership among parents, and their perceived lack of credibility as a source of information (Hardy).

Homicide prevention efforts must also address the use of alcohol and other substances. Primary prevention efforts have included the imposition of increased excise taxes on alcohol, the use of anti-alcohol advertising and promotion, and the development of responsibility training programs for servers of alcohol (Rivara, Muller, Somes, et al.).

Secondary prevention efforts have included the counseling of individuals through court-ordered programs in an effort to intervene before violence becomes a pattern and before the violence escalates to the level of homicide. Healthcare providers are now more likely to ask female patients about domestic violence—in large part due to focused training of providers and recent accreditation requirements and legal mandates imposed on healthcare institutions. It is believed that the early identification of violence in the home, coupled with modifications in legal policy—such as the increased enforcement of laws prohibiting and punishing violence—will decrease the rate of intimate partner homicide. However, efforts also require that healthcare providers assess individuals' risk for becoming violent offenders before violence has begun, and to then refer those at high risk for appropriate intervention. Patient counseling by

primary care providers to reduce excessive alcohol use and binge drinking may also help to reduce the rate of homicide by reducing the use of alcohol (Rivara, Muller, Somes, et al.).

Secondary prevention strategies also include the issuance of civil protection orders by courts. These orders prohibit individuals who have committed an act of intimate partner violence from further abusing their victims. In general, victims are more likely to seek such orders if they are financially independent from the perpetrator, if they are no longer living with him or her, and if they have seen family members or friends threatened or abused by the perpetrator (Wolf, Holt, Kernic, et al.).

HOMOSEXUALITY

• • •

I. CLINICAL AND BEHAVIORAL ASPECTS

It is believed that 2 to 10 percent of the U.S. population is gay or lesbisan (Gadpaille). However, there is no consensus among clinicians and behavioral scientists about the definition of homosexuality (Mondimore) and there are multiple definitions of the terms *bisexual, gay,* and *lesbian* (Francoeur, Perper, and Scherzer). Researchers, for instance, often fail to distinguish between sexuality (I am gay/lesbian), sexual behavior (I have sex with men/women), and community participation (I am a member of a gay/lesbian community) (Rothblum). These three dimensions, although somewhat overlapping, are not synonymous. Additionally, individuals' self-identity may change over time and in different contexts (Rothblum), as may the meanings ascribed to these terms by society.

Historically, homosexuality has been defined by reference to a person's physical behavior. An individual's orientation was determined by his or her biological sex and by the sex of his or her sexual partners. This view focuses on behavior as determinate and assumes that (1) only two sexual orientations—homosexuality and heterosexuality—exist and (2) an individual acquires his or her sexual orientation when he or she has sex for the first time.

Additional perspectives, however, may be critical to an understanding of sexual orientation. The self-identification view posits that sexual orientation may be discordant with behavior. Accordingly, the fact that an individual self-identifies as a homosexual does not preclude the possibility of that person having sexual relations with an individual of the opposite sex. Similarly, self-identity as a heterosexual allows for the possibility of sexual intimacy with a person of the same sex. The dispositional view of sexual orientation also considers an individual's sexual desires and fantasies and the sexual behaviors in which he or she is disposed to engage in ideal circumstances.

Dimensionality of Sexual Orientation

In the past sexual orientation was understood somewhat simplistically. Sexual orientation was treated as a binary construct: An individual was either heterosexual or homosexual. However, that understanding failed to explain bisexuality. The bipolar view of sexual orientation utilized by Alfred Kinsey conceived of sexual orientation along a continuous scale, with exclusive homosexuality at one end and exclusive heterosexuality at the other. According to this view, bisexuals are individuals who (1) are strongly attracted to people of the same sex and to those of the opposite sex, (2) are moderately attracted to those of the same sex and to those of the opposite sex, or (3) are weakly attracted to those of the same sex and to those of the opposite sex. The bipolar conceptualization of sexual orientation has been criticized for being one-dimensional and characterized as being similar to seeing masculinity and femininity as the opposite ends of a scale.

Most recently clinicians and researchers have employed either a two-dimensional or a four-dimensional scale to determine sexual orientation. The two-dimensional view posits that one dimension represents the degree of an individual's attraction to individuals of the same sex whereas the second dimension represents the degree of that person's attraction to those of the opposite sex. The four-dimensional view, which considers the varying levels of complexity inherent in defining sexual orientation, focuses also on an individual's choice of a sexual object, that is, the sex and sexual orientation of the individual and of those to whom that individual is sexually attracted, such as gay men, gay women, and straight men.

Theories on the Cause of Homosexuality

Same-sex eroticism and sexual behavior often have been viewed as abnormal or maladaptive. For instance, Richard von Krafft-Ebing, a late nineteenth-century neurologist,

concluded that homosexuality represents an aberration in sexual behavior that results from the effect of worldly stress on a neuropathic disposition; thus, it constitutes a pathological condition rather than an immoral, criminal act (Mondimore). Havelock Ellis, a late nineteenth-century physician with a strong interest in anthropology, viewed homosexuality, or *sexual inversion,* as an inborn trait that reflects a permanent deviation in sexual development.

In contrast to those views, Kinsey concluded from his research that homosexuality is the product of cultural and socialization processes and therefore should not be considered criminal or the basis for the social ostracism of individuals (cited in Pomeroy). John Money, a sexologist, ultimately determined that homosexuality is a normal variation of sexual expression that results from prenatal influences interacting with environmental influences at critical unspecified periods.

A number of biological models have been developed in an attempt to explain sexual orientation and, specifically, homosexuality. The permissive model asserts that biological factors shape the brain structure on which experiences inscribe sexual orientations, whereas genetic factors constrain the period during which that experience can affect an individual's sexual orientation. The direct model attributes the responsibility for sexual orientation directly to genes, hormones, and other biological factors and their direct influence on the brain structures that underlie sexual orientation. The indirect model posits that biological factors shape an individual's temperament and/or personality, which in turn shapes the development of sexual orientation; genes may predispose a person to homosexuality in certain environments.

Proponents of biological theories of homosexuality have claimed support for their view from various findings. First, precursors of the reproductive organ systems of both sexes are present in the both male and female embryos. Second, various conditions related to sexual differentiation are thought to support the role of biology in determining sexual orientation. For instance, androgen insensitivity syndrome results from an inherited defect in the receptor molecule for testosterone; in persons with this syndrome testosterone has no effect on any of the target tissues. Individuals with this condition appear to be women and most often are attracted to men. Individuals with congenital adrenal hyperplasia experience abnormally high levels of circulating testosterone during embryonic development. As a result, genetic females develop masculinized genitalia. The condition 5-alpha-reductase deficiency results in the absence in genetic males of the enzyme required to develop external genitalia. At puberty females with this condition may experience an enlargement of apparently female organs into a penis-size organ, the secretion of testosterone, and a deepening of the voice.

Experiential theories of homosexuality encompass four major perspectives. One view focuses on the nature of an individual's early sexual experience and posits that through the process of operant conditioning an early pleasurable experience with an individual of the same sex will result in same-sex attraction. This theory has provided the basis for the seduction and first-encounter theories of homosexuality, which assert that individuals are *recruited* into a *homosexual lifestyle.* Other experientialists focus on the importance of family dynamics, theorizing that male homosexuality results from the influences of a strong mother and a distant father. This theory has served as the basis for many of society's stereotypes about the development of homosexuality and the characteristics of homosexuals and their families. Childhood gender roles are also a focus: It is believed that gender-atypical children such as girls who are "tomboys" and boys who are "sissy boys" develop into homosexuals.

Unlike these first three perspectives, experience-based developmental theory recognizes the potential role of biology and posits that biological factors code for childhood personality types and temperaments, which then are molded into gender roles. Once children develop gender roles, those who are different are seen as exotic and other. Lesbians develop from girls who fit masculine gender roles, and heterosexual women develop from girls who fit feminine gender roles. This theory is similar in many respects to the indirect biological model of homosexuality.

These biological models have proved to be controversial for a number of reasons. First, replication studies are lacking. Second, the results have significant implications for society's response to individuals who self-identify or are labeled as homosexuals. Some individuals argue that if homosexuality results from biology and does not signify a *lifestyle choice,* homosexuals cannot be considered morally depraved or criminal and consequently should receive the same legal rights and social recognition as any other identified group. Others fear that the identification of a biological basis for homosexuality ultimately will lead to attempts to correct what is perceived of as a biological *mistake.*

Only relatively recently has psychiatry declassified homosexuality per se as a mental illness by eliminating it as a category of illness in the *Diagnostic and Statistical Manual,* which guides clinicians in the diagnosis of mental disorders. However, the concept of illness has been retained through the incorporation into that text of a category for "sexual disorder not otherwise specified," which applies to individuals who experience "persistent and marked distress about sexual orientation" (American Psychiatric Association, p.

582). This definition does not recognize that the distress may result not from a person's sexual orientation but from the societal response to that orientation. Despite these changes some professionals and laypersons continue to view homosexuality as the result of an abnormal process of development and as reflective of an underlying pathology (Socarides).

The Formation of Gay Identity

Research suggests that individuals develop their sexual identity in stages. However, the specific process by which people develop sexual identity is not well understood and is subject to great variation across individuals.

Troiden (1989), who has written extensively about the process of identity formation among homosexuals, has posited that identity formation proceeds through four phases: sensitization, identity confusion, identity assumption, and commitment. Troiden observed that children may first feel a sense of "differentness." For example, boys may feel less interested in sports than do their male peers. Often this sense of differentness is experienced at an early age. Troiden has labeled these years of sensitization to one's differentness as the "sensitization stage," which generally spans the ages of six through twelve. During these years, children do not think of themselves as sexually different and the term *homosexual* has little, if any, meaning for most of them. In addition to feelings of differentness, children may become sensitized to a set of labels and attitudes inflicted on them by their peers; those labels may include terms such as *faggot, dyke,* and *queer.* An antihomosexual bias may be absorbed by children from their parents and peers, resulting in an internalized homophobia that causes extreme psychic damage during adolescence and adulthood.

It is during adolescence, generally before the age of fifteen, that children may recognize an incongruity between their sexual feelings and those reported by their peers. This stage in the process of identity formation has been labeled *identity confusion* (Cass; Troiden, 1988). The confusion often results from the conflict between an awareness of their sexual feelings toward members of their own sex and the others' assumption that they are like everyone else. A child's confusion may exacerbated by fears that he or she is not *normal* but instead is *abnormal, perverted,* or *sinful.*

As a result the child may experience cognitive dissonance, a psychological state that results when one is confronted by contradictory facts that both appear to be true. This disorienting state often is accompanied by intense fear and anxiety. The conflict may be resolved through an acceptance of one's homosexuality or a complete refusal to acknowledge one's feelings, that is, denial. Adolescents who are in denial may isolate themselves from individuals of the opposite sex or, conversely, engage in a frenzy of heterosexual dating. Denial may be accompanied by alcohol and drug use in an attempt to create distractions from these uncomfortable feelings. Some individuals may experience *identity foreclosure,* in which they use their energy to deny, avoid, or redefine homosexual thoughts and feelings in an attempt to prevent their incorporation into their identity (Cass). It is believed that most homosexuals go through a period of cognitive dissonance.

Once individuals have self-labeled as homosexuals, that is, have reached the stage of *identity assumption or acceptance* (Troiden, 1989), they must decide how to incorporate that information into other aspects of their lives. This decision may be extremely difficult because of the potential for stigmatization and rejection by their families and friends and in the workplace. Individuals may become increasingly aware of the discrepancy between their positive attitudes toward homosexuality and society's disparaging views and discriminatory treatment. In an effort to cope with this stigmatization some individuals may seek to separate themselves completely from the heterosexual world, viewing everything that is gay as "good" and everything that is not gay as "bad." This approach constitutes one variation of identity foreclosure (Cass). Others may proceed to the *commitment* phase, in which they disclose their sexual orientation to others, experience same-sex intimacy, and become involved with the homosexual community (Troiden, 1988).

A number of factors have been found to be helpful to individuals as they struggle with their identity. They include the presence of a gay or lesbian family member who has disclosed his or her own sexual orientation, the presence of a gay or lesbian role model, the support and acknowledgment of heterosexual friends, the presence of gay-positive media messages, the increasing visibility of gay issues, and open discussions in the course of receiving confidential healthcare services (Perrin).

Medical and Social Attitudes toward Homosexuals

Medical professionals have participated in widespread discrimination against individuals who self-identify as gay or lesbian. A study of 278 nursing students found that 38 percent believed that lesbians try to seduce heterosexual women and provide a negative role model for children (11%) (Eliason, Donelan, and Randall). A survey of 100 nursing educators found that 24 percent believed that lesbian behavior is wrong, 23 percent believed that lesbianism is immoral, and 15 percent felt that lesbians are perverted (Randall). Heterosexist and homophobic attitudes also have

been noted among social workers (Berkman and Zinberg) and physicians (Douglas, Kalman, and Kalman; Matthews et al.; Oriel et al.; Pauly and Goldstein). These attitudes have been found to affect the quality of the care provided (Schatz and O'Hanlan; Wise and Bowman) and may interfere with the ability of gay and lesbian parents to obtain pediatric care for their children (Perrin and Kulkin).

A number of professional organizations have attempted to dispel prejudice among their members. The American Academy of Pediatrics, for example, stated:

> Teenagers, their parents, and community organizations with which they interact may look to the pediatrician for clarification of the medical and social issues involved when the question or fact of adolescent homosexual practices arises.… The American Academy of Pediatrics recognizes the physician's responsibility to provide healthcare for homosexual adolescents and for those young people struggling with the problems of sexual expression. (pp. 249–250)

Various other changes reflect an increasing acceptance of homosexuals, including the adoption of antidiscrimination provisions by many state and local governments, the availability of healthcare and other benefits to partners of gay and lesbian employees, and the ability of gay and lesbian couples to adopt children (Cain). However, there also has been an escalation in the number of hate crimes reported. National attention most recently was focused on antigay sentiment as a result of the 1998 murder of Matthew Shepard in Wyoming (Loffreda).

Ethical Issues in Psychiatric and Psychological Care

Ethical issues arising in the context of psychiatric and psychological care provided to homosexual patients are similar, for the most part, to issues that arise in the context of providing care to individuals who are heterosexual. Ethical issues related to the "conversion" of homosexuals to heterosexuality arise only for those who continue to believe that homosexuality is abnormal or an illness. There is no evidence that therapy will result in long-term change in the sexual orientation of adults (Coleman). Although parents may place their children in therapy to ensure that they are or will become heterosexual, evidence indicates that such experiences may be psychologically injurious (Isay).

Nevertheless, some psychoanalysts believe that attempts to change an individual's sexual orientation are ethical as long as the individual wants that change (Nicolosi; Socarides). Significantly, Gerald C. Davidson (pp. 97–98), one of the original pioneers of conversion therapy, ultimately concluded:

> Change of orientation therapy programs should be eliminated. Their availability only confirms professional and societal biases against homosexuality, despite seemingly progressive rhetoric about its normalcy. Forsaking the reorientation option will encourage therapists to examine the life problems of some homosexuals, rather than focusing on the so-called problem of homosexuality.
>
> It is critical that health professionals create an atmosphere in which their patient can openly discuss issues related to sexuality and sexual behavior. As with heterosexual patients, the focus should be on the patient's sexual behavior, not his or her sexual orientation. (quoted in Perrin)

Additional research is needed to address many unresolved issues. Physicians and therapists may be called on to offer their professional opinions in cases involving adoption by gay or lesbian parents. There is no evidence of mental health problems among children raised by lesbian mothers in the absence of a biological father. However, a related but relatively unexplored issue is the extent to which children may be especially vulnerable to societal stressors as a result of the societal bias against homosexuality.

Further research is needed to examine whether the sexual orientation of a clinician should be a factor in the selection of a healthcare provider, whether a provider should disclose his or her sexual orientation during the therapeutic process, and what effect the disclosure of the sexual orientation of a provider may have on the therapeutic process and its outcome.

II. ETHICAL ISSUES

The practice of medicine involves a body of knowledge, a body of practitioners, and the people who seek healthcare services. Homosexuality is of moral interest to medicine in all these areas. The term *homosexuality* was coined in 1869 by Karoly Maria Benkert to refer to same-sex eroticism, and it has prevailed over other proposed names, such as sodomy, contrary sexual feeling, inversion, and Uranism (Kennedy). To be sure, same-sex eroticism predates contemporary terminology and has a long—if contested—cultural history. The relationship between medicine and homosexuality has reflected both cultural prejudices as well as scientific advances.

History and Prevalence

In ancient Greek and Roman cultures, same-sex interactions were part of the cultural background, notwithstanding critics in those very societies. Educational relations among the Greek aristocracy took the form of mentoring relationships between older men and adolescent males, and schools for women sometimes followed this model (Marrou). It is not surprising that intimate mentoring relationships would sometimes become sexual. Roman civilization also had its share of same-sex eroticism, with some notorious emperors having harems of male lovers at their disposal (Gibbon). The

Emperor Hadrian was so distraught after the death of a beloved youth, Antinous, that he deified him, erected statues of him through the empire, and founded a city in his name (Birley).

In later times, the social and religious circumstances of medieval Europe worked to limit the visibility of homosexuality, but subcultures and literary and artistic expressions of same-sex love were far from unknown even in ecclesiastical communities (Boswell). Homosexuality has expressed itself elsewhere around the globe, as well, including Africa, China, and among Native American cultures.

In ways without precedent in human history, a same-sex culture has emerged in the large contemporary cities of the developed world and, it is a social force in communication, entertainment, business and commerce, and politics. Men and women who acknowledge their homosexuality hold prominent and influential social positions, as do men and women who choose not to disclose their homosexuality. The social visibility of homosexuality has not dispelled all moral and religious condemnation. In less developed parts of the world, homosexuality is sometimes far less visible but not altogether absent.

The extent of homosexuality in a given human society is difficult to estimate, for a number of reasons. Studies of sexual behavior face certain methodological problems, including adequate study samples and reluctance to discuss sex freely. Several ambitious studies have nevertheless tried to estimate the extent of homosexuality among men and women in the United States. In the mid–twentieth century, one Kinsey study of approximately 6,000 men showed that about 4 percent of them behaved exclusively as homosexuals after adolescence, and that 37 percent of men overall had some sexual experience with another man to the point of orgasm at some point during their lives (Kinsey). Another study showed that 1.32 to 2 percent of approximately 6,000 women behaved exclusively as homosexuals after adolescence, and that 13 percent of the women overall had had sexual experience with another woman to the point of orgasm at some point during their lives (Kinsey). At the end of the century, Laumann and colleagues also found that many people engage in homosexuality at some point. They found that 2.8 percent of their 1,749 male subjects and 1.4 percent of their females subjects claimed a homosexual identity (Laumann et al.).

Taken together, these studies show that many adolescents, and adult men and women, have same-sex fantasies and desires and engage in same-sex behavior. That said, there is often a fluidity to human sexuality that does not allow any easy division of humanity into homosexuals and heterosexuals, even if most people come to have entrenched sexual interests in males or females alone. This fluidity sometimes stands in the way of precise definitions of homosexuality, and of scientific accounts of why people behave a certain way.

Scientific Study

For most of human history, the origins of homosexuality did not elicit scientific interest. Neither was homosexuality treated as a pathological state. Instead, homosexuality was evaluated in moral and religious terms, and it was often condemned. In nineteenth-century Europe, however, many researchers and physicians began to study homosexuality in a systematic way and treat it as pathological. Describing homosexuality as a disease or disorder laid the foundations for discovering its causes and for developing treatments. For a variety of reasons, these researchers were often more interested in the origins and treatment of male homosexuality than female homosexuality. This emphasis may have resulted from greater social visibility of male homosexuality and a bias toward the selection of male subjects in medicine.

Many studies worked to show that homosexuality represented a kind of degenerate or defective human biology (Kraft-Ebing). Locating the origins of homosexuality in biology did not, however, always impose a pathological interpretation. For example, the German sex researcher Karl Heinrich Ulrichs (1825–1895) argued that homosexual men and women represented a *third sex,* and he offered an elaborate account of how the biological natures of men and women were blended in this sexual variation (Ulrichs). This view led Ulrichs to argue that homosexual men and women should not be punished by the law or mistreated by medicine for acting according to their biological natures (Hirschfeld).

Biology was only one field of study, of course, and not all theorists held that biology dictated the nature of one's sexual interests. Many psychologists looked to experiences in development for the factors that determined the nature and scope of homosexuality in men and women (Ellis). By contrast, the father of psychoanalysis, Sigmund Freud (1856–1939), drew no sharp distinctions between biology and psychology. He looked rather to an interplay of psychology and biology, believing that some people developed homosexually for psychological reasons, while biology played a more decisive role in the sexual development of others (Freud, 1953). In any case, Freud did not think that homosexuality was inherently pathological, though he did not think it represented full sexual maturity.

In the United States, organized psychiatry in the twentieth century first affirmed, and later repudiated, the view that homosexuality was pathological (Bayer). In 1952 the

American Psychiatric Association (APA) described its categories of disease for the first time, and it labeled homosexuality as a "sociopathic personality disorder" (APA, 1952). A 1968 revision of this classification described homosexuality as a "personality disorder," and in 1973 the APA formally abandoned the view that homosexuality was pathological. Yet another revision, in 1980, led the APA to identify homosexuality as an "ego-dystonic disorder," meaning that it could be treated as a disorder if an individual suffered from it. There is no specific mention of homosexuality in the most recent versions of the APA diagnostic nomenclature, but the APA does recognize "sexual orientation distress," which involves persistent and marked distress about sexual orientation (APA, 1994). However, sexual orientation distress would apply to all unwanted and distressing orientations, not just homosexuality. In 1981 the World Health Organization removed homosexuality from its list of diseases. Despite this sea change in the views of the medical profession generally, some physicians and psychologists still maintain that homosexuality is a serious disorder.

Even after the APA depathologized homosexuality, debates about the relationship of homosexuality to health, disease, and illness continued. Some commentators in bioethics tried to describe health and disease in *naturalist,* or objective, terms that transcended cultural and social variation. These commentators described disease in terms of impediments to the central species functions of survival and reproduction. Heart dysfunction, for example, poses a threat to individual survival no matter the culture in which it occurs. Other commentators were not persuaded that categories of disease and health could be identified apart from moral evaluations about the worth and merit of particular states. For these *normativist* commentators, human moral evaluations always played a role in determining how a given society defined its states of disease and health (Engelhardt). From either the naturalist or normativist perspectives, it is hard to make the case that homosexuality is necessarily pathological.

Arguing from a naturalist perspective, the philosopher Christopher Boorse has maintained that homosexuality can be treated as a disease because of its interference with reproduction—whatever else it is, homosexuality is sterile (Boorse). In fact, however, homosexuality does not rule out having children, and some cultures manage to accommodate the marriage and parenting of people whose sexuality is primarily homosexual.

It is also doubtful that homosexuality is always a threat to species survival. Sociobiologists have hypothesized that homosexuality might even confer survival advantages to groups, since homosexual men and women may play roles in a society that offset any reduced number of children they might have (Ruse). As to their own survival, homosexual men and women may face individual health risks that others do not, but these risks may be tied to social circumstance rather than to homosexuality itself. For example, even if homosexual men face increased risks of disease and death, those risks are contingent, in the sense that successful treatments and vaccines could significantly dispel the danger.

As for normativist evaluations, it is clear that many men and women embrace their homosexuality without complication, and many cultures have also accommodated those people in one way or another. It is therefore hard to argue that—all other things being equal—homosexuality must lead to disorder and suffering. This is not to deny that some people and some cultures may disapprove of homosexuality, but the variance of response seems to show that it is not homosexuality per se, but how it is valued and treated that sometimes provokes its designation as disease.

For most of human history, medicine did not think of homosexuality in terms of disease. As both naturalist and normativist approaches show, what counts as disease—and what therefore deserves biomedical study and treatment—very much depends on one's theoretical starting points.

More recent commentary has challenged not the roles of health and disease in the study of homosexuality, but the very idea that homosexuality has root causes that science can discover. Indeed, the very fluidity of sexuality—both in individuals and in the sexual roles of various cultures—leads some commentators to maintain that sexual orientations are socially constructed. In this view, there are no homosexuals or heterosexuals in the sense that these are distinct kinds of people (Halperin). It would therefore be a mistake to look for genetic or hormonal causes of sexual orientation, just as it would be a mistake to study the biology of human beings in order to learn why some people are baseball fans and some people are not. Circumstance and society shape baseball fans, not human nature, and some commentators, known as *social constructionists,* hold the same view of sexual orientation.

In contrast, *essentialists* argue that human beings have sexual orientations by reason of their given nature, and that sexual orientation is likely rooted in biology. In other words, people are of *natural kinds* in regard to their sexual nature, and there are homosexuals and heterosexuals in the same way that there are elm trees and maple trees or people with blue eyes and people with brown eyes. From this perspective, sexual orientation amounts to an essential trait, and people express sexuality according to their natural kind (Stein). To essentialists, it is not a mistake to search out the root causes that distinguish people by sexual orientation.

The scientific study of fantasies, desires, and behaviors does not commit social-science researchers to either social

constructionism or essentialism. It is possible to study many aspects of sexual psychology and behavior whether sexual orientation is rooted in nature or is simply a reflection of habits and patterns that people acquire in the course of their social development. However, the debate between constructionism and essentialism does have important implications for the causal study of sexual interests. It would be a mistake to look for the root biological causes of sexual interest where they do not exist.There is no well-validated account of how human beings come to have the entrenched sexual interests they have, though it is clear that genetics, anatomy, hormones, and psychological history all play a role. So it is not unscientific to ask why homosexuality comes to the fore in some people, why heterosexuality comes to the fore in others, and why others blend their sexual interests. There may well be genes or neurological features that dispose some people to the sexual interests they have. To be sure, there may be dubious motives behind some researchers' quest to understand the pathways of sexual development, but it is not unscientific to investigate the origins and determinants of sexual orientation.

The origins of sexuality—and homosexuality in particular—have attracted a good deal of scientific interest. Researchers across the life sciences have looked to see whether homosexual men and women have traits in body or mind that others do not have, and to learn whether those traits are causally connected to their sexual interests. Researchers have looked at body shape, the nervous system, hormones, genetics, and so on to discern the influences behind sexual orientation. They have also looked at psychological and behavioral differences, including the ability to whistle, the preference for certain colors, and relationships with family members (LeVay, 1996). There has been no shortage of studies along these lines, and contemporary researchers have continued to add to this domain of research.

In 1991 the neuroanatomist Simon LeVay published a report showing that some brain structures in homosexual men are statistically smaller than the same structures in heterosexual men. But because the size of these structures does not correspond exactly with sexual orientation, this study could not establish any definitive link between neuroanatomy and sexual interests. In 1993 the geneticist Dean Hamer and colleagues published a study showing that homosexual men are more likely than others to have male homosexual relatives, and the pattern of distribution of these male homosexual relatives suggests a genetic inheritance passed through mothers. The study also showed that male homosexual brothers are more likely to share a genetic region in common than nonhomosexual brothers, which also suggests there is a genetic contribution to sexual orientation. Again, however, because this shared genetic region does not correspond exactly with sexual orientation, these patterns do not prove that there is a "gay gene."

Both the LeVay and Hamer studies are preliminary and suggestive, but they are not definitive. Some commentators have nevertheless interpreted these studies as showing that homosexuality is *natural,* in the sense that there is a describable biology behind it (LeVay, 1993). These commentators think scientific study will protect homosexuality from social condemnation by confirming it as part of human biological nature. Others fear that these studies will revive theories that homosexuality is pathological (Bersani).

Where there is scientific uncertainty, there will be speculation and disagreement. For this reason, many analysts turn to ethics rather than science as a guide to the meaning and significance of homosexuality. Ethical analysis of homosexuality has a far longer history than its scientific study, and it will continue to have a role as the findings of science unfold.

Ethical and Legal Evaluation

Ethical theories try to describe an overarching view of what is good for human beings and to describe ways of distinguishing among states, choices, and behaviors that contribute to—or at least do not detract from—that overarching good. Ethical theories vary in their interpretations of homosexuality.

PREMODERN ETHICAL THEORIES. In ancient Greece, there were disagreements among intellectuals about erotic interactions between males. According to his chroniclers, Socrates (470–399 B.C.E.) experienced attraction toward other males, but he saw it as a means to achieve spiritual wisdom rather than physical gratification. Plato's (427–347 B.C.E.) views modulated over his long lifetime—from prudential accommodation of the spiritual aspects of homosexuality to more or less outright condemnation of this sexuality as being contrary to nature (Dover). His sympathetic references to erotic attraction between adult and adolescent males do not undercut his more fully considered view. Aristotle (384–322 B.C.E.) had less to say about homosexuality, though he also disapproved, describing homosexuality, in his *Nicomachean Ethics,* as a pleasure of those with bad natures.

In Medieval Europe, it was Thomas Aquinas (1225–1274) who—from a Catholic background—offered the next major treatment of homosexuality, calling it the most sinful species of lust. He did so in the context of *natural law*—a law defined in terms of the goals said to be inherent in human life. In his *Summa Theologiae,* he describes homosexuality as a violation of animal nature and of the

order of sexual acts generally. The historian John Boswell has criticized this view by arguing that bodies and body parts have multiple purposes, and that the use of human genitals is meaningful only in sexual acts capable of begetting children. It is also the case that that there are analogues to homosexuality in other animals (Bagemihl), though even if there were not, it is unclear why animal behavior should be taken as a guide for human beings capable of reasoned evaluations of their choices.

MODERN ETHICAL THEORIES. The German philosopher Immanuel Kant (1724–1804) had a number of things to say about homosexuality, though he found doing so distasteful. Kant defended the categorical imperative as the central guide to human action. There are various formulations of the categorical imperative. What they share in common is the counsel to abide by rules that one would wish to see function as universal law. To use a negative example of how this would apply, one should not like because one would not wish to live in a world where lying was the universal norm. To use a positive example, one should be charitable because one could possibly want charity from others in the future. Kant argued that homosexuality was wrong because it could not function as a universally accepted practice. Applied to everyone, the sterility of homosexuality would put an end to the birth of children. Kant also found same-sex erotic behavior especially degrading to the parties involved.

By way of response to the Kantian view, it should be noted that it is sometimes difficult to see how precisely, or how broadly or narrowly, a moral maxim should be drawn. For example, it might be possible to frame a maxim of behavior this way: if—and only if—people find themselves sexually attracted to their own sex, then they should act accordingly, but not otherwise. In this way, the future of the human race would be secure and people would not have to act contrary to their actual sexual interests. And, of course, some heterosexual acts are just as disrespectful of sexual partners as homosexual acts—selfish sexual gratification is not the province of one sexual orientation alone.

In striking contrast to Kant, the British utilitarian philosopher Jeremy Bentham (1748–1832) came to almost the opposite conclusion about the morality of homosexuality. In works that were not published in his lifetime, he defended homosexuality for those inclined to it, saying it gives them pleasure and leads to happiness. In keeping with his utilitarian view that actions should be judged in terms of their capacity to contribute to human happiness through pleasure, Bentham thought it undeniable that homosexuality was one way to human pleasure. For some people, therefore, the pursuit of same-sex relations would be a positive good. Bentham was not especially worried that social accommodation of homosexuality might lead to more homosexuality, for if there is nothing wrong with homosexuality (for those interested in it), then increasing the amount of homosexuality in a society is not wrong either. He was convinced, too, that the forces of heterosexual lust were stronger than any threat to the birth rate that homosexuality might pose. In a strict sense, from this point of view, homosexual orientation and behavior are not of inherent moral interest.

Another utilitarian philosopher, John Stuart Mill (1806–1873), also believed that actions were moral to the extent that they promoted happiness. Given that adults are ordinarily the best judges of what makes them happy, Mill wanted to limit social interference with individual pursuits. He articulated his "liberty principle" in order to define a sphere of behavior that did not warrant social action. To Mill, social interference with the actions of others is justified only to prevent harm to others. Harm to one's own self is not a sufficient reason for interfering with an adult's beliefs and choices. With this conceptual background, it is possible to articulate a formidable boundary against social interference with homosexuality. Unless their behavior harms others—as in rape, for example—men and women should be able to pursue same-sex partners without social interference.

Alan H. Goldman, a commentator on sexual ethics, has argued that there are no moral rules specific to sexuality alone. He argues that the moral rules or precepts that apply across the range of human relations are the rules that should apply to sexuality as well. This means that the same rules that apply in heterosexual relationships should apply in others as well: if sexual fidelity is promised, it should be honored; there should be no deception or mistreatment; and so on. In one sense it is this very attempt to make social relations consistent across sexual orientations that has led to ambitious attempts to reform laws that criminalize homosexuality.

DEVELOPMENTS IN THE LAW. The ethical standards reflected in laws around the world are widely variable. In some nations, sex between males or between females is strictly forbidden and severely punished. In others, homosexuality is illegal as a matter of formal statutes but is not punished in practice. In other countries, homosexuality is not an object of legal interest in itself, only insofar as sexual relations may be involuntary or public. In 1957, in England, the Committee on Homosexual Offenses and Prostitution issued a report, commonly known as the *Wolfenden Report,* that recommended that the United Kingdom decriminalize consensual "sodomy" among adults. In coming to this conclusion, it drew heavily on notions of privacy and

protection from social intrusion. In this regard, the report shared parallels with the Napoleonic Code, put in place in 1804. In that code there was no explicit mention of homosexuality, only of criminalization of involuntary and public sexual crimes, regardless of the sex of the parties involved. Lord Patrick Devlin argued against the conclusions of the *Wolfenden Report* by saying that society's moral revulsion toward homosexuality should count as a valid reason for legal restrictions. Devlin argued that a society requires shared moral values and political beliefs and that even acts that occur in private threaten the existence of society, and are not beyond the reach of social suppression. Nevertheless, Britain did decriminalize homosexuality among adults.

In 1986 the U.S. Supreme Court, in *Bowers v. Hardwick,* affirmed the right of states to enact laws prohibiting homosexuality among adults. In the case of *Romer v. Evans* (1996), however, the Court maintained that states could not deprive homosexual men and women of particular rights. As of this writing, the Court has heard a sodomy case which may undercut the conclusions of *Bowers v. Hardwick.*

In general, there is a trend in the United States to decriminalize homosexuality. In many other jurisdictions around the world, the legal battles have shifted away from the simple question of whether sexual relations between men and between women should be criminal or not. Newer legal battles have engaged such topics as protection from discrimination in employment, housing, and public accommodations, and many jurisdictions are debating broader civic rights for same-sex couples. For example, the Netherlands and Belgium have recognized same-sex marriage. In the United States, the state of Vermont recognizes a *civil union* that parallels marriage. Other issues advancing on the legal frontier for homosexual men and women are the right to custody of children and the right to serve openly in the military.

The Uses of Sexual-Orientation Science

Despite social and legal acceptance in many quarters, the place of homosexual men, women, and adolescents is not secure in all societies. Many societies, for example, lack basic protections for homosexual men and women. For this reason, some observers are wary of going forward with sexual-orientation research. Some observers believe that sexual-orientation science is not valuable (Suppe), while others believe it will be harmful to homosexual men and women (Bersani). Such research might be used to "treat" homosexuality in adults, or even to control the sexual orientation of children, sometimes through prenatal interventions. Each of these uses raises moral concerns.

SEXUAL-ORIENTATION THERAPY. As a matter of ethics, sexual-reorientation therapies should be guided by the standards of informed consent that guide clinical treatmentin other areas. At the very least, patients should understand and freely consent to treatment, appreciate the risks and benefits of treatment, and be advised about alternatives to treatment. These conditions have not always been met in sexual orientation therapy, especially involuntary treatment imposed by family and the state. As a matter of science, a broad array of techniques has been used with men and women to redirect sexual orientation from homosexuality to heterosexuality. Techniques used toward this end have generally reflected prevailing treatment methods of the time. Drug and hormone treatment, behavioral therapy, surgery, and psychotherapies have all been deployed at one time or another (Murphy, 1992). While some of this therapy has gone forward with professional integrity, there has also been involuntary treatment, gruesome castrations in the Nazi camps, and chemical and electrical aversive therapies that can only be called abusive.

While there are some reports in the scientific literature that describe successful re-orientations (Spitzer), it is unclear that sexual orientation therapies consistently deliver what they promise, especially when applied to randomly selected groups of people. Reports of success in reorientation come most typically from psychoanalysts, behavior therapists, and religious programs. These reports have been criticized for problems related to method, sample size, the lack of long-term assessment, a focus on behavior change (instead of psychic change), and the lack of control groups.

For therapists and their patients who still maintain that homosexuality is pathological, research that led to truly effective therapy would be all to the good. Other therapists do not maintain that homosexuality is pathological, but still believe that some treatments are justified in the name of respecting wishes about unwanted traits (Schwartz and Masters). For these therapists, research into treatments is also highly desirable, but it would remain a matter of debate whether the extinguishing of unwanted traits is a legitimate objective for medicine. Some commentators have argued that sexual-orientation therapy is immoral because it contributes to social prejudice against gay men and lesbians. For these commentators, further investigation into causes and therapies for sexual orientation is objectionable. The psychologist Gerald C. Davison has held that the mere availability of such therapy encourages its use, thereby perpetuating oppressive views about homosexuality. In contrast, the philosopher Frederick Suppe has pointed out that such an argument is persuasive only if the therapy: (1) presupposes that homosexuality is inherently inferior to heterosexuality,

and (2) is socially influential in perpetuating injustice. It is not always clear that therapy programs meet these two conditions. It can be said, however, that pursuit of sexual orientation therapy may be an artifact of social injustice rather than an injustice in itself. In other words, people might look to therapy as a remedy for mistreatment in society at large.

THERAPY WITH ADOLESCENTS. Sexual orientation therapy is not confined to adults. In the past, parents have turned to punishment, moral exhortation, religious counsel, reform school, and even electroshock therapy in order to bring their children to heterosexuality. Both ethics and the law converge in the view that the people with the strongest immediate interest in protecting children are their parents. For this reason, parents are ordinarily entrusted to make even profoundly life-affecting decisions about their children. However, if parents' choices interfere with their children's well-being, then those children are entitled to protection. For example, the state can intervene when parents endanger children, deprive them of essential food and medical treatment, interfere with their education, and so on. Should ethics and the law recognize the right of parents to choose the sexual orientation of their children? The answer is "it depends."

To the extent that children do not have an interest in one sexual orientation over another, it would seem that parents should be able to plot the course of their children's lives, provided their actions are not harmful. For example, if parents wanted to ensure that they have only heterosexual boys, they might encourage their young boys to act in ways that they think (rightly or wrongly) will ensure that sexual orientation. They could therefore encourage boys to play vigorous contact sports and socialize with other boys. Unless it is hectoring and abusive, this encouragement does not by itself interfere with the child's well-being.

However, as they mature, children develop some degree of moral right to protection from parents' choices, even if those choices are well-meaning. Both ethics and the law recognize, for example, the rights of maturing adolescents to enroll in clinical trials and to refuse life-sustaining treatment when they are profoundly ill. That is, maturing adolescents are entitled to act in ways that protect their interests, even if their parents profoundly disagree with the choices made. This model can be extended to sexual orientation therapy as well: if maturing adolescents are profoundly unhappy about their emerging sexual interests, they might well accede to their parents' wishes and seek therapy. If, however, adolescents are not unhappy about their emerging sexual identity, it is unclear, as a matter of morality, why their parents' choice ought to prevail, especially if therapies or treatments carry risks that outweigh the possible gains of success.

PRENATAL INTERVENTIONS. Some commentators worry that research programs aimed at identifying the origins of homosexuality may lead to the elimination of homosexual progeny through prenatal interventions. They worry that markers for sexual orientation might be discovered that could predict a child's eventual sexual orientation. If this were possible, some parents might want to use various interventions to control the sexual interests of their children. This might be done—hypothetically speaking—through gamete selection, embryo biopsy, genetic manipulations, fetal treatments, or even abortion. This discussion is speculative, but it does illuminate key moral issues in parents' choices about their children.

In the United States, women are entitled, as a matter of ethics and law, to the prenatal information that bears on their choice whether to have children or not, as well as information related to fetal well being. They are also entitled to make abortion decisions for reasons of their own. The question under debate is whether this general approach is appropriate for choices about the sexual orientation of children. On one level, it would be idiosyncratic to forbid the use of prenatal diagnostics or even abortion when there are no legal barriers to doing so in regard to other traits of children (LeVay, 1996; Murphy, 1999). Some commentators worry, however, that the use of prenatal interventions could jeopardize the status and well-being of homosexual men and women in general (Stein). If used widely, these interventions could reduce the total number of homosexual men and women in the world, making group self-protection more difficult. By the same token, legal interference with parents' choices about the use of prenatal diagnostics could lead to circumstances in which homosexual children are born into families that do not want them. Parents could also use these techniques as a way of having homosexual children, and some parents no doubt would choose this option.

These considerations weigh against a moral conclusion that society should forbid prenatal interventions in the name of protecting homosexual men and women in general. In order to reach that conclusion it would have to be shown that sexual minorities could only be protected by such intrusive measures, and that these measures are ultimately more important than allowing parents to have children according to their own best judgments. It is to be remembered that this discussion is hypothetical, and there are no known means for ensuring the sexual orientation of a child.

Beyond Diagnosis and Treatment

Since the 1800s, the debate about the pathology of homosexuality has occupied center stage in the relationship between homosexuality and medicine. That focus notwithstanding, the vast majority of homosexual men and women never wanted, sought, or received therapy for their sexual orientation. Each one of these men and women has, however, other healthcare needs. At the very least, males who have sex with males and females who have sex with females have specific risks to their health, and this is especially true for homosexual youth who seem to be at increased risk of suicide (Gibson). Against this background, it is important to ask whether health professionals have the knowledge and communication skills necessary to meet the health needs of this group. Certainly some health professionals and academic commentators have paid attention to the healthcare needs of homosexual people (Solarz). However, medicine's own history in regard to homosexuality can stand in the way of appropriate degrees of study and effective healthcare.

No matter what their sexual interests, patients already face a problematic relationship with healthcare: medicine is distant from them by reason of its complex and intricate knowledge, cultural expectations about the role of the physician, and professional commitments within medicine (Engelhardt, p. 291). People with same-sex interests are perhaps at a further disadvantage because they cannot uniformly expect to encounter healthcare practitioners who are conversant with the specific health risks of homosexual men and women and who are comfortable with the nature of their sexual lives.

Indeed, some practitioners may believe that health risks associated with homosexuality are *deserved* and therefore require less social attention than other problems. In the 1980s, for example, some commentators argued that the AIDS epidemic was a divine punishment for immoral homosexuality. This view is hard to credit for a variety of reasons. In the first place, the view is suspect because the "punishment" is applied inconsistently. Some men who have sex with other men have developed AIDS, but most others—across history and even in the present—have not. Further, why should homosexuality receive this sort of punishment while other moral transgressions go unpunished? How is the punishment proportionate in its effect, and why should consensual behavior be punished so severely?

Rather than tie AIDS to divine punishment, some commentators pointed to social injustice as a root cause of the epidemic. These commentators argue that the sexual behavior of many homosexual men is affected by social prejudice. In other words, some men take sexual risks as *adverse preferences,* something they would not do if they had the same array of options in relationships and social status as others. Because they do not, they make poorer choices. According to these commentators, society has an obligation to make amends to those whose disease can be traced back to social inequality (Mohr).

Are there social factors that stand in the way of the health of homosexual men, women, and adolescents? One factor might be obstacles to the formation of long-term relationships and families that are especially important when it comes to healthcare and caregiving. Some homosexual people have no access to health insurance through their partner's employment, as married partners have, and others have no presumptive right of inheritance or decision making at the bedside of a partner who cannot direct his or her medical choices. The law does allow homosexual men and women to make health decisions for their partners who lose the ability to do so, but this recognition ordinarily requires advance directives such as a power-of-attorney for healthcare. When such arrangements are not put in place, some partners are excluded from decision making. Some healthcare services are not available to homosexual people. Some commentators think infertility clinics should not offer services to people in same-sex relationships, and some clinics do exactly that (Ford). For reasons like these, it is certainly worth asking whether deficits in the health and well-being of homosexual men and women are rooted in social injustice, with injustice minimally defined as the social failure to treat like cases alike.

Patients are not the only people in healthcare relationships, of course, and it is important to note that many gay and lesbian health professionals—physicians, nurses, and others—believe that certain social attitudes work against their full acceptance in the medical community. For example, some residency directors do not wish to have homosexuals in their graduate training programs. These hurdles may not have the same force everywhere and for everyone, but they nevertheless work against the equal standing of gay, lesbian, and bisexual healthcare practitioners (Potter).

The debate about the ethics of homosexuality has extended into discussions about cloned human beings. Some commentators have argued broadly that no one—single people, coupled partners, or married people—ought to use cloning to have children (President's Council on Bioethics). Others open the door to the use of cloning by some infertile couples and would allow same-sex female couples to use cloning technologies if they become safe and effective, since these couples have fewer options available to them. Still other commentators have argued that if cloning technology is safe and effective, there is no obvious reason why all same-sex couples should not have access to it. In

cloning, as in other aspects of social and moral life, unwritten ethical rules and social opinion often guide the application of biomedical technologies and the distribution of healthcare benefits. When it comes to homosexuality and healthcare, it is often these unwritten rules of social opinion that are decisive and most in need of analysis.

III. RELIGIOUS PERSPECTIVES

Homosexuality is one of the most contentious issues of contemporary times, though important scholarship has indicated that it was not always so. This article will trace Western religious perspectives on homosexuality in Judaism, Roman Catholicism, and Protestantism from Greco-Roman times to the twenty-first century, as well as summarize homosexuality's position in Islam.

Pre-Christian Greece and Rome

In the Greco-Roman ancient world, same-sex relationships were parts of the warp and woof of civilization, though there is no evidence that the word *homosexuality* existed in either Greek or Latin. However, same-sex unions paralleling heterosexual marriage appear to have existed from ancient times through the Middle Ages (Boswell, 1994). Both Jonathan Ned Katz and John Boswell argue that *homosexuality* is a nineteenth-century invention. Anne Zachary reports that "the term, 'homosexuality,' was first coined as recently as 1869 by Benkert."

Scholars have long known that in ancient Greece, adult male citizens engaged in pederasty (sex between men and boys), a practice that was a thoroughly acceptable part of Greek social and cultural anthropology. It was common for adult male citizens (not slaves) to initiate young boys into the rituals of manhood, which included sexual partnering. This same practice was not followed in ancient Rome, though same-sex relationships did exist there.

In the Mediterranean world, social stratification was commonplace and included rigid demarcations between free men and slaves, as well as between adult males and adult free women. Bernadette Brooten has argued that attitudes toward same-sex relationships between women in the ancient world ought to be viewed within the context of attitudes towards women in general (1996). Since gender stratification undergirded the Mediterranean worldview, the ancients commonly regarded women as inferior to males, and they held derivative positions by virtue of their relationships to their husbands and fathers. Such a realization is important in understanding the place of same-sex relations within the Greco-Roman context.

In Greek and Roman anthropology, human nature was bifurcated—either active or passive. Under this view, males were thought to possess an active nature and women a passive nature. In terms of sexuality, the ancients recognized a fluidity that extended to any sexual expression of the male nature. Sexual expression would have taken place between "one active and one passive partner, regardless of gender…." (Brooten, 1996, p. 2). Some scholars point to social condemnation of the penetrated male because he was thought to violate the male *nature* by assuming a role fitted for women. The male penetrator did not appear to be similarly reviled, since he was acting in accord with man's *active nature.*

Within the context of this worldview, sex between two women simply had no place in the social and gender hierarchy of the ancient world. However, the ancients may have been less condemnatory of the partner who was penetrated as she was at least behaving according to nature (*kata physin,* in Greek). Both Roman and Greek sources indicate a knowledge of female homoeroticism: *frictrix/fricatrix* and *tribas/tribades* in Latin, for women who "rubbed" other women, as well as the Greek words, *tribas* and *Lesbia.* Although ancient authors were certainly aware of female homoerotic relationships, it remains unclear whether this was regarded as a matter of particular concern since it was out of the bounds of gender hierarchy on which the ancient world was based.

Was there an anti-homosexual attitude in ancient Greece and Rome? The question is itself reflective of a twenty-first-century bias. It has been established that the term was

unknown to the ancients, and scholars such as Brooten (1996) argue that what the ancients condemned was the transgression of rigid gender hierarchies (the active/passive distinction), rather than *homosexuality.* Boswell (1994) argues that same-sex relationships were not condemned, though he did not apply a gender analysis to his research. R. T. France, an Evangelical scholar, holds that "Homosexual partnerships, whether pederastic or between adults, are accepted without comment, and described with appreciation, across a wide range of Greek literature" (France, p. 248).

Some scholars argue that a bias against same-sex relations did exist, though most write chiefly of male-male relations. Ward, for example, argues that such a bias can be found in Plato (*The Timaeus,* and *Laws*), as well as in Philo, a first-century C.E. Hellenistic Jewish philosopher, and in the *Sentences of Pseudo-Phocylides,* contemporary with Philo (Ward). The bias articulated in these sources, according to Roy Bowen Ward, is one of anti-hedonism and pro-procreationism. In this view, homoeroticism in the Greco-Roman world was seen to be *para physin* (against nature) because it is hedonistic behavior that cannot lead to procreation.

Biblical Issues

By far the most contentious terrain in the battle over homosexuality and religion is that of the Bible; this is particularly so for Christians. Genesis 19: 1–11 and Judges 19: 22–30 each contain a reference to a similar story in which God punishes ancient Israel for its behavior. Exactly what *kind* of behavior is the hermeneutical issue for biblical scholars. Theological conservatives tend to interpret Genesis 19 and Judges 19 as stories of God's condemnation for attempted homosexual rape, while more liberal exegetes have taken the position that the violations condemned are violations against the ancient code of hospitality so central in the Biblical world. Feminist biblical scholars have pointed to the misogyny of Judges 19 as an interpretive key.

There are only two places in the Hebrew Scriptures (Old Testament) that contain explicit prohibitions against what is referred to as homosexuality, though the word itself is never mentioned in the Bible. Both are contained in the book of Leviticus, mentioned in the context of the codes of ritual purity by which Israel is to set itself apart from other people. The New Revised Standard Version (NRSV) of the Bible translates as follows: Leviticus 18:22, "You shall not lie with a male as with a woman; it is an abomination"; Leviticus 20: 13, "If a man lies with a male as with a woman, both of them have committed an abomination; they shall be put to death; their blood is upon them."

Scholars debate both the meaning of word choices (what does it mean to "lie with a male as with a woman"? what does *abomination* mean?), and of historical/cultural context. Not surprisingly, Evangelical and conservative Christian exegetes tend to interpret the passages to mean that God condemns acts of same-sex eroticism between men; a few Biblical literalists use Leviticus 20:13 to argue for the death penalty for homosexuals today (see <www.godhatesfags.com>). If the writer of Leviticus does intend to signal God's condemnation of homosexual sex between men, what is the basis for the condemnation? Conservative exegetes argue that the *abomination* (*toevah* in Hebrew) in question is quite simply *sodomy,* or anal intercourse between two men; hence the meaning of to "lie with a male as with a woman." Lynne C. Broughton claims that *toevah* signifies something inherently wrong and contradictory to nature.

More liberal Christian exegetes make two kinds of hermeneutical claims. The first view is that the ritual codes of ancient Israel were written for a particular context and that few of these commands are observed today (Borg). Indeed, few Christians observe other prohibitions found in Leviticus, such as having sex with a menstruating woman (18:19), eating certain foods (19:26), cutting beards (19:27), wearing clothes made from two kinds of fabrics (19:19), or tattooing (19:28). Marcus J. Borg maintains that Christians who set aside these laws must assume the burden of proof for following any one of them, including the proscription on *homosexuality.* Others who view the New Testament as superceding the Old Testament might claim that the New Testament already invalidates much of the Levitical ritual concerns, rendering them less authoritative for Christians.

A second view, characteristic of William L. Countryman and Brooten, holds that the concerns of Leviticus 18–20 are not those of ritual and morality, but rather, as Brooten puts it, "holiness, impurity, defilement, shame and abomination" (1996, p. 288). On this view, the Levitical codes exist to secure the holiness of the people of Israel, a people bound to God. It is important to recognize the centrality of group welfare in ancient Israel—the writer's concern is not for securing individual purity, but the purity and survival of the whole people. This runs counter to the modern sense of individual liberties and rights. When seen from the perspective of group purity, many of the pieces of the Levitical codes that contemporary readers find objectionable (execution for adulterers, execution for perpetrators and victims of pederasty, and so on) can be understood as relevant to group survival and holiness: the offending violation and the violators must be cleansed from the midst of the community.

Similarly, Daniel Helminiak holds that the Levitical proscriptions are not against male homogenital relations

(women are never mentioned), but must be seen within the context of ritual purity; the taboo (a translation of *toevah*) that concerns Leviticus is one of uncleanliness or defilement in a religious sense, but not in an ethical or moral sense. The chief concern of the writer is the purity of the people of Israel over and against the Gentiles; all of the purity violations in the holiness codes are cited as *abominations* or *taboo.*

Scholars generally agree that Paul relies on Leviticus in his proscriptions against same-sex expression, particularly in Romans 1:26–27, though also in I Corinthians 6:9 and again in I Timothy 1:10. The latter texts concern lists of behaviors to be avoided by Christians (lying, adultery, idolatry, and so on), and included among the lists we find the Greek word, *arsenokoitai,* which is generally translated as "men lying with men." While this word has been translated "homosexual," it has been variously translated "sodomites" or "male prostitutes," "homosexual perversion," and even as "abusers of themselves with mankind" (Borg, p. 4; Helminiak). Boswell (1980) argues that *arsenokoitai* refers to male prostitution and not homosexuality generally. *Arsenokoitai* also appears in the Septuagint Greek translation of Leviticus 18:22, 20:13. Some scholars hold that it refers to the specific practice of pederasty in ancient Greece and that it is this practice, along with male prostitution, that is condemned by Paul, and not homosexuality per se (Scroggs; Borg, 1994; Ackerman). Others disagree with this interpretation (e.g., Furnish; Wright).

First Corinthians 6:9 also contains the word *malakoi,* which refers to soft or weak persons, though Brooten translates this term as "men who assume a passive sexual role with other men" (1996, p. 260). This translation undergirds her argument that what was reviled by the ancients, including Paul, was the violation of the active/passive distinction on which society was based. Countryman and Boswell (1980) argue that *malakoi* does not refer to homosexuality at all.

Romans 1:26–27 is cited by most Protestant religious denominations, as well as the Roman Catholic Church, as the cornerstone of a variety of positions opposed to homosexual sexual expression. It merits citing here: "For this reason God gave them up to degrading passions. Their women exchanged natural intercourse for unnatural, and in the same way also the men, giving up natural intercourse with women, were consumed with passion for one another. Men committed shameless acts with men and received in their own persons the due penalty for their error" (NSRV). Scholarly debate generally turns on the context of the passage: what is it that Paul is concerned to communicate to his audience? and what is meant by the terms *natural* (*kata physin*) and *unnatural* (*para physin*)?

Does *para physin* mean contrary to nature in keeping with the Stoic insight on the right and natural order of things (Hays, contra Boswell), or does it mean, as Boswell suggests, beyond nature, meaning extraordinary or peculiar, but not unnatural (1980)? Boswell's claim is that the term was in some sense morally neutral for Paul, since he used it with respect to salvation of the Gentiles as well as to sex between men. Picking up from Boswell, Helminiak suggests that Paul meant *surprising* behavior, which is to say, "When people acted as was expected … they were acting 'naturally.' When people did something … out of character, they were acting 'unnaturally'" (Helminiak, p. 64). Thus "exchanging natural intercourse for unnatural" would have indicated sex that was surprising and out-of-the-ordinary, but not inherently wrong or disordered in the Stoic sense of "the laws of nature."

Stoic philosophy did make use of the term *para physin* and the Stoic philosophy of the *natural law* was pervasive in the Roman Empire. Robin Scroggs, however, maintains that *para physin* was "a commonplace Greco-Roman attack on pederasty" (p. 115), while Ward sees in it echoes of the emphasis on the importance of procreation typical of the Hellenistic Jewish community (and Stoic thought) of which Paul was a part. In terms of the procreation concern, Helminiak believes it would have been inconsistent for Paul to have made a priority out of this issue since, as we know, the early Christian community expected the imminent return of Jesus; thus marriage and procreation were not their chief concerns.

Among the more persuasive arguments is Brooten's (1996), that *para physin* did mean *contrary to nature,* but that what is referred to as *kata physin* (according to nature) is the non-biological active/passive distinction: any sex act had to have an active and a passive partner. Accordingly, sex between two women would certainly be thought of as shameful, unnatural and impure because *natural* sex meant penetration, characterizing the active dimension of the male. "Impurity applied to gender thus means that people are not maintaining clear gender polarity and complementarity" (Brooten, 1996, p. 235).

Similarly, for a man to have intercourse with a man, instead of a woman, would be a violation of the social order in which the *male nature* was believed to be active and penetrating. Boswell, on the other hand, argues that to exchange natural for unnatural intercourse refers to heterosexuals engaging in homosexual sex, since Paul presumes that such persons are capable of *natural intercourse.* He further maintains that Paul is making a distinction between homosexual persons and homosexual acts, and is really concerned only with the latter (Boswell, 1980). Richard B.

Hays disputes Boswell on this point, arguing that for Paul homoerotic expression does constitute a willful upending of the sexual differences that God intended for creation. Brooten adds that neither scholar takes a gendered analysis of Paul's position and his cultural assumptions into account, and that "Gender ambiguity is also the best framework within which to view Paul's understanding of unnatural relations in Romans I" (Brooten, 1996, p. 252).

Homosexuality and Judaism

Rabbinic Judaism, emphasizing the *halakhic* or legal side of the Talmud, has been largely opposed to same-sex sexual expression between males. Such expression between women is not addressed in the Torah, although it was later condemned by the rabbis (e.g., *Sifra* 98 and *Mishneh Torah Issurei Biah* 21:8). Perhaps silence on same-sex eroticism between women in the biblical period of ancient Judaism reflects the patriarchal nature of culture; one cannot really be certain. However, it is clear that male homoeroticism was condemned as an "abomination" (*toevah*) in Leviticus 18:22 and punishable by death in Leviticus 20:13. The reasons for the condemnation have been debated both in the Talmud and by scholars up to the present.

In contemporary Judaism, Saul Olyan, for example, argues that what the Torah actually prohibits in Leviticus is male anal intercourse and not other instances of male-male coupling (see also Boyarin). For contemporary explanations on the differing treatment of male and female homoeroticism in Jewish law, see the work of Rebecca Alpert and Rachel Biale. One of the debates in contemporary Judaism has been whether or not *halakhah* is open to change on homosexuality in light of new realities, or whether its character is fixed. In one sense, within *halakhic* Judaism it is apparent that homoerotic acts (though not necessarily inclinations) between men are to be regarded as an abomination, and as an aberration from the commonly held norm of heterosexual acts that ensure procreation and the promotion of family life, primary values in Judaism. David M. Feldman, for instance, does not agree that the proscription in Leviticus has anything to do with procreation. He summarizes three possible reasons for the prohibition according to his reading of rabbinic sources: that male homosexuality cannot result in procreation; that such sexual activity will result in men leaving their wives and families; that it constitutes "going astray" (*toeh attah bah,* play on *toevah*) from the Creator's design for creation (Feldman, p. 428).

Following the rabbis, Feldman regards homosexual acts as sinful, but makes the distinction that "If the aberration is the result of 'sickness,' no guilt can attach to it; if it is advocated as an 'alternative lifestyle,' this then is consciously immoral and soberly sinful"; thus volition plays a key part in the condemnation (Feldman, p. 426). Under this view, *halakhah* and homosexuality are regarded as incompatible, and it is interesting to note that the rabbis apparently regarded male homosexuality and Judaism as an unlikely combination—that Jews could not really *be homosexual.* There is much discussion, from Talmud to Maimonides, on *yihud,* "being alone together." Generally, proscriptions against *yihud* reflect concerns with heterosexual adultery so that the Talmud actually allows two men to be alone together and even to sleep under the same blanket. This might reflect the relative lack of attention paid to homosexuality as a reality in ancient Judaism, in contrast to the gentile communities in Greece and Rome.

Robert Kirschner, opposing Feldman and David J. Bleich, argues that *halakhah* is capable of change on this matter, as it has been on many others (e.g., the debate over *heresh* deaf mute), since the power of interpretation is a cornerstone of rabbinic tradition. Kirschner makes a case for Judaism taking into consideration scientific evidence about sexuality, including theories on the etiology of homosexuality. Contemporary science confirms, for example, what the rabbis did not think to be the case—that sexuality and its expression is variable, fluid and not dichotomous; therefore, homosexuality can be seen "not as a perversion but, rather, in its multiple manifestations, a state of sexual being" (Kirschner, p. 457).

Currently, the four branches of Judaism in the United States (Orthodox, Conservative, Reform, and Reconstructionist) take a variety of positions on homosexuality. Orthodox Judaism is largely settled on these questions and it accepts the Levitical condemnation on male same-sex acts as an abomination. Some more liberal Orthodox Jews maintain a distinction between the act and the person (the sin and the sinner), regarding the homosexual Jew as sinning, but a Jew nonetheless. In recent years, support networks of Orthodox homosexual Jews have emerged, despite the fact that Orthodoxy does not recognize homosexuality as an orientation or state of being. Examples of these networks include: Gay and Lesbian Yeshiva Day School Alumni Association (GLYDSA), Orthogays, and Orthodykes, all of which have a presence on the Internet. In 1999, Rabbi Steven Greenberg became the first Orthodox rabbi to *come out* as a homosexual Jew, a subject of great controversy in Orthodox Judaism (see Grossman). In 2000, the Rabbinical Council of America condemned the position taken by the Reform rabbis to affirm same-sex relationships in Jewish ritual. In 1999, the Council publicly opposed the state of Vermont's ruling legalizing same-sex civil unions, on the grounds that marriage is only between heterosexuals.

In 1991, the Conservative Movement in Judaism (both the Rabbinical Assembly and the United Synagogue of Conservative Judaism) passed a resolution affirming its *halakhic* commitment to heterosexual relationships, while simultaneously opposing civil restrictions on and expressions of hatred against gays and lesbians. The movement officially welcomes gay and lesbian persons at synagogue and encourages education among Jews about homosexuality. Since 1992, the official policy of the Conservative movement's Committee on Jewish Law and Standards has been to prohibit the ordination of gay and lesbian rabbis, as well as to prohibit same-sex marriages or commitment ceremonies. That policy was under discussion at the beginning of the twenty-first century, and is opposed by some rabbis within the movement. Conservative rabbis are permitted to serve gay and lesbian congregations, but they are *halakhicly* prohibited from officiating at commitment ceremonies. For a helpful and balanced overview on homosexuality in Judaism, see *Matters of Life and Death,* by Conservative rabbi Elliot Dorff (1998). The Rabbinical Assembly of Conservative Judaism published an official rabbinical letter on human intimacy in which it stated, with reference to the Levitical codes, that some acts of sexual expression are abominations (cultic, oppressive, or promiscuous sex, whether by homosexuals or heterosexuals), but that monogamous, loving sex is sacred and should be sanctified, whether heterosexual or homosexual (see Dorff, 1996).

For the Reform Movement and for Reconstructionist Judaism, homosexuality is almost a non-issue, in that the Union of American Hebrew Congregations (UAHC) voted in 1973 to accept full membership of a synagogue that had a specific outreach to homosexual Jews. In the 1980s the official seminary of Reform Judaism, Hebrew Union College, voted to accept gay or lesbian rabbinical students; the Reconstructionist Rabbinical College preceded Hebrew Union in doing so. In 1993, UAHC adopted a resolution calling for full legal equality for gay and lesbian monogamous partnerships. In 1997, the UAHC reaffirmed its commitment to welcoming gays and lesbians into full participation in all aspects of Jewish life, and officially resolved (1) to support efforts towards civil gay and lesbian marriages; (2) to urge Reform congregations to honor monogamous gay and lesbian partnerships; (3) to support the Central Conference of American Rabbis (CCAR) in its study of the possibility of religious commitment ceremonies for gay and lesbian unions between Jews. In March 2000, the CCAR became the first major congregation of American clergy to give its clergy permission to perform gay and lesbian commitment ceremonies. Although the UAHC and the CCAR have been very supportive of gay rights issues, there is no official position on the adoption of children by homosexuals.

Homosexuality and Roman Catholicism

Since Roman Catholicism and Christianity were synonymous until the Reformation, Christian attitudes towards homosexuality were, *de facto,* Roman Catholic attitudes, although popular attitudes were not necessarily synonymous with official Catholic teaching, as is true today. Boswell (1994) contends that evidence from liturgical texts and cultural history indicates that Christians once accepted same-sex relationships. Moreover, he argues that a distinctive contribution of early Christianity was an emphasis on the celibate life as spiritually superior to the heterosexual married state; eroticism thus became suspect and marriage was seen as a distraction from the important preparation of the Second Coming, and at best a compromise with the material world. These attitudes held sway in the church for the first thousand years of its existence (Boswell, 1994). Mary Rose d'Angelo shows how pairs of women missionaries in the New Testament can be seen as evidence of commitment both to the mission and to each other. Boswell, too, discusses the influence of "paired saints," such as Perpetua and Felicity, Serge and Bacchus, and even Jesus and John, on ordinary Christians.

Christian thinkers from late antiquity to the high Middle Ages have had an influence on official Catholic teaching on homosexuality. Among these are Augustine of Hippo, John Chrysostom, Clement of Alexandria and Thomas Aquinas. St. Augustine (354–430) contributed heavily to the Catholic view that marriage was for procreation, monogamy, and fidelity, or as Augustine put it, *fides, proles, sacramentum* (Boswell, 1994; Augustine, 2000). So influential was this view that traces of it are found in papal documents up through the twentieth century. Augustine was influenced by his membership in the Manichean movement that viewed the natural world as an inherent evil. Hence one finds in Augustine an insistence on sex within marriage exclusively for the purpose of procreation—husbands were encouraged to make use of prostitutes if they had a need for non-procreative sex (Augustine, 2000). Boswell (1980) maintains that Augustine's view of *nature* is to be understood in the sense of *out of the ordinary,* not the *normal* use of something. Thus Augustine condemned same-sex eroticism since it was certainly not the *normal* use of sex with which he was familiar. *Contra naturum* meant that which did not conform to *ordo,* or order of the world, the divine plan (see Augustine's "De ordine.") In this view, conformity was the issue for Augustine, not *nature* itself. Part of the order of things, as Brooten tells us, is the maintenance of gender boundaries. Augustine was one of the Christian thinkers who, perhaps reflecting the culture around him, insisted on the male nature as superior to the female.

Clement of Alexandria (150–c. 215) argues against homosexuality in the *Paedagogus,* an instruction manual for Christian parents. Clement did espouse the procreation argument for moral intercourse, but his rationale against same-sex eroticism was grounded primarily in the Epistle of Barnabas's view that such acts were *animalistic.* (The comparison to animals figured prominently in theological treatises up through Thomas Aquinas.) This popular first century Epistle (now part of the Catholic Apocrypha) equated the eating of certain animals in Leviticus (notably the hare, the hyena, and the weasel) with sexual sins. Though regarded as erroneous, the Epistle's influence is evident in Clement's writing, which itself was influential in the early church. Clement is one of the few sources who explicitly opposed *woman-woman marriage,* believing it to be unnatural in that it flaunts God's plan for woman as the receptacle of male seed. Drawing on both Plato and St. Paul, Clement held that same-sex relations were *para physin.*

John Chrysostom or John of Antioch (347–407) was another of the early Christian thinkers who was influenced by the Manichees, as well as by the Stoics, a combination of belief systems that "led him into the paradoxical position of condemning sexual pleasure … while at the same time denouncing homosexual acts for not providing pleasure: 'Sins against nature … are more difficult and less rewarding, so much so that they cannot even claim to provide pleasure, since real pleasure is only in accordance with nature.'" (Boswell, 1980, p. 156). Chrysostom, also a product of Mediterranean misogynistic culture, was repulsed by the idea of a male taking on the role of a woman and this transgression was part of his opposition to same-sex eroticism. Both Boswell and Brooten agree on this. Brooten notes that Chrysostom began to use the language of disease with respect to same-sex eroticism, adding this to the language of sin in early Christianity and ancient Judaism (1996).

Thomas Aquinas (c. 1225–1274), the influential Dominican scholar, argued that same-sex acts were to be regarded as sinful because they thwarted the *natural law,* as ordained by God. The thirteenth century is the period in which civil laws against homosexuals arose; anti-homosexual rhetoric became vitriolic and remained so through the twentieth century. In this light, Boswell (1980) regarded Aquinas as reflecting the popular attitudes of his time rather than responding to the substance of church tradition on this issue. It is important to recall that Aristotle, the Stoics, and *natural law* discussions of the first centuries of Christian history heavily influenced Aquinas. His articulation of what constitutes *nature* and *natural law,* particularly in his *Summa theologiae,* has been given decisive weight in Roman Catholic moral theology up through the present day. Aquinas devotes much of the *Summa* to considerations of *natural law*; one succinct definition is as follows: "It is clear that natural law is nothing other than the participation of rational creatures in eternal law" (Aquinas, 1952, Ia.2ae.91.2). Aquinas held that reason is that which distinguishes what is natural to humans from what is natural to animals. Therefore, one might expect Aquinas to argue that homosexual acts are contrary to reason, and in this sense unnatural. But this was not the rationale that he employed.

In the *Summa* there are three places of commentary on same-sex eroticism (Ia.2ae.31.7; Ia.2ae.94.3 ad 2; 2a.2ae.154.11–12), though "only the last has received scholarly attention in the context of Scholastic attitudes towards homosexuality" (Boswell, 1980, p. 323). In 2a.2ae.154.11–12, Aquinas discusses "vices against nature," which for him included heterosexual intercourse without intent to procreate, intercourse with animals, homosexual intercourse, and masturbation. These constitute the most sinful forms of lust, though Aquinas does not here discuss what order of nature is violated by these sins; he does hold that all sins are unnatural because they are "against the order of reason, which must order all things according to their ends" (Aquinas, 1952, 2a.2ae.153.2 Resp.). Why then is homoeroticism particularly unnatural? One might expect Aquinas to ground his opposition in the "spilling of seed" argument that had been popular (nature intended semen to find its end in procreation of children), and indeed he did consider this rationale (Aquinas, 1923). But he disposed of the argument after considering that nature fitted other body parts for uses to which they were not always put and therefore, misusing a part of the body could not be the sin; the sin was rather to impede the propagation of the species, which itself is a good. If homosexual sex precludes procreation, he the might have applied the same argument to celibacy and to virginity, but he did not.

However, Aquinas considered that there were some things that might seem against human nature generally, though peculiar to certain individuals and, therefore, *natural* to those individuals as everything in nature was believed to be ordered by God to some good end. One might have a *defect* of nature, but that defect of nature could be quite *natural;* indeed this was the way in which Aquinas regarded females (as "defective" males) (see Aquinas, 1952, Ia.92.I). As he writes, "In fact, because of the diverse conditions of humans, it happens that some acts are virtuous to some people, as appropriate and suitable to them, while the same acts are immoral for others, as appropriate to them" (Aquinas, 1952, Ia.2ae.94 ad 3). And in a footnote to history, Boswell writes, "It would seem that Saint Thomas would have been constrained to admit that homosexual acts were 'appropriate' to those whom he considered 'naturally' homosexual"

(1980, p. 327). Perhaps reflecting the attitudes of his day, Aquinas did not do so, as he also did not show why homosexual acts were immoral theologically, apart from being unnatural—neither is this point considered in official Catholic teaching on homosexuality.

The Roman Catholic Church has issued five key statements that are meant to instruct the faithful as to its official teaching on homosexuality:

1. in December 1975, homosexuality is considered within the document, "Declaration on Certain Problems of Sexual Ethics" ;
2. in October 1986, the Vatican issued "The Pastoral Care of Homosexual Persons";
3. in July 1992, "Responding to Legislative Proposals on Discrimination Against Homosexuals" was issued;
4. in 1995 the Catechism of the Catholic Church was revised, containing three sections on homosexuality (paragraphs 2357, 2358, 2359);
5. in 1997, the United States Catholic Bishops issued a pastoral letter on homosexuality, "Always Our Children."

With remarkable consistency, the church has always held that homosexual acts are *disordered* and against nature. Thus the church has never sanctioned such acts, though its documents on the matter do indicate a shift from a complete condemnation in the documents from 1975 and 1986 (Congregation for the Doctrine of the Faith, 1982; Congregation for the Doctrine of the Faith, 1986) to a more recent distinction between the act and the actor, or the sin and the sinner in the documents from 1995 and 1997. For an alternative claim by a contemporary Catholic moral theologian, see Margaret Farley, "An Ethic for Same-Sex Relationships."

If the church is now making a distinction between homosexual acts, which it condemns as against the natural law, and homosexual persons, who deserve compassion, it does so because it believes that homosexuality is not chosen (Roman Catholic Church). Earlier, the church had distinguished between curable and incurable homosexuals, yet it counseled the faithful to instill hope "in them of one day overcoming their difficulties and their alienation from society" (Congregation for the Doctrine of the Faith, 1982, para. 8). It would seem that Pope John Paul II is aware of the scientific data about the origins of homosexuality and that his position in the Catechism accounts for some openness to science and social science. In rather non-judgmental language, the *Catechism* observes: "Homosexuality refers to relations between men or between women who experience an exclusive or predominant sexual attraction toward persons of the same sex. It has taken a great variety of forms throughout the centuries and in different cultures. Its psychological genesis remains largely unexplained" (Roman Catholic Church, p. 2357).

All of this notwithstanding, the Roman Catholic Church does not condone homosexuality and recommends celibacy as the only acceptable form of sexual expression for homosexuals. Accordingly, it does not approve of civil unions, such as the state of Vermont's; nor does it condone homosexual marriages or unions in its churches, nor adoption of children by gay and lesbian persons. It should be noted, however, that there is a substantive gay-affirming movement within the Roman Catholic tradition known as Dignity. During the 1970s, 1980s and into the mid-1990s, a Catholic priest, Robert Nugent, and a Catholic nun, Jeanine Gramick, ran New Ways Ministry, a ministry to gay and lesbian Catholics. In 2000, they were ordered by the Vatican to cease teaching publicly or face expulsion from their respective orders.

Homosexuality and Protestantism

Most of the major Protestant denominations in the United States have positions on homosexuality. Since Martin Luther's movement back to the authority of the Bible defined Protestantism, interpretations of scripture tend to play the major role in shaping Protestant denominations. Protestantism in the United States exists on a kind of continuum with conservative Protestant denominations on one end (Southern Baptist Convention, Assemblies of God, independent Evangelical churches), liberal Protestant churches on the other end (Episcopal Church, American Baptist Church, United Church of Christ), and moderate Protestant churches in the middle (Presbyterian Church U. S. A., United Methodist Church, the Evangelical Lutheran Church in America).

In general terms, conservative Protestants tend to regard homosexuality as a perversion of God's intent for creation (heterosexual marriage and children). They regard the institution of the heterosexual family as the bedrock of God's plan and are opposed to anything that thwarts this plan. Homosexuality is a grave sin and homosexuals are regarded as sinners; some conservative Protestants believe that there is an inherent contradiction between being Christian and being homosexual. Such Protestants hold that the Bible condemns homosexuality unequivocally and Christians are called to do likewise and to help homosexuals repent of their sin (see, for example, <www.sbc.net>). *Conversion ministries,* in which ex-homosexuals help homosexual persons convert to heterosexuality through Jesus Christ, are

a suggested means of dealing with this aberrant lifestyle (see Exodus International, for example). Conservative Protestants view homosexual *inclinations* as either a depravity of nature or a willful choice to violate God's intent, and thus these denominations retain an ambivalent attitude with regard to developments in science and genetics (Green and Numrich).

Liberal Protestant denominations, on the other hand, tend to regard homosexuality as an alternative expression of the variety and goodness of sexuality given by God. While affirming the inherent dignity of homosexual persons, such churches have taken advocacy positions for full civil rights for gay, lesbian, and transgendered persons, usually including recognizing legal status of domestic partners, and adoption of children. Some of these churches perform holy unions or commitment ceremonies for same-sex members of their churches, and some also ordain "out" homosexual clergy. Liberal Protestants tend to embrace developments in science; in fact many are sanguine about the benefits of science for humankind, particularly genetic science. One finds openness to the possible genetic etiology of homosexuality among liberal Protestants. The United Church of Christ has taken several public stands affirming gay and lesbian persons and "it was also one of the first American churches to affirm and ordain gays and lesbians in ministry" (Green and Numrich, p. 23). The Episcopal Church has called for full participation in the life of the church for gay and lesbian persons, including church leadership, and is studying the possibility of holy unions. Still, many of these churches struggle over the issue of how to regard homosexuality within the confines of their respective traditions.

Moderate Protestant denominations are a hotbed of struggle over homosexuality. The question of whether homosexuality is compatible with Christian teaching (especially the Bible) is intensely debated, and some have speculated that it could produce a schism in the church. Moderate Protestants are clear, however, that homosexuals are children of God and deserve a place in their congregations. Commitment ceremonies for same-sex unions have been intensely debated in recent years in these denominations, as has the ordination of *practicing* homosexual clergy. The Presbyterian Church (U.S.A.) agreed to lift its ban on ordination of gay and lesbian clergy in, though the issue appears far from settled. The Methodist Church has been in conflict over the disciplining of clergy who perform same-sex union ceremonies in its churches, as well as over the sanctioning of clergy who have "come out" as homosexual. The Evangelical Lutheran Church will spend until 2005 studying issues of ordination of homosexual clergy, same-sex blessing ceremonies, and so on.

Currently, "out" homosexual clergy in most denominations are expected to be celibate. Moderate Protestants are not settled on these questions, or on the issue of whether homosexuals may adopt children. However, rooted in an affirmation of Biblical justice, all moderate Protestant denominations reject efforts to curb the civil rights of homosexuals, and advocate non-discrimination of gay and lesbian persons.

There are also movements within a variety of Protestant denominations to affirm the rights and dignity of homosexuals. For example, in the Presbyterian Church there are "More Light churches"; the United Church of Christ has the "Open and Affirming Movement"; the Episcopal Church has a national gay and lesbian affirmation movement called "Integrity."

Homosexuality and Islam

The Western concept of *homosexuality,* as sexual orientation and lifestyle, is unknown in the Islamic world. As Amreen Jamal notes, "the term 'homosexuality' is erroneous when it is used in Islam, unless it is used by Muslims who identify also with the Western description of the queer lifestyle which includes both behavior and orientation" (Jamal, p. 69). It must be stated that just as there are many versions of Christianity and Judaism, so Islam is not monolithic in its expression. For the purposes of this discussion, however, it may be assumed that Islam is in wide agreement in its outlook and teachings on same-sex activity.

The authoritative text for Muslims, *Al-Qur'an* (believed to be the divine revelation from God to the Prophet Muhammad as told to him by Gabriel) is generally thought to be explicit in its condemnation of same-gender sexual activity. Al-Qur'an (Koran) references the same story that some Jewish and Christian scholars reference in the Hebrew Bible, the story of Lot and the destruction of Sodom (Genesis 19), as evidence of God's condemnation of same-gender sex. "In Islamic terminology," Khalid Duran notes, "homosexuals are called *qaum Lut,* Lot's people, or, briefly, *Luti*" (Duran, p. 181). Traditional Islamic scholars tend to interpret this story as evidence of God's disproval of the actions of Lot's people, anal penetration.

Beyond the Lot narrative (mentioned five times in Al-Qur'an), the Qur'an permits sex for pleasure, but indicates that the express purpose of sex is procreation. Marriage and procreation are central values of Islam, and the Prophet Muhammad is reported to have said, "Marriage is half the religion." In light of this, the *shari'a* (traditional Islamic law) finds same-sex activity, particularly between men, to be a punishable offense, though the offense must offend publicly

and solid evidence of the offense must be established. In other words, the *shari'a* has little concern for what occurs in private, but what is publicly offensive is punishable. While there is a range of opinion among scholars, traditionalists interpret homosexuality as a crime and not just a sin; since the penalty is not specified in the Qur'an, it is a matter for contemporary authorities to debate, and death has been interpreted as one of punishments. In summary, Islam generally teaches that such sexual acts are against the natural order God intended for humans and are therefore sinful violations, and a deviation of the proper intent for human sexuality, marriage and procreation.

At least one scholar notes that there may be some openness to reform of the Muslim position within the context of its mystical branch, Sufism, and the freedom and justice teachings of Ustadh Mahmud Muhammad Taha (d. 1985) of Sudan. Ustadh Mahmud's teachings involved the development of a new or revised *shari'a* that was not dependent on the social constructs of seventh-century Islam (Duran). For an interesting contemporary study of the possibility of reform interpretations of homosexuality in Islam, see Amreen Jamal, 2001.

HOSPITAL, CONTEMPORARY ETHICAL PROBLEMS OF THE

• • •

Hospitals are complicated institutions that bring together technological innovations and social services, salaried and unsalaried personnel, private and public funding, a charitable mission and a business orientation. Hospitals are accountable to patients, physicians, board members, employees, the local community, third-party payers, business partners, and other providers. It is no wonder that hospitals encounter ethical issues and problems.

Ethical concerns confronting hospitals in the United States are discussed in the following categories: identity and mission; special sponsorship; clinical issues; and relationships with healthcare professionals.

Identity and Mission

Perhaps the most fundamental ethical issue has to do with identity and mission. Is a hospital a business like any other, subject to the pressures of the marketplace, and primarily motivated by commercial interests and incentives? Or is it a social institution, primarily responsible for serving the health needs of the community and sometimes suffering financial loss in the process? These questions fall within the purview of the relatively recently established field of organizational ethics in healthcare. Two edited volumes (by Boyle, DuBose, Ellingson, et al.; and Spencer, Mills, Rorty, et al.) elaborate on these questions and show how hospitals experience tensions between their role as community servants and their role as entrepreneurs. These roles can coexist, as for-profit hospitals have tried to show. However, the public has come to expect more from the nonprofits—for example, that they provide care that is not reimbursed, support unprofitable services, and be alert to community healthcare needs.

Hospitals in the United States face more difficult questions of identity and mission than do hospitals in countries where healthcare is typically regarded as an essential service, not subject to the usual marketplace forces. A

confluence of factors—including the growth of scientific medicine, the alliance of physicians and hospitals, the phenomenon of specialization, enormous capital investments, commercial ventures, and the payment system—has caused U.S. hospitals to behave much like businesses. Public policy has encouraged this by endorsing antitrust laws that discourage hospitals' collaboration with one another; by inadequate government-reimbursement programs; and by the failure to ensure universal entitlement to healthcare. These factors create financial incentives for hospitals that conflict with their stated mission, namely, to serve all people and to meet the needs of their communities.

Most hospitals remain not-for-profit and therefore tax-exempt. Voluntary hospitals, whose boards of trustees receive no pay because they are understood to serve the community, believe that this community orientation is the most effective way to deliver care. In their rhetoric, they cultivate an image of benevolence and moral worth that obscures their business orientation, seeking government subsidies but eschewing government control. Some business practices adopted by both for-profit and not-for-profit hospitals have tarnished this image of benevolence. These practices include aggressive marketing, advertising, and competition for paying patients; the creation of for-profit ventures, often with physicians, thus creating the potential for conflict of interest; resistance or refusal to care for the indigent; and expensive duplication of services to compete with other hospitals.

Until the latter part of the twentieth century, hospitals could count on the public's trust and support. The special nature of healthcare and the religious affiliation of many hospitals fostered this trust. Contemporary hospitals, however, face increasing skepticism and criticism from patients and the public at large. This dissatisfaction with hospitals' behavior arises from an expectation that hospitals will behave differently from ordinary businesses, that they have a "higher purpose." Distrust also stems from the Institute of Medicine's 2000 report, *To Err is Human,* which documents high rates of medical errors or unanticipated outcomes occurring in hospitals. It is imperative for hospitals to establish policies toward disclosure of such outcomes, since disclosure facilitates patient trust and reduces legal liability. Yet some hospitals are regaining public trust by various innovations that aim to empower patients to participate in their care (Nolon, Dickinson, and Bolton). Thus, one of the most pressing ethical issues facing hospitals is whether to rededicate themselves to a mission based on altruism and community service. The decision may be compounded by new hospital networks, mergers, and acquisitions. Hospitals still have fundamental ethical choices about whom they serve, how they allocate their resources, and what sort of leadership and vision they bring to providing quality healthcare.

Special Sponsorship

Hospitals under religious sponsorship—Catholic, Jewish, Episcopal, Lutheran, Adventist, Presbyterian, Methodist—have special concerns. They were founded by traditions having particular beliefs and aspirations, yet they provide care in a pluralistic society. They neither employ nor provide care solely for persons of the faith of their founders. Like other hospitals, they are heavily dependent on state and federal payment for services rendered. In some cases, a hospital under religious sponsorship may be the only hospital serving a particular community. Ethical conflicts may arise between hospitals' allegiance to their religious sponsors and their obligation to provide needed services to the community.

This is especially the case in rural settings where, with government funding cuts, hospital closures or consolidations are increasingly common and Catholic health systems acquire nondenominational hospitals in the process. When Catholic hospitals become the primary source of healthcare in a region, rural residents, especially lower-income women, may find it difficult to obtain reproductive health services (Bennett; Bellandi).

Identity and mission are of particular concern here. In the United States, the majority of hospitals are *private,* that is, they are free to follow their own moral mission in religious matters. A hospital may therefore choose, on religious grounds, to offer different services from others in the community; for example, to follow certain dietary practices, or not to perform blood transfusions, abortions, or sterilizations. Hospitals are also heavily affected by the liability insurance crisis which has lead to the elimination of medical services, such as trauma, and to considerations of tort reform (Haugh; Taylor).

Thus far, the policies of hospitals with religious affiliations have not been proscribed by law, and arguably should not be proscribed ethically, unless they create undue hardship for patients. This would occur if patients could not gain reasonable access to needed services in any other way. The definition of what is reasonable will be interpreted variously, of course, depending on whether the perspective adopted is that of the sponsor and its adherents or of those who desire the service. Sponsored hospitals occasionally find themselves with conflicting loyalties, as they strive to be faithful to both their religious tradition and their constituents.

The growth of managed care and alliances among hospitals of different sponsorships creates another set of

ethical conflicts for religious hospitals. If they are part of the new system of healthcare delivery, they will be closely associated with those who practice differently from them. This will result in their cooperating with and financially profiting from the very practices they prohibit in their own hospitals. How hospitals work this out requires careful consideration of their various ethical commitments.

Clinical Issues

With advances in medical technology, hospitals have encountered a number of new and perplexing ethical questions, some of the most contentious arising in relation to the use of life-sustaining treatment. When is it appropriate to withhold or withdraw medical treatment from a critically ill patient? Who should make the decision if the patient cannot? What are the rights and obligations of nurses, physicians, family members? What role should the hospital play in disputes among these groups? What policies should the hospital have in place to deal with these questions?

In 1991, the Joint Commission on Accreditation of Healthcare Organizations (findings published 1992) mandated that hospitals have a process for addressing ethical issues in patient care to protect patients' rights. To satisfy this policy, most hospitals created interdisciplinary ethics committees and used ethics consultants to aid physicians, hospital staff, and patients and their families in mediating individual cases as well as to recommend new policies on forgoing treatment that recognized the preeminence of patient choices. Resuscitation, ventilation, tube and intravenous feeding, renal dialysis, and antibiotic therapy continue to be some of the treatments discussed. Regardless of treatment, patients became entitled to full disclosure about the risks, benefits, and alternatives of treatment; and they, or surrogates, now have the ethical and legal right to accept or refuse any treatment. Many, but not all, physicians and hospitals changed their policies and developed new practices to reflect this situation.

The principle of patient autonomy caused additional ethical dilemmas for hospitals. In the early 1990s, some well-publicized cases arose in which patients' surrogates wanted life-sustaining interventions, but physicians and hospitals did not want to provide them. A claim of medical futility was the usual reason for this reluctance, although disputes about whether research had shown the desired treatment, such as cardiopulmonary resuscitation (CPR), to be reasonably effective also arose. Patients and surrogates invoked the principle of autonomy to justify their demands for treatment. These demands were particularly strong if the patient, or the patient's insurer, was willing to pay for the treatment.

Physicians and hospitals thus faced new issues: What are the limits of patients' or surrogates' rights to medical treatment? Are there situations in which physicians are justified in refusing to provide it? Is it ethical for physicians to have in mind scarce hospital resources when treating individual patients? What is the meaning, and what are the ethical implications, of medical futility? What are the economic and/or ethical conflicts of interest for hospitals in these cases?

These questions are inextricably related to the nature of insurance coverage. If insurance companies pay on a per diem or fee-for-service basis, it is to the hospital's advantage that patients have extensive treatment and long hospital stays, particularly if the insurance pays close to the actual cost of caring for the patient. In the late 1980s, many insurers changed the method of payment to capitation. Under this method, hospitals are *at risk* and receive a predetermined reimbursement for each patient, regardless of the actual costs of caring for the patient. Capitation creates very different economic incentives for physicians and hospitals than they have under a fee-for-service system. Thus, money becomes a factor in responding to the ethical question of *who* should decide when treatment should be provided. If the public thinks it is not receiving the medical care it needs because hospitals and/or physicians fear losing money, trust between healthcare providers and those they serve will be further eroded. Hospitals must therefore demonstrate their commitment to community service and educate the public about the importance of cost control. In order for trust to be renewed, the public must understand the connection between limiting expensive treatments for some patients and providing more basic care for others. They will need to agree that such changes are not primarily for the economic benefit of healthcare providers but are for the benefit of society as a whole.

Public trust in hospitals and clinical care is also waning due to greater awareness or experiences of sociodemographic disparities in healthcare (Smedley, Stith, and Nelson). The U.S. Department of Health and Human Services has established as a top priority the elimination of health disparities across racial/ethnic groups, sex, age, and geographic location. Hospitals have the capacity to contribute substantially toward this aim by ensuring the availability of qualified interpreters, employing healthcare professionals of diverse ethnic backgrounds, and providing culturally competent care. When justice can be secured through the provision of healthcare to individuals regardless of their cultural or religious backgrounds, the quality of healthcare will improve (Smedley, et al.; Committee on Quality of Health Care in America).

Relationships with Healthcare Professionals

Hospitals and physicians have always had an uneasy alliance: They need each other but often do not trust each other. For the first half of the twentieth century, hospitals were referred to as the "physicians' workshop." Hospitals provided the beds, equipment, nurses, and other personnel, and physicians provided the patients. Except in teaching institutions, hospitals and physicians had few common goals and mutual responsibilities beyond providing a place to care for patients. Physicians directed all aspects of patient care, and expected hospitals and their personnel to provide whatever the physicians deemed necessary. Until the middle of the twentieth century, hospitals themselves were not legally responsible for the care provided by physicians. At that time, courts began finding hospitals and their employees liable for not intervening to protect the patient when physicians provided inferior care. Since that time, hospitals have instituted mechanisms to monitor and intervene when necessary in physicians' care of patients.

This change was good for patients, but strained the relationship between hospitals and physicians. It created ethical conflicts for hospitals when, for example, physicians who admitted large numbers of patients were questioned or disciplined regarding quality of care. Some of these physicians left the hospitals, taking a large source of revenue with them. Accountability to patients required that hospitals and their organized medical staffs be vigilant about monitoring and intervening in the quality of care practiced by physicians. Economic self-interest, however, tempted hospitals to be more lenient with physicians.

Toward the end of the twentieth century, relationships between hospitals and physicians began to change again. Integrated delivery systems, through which healthcare providers and payers (such as insurance companies) collaborate to deliver care to patients in a particular geographic region, align the economic incentives affecting both physicians and hospitals. Capitation, a fixed fee paid to a group of providers to provide care for a fixed number of patients, resolves some of the ethical problems of the past related to hospital reimbursement. But capitation creates new ethical issues due to economic incentives to provide the least expensive care to patients. This change is good for some patients, but may not be good for others. Hospitals will continue to face ethical dilemmas of conflicting loyalties to patients and physicians.

The introduction of integrated delivery systems changes the relationships between hospitals and physicians in other ways. Some managed care plans require that primary-care physicians be the "gatekeepers," seeing patients first and referring them to specialists only if absolutely necessary. This, combined with capitation systems, creates incentives for hospitals and primary-care physicians to offer their services as one unit. However, the retreat of managed care has signaled increased access to healthcare providers while increasing healthcare costs (Robinson, 2001). Many hospitals that purchase physicians' medical practices manage the business side of the practices. This is extremely difficult to accomplish with ethical integrity on both sides, because physicians and hospitals have historically operated independently of one another—both psychologically and practically—even though they are in the same building.

A related problem is that, after having courted specialists for years, hospitals now rely on primary-care physicians to direct patients to specialists. Nevertheless, ethical issues of loyalty and integrity are raised, as physicians in specialty practices find themselves in professional and economic jeopardy when their interests no longer match those of their hospital.

In response to the restrictions healthcare organizations impose upon physicians to control costs and medical decision-making, the American Medical Association established a union, Physicians for Responsible Negotiations, in 1999. Subsequently, medical residents separately unionized in 1999, limiting the number of work hours required per week. These unionizations can have a profound impact on hospitals (Yacht; Cohen). Some hospitals and physicians are concerned that unionization will lead to strikes, interfere with education and patient care, and add to hospital finances, as well as undermine the meaning of medical professionalism. Accounts of unionization at some hospitals, however, reveal that such fears do not materialize, given that these labor organizations have banned strikes to prioritize patient care (Yacht).

Hospitals face other problems with the delivery of medical care in relation to physicians and managed care. Managed care plans are increasingly utilizing evidence-based medicine guidelines to enhance efficiency in medical care by eliminating overtreatment and undertreatment (Sackett, Straus, Richardson, et al.). Many physicians fear that such guidelines interfere with personalized patient care, which deters their willingness to implement them. Consequently, hospitals may not be able to reach levels of clinical practice to which they aspire.

Much attention has also turned to the relationship between hospitals and nurses, given the critical shortage of nurses. This shortage results from efforts to contain hospital costs, and it contributes to medical errors and poor patient care. Although technicians and nursing aids have been hired to perform some nursing duties, it remains to be determined

how hospitals will recruit a sufficient number to provide appropriate nursing care.

Conclusion

Contemporary hospitals encounter many ethical concerns and problems. All constituents—patients, physicians, employees, board members, volunteers, the community at large, payers, business partners—have a stake in the way these ethical issues are considered and resolved.

HOSPITAL, MEDIEVAL AND RENAISSANCE HISTORY OF THE

• • •

Hospitals have become the primary theaters of modern medical practice. The early history of these institutions dates from about 400 to 1600, and includes these developments: (1) the origins of hospitals; (2) their development in the Byzantine and Islamic worlds; (3) their history in medieval western Europe; and (4) their flowering in Renaissance Italy. For purposes of this discussion, the term *hospital* refers to an institution that focused on caring for patients and, if possible, curing them. *Hospice* describes an institution that offered food and shelter to the poor, travelers, and the homeless sick but did not maintain specific services, such as the attentions of physicians, to treat those who were ill.

Hospital Origins

Several early cultures developed institutions to care for the sick. Ancient Indian sources describe centers that dispensed medicines and engaged specially trained personnel to care for the ill. Classical Greek society produced the *asklepieia*, the temples of the god of medicine, where the sick sought divine and natural cures. The Roman Empire supported *valetudinaria* (infirmaries) providing medical care to legionaries stationed on the barbarous northern frontier. None of these institutions, however, was strong enough to survive the upheavals that destroyed much of ancient civilization in Eurasia between 200 and 600. Modern hospitals trace their origins, and even their name, not to Indian treatment centers, Greek *asklepieia*, or Roman *valetudinaria* but to the hospices and hospitals established by the Christian church during the late Roman Empire.

From its earliest days, Christianity demanded that its adherents aid sick and needy people. Christians believed that on the Last Day, God would judge according to the love one had shown those in need. Had one fed the hungry, sheltered the homeless, visited the sick (Matt. 25:31–46)? By the early second century, bishops such as Polykarp of Smyrna expected Christian clergy to take care of the sick, orphans, and widows.

Local Christian clergy assisted the unfortunate without any formal charitable institutions until the fourth century. Thereafter, in the eastern Greek-speaking provinces of the Roman Empire, the demand for charity became so great, especially in the larger cities, that specialized institutions called *xenodocheia* (hospices) appeared. By the 320s the church in Antioch operated a hospice to feed and shelter the poor of Syria. By the mid-fourth century, the pagan emperor Julian referred to hospices as common Christian institutions.

Before 360, Christian hospices did not focus attention on the sick; but during the 370s Basil, bishop of Caesarea in Asia Minor, opened an institution where physicians and nurses treated patients. Two decades later, Bishop John Chrysostom supervised hospitals in Constantinople where doctors tended the sick. By about 410, the monk Neilos of Ankyra considered the hospital physician a common figure in the Greek Christian world. These early hospitals thus evolved from simpler hospices by expanding their services to include free medical care for needy guests.

Christian bishops built hospices during the fourth century and subsequently created more specialized hospitals for the sick, not only because they wished to follow Christ's command to practice charity but also because they sought support for the new religion among the urban lower classes. During the fourth century the cities of the Eastern provinces experienced an influx of rural poor who migrated to towns in search of food and employment. Classical civic institutions could not feed, house, and care for these new residents. The local bishops used the expanding resources of the Christian church to build hospices and hospitals for these migrants, and thereby won support both from the many poor and from the urban aristocrats. When Emperor Julian (361–363) tried to halt the spread of Christianity, he emphasized that the "Galilaeans" had succeeded in part because of their charitable institutions.

Early hospitals met their expenses from the revenue of lands that local bishops had donated. Subsequently, wealthy aristocrats and the emperors augmented these resources. As Christianity expanded it destroyed some aspects of classical civilization, but others it simply reoriented. For example, Christianity wholeheartedly accepted the classical obligation of aristocrats to benefit local cities, but the Christian church

encouraged donors to endow institutions such as hospitals rather than traditional theaters, baths, and ornamental colonnades. By supporting hospitals a Christian aristocrat not only acted charitably but also fulfilled the classical duty toward the city. Moreover, such benefactions cemented local political support. This same combination of Christian morality, classical traditionalism, and political realism motivated emperors in their benefactions (Miller, 1985).

Hospitals of the Byzantine and Muslim Worlds

Hospitals developed most rapidly where they had first appeared, in the eastern half of the Roman Empire. The large cities of the eastern Mediterranean and the stable political conditions of the eastern Roman, or Byzantine, Empire fostered their hospitals' further evolution. By the late sixth century, Christian hospitals such as the Sampson Xenon (hospital) of Constantinople maintained specialized wards for surgery patients and those with eye diseases. Moreover, the premier physicians (*archiatroi*) of the Byzantine capital were assigned monthly shifts to treat patients in the Sampson and in other hospitals of the city. By the twelfth century the hospitals of Constantinople had evolved into relatively sophisticated medical centers. The Pantokrator Xenon maintained five specialized wards, seventeen physicians, thirty-four nurses, eleven servants, and a store of medicines supervised by six pharmacists. The Pantokrator treated outpatients as well as those who were hospitalized. Emperor John II (1118–1143), the founder of the Pantokrator, reminded the hospital's staff that the sick were God's special friends and that caring for patients was more important than maintaining buildings (Volk).

From their beginnings, the Christian hospitals of Byzantine cities were designed for the poor, but as these institutions became increasingly sophisticated medical centers served by the best physicians, some middle-class and a few wealthy patients began to use them. In this regard Byzantine practice differed markedly from the medieval West, where the bourgeoisie and nobility shunned hospitals as institutions solely for the destitute.

Medieval Islamic society maintained hospitals (in Persian, *bimaristani*) that equaled those of Byzantium. The first Islamic hospitals were founded in Baghdad during the reign of the caliph Harun al-Rashid (786–809). According to a governor of the caliph, Islamic hospitals had become common by the 820s; subsequently Muslims considered support of hospitals a mark of true piety.

Like Byzantine hospitals, *bimaristani* had evolved from earlier Christian philanthropic institutions in large cities of the Byzantine Empire. When Emperor Zeno expelled Nestorian Christians from Syria in 489, many sought refuge in Persia, where they established institutions, including hospitals, modeled on those in Byzantine cities such as Antioch. After the Muslims conquered Sassanid Persia in the seventh century, they came in contact with Nestorians. Impressed by Nestorian medical skills, they adopted many Syrian medical traditions—teaching methods, scientific texts, and hospitals—as models for shaping Islamic institutions.

Although Islamic hospitals evolved from Christian institutions, they experienced a unique development. They differed strikingly from their Byzantine counterparts by including separate sections for mental patients. Gradually these psychiatric wards became the most prominent features of *bimaristani.* Neither Byzantine nor medieval Western hospitals had wards for mental patients (Dols).

Medieval Western Europe

Hospitals developed more slowly in the western Roman Empire. Saint Jerome (ca. 331–420) mentioned two small hospitals near Rome about 400. During the early Middle Ages, however, social conditions retarded hospital development in western Europe. Barbarian invasions from the north and Muslim advances in Africa inhibited political, economic, and social life. Few towns of the size and complexity that could support medical centers such as the Byzantine and Muslim hospitals survived. In the domains of Charlemagne (768–814), hospitals did not evolve beyond simple hospices. As late as the thirteenth century, hospitals were rare in Europe. None of the 112 houses for the sick in medieval England provided physicians for their patients, nor did they stock any medicines (Carlin).

In the twelfth century, a new religious order, the Knights of the Hospital of Saint John of Jerusalem (known today as the Knights of Malta) reintroduced into Europe specialized medical care for the sick when they organized their renowned hospital in Jerusalem. Under Byzantine influence, the Knights' rule for this hospital mandated a permanent medical staff of four physicians and four surgeons to treat patients. Moreover, the Knights developed a unique philanthropic ethic by adapting feudal notions to the traditional Christian command to aid those in need. The Knights were to treat the sick in the Jerusalem hospital as vassals served their overlords. As the Knights expanded, they built many smaller hospitals in the towns of Europe where they introduced practices they had established in Jerusalem (Sire).

The Knights' hospital in Jerusalem inspired many similar institutions throughout western Europe. Using its

rule as a model, Pope Innocent III established in 1200 the famous Hospital of the Holy Spirit in Rome. In 1217 the church in Paris reorganized its ancient hospice, the Hôtel-Dieu, by drafting a new constitution based on the regulations of the Jerusalem hospital (Miller, 1978).

The Knights of Saint John had such a wide-ranging effect not only because their rule inspired western Europeans to help the needy, especially the sick, but also because Latin Christendom was entering a new phase of urban growth. As country dwellers migrated to the towns in growing numbers, these newcomers were exposed to a wider range of diseases. Hospitals became necessary to treat the rapidly growing number of sick among the urban poor. In fact, the economic and social conditions in the expanding towns of thirteenth-century Europe were remarkably similar to those in the fourth-century Byzantine cities where hospitals had first appeared.

An examination of the rule for the Roman Hospital of the Holy Spirit, however, indicates one important difference between the new institutions of the West and the Jerusalem hospital. The Roman rule mandated many of the Knights' practices, but it omitted any reference to physicians or surgeons. The same is true of the rule for the Hôtel-Dieu of Paris. Only gradually did physicians come to serve in these hospitals. The records of the Hôtel-Dieu do not mention a permanent staff physician until 1328. As late as the eighteenth century a physician visited Saint Bartholomew's Hospital in London only once a week. That trained doctors did not assume a major role in caring for patients in Western medieval hospitals distinguishes them from Byzantine *xenones* and Moslem *bimaristani*, where doctors not only treated the sick but supervised hospital administration.

It is also clear that some of the Western medieval hospitals did not provide care on the same level as did the Eastern medical facilities. The twelfth-century hospital at Saint-Pol in northern France maintained only six nurses (or nursing sisters) for sixty patients. Iconographic evidence indicates that at the Hôtel-Dieu in Paris patients sometimes shared beds. The wards of many medieval hospitals were also poorly heated. Conditions such as these no doubt made it difficult for hospitals to heal the sick and provided some support for the charges of later Enlightenment reformers that all medieval hospitals had in fact been death traps (Miller, 1985).

Renaissance Italy

Inspired by the Jerusalem hospital, the communes of Tuscany began building hospitals during the thirteenth century. Before 1300, for example, the town of Siena built an institution that differed from the Hôtel-Dieu of Paris in that it maintained on its staff a physician, a surgeon, and a pharmacist. In 1288 Folco Portinari, the father of Dante's Beatrice, founded the Hospital of Santa Maria Nuova in Florence; by the fifteenth century, this institution had developed into an elaborate center for medical treatment. A document dated 1500, but reflecting earlier arrangements, reveals that Santa Maria paid six of the best physicians of Florence to visit patients each morning. In addition, three young interns lived permanently at the hospital. In return for room and board and a valuable opportunity to gain experience in medical practice, they served the hospital's 300 patients by monitoring their conditions and making daily reports to the senior physicians.

Santa Maria Nuova was not a death trap, as were some less well-organized hospitals, nor was it a hospice where poor sick people were simply nourished. It provided its patients access to society's best physicians and boasted an excellent rate of cure. Hospital records reveal that about 85 percent of the patients recovered from their ailments (Park; Henderson).

At Santa Maria Nuova, the interns were willing to serve patients for free not only because such service was virtuous but also because it offered them an unparalleled opportunity to observe the course of many diseases. During the sixteenth century, the medical professors of Padua (in Venetian territory) established formal clinical instruction at the Hospital of San Francesco. Many students from northern Europe came to study at Padua because of its excellent empirical training (Bylebyl).

Conclusion

Modern scholars have not been inclined to examine medieval hospitals because of the prevailing view that these were poorly equipped asylums that offered the sick only minimal medical care. Such institutions supposedly had nothing in common with today's hospitals. This view has its origins in Enlightenment skepticism concerning religious institutions. Eighteenth-century intellectuals contrasted the efficacy of science in curing human ills, including disease, with the helplessness of Christian charity, which at best provided only comfort, not true remedies.

However, hospitals in Renaissance Italy, as well as those in medieval Constantinople and Baghdad, demonstrate that philanthropic institutions were not necessarily isolated from scientific medicine. In fact, hospital service in Italy came to form a vital part of medical training, first in Florence and then at the University of Padua. In hospitals such as Santa Maria Nuova, the Christian command to aid the needy interacted with a sense of civic pride and with a concept of

professional ethics on the part of physicians to create institutions that were both truly philanthropic and efficient in curing the sick.

HOSPITAL, MODERN HISTORY OF THE

• • •

Although a few Renaissance institutions supplemented charitable assistance with professional medical care, the hospital's gradual *medicalization* occurred from the seventeenth century onward, within changing social and scientific frameworks. Three distinct periods can be identified within this development: (1) the early shift of the hospital from welfare to medical establishment, 1650–1870; (2) the evolution of a successfully medicalized institution for all social classes, 1870–1945; and (3) the creation of a specialized showcase of scientific medicine, 1945 to the present.

From Welfare to Medicine: 1650–1870

During the early modern period, hospitals in Europe's urban centers were charitable shelters for the poor and working classes, functioning primarily as instruments of religious charity and social control with minimal involvement of the medical profession. Whether the patients were Catholic or Protestant, hospitalization continued to be an opportunity for physical comfort as well as moral rehabilitation. However, in time of epidemics such as plague and syphilis, specialized hospitals were created to ensure the isolation of the sick and thus avoid the spread of contagion. Given the expanding institutionalization of charity, the decline of religious institutions, and new roles in the preservation of public health, hospitals increasingly came under lay control, including municipal governments, fraternal organizations, and private patrons.

After 1650, new geopolitical agendas designed to increase the power and prosperity of the emerging national states pressed hospitals into new roles. Human life was given greater financial value as population policies were aimed at increasing the number of inhabitants as a base for state power, economic development, and military strength. Proponents of emerging European mercantilism viewed labor as the key source of wealth and urged that the nation's workforce be mobilized and kept at an optimum state of productivity. Within such a framework, the desire to promote the health of citizens inspired new programs of public health, hygiene, and medical care.

At the same time, more optimistic visions of health preservation and rehabilitation elaborated by Enlightenment thinkers suggested that sickness, instead of an inevitable, sinful, and often long-term human burden, could be controlled and eliminated. In addition to their traditional moral and physical aims, hospitals were now envisioned as institutions for physical rehabilitation and cure, places of early rather than last resort, especially for military personnel and the labor force. This agenda implied a greater involvement of the healthcare professions with large sectors of the population hitherto without such contacts.

To implement their new health policies, national governments, local authorities, and corporate professional bodies organized efforts to reform the existing medical and surgical professions. Physicians and surgeons were granted new forms of access to hospitals and given new rules to guide their institutional activities. Early models for the medicalization process came from military and naval establishments that provided for the sick and wounded members of Europe's expanding military forces. Later, medical professionals working in civil hospitals also began to argue successfully that their management of patients provided a valuable addition to the rest and food traditionally furnished to inmates in religious shelters. During the late eighteenth and early nineteenth centuries, medical objectives dramatically reshaped hospital routines from admission to the discharge or death of the patient. Acute rather than chronic illnesses were preferred; young rather than old patients were accepted. Rehabilitation and cure were the new goals.

HOSPITALS AS TRAINING INSTITUTIONS. At the same time, surgeons—and later physicians—recognized the great opportunities hospitals offered to improve their clinical skills and thus increase their power and status. By the eighteenth century, shifts in scientific ideology emphasized the importance of empirical studies and the construction of knowledge based on observed facts. Surgeons in France and Great Britain were especially keen to acquire practical knowledge of anatomy, pathology, and clinical management. After the French Revolution, physicians in that country initiated a new strategy of professional and social advancement under the banner of what was generically called the *medicine of observation.* With significant numbers of sick people assembled in hospital wards, doctors could observe at the bedside the evolution of individual diseases and their diagnoses on a much larger scale than they could in private practice. Postmortem dissections performed on former hospital inmates provided further information on the pathology responsible for the symptoms. Moreover, patient management offered unequaled opportunities to check the usefulness of the traditional medical regimens, especially the effects of older remedies. Efforts to upgrade the preparation and uses of drugs involved clinical trials and statistical analysis. Hospitals became the focal points of comprehensive bedside research programs.

Finally, the expanding medical and surgical presence in European hospitals made such institutions increasingly attractive as places for education and training of rank-and-file practitioners. Hospitals were seen as "great nurseries" that could "breed some of the best physicians and chirurgeons because they may see as much there in one year as in seven any where else" (Bellers, 1714). In certain establishments, the authorities created special teaching wards where professors and attendants, followed by their students, made regular rounds of the patients. Instruction varied greatly, from passive observation to supervised and even independent, hands-on examination and management of the patients by students and apprentices.

REORGANIZATION OF THE HOSPITAL STRUCTURE. How did the hospital as an institution adapt to these new agendas? France possessed several types of organizations, including massive *hôpitaux générales,* or hospices, for the elderly poor, beggars, vagrants, incurables, and prostitutes. There were also small welfare establishments at the parish level for similar cases. In larger urban areas, the traditional *Hôtels-Dieux* now limited admissions to the sick but excluded incurables, the insane, and venereal cases. All original ward layouts were based on medieval principles, providing in a shelter as many beds as possible and still crowding three to four individuals into each bed. Hospital size was fiercely debated, with advocates of medicalization arguing for smaller institutions to prevent cross-infections.

In Great Britain and the young American republic, major population centers possessed a number of *voluntary infirmaries,* or private hospitals, founded and operated by local philanthropists and often financed by a system of yearly

subscriptions solicited from local merchants and professionals. Except for accident cases, these establishments admitted only a very restricted number of the sick poor. These persons, recommended for admission by the subscribers, were judged by the community to be willing to work and thus *deserving* of hospital care and rehabilitation. In addition, there were a number of private special hospitals, especially in London after 1800, supported by contributions and patient fees and operating under the direction of medical professionals. By contrast, English "poor law" infirmaries were supported financially by parish taxes and linked to local workhouses, which provided free care to the sick poor deemed able bodied, or vagrant, and thus *undeserving* of other charitable assistance. Later, in the nineteenth century, many of these workhouse infirmaries evolved into municipal hospitals and were placed under the direction of salaried medical superintendents. At the same time, and with financial support from leading local citizens, Great Britain also created a string of small cottage hospitals, providing paid medical care to those who could afford it.

To support expanding medical services and teaching activities, nineteenth-century hospitals required more money and changes in their physical plants and administrative organizations. By the 1870s, hygienic principles had come to dominate the construction and functioning of new establishments, now equipped with single beds for the sick and providing ample ventilation in their pavilion-type wards. Isolation chambers, surgical amphitheaters, emergency rooms, morgues, libraries, and outpatient facilities became indispensable adjuncts. Medical control also shifted power from patients and caregivers to attending physicians, thereby creating conflicts between traditional charitable practices and scientific goals of disease identification and management. Medicalization implied a shift from the primary focus on shelter and food for the needy to the diagnosis and treatment of diseases exhibited by sick patients.

A Hospital for All Social Classes: 1870–1945

Thanks in part to advances in medical knowledge and technology, the medicalization process of Western society was significantly advanced before the end of World War II. By 1900, upper- and middle-class patients in Europe and the United States were seeking and paying for medical care in hospitals. Staffed by competent medical and nursing professionals, and equipped with clinical laboratories and other diagnostic tools, hospitals became the preferred destination of those who were acutely sick and in need of surgical and medical care. The newly created demand for hospital care, spurred by urbanization and industrialization, expanded further to include the needs of birthing and child care.

In the United States, such requirements were eagerly met by the establishment of a vast, decentralized system of voluntary hospitals fiercely competing for community resources, physicians, and their patients. Local private citizens provided the necessary funds and volunteer service required to create general community hospitals. Alongside schools, police stations, and firehouses, U.S. general hospitals became emblems of community life, the pride of Main Street. In Europe, many hospitals became governmental facilities managed by paid professionals.

The new hospital mission was a result of converging ideologies, policies, and needs, some traditional, others new. Religious values and charitable donations still played an important role in the early 1900s, while developing economic tenets based on capitalism suggested that the health of workers in the industrial world was of great importance both to the state and to the private sector. In the United States, new social conditions favored the creation and utilization of more hospitals. Urbanization was accelerating at a rapid pace, bringing an ever-increasing number of adults into crowded city quarters. Among them were waves of new immigrants with multiple healthcare needs and few resources. Industrialization, in turn, created a new panorama of occupational diseases and accidents. Without the means or family networks to get the necessary help, many sick or injured individuals were thus forced to seek medical care in hospitals.

Under the new banner of scientific medicine, hospitals became the institutions of first rather than last resort. Thanks to the increasingly sophisticated diagnostic and therapeutic procedures offered in hospitals after 1900, optimistic Enlightenment notions of physical rehabilitation and cure were becoming a reality. Radiology, electrocardiography, and the clinical laboratory greatly improved the ability of hospital personnel to refine diagnoses. In addition to providing rest and a healthier diet, hospitals focused increasingly on managing acute diseases, especially life-threatening conditions that required intensive and highly technical care. A new generation of chemotherapeutic agents and vaccines improved the odds of success in the battle against certain diseases. Following the adoption of anesthesia and antisepsis, hospitals became the primary centers for surgical operations. Surgeons recognized the advantage of centralizing their new and expensive equipment within the *surgical suites* of a hospital.

THE CHANGING STATUS OF NURSES, PHYSICIANS. For patient care, hospitals relied increasingly on a new generation of nurses, drawn from the middle class and trained in

professional education programs based on the model established by Florence Nightingale (1820–1910). Shedding their previous low-status role of cleaning women and servants, these new hospital nurses gradually displaced the dwindling number of religious staff members who had traditionally performed patient services. In time, the Nightingale nurses became valuable assistants to the medical profession in patient management.

By the 1910s, more physicians joined hospital staffs, staking their professional reputations on the achievements of scientific medicine such institutions seemed to make possible. In U.S. voluntary hospitals, medical staff organizations remained flexible, bestowing admission privileges on both local general practitioners and specialists who could deliver paying patients. In Great Britain, however, traditional social and professional barriers between general practitioners, on the one hand, and hospital-appointed physicians and surgeons, on the other, created insurmountable barriers in voluntary establishments. Although referring their patients to hospitals, the former were not allowed to practice within them. As so-called consultants, the latter operated small units and exclusively took care of a specific number of patients.

Since the hospital was rapidly becoming the physician's primary workshop in the 1920s, medical goals, including specialization, education, and research, needed to become top institutional priorities. Twentieth-century hospitals witnessed a dramatic growth of specialized care through the creation of clinical departments, an increase in student doctors, called *house staff,* and the performance of clinical research. Such activities became central to educational and licensing requirements, and conferred prestige and higher professional status on those allowed to work in the most preeminent institutions.

THE CHANGING FOCUS OF HOSPITALS. Once again the hospital as an institution adapted to these new agendas. Some new hospitals were associated or affiliated with medical and nursing schools. Others, especially in the United States, sprouted between 1890 and 1920 in ethnic urban neighborhoods, or strategic suburban locations, their creation influenced by state and local governments, population, philanthropy, or industry. Sectarian Jewish, Catholic, and Protestant institutions, German- and French-speaking clinics, municipal and state hospitals, private establishments sponsored by railroads and universities—all formed a constellation of autonomous units across the U.S. landscape.

In Europe, governments became increasingly involved in sponsoring and managing hospitals. In Great Britain, the Public Health Act of 1875 encouraged municipalities to establish isolation hospitals for persons suffering from infectious diseases. The poor law infirmaries were gradually taken over by local health departments and converted to general hospitals. The National Health Insurance Act of 1911 eliminated the charitable character of the voluntary hospitals and brought their services under the umbrella of regional healthcare schemes.

In the United States, hospital organizations in the 1920s changed to serve the new medical objectives and compete for paying patients, an ever-greater source of needed revenue. The rapid growth of medical technology generated further budgetary pressures, forcing voluntary hospitals to redouble their fundraising efforts and use endowment income for capital expenditures. As they became individual corporations in a competitive healthcare market, demands for greater efficiency prompted hospitals to bolster their administrations and institute stringent financial measures. Institutional care became a commodity, a product to be furnished mostly to those willing to pay for it directly or through health-insurance policies.

By the 1930s, economic conditions stemming from the Depression forced the creation of new funding systems, such as the Blue Cross health-insurance companies, organized by physicians. As competition for philanthropic support and patient revenue accelerated, accountability and public relations dominated the hospitals' administrative agendas. Since each U.S. institution was the proud product of individual community efforts, cooperation among hospital administrations was resisted.

As the hospital became the preferred locus for the application of scientific principles to medicine, new ethical problems appeared. The medicalization of life processes expanded the range of life experiences now addressed as medical problems by health professionals in hospital settings: Birth and death, formerly events that occurred in the home, now took place in the hospital. Since the early nineteenth century, a depersonalized, disease- and organ-centered approach had already replaced earlier holistic notions of sickness. As hospital routines became increasingly technical and standardized, patients came to be seen as merely embodiments of diseases that were the primary objects of inquiry and treatment. This approach affected the nature of the physician-patient relationship, as professionals focused primarily on successful problem solving in diagnosing and arresting human pathology. The physician's moral authority, hitherto based on personal qualities, now became grounded in scientific competence. Clinical experimentation became rampant, sometimes abusive, with few safeguards provided for the patients.

The Hospital as Biomedical Showcase: 1945 to the Present

Following World War II, the hospital rapidly consolidated its position as the embodiment of scientific and technologically sophisticated medicine. An explosion in medical knowledge led to the expansion of diagnostic and therapeutic services at hospitals. This development had far-reaching implications for institutional access, cost, and quality of care as delivered to a broad spectrum of the public under various private and state-sponsored health plans. The hospital's mission continued to reflect converging agendas, including the religious, political, economic, and scientific goals set in preceding decades.

In the United States, the federal government's involvement in sponsoring hospital care gradually expanded as the demand for institutional beds and services multiplied. Beginning with the Hill Burton Act in 1946, the federal authorities supported the existing system of decentralized, private hospitals—first, through the provision of construction subsidies, and later, through reimbursement schemes for services, such as the Medicare and Medicaid programs in 1966. This supportive rather than regulatory role preserved a network of independent and competing municipal, sectarian, and academic hospitals in each community. In marked contrast with events in Europe, the 1950s through the 1970s witnessed an impressive growth in U.S. hospital facilities, including neonatology and intensive-care units, imaging facilities, and transplantation services. Individual hospitals continue to operate as independent business organizations within a burgeoning healthcare *industry.* Periodic institutional accreditation by a joint commission of the American Medical Association and the American Hospital Association ensures compliance with a number of performance standards.

To work in hospitals of their choice, all practicing physicians in the United States must secure admission *privileges* in such institutions. Most hospital care is indeed rendered by private practitioners who briefly visit the hospital to check on the status of their patients. This system allows the establishment of larger and more mobile medical staffs whose authority remains diffuse. To exert some measure of control, medical staffs usually create a number of committees to deal with the issues of credentials, admissions, education, and quality control. (Hospital ethics committees grapple with a host of issues, from informed consent and patient autonomy to advance directives and the definition of death.) The resulting administrative complexity and instability require a great deal of consensus building, achieved through frequent meetings and written communications. This record keeping effort is especially important among the attending physicians and more permanent hospital personnel to achieve a necessary degree of internal standardization of medical and administrative procedures.

Hospitals in Europe, even those owned by municipalities or private bodies, continue to be closely supervised by central governments. All hospital planning, construction, management, and recruitment of medical personnel remains subject to state control. In Great Britain, the government has assumed responsibilities for ensuring free access to hospital care as a social right. The implementation of the National Health Service Act of 1946 brought about the outright nationalization of all hospitals and placed them under the authority of regional boards appointed by the government and responsible to the Ministry of Health. In many European communities, the larger municipal and voluntary hospitals erected more than a century earlier remain in full operation. Greater administrative uniformity has allowed for smaller staff requirements. Given these hospitals' outdated physical plants, limited technology, and often a lingering stigma from their charitable past, well-to-do patients still prefer smaller, privately owned hospitals or clinics, many of which are still owned or managed by religious orders.

European hospitals operate with closed, full-time medical staffs hierarchically organized within smaller, autonomous divisions, each of which operates its own clinical, diagnostic, and rehabilitative services. While such internal arrangements reduce administrative overhead and foster more stable relationships among patients, physicians, and nurses, the schism between hospital and private practice remains. In Great Britain, this decentralized staffing framework follows the traditional, voluntary models of allocating a specific block of beds to each hospital physician or consultant, who is assisted by a stratified junior medical staff in training for specialist status.

Financial Difficulties of Hospitals

Although outpatient facilities are quickly becoming an integral component of professional education, hospital-based training continues to be the backbone of all medical education programs. Given the range of diagnostic and therapeutic options available, hospital practice remains at the center of biomedicine, providing the specialized clinical experience and technical proficiency required for today's professional status. With medical specialization and subspecialization on the rise, U.S. hospitals have expanded dramatically and have extended their residency training programs. As a result, physicians in training exercise greater management responsibility and are better remunerated than ever before.

Due to restrictive reimbursement schemes instituted by government and the private insurance industry, and the escalating costs of technologically assisted medical care, together with a gradual fragmentation of the medical marketplace, many U.S. hospitals find themselves increasingly under siege, victims, in part, of their previous success. Excessively bureaucratized and inefficient, their physical facilities overexpanded, hospitals are struggling to maintain their patient volumes as costs continue to increase. Unable to survive in a highly competitive environment, some institutions have already merged while others are closing wards or their doors altogether, thus forcing a major restructuring of the entire medical-care delivery system. Many hospitals are being reorganized into for-profit corporations, extending their services into networks of clinics and practitioners, and offering health insurance and service plans.

Conclusion

Ultimately, the evolution of the hospital in recent centuries poses the central question of whether care is still the primary function of this institution. While subjected to competing agendas—including religious beliefs, social control, secular philanthropy, scientific curiosity, communal pride, and economic autonomy—the hospital's original purpose was to shelter and comfort all sufferers in need. To a great extent, hospitals now restrict admission to seriously ill patients who require the most sophisticated diagnostic and therapeutic measures. The tilt toward acute episodes of physical illness, complex technological interventions, and the increasing costs of confinement have made hospital stays episodic and brief. Bureaucratization, financial constraints, and the pervasive presence of instrumentation only accentuate the essential impersonality of institutional care. The trade-offs are clear. Three centuries of medicalization transformed the hospital from a caring shelter for the poor into a disease-oriented machine for the sick who can afford to be cured.

HUMAN DIGNITY

• • •

Few terms or ideas are more central to bioethics or less clearly defined than human dignity. Although the core idea of human dignity has to do with the worth of human beings, the precise meaning of the term is controversial. Respect for human dignity is an ethical mandate to which both sides of many bioethical debates appeal. For example, the state of Oregon legalized physician-assisted suicide by passing the Death with Dignity Act, but opponents claimed that legalizing that practice would undermine the dignity of elderly, disabled, and dying patients. Similarly, in response to claims that respect for the dignity of those patients demands the pursuit of cures through the production of embryos by means of cloning for embryonic stem cell research, others claim that producing human beings in embryonic form and destroying them for the benefit of others is an affront to human dignity.

Views of Dignity

This term also is surfacing more frequently in important bioethical and other public documents. It has played a role in the constitutions of a politically diverse array of countries, including Afghanistan, Brazil, Canada, Costa Rica, the former Federal Republic of Germany, Greece, Guatemala, Ireland, Italy, Nicaragua, Peru, Portugal, South Korea, Spain, Sweden, and Turkey. In some of those countries, such as Germany, the role of human dignity is substantial. Affirming that "the dignity of the human being is inviolable," the German constitution recognizes various human rights that the law must respect. Even in countries where the term has not been influential in constitutional language, it has come to play an important role. For example, the U.S. Supreme Court has employed the term in its deliberations over the meaning of the First, Fourth, Fifth, Sixth, Eighth, and Fourteenth Amendments to the Constitution.

International documents that are relevant to issues in bioethics also have affirmed the critical importance of human dignity. The United Nations, whose charter celebrates the "inherent dignity" of "all members of the human family," issued a Universal Declaration of Human Rights in 1948 whose preamble contains the same language. Article 1 specifically affirms that "all human beings" are born "equal in dignity." Two other documents—the International Covenant on Economic, Social and Cultural Rights and the International Covenant on Civil and Political Rights—were joined to that document in 1966 to constitute the so-called International Bill of Rights. All three documents ground the various rights of all human beings in their human dignity. In line with this outlook, the Council of Europe's 1996 Convention on Human Rights and Biomedicine was designed explicitly to "protect the dignity" of "all human beings."

These documents reflect the primary sense in which human dignity is invoked today: as an attribute of all human beings that establishes their great significance or worth. The word *dignity* comes from the Latin words *dignitas* ("worth") and *dignus* ("worthy"), suggesting that dignity points to a standard by which people should be viewed and treated. Although the standard usually has an egalitarian bent today, in ancient Greece and Rome the standard more commonly was attached to inegalitarian traits such as physical prowess and intellectual wisdom, as exemplified in figures such as Hercules and Socrates. People differed in dignity according to the degree to which they manifested the relevant traits, and the honor due them varied accordingly. This sense of dignity persists today when one speaks of dignitaries who warrant special honor or behavior that is dignified or undignified. Dignity in this sense can increase or decrease, can be gained or lost (Spiegelberg).

Dignity can refer to something that is variable in other ways as well. There is a difference between having dignity, on the one hand, and having an awareness of dignity or being treated with dignity, on the other hand. Someone may not be aware of having dignity though possessing it nevertheless; someone may not treat people in a particular group as having dignity though they may possess it. Such variability, however, should not be confused with the contemporary concept of dignity that is beyond the perceptions or actions of particular individuals and is rooted in what all human beings have in common. This is the concept that typically is operative when human dignity is invoked as the basis for the ways in which human beings should be viewed or treated.

Respect for human dignity is connected to a virtue as well as an ethical standard. A virtue-oriented approach to human dignity may take different forms. For example, exhibiting human dignity (usually referred to simply as dignity) can be a virtue in a way that is reminiscent of the notion of dignified behavior discussed above. To say that certain people exhibit dignity or are dignified can be a way of commending their courageous attitudes or actions in the face of adversity. However, the virtue of human dignity may

refer to a person's capacity to recognize and live in accordance with a particular standard of human dignity. This form of the virtue serves as a reminder of how important it is that respect for human dignity be lived out in practice rather than existing only as an abstract concept. Exercising such a virtue still requires specifying what human dignity is.

People most commonly view human dignity in one of two basic ways. Some see it as grounded in particular characteristics of human beings; others view it as attached to being human per se. Both understandings are examined below, and then this entry surveys some of the bioethical implications of those views. First, it is necessary to clarify the significance and meaning of the concept by noting arenas in which it has been denied.

Challenges to Human Dignity

In the twentieth century perhaps the most widely decried denial of human dignity took place under the fascist regime in Germany; this accounts for the emphasis on dignity in the German constitution and the international and European documents discussed above. Millions of people were forced to be subjects of experimentation against their will or were tortured or killed for other reasons. As a result, the importance of human freedom and bodily integrity became much clearer and the danger of compromising them in the interests of the larger society became widely evident.

A tension necessarily exists between the idea of human dignity and ethical outlooks, such as utilitarianism, that, at least in their more popular and influential forms, affirm human dignity only to the degree that doing so is recognized to be sufficiently beneficial. Although the good of society is important, it potentially can justify doing anything to certain individuals, no matter how destructive, unless some standard of human dignity prevents that from happening. From a utilitarian perspective, what ultimately matters is the benefit itself (e.g., pleasure or preference satisfaction), not the individuals who benefit.

Others who are not well disposed to the notion of human dignity reject its high regard for freedom of choice or bodily integrity. Those who are most skeptical about freedom of choice include some in the social and biological sciences. Psychiatrists and psychologists who follow Sigmund Freud, for example, argue that freedom of choice is an illusion: Choices are driven largely by unconscious and irrational forces. Behaviorists who follow B. F. Skinner see such freedom as illusory because in their view behavior is driven more by environmental stimuli than by freely willed choices. Some biologists are skeptical about attributing any special dignity to humans because they are less impressed by any apparent differences between the abilities of people and animals to make free choices than they are by biological similarities between humans and animals. Those similarities go beyond the ability to experience pleasure and pain to encompass certain genetic, physiological, and other mental similarities.

Those who are skeptical about the high regard for bodily integrity in the notion of human dignity include so-called postmodernists and posthumanists. Postmodernists reject the "modernist" notion of a universally binding objective truth that has a wide range of implications for the ways in which people should be treated. Many postmodernists would characterize as oppressive the idea that certain applications of technology to the human body are inherently unethical (i.e., violations of human dignity). Posthumanists, in contrast, doubt the value of the human body. Bodily form is seen as an accident of history that eventually will be replaced through developments in cybernetics and artificial intelligence. According to this view, because human beings have no lasting significance, human dignity is an illusion.

Characteristics That Give Humans Dignity

In the face of such challenges there has persisted a widely shared commitment to human dignity: the conviction that human beings have a special worth that warrants respect and protection. The big question is: For what reason? Many people have addressed this question, and their responses are basically of two types. The first type of response maintains that human beings have dignity because of one or more characteristics that are typically human. This view can be traced back at least to Marcus Aurelius and earlier Stoic philosophers who held that human beings have a basic equality that is rooted in their common ability to reason. It can be spotted occasionally in later periods—for example in Renaissance thinkers such as Pico della Mirandola and Enlightenment philosophers such as John Locke.

A full-blown account of human dignity rooted in reason took on its most complete form in the work of Immanuel Kant, especially in his *Groundwork of the Metaphysics of Morals,* where he argues that "morality, and humanity so far as it is capable of morality, is the only thing which has dignity" (p. 102). In other words, human beings do not have dignity simply because they are human but because and to the extent to which they are capable of morality. Because for Kant "morality lies in the relation of actions to the autonomy of the will" (p. 107), he concludes that "autonomy is therefore the ground of the dignity of

human nature" (p. 103). Simply put, human beings have dignity because autonomous reason rather than impulses or the pursuit of personal or social benefit governs their actions.

According to Kant's principle of autonomy, a human being "is subject only to laws which are made by himself and yet are universal" (p. 100). Both parts of this principle are essential. Moral decisions must be self-made rather than imposed by others, even by God, but they also must be decisions that could be made consistently and acted on by everyone rather than products of an individual's personal view of reality, as in postmodern autonomy. In Kant's words, "all merely relative" ends are excluded: "The principle of autonomy is 'Never to choose except in such a way that in the same volition the maxims of your choice are also present as universal law'" (p. 108). Because they have autonomy, human beings have dignity, as opposed to price: "Everything has either a price or a dignity. If it has a price, something else can be put in its place as an equivalent; if it is exalted above all price and so admits of no equivalent, then it has a dignity" (p. 102). Accordingly, human dignity requires that a human being be treated "never merely as a means" but "always also as an end" (p. 105).

Deryck Beyleveld and Roger Brownsword, among others, have tried to go beyond Kant and develop a reason-based approach to human dignity together with its implications for bioethics. They affirm Kant's attempt to root human dignity in people's reason and capacity to be moral agents, but they prefer to follow Alan Gewirth in adopting an understanding of agency that is focused more on choice. For Beyleveld and Brownsword "the essence of the dignity of agents resides in their capacity to choose, to set their own ends" (p. 5). Consequently, they prefer to see human dignity more as empowerment than as constraint. Whereas Kant's emphasis on people as "ends in themselves" fosters significant attention to limits on the ways in which people may be treated, even by themselves, these authors see the protection of each individual's right to choose as the primary mandate flowing from the rooting of human dignity in reason.

Despite the preoccupation with individual rights in many discussions of human dignity, especially in the West, the focus on the individual as opposed to the community is not inherent in the concept. A communitarian approach can champion human dignity in various ways. For example, it can establish respect for autonomy and choice as the hallmark of what should characterize a society. However, it also can promote a vision of how people should and should not be treated that limits individual choices.

Regardless of its individualistic or communitarian bent, any attempt to root human dignity in human characteristics such as reason and autonomy faces at least two important hurdles. First, it is possible for a living human being to lack such characteristics yet still be recognized as a human being. Are there human beings who lack human dignity? If having human dignity requires possessing the ability currently to exercise moral capacity or autonomy, for example, those who have mental disabilities, are comatose, are children, or are still in the womb do not have human dignity even if they are recognized as human beings (Gaylin). Often these are the individuals who are most in need of the protection that a concept of human dignity is designed to give.

Proponents of autonomy-based approaches have tried to give at least partial status and protection to those human beings in various ways. For example, Gewirth ties the level of a being's moral status to the degree to which that being has the necessary characteristic or characteristics. However, if human dignity is something one either has or does not have, as is affirmed typically, and if autonomy is the characteristic on which human dignity is based, then anyone without true autonomy does not have human dignity. Beyleveld and Brownsword agree but think it possible to grant those persons moral status on the basis and to the degree to which they may be moral agents who have autonomy. However, in cases in which there is a significant possibility that beings with autonomy are present, many people would consider it better to recognize and respect their human dignity rather than giving partial respect even to the simplest life forms under the assumption that they may be autonomous beings.

The second hurdle for this approach to human dignity is the plausibility of holding that what matters about human beings can be reduced to specific characteristics. Kant, for example, has been criticized for reducing what ultimately matters about human beings to the mind—to the rational—for that demeans bodily existence, which is essential in matters of bioethics (Kass). In fact, the focus on characteristics is vulnerable to the very criticism that it uses against its alternatives: It reduces human beings to what people in general or a particular community values about them and so in principle invalidates ascribing human dignity to them. The view that a particular characteristic such as moral capacity or autonomy is a sufficient basis for granting human beings an exalted status called human dignity may seem intuitively plausible to many, but it does not seem so to others. Accordingly, this approach is "based upon an anthropological 'creed'—not necessarily a religious creed" (Hailer and Ritschl, p. 99).

Dignity Rooted in Being Human

Because basing human dignity on particular human characteristics has difficulties, it may be preferable to root that

dignity in being human per se. One way to do that is to focus on a basis from which all characteristics may be said to flow, such as the human genetic code. The 1997 Universal Declaration on the Human Genome and Human Rights of the United Nations Educational, Scientific, and Cultural Organization, for example, affirms that all human beings are equal in dignity because of the underlying unity provided by the human genome. Although this commonality may suggest a basic equality in all human beings, it does not address the significance of all human beings.

If their significance cannot be rooted in who people are, that is, in the specific characteristics discussed above, perhaps it can be found in something or someone beyond themselves. One candidate would be the sort of universal force acknowledged in Buddhism (Inoue). Because that force is in all living things, though, whatever dignity it imparts is not particularly human. However, if there is a God who establishes a special relationship with human beings that confers special worth on them, all people may be said to have a dignity that is distinctively human.

No such account of human dignity has had greater influence than the one portrayed in the authoritative writings of several major religious traditions, in which human beings are described as the "image of God." In addition to its role within religious traditions such as Judaism (Cohn), Christianity (Moltmann), and Islam (Bielefeldt et al.), this account has had a substantial impact on public formulations of the concept of human dignity (Bayertz). For illustrative purposes, this entry will consider this notion as it appears in the Christian Bible, since much of the Bible's relevant content is shared by other religious traditions.

The Bible uses two basic terms for *image*: the Hebrew *tselem*/Greek *eikon* (generally translated as *image*) and the Hebrew *demut*/Greek *homoiosis* (generally translated as *likeness*). Although there have been attempts to distinguish the two terms, it generally is recognized that they are used almost synonymously throughout the Bible. Usually one or the other appears, but occasionally, as in the account of the original creation of humanity in Genesis, both are employed. The sense conveyed is that of an image that is truly representative of God (Bray). In this view human dignity is not tied to a claim that human beings are divine or inherently worthy apart from God, and it is not because of human autonomy independent of God that people assume the authority to declare their own worth. Instead, human dignity is grounded in humanity's unique connection with God, by God's own initiative. This connection has three aspects: creation, alienation, and renewal. The first two have special significance for human dignity as an ethical standard, and the third for human dignity as a virtue.

In terms of creation, Genesis 1 (with a reaffirmation in Genesis 9) indicates that the image of God attaches to that which is human as opposed to that which is animal or plant. As a human child was considered the *tselem* of a parent (Genesis 5) and a *tselem* in the ancient Near East could refer to a statue reminding people of a king's presence (Westermann), human beings were created to have a special, personal relationship with God that includes their being God's representative in the world. Accordingly, the Bible speaks of human beings not only as being created in the image of God but also as being the image of God. This is striking because images of God are strictly forbidden in the Bible (e.g., Deuteronomy 4). However, the consistent message is that people are not to fashion images to make God the way they want God to be any more than they are to be God themselves. They are to manifest God to the world in accordance with the way God has made them and continues to direct them to be.

There have been attempts to attach more specific content to being the image of God. Some have seen its essence as involving humanity's (like God's) ability to reason, relate to others, or rule the world. However, others have maintained that those interpretations are read into the biblical text rather than read from it. For instance, Genesis does identify creation in God's image as unique to human beings, as opposed to other living things, and does instruct people about their responsibility to exercise stewardship over the rest of creation. However, the second instruction, some note, is not part of the description of what creation in God's image is; it is a separate matter that exemplifies what can be expected of one who is created in God's image. Similarly, they add, it is not surprising to find rational and relational abilities in those created in God's image, but they are never identified as what constitute that image (Cheshire). Angels, for instance, appear to have similar abilities but never are identified as being created in God's image. The picture presented in the biblical writings is that human beings themselves, not particular attributes or functions, are through God's creation the image of God.

The Bible goes on to record, however, that human beings were not and never have been content simply to be who God made them to be. In deciding to do things their own way, to give in to the temptation to "be like God" on their terms rather than God's (Genesis 3), they have experienced alienation not only from God but also from their own best selves, other people, and the rest of creation. Their capacities to reason, relate, and rule well have been damaged severely (Psalm 14, expanded in Romans 1, 8), and people now seek to create images to worship (including themselves) because they have lost sight of the fact that they are images of

God created to reflect and direct worship toward God rather than to be worshiped themselves.

Even in this alienation human beings remain the images of God, for God will not allow all connection with their Creator to be broken. The ethical standard of respect for human dignity gains its force precisely from this ongoing connection, for those who are dealing with human beings are dealing in a significant sense with God. Killing an innocent human being is equivalent to destroying an image of God without warrant from God and for that reason is unacceptable (Genesis 9), as is the attempt to tear down a human image of God verbally through cursing (James 3). Human dignity as constraint thus joins human dignity as empowerment once alienation has occurred and protection of human beings has become necessary.

The ethical standard of respect for human dignity rooted in the biblical accounts of creation and alienation, as was noted above, is affirmed in various religious traditions, as is the virtue of recognizing the dignity of human beings in words and actions, along with the difficulty of doing that once one is alienated from God. What the remainder of the biblical story adds is a particularly Christian account of how that marred image of God can be renewed, and with it the ability to live out the virtue of human dignity. For alienation to be replaced by reconciliation—for renewal to occur—according to this account, people literally must undergo a new creation (2 Corinthians 5). They must recognize the hopelessness of their alienation, give up all attempts to improve their situation through their own (futile) efforts, and invite God to re-create them in the image of God revealed in Jesus Christ. Although the creation is new, the image on which it is based is not, for Christ is identified not only as the image of God but also as God who created humanity in God's image in the first place (Colossians 1).

The new creation is portrayed as both ontological and logical. It is ontological in that it is an event in time that involves a change in being; it is logical in that it involves a process that flows logically from that event. People become in practice who they already are in being. This is said to be God's doing—people "are transformed" into the image/likeness of Christ (2 Corinthians 3)—but it also requires them to "be who they are" and "put on the new self, created to be like God" (Ephesians 4).

When people are renewed "in the image of their Creator," the result is described in terms of not only renewed individuals but also a renewed community: "Here there is no Greek or Jew, circumcised or uncircumcised, barbarian, Scythian, slave or free" (Colossians 3). Differences no longer divide; they disappear or in some cases can even enhance community, in which the human dignity of all is recognized. Those who are renewed images of God warrant no better treatment than does any other human being in this view because all human beings have human dignity by virtue of their original creation in God's image. However, those who are renewed images are characterized as increasingly more capable of exercising the virtue of human dignity than they would be otherwise.

God makes covenants with human beings, became a human being in Jesus Christ, retains that humanity eternally, died in humanity's place to pay the penalty for human rebellion against God, and will appear personally to bring humanity into an unending celebration of life with God, at which point people finally will understand all that being in the likeness of God entails (1 John 3). All these historical developments fill out the biblical account of human dignity but also rest on the basis that human beings are images of God, which some identify as the *essence* of what it means to be human (Berkouwer).

Rooting human dignity in being human, like basing it on specific human characteristics, faces at least two important hurdles. First, although it avoids the problematic idea that there could be human beings without human dignity, it begs the question of who is a human being. Does anyone with a human genome qualify, and if so, how much of the human genetic code must be missing or nonfunctional before status as a human being is lost? Are certain capacities instead or in addition what constitute a human being, and if so, must the exercise of those capacities be actual or may it be potential?

The second hurdle for this approach also has to do with its plausibility. Those who reject the existence of God or the notion of the image of God necessarily reject this approach. Some go further and find the idea of according a special dignity to the human race per se to be a form of "speciesism" that is ethically akin to racism or sexism (Singer). Just as that critique is not necessarily a religious one, attempted refutations do not necessarily depend on religious argument (Chappell). In any case, as was noted above, every approach to human dignity rests on some form of an *anthropological creed* whose plausibility must be assessed.

Specific Implications for Bioethics

As has been suggested here, people most commonly invoke human dignity in situations in which the worth of human beings is brought into question when they are used, forced, or injured. Human beings should not be used because their dignity requires that they be treated as having intrinsic, not

merely instrumental, worth. They should not usually be forced because their dignity mandates that their wishes be respected. They should not normally be injured because their dignity entails that their well-being be preserved.

In some bioethical issues these dignity-related concerns argue persuasively against other considerations and typically claim to trump them. For example, in evaluating a form of human experimentation people commonly insist on obtaining the informed consent of participants lest the participants' dignity be violated when something is done to them against their wishes. No amount of benefit to society warrants such a violation. In matters of resource allocation some people invoke human dignity to argue that the allocation producing the greatest overall social benefit is not the right one if the burden that certain individuals must bear to bring it about is too heavy. Not only may some people be injured, the very process by which anything can be done to them if it results in greater benefit to society is demeaning. Human dignity also is invoked to protest the injury involved in human cloning for reproductive purposes as long as animal studies show that attempts to clone humans almost certainly would result in the birth of children who eventually would develop serious deformities.

In other bioethical debates human dignity is not so unambiguously on one side of the issue. The reason for this is that more than one anthropological creed is influential, leading to competing conceptions of human dignity. Sometimes the clash involves a conflict between those concerned about injuring people and those concerned about forcing people. In the debate over abortion, for instance, people who consider the freedom to choose as central to human dignity often see no conflict. In regard to the mother and the fetus there is only one human being with the ability to choose, and so her decision prevails. Opponents of abortion with a different view of anthropology may hold that two human beings are present. Accordingly, they see the situation as a conflict between two affronts to dignity in which a greater violation would be done by fatally injuring the unborn child than would be done by forcing the mother to carry the child to term. The debate over embryonic stem cell research can be construed similarly, with supporters championing the dignity (choice) of researchers and the potential beneficiaries of the research and opponents decrying the greater violation that would occur if embryonic human beings were destroyed.

Other bioethical debates are even more complicated in that two elements of human dignity—preventing people from being injured and preventing people from being used—are in conflict with a third element: preventing people from being forced. For this reason the groups of people on each side of these debates are not the same groups as those in the debates mentioned above. For example, in the debate over germline intervention to enhance future generations of human beings those who see the only threat to human dignity as the limitation of people's choices tend to favor giving parents and society freedom to pursue such avenues. Others, more concerned to protect people against injury even if their choices are limited in the process, identify a threat to human dignity in subjecting young human beings to such procedures when the potential negative effects of genetic alterations for enhancement purposes are not well understood. That opposition is strengthened for many by seeing not just the potential injury involved but also the fact that the people doing the enhancement unacceptably use other human beings by altering them to exhibit traits that parents or society may like but that the ones who are altered may not. Similar issues arise in the debate over the genetic determination of human beings through cloning; the indignity involved is made worse for some if the cloning is done with the intentional injury, that is, death, of the cloned embryo in view.

In end-of-life debates a similar complex of considerations involving human dignity commonly arises. On one side are those who insist that human dignity requires that people have all choices open to them at the end of their lives, including physician-assisted suicide. On the other side are those concerned that the dignity of patients will be demeaned by overt or subtle pressures to give up their lives or by the necessity for them to justify their continued existence in the face of familial and societal burdens. As some see it, patients who are mentally disabled may even be injured directly by inadequate treatment or acts of euthanasia.

Conclusion

Human dignity plays a significant role in many bioethical debates. Because human dignity can be invoked on both sides of various issues, there is a pressing need for those who use that term to clarify what they mean by it. At some point they also need to defend the plausibility of the *anthropological creed* that underlies their view.

HUMAN EVOLUTION AND ETHICS

• • •

The idea of evolution—that all organisms living and dead come by a naturalistic process of development from one or just a few forms—dates to the eighteenth century, but it was not until 1859 that Charles Darwin (in his *Origin of Species*) proposed the causal mechanism that today is generally thought the main force behind evolutionary change. Noting the potential population explosion existing among animals and plants, Darwin argued that there will be an inevitable struggle for existence and that this in turn leads to a natural selection of the ones with certain advantageous features. *Adaptations* like the eye and the hand are, therefore, the key mark of living beings.

The earliest of evolutionists all saw humans as being part of the process—usually the end point of a progressivist march upwards, from the primitive to the complex. Darwin initially said little about *Homo sapiens,* not because he did not want to include them in the evolutionary picture, but because he wanted first to establish the main outlines of the general case. In 1871 he did turn explicitly to humankind, and in the *Descent of Man* he argued that humans are completely and utterly part of the natural, living world. Drawing on a secondary mechanism, sexual selection, Darwin argued that the differences between men and women and between races are adaptive, although generally less for the immediate needs of survival and reproduction and more for the competition for mates between humans themselves.

Hominid History

It was around the time of the publication of the *Origin of the Species* that the first evidence of fossil humans were uncovered, remains of so-called Neanderthal Man, although it was not until the end of the nineteenth century that bones of the first unambiguous link between humans and their ancestors were discovered (Java Man, by the Dutch doctor Eugene Dubois). Since then a great deal of evidence has been unearthed about humans and their ancestors—the *hominids.* Most famously there is Lucy, *Australopithecus afarensis,* a being that lived in Africa about 4 million years ago, that walked upright and yet had an ape-size brain.

Modern thinking—based both on fossils and on molecular evidence—is that humans and the great apes (especially gorillas and chimpanzees) broke apart about 6 million years ago (Lewin). Most likely humans are more closely related to chimps than they are to gorillas. There was an upward growth of brain to the present size (about 1200 cubic centimeters), although there was a fair amount of diversification rather than one single line leading just to humans. Apparently all modern humans came from Africa about 150,000 years ago and are probably not related directly to the Neanderthals (who, incidentally, had slightly larger brains than present day humans). Sophisticated powers of speech are probably fairly recent (some argue that that was the key advantage of *Homo sapiens* over the Neanderthals), and full-blown culture and agriculture is very recent—only 10,000 years or more old.

Social Adaptations

As Darwin noted in the *Descent of Man,* apart from speech, one of the most distinctive aspects of humankind is that they are ethical beings. Humankind has a sense of right and wrong, and thus is led to act morally or ethically. Humans do things for others because they think them right rather than simply because they appeal to the self-interest of the doer. In fact sometimes people do things that are very much not in their own self-interest, like attempting to save a drowning child from a rapid river. If one takes a hard-line Darwinian position, arguing that adaptations are produced by selection to aid their possessors—I have eyes and hands because they help me—then the existence of the ethical sense is somewhat of a puzzle (Wright). Why do something for others when it puts the doer at risk? In the family situation, where the mother for instance aids her child, this is readily understandable. If the child does not survive then the mother does not reproduce. But what about the cases in which there is no relationship? One does not jump into the river only to save one's own children.

It has been stressed by students of animal behavior, especially by students of the behavior of higher organisms like the great apes, that there is no necessity to the appearance of an ethical sense and consequent behavior (Goodall,

1986). Ethical sense will not come into existence as a matter of course, even if the brain grows in size and power. There has to be a reason, and this reason most obviously is that this is an adaptation for social beings. There are great advantages to being social. Two or three can often do that which is impossible for one animal on its own—especially when the animals are foraging or hunting, practices that provide the high-protein supplies needed by organisms with high-maintenance adaptations like brains. At the same time, there are costs to being social, like the potential for spread of disease. Hence social animals tend to have (and need) special adaptations to exploit their sociality and to prevent the costs. Often, for instance, social animals have much better degrees of immunity against disease than do solitary animals.

Social animals—and humans are beyond all others, social animals—need abilities to help each other and at the same time to reduce intragroup strife. (It is for this reason that researchers often find that a better model for humans than close relatives like the orangutans—who are asocial—are less close relatives like the wolves—who are very social.) On the negative side, as one might say, humans are notable for not having very good physical methods of attack—their teeth, for instance, are puny besides those of chimpanzees. If one turns on a fellow human, the attacker is not very likely to rip the victim apart physically. Another important negative aspect of humans is the way in which the females do not come into heat or advertise their ovulation. There has been much discussion about the reason for this—sociobiologist Sarah Hrdy argues that a major reason for this behavior is that it keeps males guessing and hence in doubt about paternity, if they do not stay around and help with the family. Another reason obviously is that it keeps the group quieter and more stable—imagine trying to run complex social lives if women were often in heat.

On the positive side, a sense of morality is surely (in the opinion of Darwinian biologists) an adaptation for sociality. Organisms that take seriously their obligations to others are more stable and work together better than those that do not. Expectedly one finds what might at least be called proto-morality—with senior group members enforcing behavior—in other social animals, especially (as emphasized by ethologist Frans de Waal) the chimpanzees.

What sort of morality might one expect an evolutionary process to produce? Will it decide, for instance, between utilitarians and Kantians? Probably not, for it will be too coarse grained for that—giving just basic directions that will then be fleshed out by culture. Significant is that both utilitarians (like Peter Singer) and Kantians (like John Rawls) have welcomed an evolutionary approach. Rawls particularly points out that it solves the big lacuna in any social contract approach to morality, namely how did the contract get put in place in the first place. It was not a group of old men around a fire but the genes. "The theory of evolution would suggest it is the outcome of natural selection; the capacity for a sense of justice and the moral feelings is an adaptation of mankind to its place in nature. As ethologists maintain, the behavior patterns of a species, and the psychological mechanisms of their acquisition, are just as much its characteristics as are the distinctive features of its bodily strictures; and these patterns of behavior have an evolution exactly as organs and bones do. It seems clear that for members of a species which lives in stable social groups, the ability to comply with fair cooperative arrangements and to develop the sentiments necessary to support them is highly advantageous, especially when individuals have a long life and are dependent on one another. These conditions guarantee innumerable occasions when mutual justice consistently adhered to is beneficial to all parties." (Rawls, p. 502–503).

Altruism

The technical biological term for organisms giving to others, at cost to themselves, is *altruism* (Wilson, 1975). It is important to note that this is a metaphor—it does not necessarily mean the altruism to which one refers when speaking of a good person, as in: Mother Teresa showed great altruism towards the poor of India. Ants helping others in the nest would be called altruistic, even though (as against the literal sense) there is clearly no implication that the ants consciously set out to do the right thing. Human altruism, or goodness as one might say, is therefore a sub-class of the general biological notion of altruism.

But why have humans developed so elaborate a method of interacting as a moral sense? Why, unlike the ants, are humans simply not hard-wired? There is a simple reason. Being hard-wired has virtues—there is no need for learning. The cost however is high. One cannot regroup and do something else if the situation changes. An ant will behave instinctively even though (because of changed circumstances) it may be doing itself or its nest a harm. Generally this does not matter, because ants are produced cheaply—a queen can afford the loss of a few thousand. Humans on the other hand are beings that require a great deal of care and only a few can be produced. (Technically humans are K-selected as opposed to ants that are r-selected.)

Humans need the ability to respond to change, especially to change brought on by fellow species members. A

moral sense allows humans to do this. They can assess different or changing situations and act in the best interests of themselves and their brood. As philosopher Daniel Dennett has pointed out, this fact diffuses the oft-brought charge that any evolutionary approach to ethics must fail because it presupposed that humans have no real choices, they are *genetically determined.* It is true that humans are part of the causal chain, but they have a dimension of freedom not possessed by the ants. (In a sense humans are like the rockets that can adjust to moving targets, whereas ants are like cheap rockets that cannot change direction once fired.)

Selfish Genes

How does selection bring on altruism (using this now in the biological sense)? There is much debate. After Darwin most biologists assumed that selection could work for the group and that morality would emerge automatically—a species member that helped another was thereby helping the species. Famous was the notion of *mutual aid,* promoted by the Russian-born anarchist, Prince Petr Kropotkin. In the 1960s there was a sea change in opinion (going back in fact to the insights of Darwin himself). It was pointed out that group selection (selection for the benefit of the group over the individual) was too open to cheating. A selfish individual could take advantage of others (Williams). Hence came what Richard Dawkins has labeled the *selfish gene* view of the evolutionary process—in some sense, all adaptations (including social and behavioral adaptations) must be related back to self-interest. If they do not help the individual first and foremost, they will be wiped out.

The selfish-gene way of thinking was applied very fruitfully to the problem of altruism. William Hamilton (1964a, 1964b) introduced the idea of *kin selection,* arguing that altruistic behavior could be a very good strategy if one is helping others who share the same copies of genes as oneself—one is thereby reproducing by proxy as it were. Most dramatically Hamilton solved the question of why sterile workers (always female) in the hymenoptera (ants, bees, and wasps) devote their lives to their nest mates. In the hymenoptera only females have two parents, hence females are more closely related to sisters than to offspring and so it pays to raise fertile sisters rather than fertile daughters. More generally Hamilton showed that in any animal, if the conditions are right, then altruism will come into being.

Robert Trivers introduced a more general mechanism, that can function between non related organisms (even organisms of different species). *Reciprocal altruism,* so-called, suggests that if one gets a benefit by helping others, especially if others will thereby be more likely to help in response, then altruistic adaptations should come into play. Essentially, as Darwin himself realized, this is a case of: "If you scratch my back, then I will scratch your back." In complex, thinking animals like humans, one could expect this to be a powerful mechanism. There will be times—when one is young, old, or sick—when even the most powerful will appreciate aid. In conjunction with this will be memory, so that humans are able to enforce reciprocation, and learn quickly to exclude those who do not play the game. Those who receive and do not give will soon be excluded.

More generally the ideas and techniques of game theory have been applied profitably to questions of sociability generally and morality particularly (Maynard Smith 1982). Sophisticated models can now be built showing how and when particularly moral traits might be expected to emerge (Skyrms). At the same time, experimentation can show whether or not specific hypotheses are well-taken. There have, for instance, been serious studies on questions about when commitments are kept and when broken. Also on how people respond to fairness or the lack thereof.

Group Selection

Criticisms of this whole selfish-gene approach tend to be of two kinds. On the one hand, there are more philosophical objections. Mary Midgely objects that the whole point about morality is that it is not selfish, nor is it simply enlightened self-interest. Morality means giving without hope or expectation of reward. But this objection is to misunderstand both the theory and the metaphor. Selfish genes do not necessarily cash out as selfish people. In fact humans might operate more efficiently (in their biological interests) if what they do is done precisely because they do not think it self-centered. One must make a distinction between what Dawkins (1982) labels the *replicators* (the genes) and the *vehicles* (the whole organism). To speak of selfish genes is to say that selection makes characteristics that rebound ultimately on the actor. Genes themselves are neither selfish nor unselfish. They just are. Individuals (vehicles) might be selfish at times and (genuinely) altruistic at times. It just depends on the situation.

On the other hand, there are objections of a more biological nature. Every biologist recognizes that sometimes a group selective force might overcome the individual selective force. For instance in a constantly fragmenting and reuniting population (that is with many sub-populations forming and disappearing) and with strong pressure towards altruistic behavior, group attributes might emerge before they can be eliminated by individual forces—these attributes

might persist by being merged into the whole group. It has been suggested that the maintenance of sexuality might result from such a group force (Maynard Smith, 1978). (Others however, including Hamilton, think that sexuality can be explained at the individual level [Hamilton et al.].)

In particular, with the human case, some think that a group selective force might be the key factor in altruism (human, literal altruism, that is). Biologist David Sloan Wilson and philosopher Elliott Sober argue this way. Illustrating their position with a short story by Stephen Crane, in which a group are caught in a life boat and can survive if and only if they all work together, Wilson and Sober conclude that only a group analysis will explain the successful outcome. Because of our ability to think and plan, humans can and do overcome the forces of individual selection and are shaped by group forces. "Behaving as part of a coordinated group is sometimes a life-or-death matter in which the slightest error—or the slightest reluctance to participate—can result in disaster for all. Situations of this sort—in which the members of a group are bound together by the prospect of a common fate—have been encountered throughout human evolution, with the important fitness consequences, so it is reasonable to expect that we are psychologically adapted to cope with them" (Sober and Wilson, p. 335–336). In 2002 Wilson extended his analysis to look at issues to do with the evolution of religion and its moral codes. He argues that something like the Calvinism of sixteenth century Geneva can be explained in terms of a kind of group selection, where adaptations appear for the benefit of the whole against the individual.

This is still very contentious. English sociobiologist John Maynard Smith argues that nothing here makes even probable the group selection hypothesis. He argues that even humans are unable to overcome the strong tug of the selfish gene. In the lifeboat case, there is no need to suppose other than that each individual saw that it was in his own interests to cooperate. As Ben Franklin said on signing the Declaration of Independence: "Gentlemen, we must all hang together or assuredly we shall all hang separately."

Conclusion

In conclusion therefore the best assessment is that evolutionary biology has brought many new insights to our thinking about human nature, including human moral nature. It would nevertheless be overly optimistic to think that we are even close to ending all debate or offering all the materials needed to solve all outstanding problems.

HUMAN GENE TRANSFER RESEARCH

• • •

Human gene transfer research (HGTR) involves the deliberate transfer of genetic material (naturally-occurring, genetically-modified, or synthetic DNA or RNA) into human subjects. Clinical success has come more slowly than was first predicted, but HGTR remains a fundamentally novel approach to medical practice. It may one day enable clinicians to cure genetic disorders at their source, as well as provide oncologists with tools designed to disable or cure specific cancers. Nonetheless, HGTR differs from other clinical modalities in a number of ways. It involves creating genetically novel organisms that are potentially both transmissible and pathogenic, and there is a risk that this could modify the human genome. Human gene transfer techniques may also be extended beyond therapy into other, more controversial, areas (Verma). Consequently, while HGTR continues to capture the public's imagination, it has received an unparalleled level of public oversight. However, only when HGTR finally achieves success will ethical concerns become real issues.

Basic Terminology and Methods

Two distinctions shape the analysis and practice of human gene transfer: between therapy and enhancement, and between somatic and germline cells. The first refers to the transfer's intended outcome. Researchers may seek to prevent or cure disease (therapy), or they may want to alter an individual's characteristics or capabilities (enhancement). The second refers to whether researchers, in order to achieve these ends, seek to alter nonreproductive (somatic) cells or reproductive (germline) cells. Somatic alteration would affect only the individual subject, while germline alteration would change genes passed on to an individual's offspring. As of 2003, federal regulatory bodies will only entertain somatic-cell gene transfer protocols conducted for preventing diseases or developing treatments (U.S. NIH).

Genetic material can be transferred to human subjects in different ways, but most methods share certain similarities. Many protocols can be classified as either *ex vivo* or *in vivo. Ex vivo* protocols obtain tissue cells from the subject, genetically modify them in the lab, and return them to the subject's body. *In vivo* protocols employ different techniques to introduce genetic material into a subject's body, hoping that it will reach the appropriate tissues. Most protocols to date have used disabled viruses as the *vector* for transferring genetic material, though other vectors are also under development. Information on how frequently different methods are used can be obtained from the "Human Gene Transfer Protocol List" compiled by the National Institutes of Health (NIH) Office of Biotechnology Activities (OBA).

Clinical Successes and Setbacks

Certain milestones and setbacks mark the progress of HGTR from 1989 through 2003. Within this period, over 545 human gene transfer protocols, involving over 4,000 patients, were registered with the OBA. The field was launched on May 22, 1989, when Steven A. Rosenberg, Michael Blaese, and W. French Anderson injected genetically modified white blood cells into a male subject with advanced skin cancer. This protocol was not designed to intervene in his disease, but rather to track where the "marked" cells went in his body. The first protocol that sought a therapeutic outcome began on September 14, 1990, when W. French Anderson and colleagues transferred genetically modified white blood cells to Ashanti DeSilva, a four-year-old girl with severe combined immune deficiency (SCID). Ashanti's immune system was strengthened, but her underlying condition was not cured. Throughout the 1990s no other protocol was able to report clinical efficacy.

The first unambiguous clinical successes were reported in the spring of 2000. In April 2000 the French researchers Marina Cavazzano-Calvo and Alain Fischer reported that two baby boys (a number later raised to nine) with a version of SCID had normal immune systems ten months after receiving cells that were genetically modified to replace a missing gene. In March 2000 Katherine A. High and Mark A. Kay reported that subjects with hemophilia B experienced an increase in factor IX protein activity for at least six months after the gene transfer.

Yet this long awaited clinical progress has been tempered by setbacks. In December 2002 a subject in the hemophilia-B study developed signs of liver injury, halting the trial. The same trial was briefly halted in December 2001 when the gene-carrying virus was found in subjects' semen, raising the specter of inadvertent germline gene transfer.

And in January 2003 the second of the nine boys treated in France developed a leukemia-like illness.

More troubling for the field was the death of Jesse Gelsinger. On September 17, 1999, Gelsinger, an 18-year-old subject, died from a gene transfer experiment being conducted at the University of Pennsylvania's Institute for Human Gene Therapy. Gelsinger was affected by ornithine transcarbamylase (OTC) deficiency. Patients with OTC deficiency lack an enzyme needed for processing nitrogen with the result that toxic levels of ammonia accumulate in their bloodstreams, leading to severe mental impairment and even death. But Gelsinger's symptoms were manageable so that, unlike subjects in other gene transfer trials, he approximated a healthy volunteer. The viral vector used in this protocol was an adenovirus—a virus that usually causes the common cold. Although used in many protocols prior to Gelsinger's death, in his case the vector triggered a deadly immune response. An inquiry into his death resulted in severe sanctions against the University of Pennsylvania and the researchers involved, and it revealed major problems with HGTR oversight and conduct nationwide.

Public Oversight of Human Gene Transfer Research

HGTR is overseen in the United States by two agencies within the Department of Health and Human Services: the NIH and the Food and Drug Administration (FDA). While FDA review is "public" insofar as it involves federal oversight, NIH review through the Recombinant DNA Advisory Committee (RAC) is truly a forum open to the public. This aspect is unique to HGTR and reflects its historical development.

EARLY CONCERNS ABOUT "GENETIC ENGINEERING." Serious debate about human gene transfer began in the 1960s, when scientists, theologians, and philosophers raised many concerns about *genetic engineering,* or *genetic manipulation.* Theoretical concerns evolved into real possibilities in 1972 when scientists discovered how to combine genetic material from different organisms. Recognizing that biologically novel organisms created through these techniques could, if inadvertently released, imperil the environment, individuals, or society, the scientific community called for a voluntary moratorium on this research—referred to as *recombinant DNA research* or *rDNA*—until safety issues could be assessed (Berg et al., 1974). The 1974 moratorium was lifted after leading scientists met in Asilomar, California, and issued strict guidelines for the safe conduct of rDNA in 1975 (Berg et al., 1975).

The self-imposed scientific moratorium on rDNA research unnerved the public, who were already disenchanted by a decade of research scandals. In response to these scientific and public concerns, the NIH established the RAC, on October 7, 1974. The RAC embodied a novel approach to federal oversight of a novel biotechnology. Because concerns about rDNA were societal as well as scientific, the RAC was staffed by both scientists and nonscientists, and its meetings were open to the public. In 1976 the RAC issued its first set of guidelines. These guidelines focused on laboratory safety and containment, required federally funded institutions conducting rDNA research to establish an Institutional Biosafety Committee (IBC), and required all rDNA research to be reviewed first by the local IBC and then by the RAC.

HGTR OVERSIGHT. The RAC's early work focused on laboratory research that created recombinant organisms, and on work with animals and plants. As safety concerns raised by specific novel techniques were allayed, the RAC regularly shifted oversight responsibility to the IBCs.

By 1983 the RAC's attention had turned to HGTR. This shift was catalyzed by a number of events that captured public attention, including two unauthorized and scientifically ill-founded human gene transfer experiments (the 1970 case of Dr. Stanfield Rogers and the 1980 case of Dr. Martin Cline) as well as the controversial decision in *Diamond v. Chakrabarty,* allowing the patenting of genetically engineered organisms (for further information on these cases, see Walters and Palmer). One of the most important outcomes of these events was the 1982 publication of *Splicing Life,* a report on human gene transfer issued by the President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research. The commission argued that only transfer into somatic tissues to prevent or treat disease could be justified.

The President's Commission also recommended that the RAC broaden its responsibilities to include HGTR—and to attend to ethical and social implications as well as safety concerns. In 1983 the RAC created the Working Group on Human Gene Therapy (later renamed the Human Gene Therapy Subcommittee) to develop guidelines for human rDNA research and to review protocols (Walters, 1991). By 1985, this working group had produced "Points to Consider," the first version of the guidelines that would eventually govern HGTR.

CLINICAL TRIALS AND CHALLENGES TO PUBLIC OVERSIGHT. In April 1988 the RAC received its first actual human gene transfer protocol, and federal oversight of HGTR began. The field grew cautiously at first, and then

exponentially, moving quickly from work with single-gene disorders to cancer research (Ross et al.).

By 1995 the NIH was spending $200 million per year (2% of its budget) on HGTR. Harold Varmus, the director of NIH, commissioned two reports on the state of the field. The first, coauthored by Stuart H. Orkin and Arno G. Motulsky, criticized researchers for exaggerating prospects for therapeutic success. They argued that more basic research was needed before moving to and investing in clinical trials. The second assessed the work of the RAC and concluded that the committee continued to serve important functions (Verma).

From the outset, RAC oversight of HGTR was contested. As early as 1990, RAC review was assailed for delaying vital medical research (U.S. NIH-RAC; Culliton). Biotech companies objected to the public nature of RAC review, while researchers felt that RAC review unnecessarily duplicated FDA review, which holds statutory authority for such approval. Human gene transfer protocols, unlike other areas of research, must be reviewed both by the RAC and by the FDA, either simultaneously or sequentially. At the FDA, responsibility for human gene transfer lies with the Center for Biologics Evaluation and Research (CBER), and review focuses on the safety and efficacy of rDNA products, the safety of the manufacturing process, and the control of the final product (Coutts). To protect proprietary interests, CBER review is closed, and it cannot, by charter, address the ethical or social implications of research. The FDA has developed its own "Points to Consider" document to advise investigators (U.S. FDA, 1998).

In 1996, with the urging of biotech lobbyists, researchers, and politically powerful patient activists, Varmus proposed to abolish the RAC, and only overwhelming public support for the RAC averted its demise. Although not abolished, the RAC was downsized and could no longer recommend approval or disapproval of specific protocols. From 1996 through 2000, the RAC reviewed approximately 10 percent of the HGTR proposals submitted to the NIH (those proposing novel methodologies) and convened occasional Gene Therapy Policy Conferences.

THE AFTERMATH OF THE GELSINGER CASE. The Gelsinger case revealed major problems with the oversight of HGTR. A primary finding concerned the reporting of adverse events (bad reactions or deaths during a human gene transfer experiment). According to the NIH Guidelines, all adverse events must be reported in a timely fashion to the RAC, but Gelsinger's investigators failed to report three adverse events to the FDA in a timely manner. Moreover, only 37 of 970 adverse events that occurred between 1993 and 1999 in trials using the adenovirus vector (approximately 25% of the HGT protocols underway at that time) were properly reported to the NIH (Walters, 2000)—these adverse events were reported to the FDA, but not relayed to the RAC.

The inquiry also uncovered problems in the informed-consent process. The informed-consent document given to subjects in Gelsinger's protocol differed from the one approved by the RAC and FDA, and it did not mention adverse events in animal studies. Public reporting about HGTR had led the Gelsingers to believe that patients had been cured by "gene therapy," and they reported that the investigators had led them to believe subjects in their particular protocol had experienced clinical benefit. Finally, adverse events experienced by other subjects in the protocol were not communicated to the Gelsingers, as required by federal guidelines (Stolberg). Ironically, the RAC's attention to informed consent was one reason given by Varmus for abolishing it (Marshall).

The Gelsinger case led to Congressional inquiries, multiple hearings, and soul-searching at the NIH and FDA. The RAC provided a unique and crucial forum for gathering, analyzing, and publicizing information relevant to this crisis. This resulted in two notable outcomes: (1) the FDA formally agreed to inform the NIH of all adverse events reports it received, and (2) the Advisory Committee to the Director of the NIH recommended that the RAC receive novel protocols at an earlier stage in their development—namely, prior to submission to the IRB and FDA.

Ethical Issues in Human Gene Transfer Research

Early ethical and social concerns surrounding HGTR were outlined in 1985 in the NIH's "Points to Consider." Since then, broader public and commercial contexts of HGTR have raised additional concerns, especially involving subject recruitment and economic conflicts of interest. These issues become increasingly important as HGTR moves toward new applications and methods.

THE ETHICAL COMMITMENTS OF THE "POINTS TO CONSIDER." The "Points to Consider in the Design and Submission of Protocols for the Transfer of Recombinant DNA Molecules into One or More Human Subjects" consists of over 100 specific questions that HGTR investigators must address for RAC approval (U.S. NIH, Appendix M). The RAC Working Group on Human Gene Therapy tested the document and developed its process of protocol review by working through a prototype HGTR protocol submitted in April 1987 by a team led by W. French Anderson (Walters and Palmer).

The ethical commitments of the "Points to Consider" reflect its historical context. The document reflects both the RAC's involvement with debates surrounding rDNA and a decade of national deliberations on the use of human subjects in biomedical research (Juengst). Its ethical framework hinges on six moral concerns. The first three derive from specific concerns about rDNA technology:

1. the need for special biosafety precautions;
2. the need for public participation in genetic research policy; and
3. potential broad and long-range research consequences (Juengst).

The final three concerns reflect the *Belmont Report*'s three central principles (beneficence, respect for the person, and justice) and the federal guidelines for the protection of human subjects issued in 1981:

4. clinical benefit to subjects;
5. free and informed consent by subjects; and
6. fair subject selection (Walters and Palmer; Juengst).

The RAC deliberations based on the "Points to Consider" tended to focus primarily on issues of safety and informed consent. Biosafety concerns focused on whether genetically modified viral vectors might be *shed,* or infect others who come into contact with research subjects. There was concern that viral vectors might revert to *wild-type* strains and become *replication competent*—that is, capable of replicating and infecting subjects or others in unanticipated ways. Further, might transferred genetic material integrate into the wrong place in the subject's genome, thus causing cancer (a hypothesized cause for the illnesses seen in the French SCID boys)? Might it inadvertently integrate into the subjects' germline tissues and be transmitted to their descendants? Scientific and clinical questions further attended to the risks particular protocols might present to subjects themselves. Nonscientific members (patient advocates, ethicists, attorneys) consistently raised concerns about informed consent and subject recruitment.

THE CHALLENGE OF RECRUITMENT. There are also important concerns about subject recruitment. HGTR initially targeted only life-threatening, incurable conditions for which no other effective therapy existed. Theoretical benefits to these subjects were believed to outweigh any possible risks. Initially, disease candidates included only single-gene disorders. By 2002, however, the pool of disease candidates had expanded to include cancers (64% of all protocols), HIV, peripheral artery disease, rheumatoid arthritis, and erectile dysfunction (U.S. NIH-OBA).

Subjects with life-threatening, incurable conditions are often in desperate straits, and it is not clear that consent can be truly voluntary in such situations? Too often, subjects misunderstand experimental protocols as their last or only *hope,* or as *therapy,* when in fact most human gene transfer trials are designed only to test safety, not efficacy. Subjects are aided in this misunderstanding by informed-consent documents that describe experimental interventions as *treatment,* or that mention a possible *benefit.* This, coupled with the misleading label of *gene therapy,* has led the field to be redescribed more accurately as "human gene transfer *research*" (Churchill et al.)

Misunderstanding gene transfer as therapy has led to questions about fair access to protocols. Before the first protocol was launched, concerns were raised about how to decide which members of even a limited subject pool would have access to the *potential benefits* of the research. Such thinking climaxed in 1993 when, in response to political pressure, Bernadine Healy, then the director of the NIH, allowed researchers to enroll a subject in an unapproved human gene transfer protocol as a last-chance therapy on the basis of "compassionate use." This would not be the last time the RAC faced political pressure to alter protocol approval (Lysaught).

COMMERCIAL INTERESTS AND "ORPHAN DISEASES." Another important issue is that of rare diseases and commercial interests. Early advocates of HGTR emphasized that this novel methodology promised, at long last, to provide cures for some 4,000 single-gene disorders. Ashanti DeSilva was afflicted with just such a disorder. But investigators quickly began applying human gene transfer techniques to clearly non-Mendelian disorders (e.g., cancer). As of 2002 only 10 percent of human gene transfer protocols approved by the RAC involved monogenic disorders. Most monogenic disorders are quite rare, with a small market for eventual therapies, and those involved in HGTR have been accused of abandoning persons with genetic disorders in order to cash in on big market payoffs (Meyers; Anderson).

The Orkin-Motulsky panel raised concerns about economic incentives surrounding human gene transfer in 1995. Due to these incentives, they noted, virtually every NIH institute had created a gene transfer program, whether equipped to do so or not, and they cautioned that the rush to find the gold in HGTR might lead investigators to ignore the pursuit of other, easier-to-achieve, conventional treatments.

Commercial interests, and the potential for conflicts of interest, also emerged in the Gelsinger case and led to a renewed examination of the relationship between academic research and industry. In Gelsinger's case, the University of

Pennsylvania's Institute for Human Gene Therapy received one-fifth of its $25 million annual budget from a company founded by the Institute's director, James M. Wilson. In return, the company had exclusive commercial rights to Wilson's discoveries. None of the subjects in the study had been informed of this relationship or this arrangement. In 2000 the American Society of Gene Therapy established a policy that its researchers should be free of significant financial involvement with companies that sponsor their studies.

FRONTIER ISSUES. Although HGTR has yet to achieve unambiguous clinical success, "frontier issues" such as prenatal gene transfer, nonrecombinant methods of DNA transfer, and the likelihood of enhancement merit mention.

Prenatal gene transfer might offer certain advantages, as early intervention might prevent the devastating effects of some conditions. The prenatal environment may provide better conditions for gene transfer and facilitate sustained gene expression. It could also offer parents at risk for conceiving a child with a genetic disorder an actual therapeutic alternative to selective abortion or preimplantation genetic diagnosis. However, *in utero* research entails unknown risks to the fetus and mother and raises the real possibility of germline modification (Fletcher and Richter). In January 1999 the RAC concluded (based on a Gene Therapy Policy Conference) that allowing prenatal gene transfer research would be premature. However, the RAC indicated its willingness to entertain *in utero* gene transfer protocols if current scientific questions were to be addressed (U.S. NIH-RAC).

Jesse Gelsinger's death and setbacks in the French SCID and hemophilia trials raised anew concerns about the risks of viral vectors. Researchers are therefore pursuing alternative methods of DNA transfer, including approaches that do not involve DNA recombination. Microinjection, where DNA or RNA is directly injected into a cell's nucleus using a glass pipette, is currently used for germline modification in animal research. A similar approach involves the injection of *naked DNA* (DNA not contained within a vector) directly into tissues. Another protocol uses high pressure to push short DNA sequences into graft tissue. Others suggest attaching DNA to other macromolecules, such as liposomes. These complexes can navigate cell membranes without the risks posed by viral vectors. And yet others are developing methods of inserting not just genes but entire *artificial chromosomes.* While these approaches may reduce certain safety concerns, they may also introduce others. For example, transmission of artificial chromosomes to offspring via germline integration raises questions about the creation of individuals with more than the standard complement of forty-six chromosomes. How does this challenge our understanding of what it means to be human? Moreover, given our limited knowledge of chromosomal interaction and gene mutation, the long-term consequences of such modifications cannot be known.

Finally, researchers clearly have an interest in pursuing gene transfer for enhancement purposes. The same techniques used for legitimate medical therapies could be used for decidedly non-therapeutic purposes by athletes for example, looking for a competitive advantage. Somatic-cell interventions might be able to strengthen muscles and bones or boost oxygen efficiency, while germline enhancements could provide a way for parents to engineer children with superior athletic skill. Researchers further anticipate developing techniques that will enable inserted genes to be "turned off" by an additional intervention if necessary. While such developments might prove therapeutically useful, they could also allow a mechanism for avoiding detection of genetic modifications. What responsibilities do researchers and physicians have with regard to such practices? Although clearly decades away at best, the World Anti-Doping Agency is taking this possibility quite seriously. With the advent of stem cell and cloning techniques, the prospect of gene transfer being used for enhancement purposes becomes increasingly probable. Certainly such applications of gene transfer technology raise serious questions about the just allocation of resources in a world where over 2 million people each year die from a lack of adequate sanitation and clean water and 44 million people in the U.S. remain without adequate health insurance.

Conclusion

The possibilities of prenatal or germline gene transfer and genetic enhancement suggest that the need for public oversight of HGTR is far from over. Initial safety and societal concerns surrounding rDNA research and HGTR have not materialized, in part because the research has received careful scrutiny and oversight in a public forum that has earned respect through hard work and responsiveness to changes in its social and scientific contexts. Unlike other biotech developments, HGTR is not perceived as being driven solely by the momentum of the market, with technology racing ahead of society's moral compass. Nor has it become intractably polarized. Public oversight has provided both a forum for discussing ethically controversial applications of human gene transfer and a mechanism for exercising prudence and caution.

Public oversight of HGTR also provides a unique venue for addressing concerns that are not unique to HGTR, but are applicable to the practice of scientific research in general. These include concerns about the commercial influence on

scientific research, the practice of informed consent, and about vulnerable patients. But because it proceeds in public view, HGTR may serendipitously lead to significant improvements in the conduct of human-subjects research in the United States and throughout the world.

HUMAN NATURE

• • •

Theories of human nature offer systematic and comprehensive accounts of human beings' most significant distinguishing characteristics. Such accounts are central in people's perennial attempts to organize their understandings of the cosmos; to figure out their relation to God, to nature, and to each other; and to uncover the possibilities, meanings, and purposes of human life.

Western Understanding of Human Nature

Modern Western theories of human nature, which will be the focus of this essay, typically differ from their classical and medieval predecessors in appealing to the findings of a variety of life and social sciences, including anthropology, medicine, physiology, psychology, economics, sociology, and even ethology. Nevertheless, although these sciences undeniably help us to understand specific aspects of human life, even contemporary theories of human nature are never simply summaries of the results of empirical research—despite their frequent claims to scientific authority.

One reason that theories of human nature are not simply generalizations from the conclusions of scientific study is that they enter into empirical investigations not only as conclusions but also as presuppositions, structuring the conceptual frameworks within which research programs are conducted. Contemporary psychological investigation, for instance, proceeds with a variety of models of the human mind, including the Freudian, the behaviorist, the existentialist or humanist, and the computer models. Empirical research cannot fully evaluate the adequacy of its own framework relative to others; determining the adequacy of an entire framework requires reference to considerations beyond empirical data, including how the framework coheres with other respected theories and even its moral and political implications.

A related reason that theories of human nature go beyond ordinary scientific claims is that typically they aspire to provide a comprehensive conceptual framework that will render coherent the contributions of all those disciplines and discourses that investigate various aspects of human life. These often represent human beings in ways that, at least on the surface, appear quite incompatible with each other; for instance, lawyers assume that people ordinarily are responsible for their actions, while psychologists may suggest that people's behavior is determined ultimately by factors outside their control. Theories of human nature endeavor to resolve these incompatibilities in a variety of ways, ranging from reinterpreting the meaning of a discourse, such as the religious, to setting limits on the domain within which its claims are accepted; occasionally, a theory of human nature may even proclaim the invalidity of a whole realm of discourse, such as the parapsychological. Rather than simply summarizing the conclusions of the various life and social sciences, therefore, theories of human nature typically perform a regulatory function, authorizing some methodological approaches while delegitimating others.

Yet another respect in which theories of human nature differ from scientific theories, at least as science is ordinarily understood, is in the prominence of their normative or evaluative component. Even if one contends that all knowledge is to some degree value-laden, the evaluative element is far more evident in theories of human nature than it is, for instance, in modern theories of the physical universe. All theories of human nature provide a general account of human capacities and human needs, human potentialities and human well-being, and thus contain at least an implicit, and often an explicit, diagnosis of human malaise and a prescription for human flourishing.

Like all theoretical constructions, theories of human nature are developed in specific historical circumstances and are designed to address specific conceptual puzzles or practical concerns; consequently, they shift their emphasis according to the scientific, moral, and political preoccupations of the time. Despite variations in focus and emphasis, however, the Western project of understanding human nature historically has centered on two questions. The first of these addresses the human aspect of *human nature*: How can human be distinguished from nonhuman nature? The second addresses the natural aspect: How can what is natural for humans be distinguished from what is unnatural, abnormal, or artificial? The concerns inherent in these two questions constitute continuing themes that link the variety of Western inquiries into the nature of human beings.

Reflection on these themes reveals that the Western project of providing a systematic theory of human nature has been predicated historically on certain assumptions. They include the following: (1) that it is possible to discover specific qualities or features that characterize human beings universally and transhistorically; (2) that these characteristics decisively distinguish humans from all other beings, notably nonhuman animals; and (3) that, from the discovery of these characteristics, it is possible to derive specific prescriptions about the proper conduct of human life. In other words, the Western project of understanding human nature generally has been motivated by a desire to derive from it universal and unchanging values.

These assumptions went unquestioned and often unarticulated throughout most of Western history. Once they are made explicit, however, it is easy to see that they are all contestable; and we shall see how, in the nineteenth and twentieth centuries, each of them was contested. For instance, Karl Marx (1818–1883) and John Dewey (1859–1952) challenged the first assumption; Charles Darwin (1809–1882) and the twentieth-century sociobiologists challenged the second; and the theorists of positivism and neopositivism challenged the third.

Since the 1970s not only these assumptions but the whole project of developing a comprehensive theory of

human nature has been subjected to more fundamental critiques, launched by poststructuralist or postmodern French writers such as Michel Foucault (1926–1984), Jacques Derrida (1930–), and Jean-François Lyotard (1924–). While these authors differ on many points, they are united in rejecting the possibility of any overarching philosophical framework capable of unifying and legitimating the specific disciplines. Such totalizing frameworks or discourses, they claim, reflect unrealizable aspirations to discover universal and absolute truths in morals, politics, or science. These authors deny that any genuinely universal truths can be found, and assert that claims to them typically are propounded by groups who wish to use them for promoting their own political agendas. Truth, they argue, is relative to specific discursive practices that are historically contingent and self-justifying. Consequently, there is no need for, as well as no possibility of, a *master* discourse designed to be the ground or foundation of these more specific discourses.

As described so far, the dominant tendency in Western thought has been to conceptualize human nature as both *universal* and *transhistorical.* Its conceptualizations typically take the form "All human beings throughout history have characteristics x, y, z," implying that x, y, and z are necessary, as well as universal, characteristics of human nature. However, the Western tradition also includes conceptions of human nature that are not universalistic although they are transhistorical. These *relational* theories take the form "Group x is inferior to group y with respect to characteristics x, y, z"; typically, relational theories are used to justify the dominance of one group over another. Finally, some Western conceptions of human nature are *historical* rather than transhistorical, used within theories that claim that as human cultures change, so do certain important human characteristics. Some theories contain elements both universal and relational—for example, the theories of Aristotle and the sociobiologists—or both transhistorical and historical—for example, the theories of Karl Marx and John Dewey.

Three Classic Western Approaches

ARISTOTLE. The origins of Western philosophy, in the sense of systematic and rational inquiries into the nature of reality, knowledge, and value, are often traced to the reflections of ancient Greek thinkers in the fifth and fourth centuries B.C.E. Plato (ca. 428–347) and Aristotle (384–322), two of the three philosophical giants of this period (the third being Socrates, ca. 470–399), developed systematic theories of human nature. Aristotle's view has been particularly influential on the Western tradition because it was incorporated into the Scholastic philosophy that dominated Europe in the Middle Ages and early Renaissance, and continues to shape the thinking of the Roman Catholic Church.

Aristotle conceptualized human beings as complexes of soul and body. The soul was the distinctively human element—the essence or form or intelligible principle of the body—but it existed only in conjunction with a living human body. Aristotle's conceptualization of the soul as inseparable from its body contrasted with Plato's view that human beings were souls united only temporarily with bodies, but Aristotle also acknowledged the possibility of the actively knowing and thinking part of the soul, the mind or intellect, being "set free from its present conditions … immortal and eternal." When this happened, however, Aristotle asserted that the mind remembered nothing of its former embodied activity and, because all connection with a specific human body was thus lost, he did not regard the human soul as personally or individually immortal.

Aristotle's view of human nature, like Plato's, was *teleological,* which is to say that he regarded human beings, like other things in the world, as having a "function" or activity peculiar to them. He further assumed, again like Plato, that the good life, or *eudaimonia,* consisted in the successful or efficient performance of that function. For Aristotle, the distinctive function of human beings was reasoning, or "an active life of that which possesses reason," and so he inferred that the good life was one in which the rational part of the soul governed the appetitive or desiring part, thus avoiding excess and living in accordance with virtue.

For Aristotle, human beings were, by nature, political animals who needed to live in a community: "He who is unable to live in society, or who has no need of it because he is sufficient to himself, must be either a beast or a god." Within human communities, however, not everyone was capable of citizenship: The nature of some was to rule and of others to be ruled. Among those whose nature was to be ruled were children, barbarians, and Greek women; thus, while Aristotle posited a universal standard for human nature, he simultaneously asserted that some groups of humans were less than fully human. The theme of dominance and subordination runs not only through Aristotle's account of the relations between human beings but even through his account of the nature of individual humans. He compared the controlling relation between form and matter with the relation between male and female, and he asserted that the proper relation between mind and body was like that of master to slave.

AQUINAS. The dominant philosophical figure of the Middle Ages was Thomas Aquinas (1226–1274), later Saint Thomas, who synthesized Greek thought and church doctrine into a Christian philosophy. He conceptualized human

nature in terms that were basically Aristotelian, with some (often Platonic) modifications made in order to adapt Aristotelian views to church doctrine.

Aquinas believed, like Aristotle, that there was a distinctive and essential human nature that could be understood teleologically; he also shared the Aristotelian belief that the good life or *eudaimonia* was action in accordance with this function. A proper understanding of the ends or purposes of human life was therefore essential to morality and should be achieved by discovering the precepts of *natural law.* Natural law, as Aquinas conceptualized it, was universal and unchanging. It described supposedly universal human tendencies, such as preserving life, but presented them not simply as empirical facts about human nature but also as manifestations of God's design for humanity. For Aquinas, therefore, natural law simultaneously described how things were and prescribed how they should be. It was discoverable by reason, which, because it gave insight into God's purposes, provided guidance on how humans should live.

Like Aristotle, Aquinas saw humans as combinations of soul and body, with the soul as the form of the body. To allow for the possibility of personal or individual immortality, however, Aquinas diverged from Aristotle, declaring that the soul was a "substantial" form, capable of existing separately from matter. Not only was personal immortality conceptually possible, according to Aquinas; it was humans' destiny. God would not have implanted the universal—and therefore natural—human desire to live forever unless this desire had an object.

While Aquinas shared the Aristotelian view that human nature had an end or purpose, he believed, in accordance with church doctrine, that this end was supernatural rather than natural: It was to spend eternity united with God in heaven, where alone perfect happiness might be enjoyed. Human life as we know it was no more than a preparation for life after death, and this world was simply a testing ground for the next. So long as humans inhabited this world, however, they should strive to live in accordance with natural law, which provided a test for the moral validity of the laws of the state.

DESCARTES. The thought of René Descartes (1596– 1650) is generally considered to mark the beginning of modern philosophy. Refusing to accept the authority of tradition, Descartes developed "rules for the direction of the understanding" and a "method for rightly conducting reason" designed to enable each individual to establish certain truth in science and philosophy. He wrote in the vernacular (French) as well as in Latin, in order to reach lay as well as clerical readers.

Descartes's conception of human nature was even more *dualistic* than that of Aristotle and Aquinas. Living human beings, for Descartes, were composed of two entirely different kinds of entities: souls, which were active, intellectual substances, immaterial and immortal; and bodies, which were unthinking, passive mechanisms, spatially extended and temporally finite. Individual humans were to be identified not with their bodies but with their souls, which were able to survive the death of the body. While Descartes's model allowed for the soul's separation from the body after death, it rendered problematic the relation of the soul to the body during life, since it was unclear how material and immaterial substances could have a causal influence on each other. Descartes never succeeded in providing a satisfactory explanation of mind-body interaction.

As a scientist, Descartes wanted his theory of human nature to be compatible with both the new developments in physical science and the doctrines of the Roman Catholic Church. He attempted to reconcile these two worldviews by postulating two spheres of reality, each governed by entirely different laws or principles. The laws of God governed spiritual or mental reality; the laws of science governed physical reality, understood by Descartes in mechanical terms. Although Descartes never developed a systematic moral philosophy, his assertion that all "men" were potentially equal in their capacity to reason laid the foundation for later egalitarian moves in ethics and politics. Simultaneously, his conceptualization of animals as mere stimulus-response mechanisms, lacking consciousness because they lacked souls, justified the exclusion of animals from moral consideration. Cartesian biologists, in defense of vivisection, have compared the howls of cut-up dogs to the squeaks of unlubricated machines.

SHARED FEATURES OF DOMINANT PRE-DARWINIAN CONCEPTIONS OF HUMAN NATURE. There are at least six common features of pre-Darwinian conceptions of human nature:

1. Human nature is the same transhistorically.
2. It is distinguished primarily by possession of a soul.
3. Human souls are characterized by their capacity to reason. This capacity exists, perhaps in varying degrees, as a potential innate in all humans, sharply distinguishing them from all other beings, including animals.
4. Humans' possession of a rational soul gives them special moral worth.
5. Lacking such a soul, animals lack comparable moral worth or value. Those biological features that are similar in humans and animals comprise humans'

"lower" nature, which humans should strive to rise above.

6. Developing our potential to reason is a key to the good life for humans. Reasoning not only tells us how to live well but actualizes our distinctively human potential. Thus, the concept of human nature is clearly normative: Our task is to realize our humanness by fulfilling our potential for rationality; those who are incapable of fulfilling this potential are less than human.

The Materialist Tradition and the Darwinian Pivot

The features listed above as characterizing pre-Darwinian conceptions of human nature represent the dominant Western tradition prior to the nineteenth century. Running counter to this *rationalist* and dualist tradition, however, Western thought also includes a less prominent *materialist* or naturalist tradition.

Anaximander (ca. 500 B.C.E.), an early pre-Socratic philosopher, developed a speculative theory of evolution in which human beings were descended from lower forms of animal life. Democritus (460–370 B.C.E.), a contemporary of Socrates, developed a speculative atomic theory in which even the human soul was composed of atoms. The English philosopher Thomas Hobbes (1588–1679) assimilated individual behavior and politics to the laws of mechanics, regarding desire as motion toward an object, and human beings as motivated entirely by self-interest. The French philosopher Julien de La Mettrie (1709–1751) accepted Descartes's assertion that animals were like machines but insisted that so, too, were human beings. The German philosopher Baron Paul Henri d'Holbach (1723–1789) argued that thinking could be reduced to the functioning of the brain and explicitly denied the existence of a soul. Another of the French philosophes, Claude-Adrien Helvétius (1715–1771), argued that all mental faculties were ultimately reducible to physical sensation and that all humans were motivated by the desire to achieve physical pleasure and reduce pain. This latter idea was developed into an elaborate ethical calculus by the nineteenth-century British utilitarians, Jeremy Bentham (1748–1832), James Mill (1773–1836), and the latter's more famous son, John Stuart Mill (1806–1873). Collectively, these philosophers suggested an alternative understanding of human nature—one that focused more on the body than on the soul, on the emotions and desires more than on reason, and on the similarities rather than the differences between humans and animals. It remained for Charles Darwin to give this materialist tradition a scientific basis by providing a naturalistic analysis of the relations between humans and animals.

In his landmark work, *On the Origin of Species* (1859), Darwin argued that the distinctive features of human nature were not divinely created in an instant but had evolved over many millennia through a process he called "natural selection". Although the word *selection* suggested conscious purpose, Darwin's use of it was metaphorical, since nature *selects* only in the sense that certain new traits or mutations that appear accidentally are sufficiently adaptive to the environmental conditions within which the organism lives for the new organism to survive. The view that human beings had evolved through accidental mutations implied that there was no preordained nature, no ultimate meaning or cosmic purpose for human life to fulfill. In an attempt to escape this conclusion and reconcile science with Christianity, some later theorists postulated a direction and a goal in evolution, characterizing more recently evolved species as *higher* or otherwise superior; but such teleological and evaluative interpretations were ultimately alien to the basically antiteleological spirit of the concept of natural selection.

When Darwin first proposed his theory of evolution, the wife of the canon of Worcester Cathedral was said to have remarked, "Descended from the apes! My dear, we will hope it is not true. But if it is, let us pray that it may not become generally known." Indeed, the church denounced Darwin, recognizing that his theories challenged not only the beliefs in divine creation and a radical discontinuity between humans and animals but also the idea of an immortal soul with special moral worth. Darwin argued that morality had developed from the social instincts of animals; and he construed the uniquely human capacity for rationality, which Aristotle had seen as the telos of human existence, as the outcome of natural selection operating on accidental mutations.

Biological Determinism: A Critique

Once Darwin had demonstrated an evolutionary continuity between humans and other animals, questions arose about the causal role of human biology in relation to other aspects of human life. For many scientists, the project became the *reductionist* one of showing how the various psychological and social characteristics of human beings were causally determined by human biology.

Many *biological determinist* theories have negative social implications because they present human characteristics like aggression and dominance as biologically determined and therefore inescapable. For instance, Sigmund Freud (1856–1939), the founder of psychoanalysis, insisted that all human motivation could be reduced to two basic drives—the sexual drive, or libido; and the aggressive drive, an ineradicable instinct to hurt, torture, or kill other human

beings (Freud). The German ethologist Konrad Lorenz (1903–1989) also posited an aggressive instinct in humans similar to that he found in his study of various animal species in their natural habitats. In each species, the instinct had evolved to serve one or more life-preserving functions, such as territorial dispersion, selection of the strongest for reproduction, defense of the young, and the establishment of a hierarchy that could provide the group with social cohesion. In species armed with sharp teeth, claws, or beaks, the aggressive instinct was generally coupled with an inhibitory mechanism preventing fighting animals from killing each other; Lorenz argued that there had been no need for such an inhibitory mechanism to evolve in humans because they were not naturally armed. With the development of weaponry, however, the absence of such a mechanism was often lethal, and the advent of nuclear weapons made it a threat to the survival of the species (Lorenz).

More recent studies of animal behavior have generated a new form of biological determinism called *sociobiology.* Two precursors of sociobiology, anthropologists Lionel Tiger (1937–) and Robin Fox (1913–1971), proposed the concept of a "biogram," a code or program genetically "wired" into the brain that produced certain forms of social behavior, including patterns of dominance and submission—hierarchy among males and dominance of males over females. Both of these were assumed to be the evolutionary heritage of the hunting life of early hominids (Tiger and Fox). The same general line of thinking was employed by entomologist Edward O. Wilson (1929–), who first coined the term *sociobiology.* Wilson insisted that "genes hold culture on a leash" and play a significant role in determining such human social behavior as altruism toward kin, communal aggression, nationalism, racism, homosexuality, and the dominance of males over females. Wilson has conceded that these biologically based tendencies might be counteracted through extreme social measures, but he argues that humans would pay a high price for doing so (1977).

While Wilson's assertion of a universal genetic tendency toward ethnocentric and racist attitudes was not an attempt to justify racism, there is a long Western tradition of using evolutionary theory to denigrate certain racial or ethnic groups. In the nineteenth century, some scientists in this tradition asserted that Caucasians and Orientals had crossed the *Homo sapiens* threshold before "Negroes," or that *Homo sapiens* had begun in Asia and migrated to Africa, where the original stock had degenerated. Others sought to prove racial, ethnic, and class inequalities in intelligence through the use of IQ (intelligence quotient) theory. Frances Galton (1822–1911), a cousin of Darwin who coined the term *eugenics,* attempted to show that the upper classes had superior intellectual capacities and that blacks were "two grades" below whites. Many of the early IQ theorists in the United States made similar claims about various immigrant groups.

After World War II, when the Nazis had shown the possible social consequences of eugenic ideas, such theories fell into disrepute. They were revived in 1969 when educational psychologist Arthur Jensen (1923–) published an article in the *Harvard Educational Review* arguing as follows: Intelligence testing has demonstrated that whites score on average about fifteen IQ points above blacks; IQ is 80 percent *heritable*; therefore, the mean difference between the scores proves a hereditary difference in innate intelligence between the two groups (Jensen). Shortly after Jensen's article appeared, Harvard psychologist Richard Herrnstein (1930–) made a similar argument concerning the difference in IQ scores between *upper-class* and *lower-class* people. He concluded that humans should give up any aspirations to democratic equality and accept the idea of a natural meritocracy (Herrnstein).

Biological determinist theories were highly controversial in the late 1960s and 1970s, but in the 1980s and 1990s they became increasingly fashionable—claiming, for instance, genetic factors in alcoholism; locating homosexuality in the structure of the brain; and asserting that men with XYY chromosomes have a tendency toward criminal violence. However, biological determinist theories of human nature are problematic in a number of respects.

Empirically, the evidence for such theories is at best inconclusive. Even within the psychoanalytic tradition, some theorists have argued against Freud that aggressive desires may be explained as derivative manifestations rather than primary instincts, resulting from situations that frustrate other, nonaggressive desires. Ethologists and sociobiologists typically move incautiously from observations of certain animal species or conjectures about early hominids to claims about modern human beings. Sometimes, like Lorenz, they focus on the behavior of fish, birds, and other animals considerably removed from humans—while they ignore studies indicating that many higher mammals, especially primates, display almost no hierarchical organization or intraspecies aggression, being instead peaceful and cooperative. Finally, regardless of how nonhuman species behave, similarities in behavior between humans and nonhuman animals do not establish that the human behavior in question is biologically determined; it may still be a learned response.

Claims for the universality of human aggression, hierarchy, and male dominance also are not confirmed by anthropological evidence. Many hunter-gatherer societies are reported to be remarkably lacking in aggressive behavior, and

some enjoy an exceptionally high degree of social equality. Assertions of women's *natural* dependence on men are undermined by evidence that gathering, a task often performed predominantly by women, is a more reliable food source than hunting in many hunter-gatherer societies. The sexual division of labor varies widely cross-culturally, and even where certain constants are observed, such as a tendency for women rather than men to care for young children, this may be a social adaptation to prevailing conditions rather than a biological predetermination.

Claims about the genetic basis of racial and ethnic differences in IQ are equally suspect. The idea of different evolutionary paths for different races is contradicted by the paleontological evidence; indeed, the concept of race itself is now widely discredited, with anthropologists preferring instead to talk about the statistical frequency of certain characteristics within a geographical population. Further, the idea that IQ tests measure innate intelligence is undermined by the recognition that all tests are culturally biased, since they all require prior learning, and that learning experience can significantly raise IQ. Finally, the very concept of *heritability* is a technical one, designating a ratio of the contribution of heredity to environment within a given population; it cannot be used, therefore, to compare one population against another.

Biological determinist theories of human nature are not just empirically unconfirmed; they also fail to acknowledge what is most distinctive of our species. The human genetic constitution determines highly developed learning and cognitive capacities that allow humans to respond flexibly rather than instinctively to environmental problems, as well as to develop a range of distinctively human cultural characteristics. The implications of this were noted by one of the world's foremost geneticists, Theodosius Dobzhansky (1900–1975), who wrote, "In a sense, human genes have surrendered their primacy in human evolution to an entirely new, nonbiological or superorganic agent, culture. However, it should not be forgotten that human culture is not possible without human genes" (p. 113). In short, what has developed in the human evolutionary process is a primate with a genetic structure capable of a new kind of evolution, cultural evolution.

Biological determinist theories of human nature contrast sharply in content with their pre-Darwinian counterparts, but they are often inspired by the same motivation of discovering universal and unchanging social values. Typically, they describe as *natural* aspects of behavior thought to be biologically determined; though few would assert that natural behavior is always to be encouraged or even permitted, characterizing some behavioral tendencies as natural provides a certain legitimation for them. Because they are understood as resulting from natural selection, such tendencies are regarded as having been necessary at least at some time for human survival; in consequence, they cannot be entirely deplored, and they may even be romanticized as clues to a more *natural* way of life. Thus, biological determinist approaches to understanding and evaluating human nature may be seen as secular analogues of Aquinas's theory of natural law.

It may be the social function of biological determinist theories of human nature, rather than their scientific credentials, that accounts for their continuing popularity. Put simply, these theories tend to rationalize existing manifestations of aggression and inequality: Biological determinist analyses of violence, war, and crime tend to deflect attention from the social and economic causes of these phenomena, just as theories about the biological determinants of male and female behavior distract us from the ways in which men and women are socialized for their respective roles. The implication often drawn from biological determinist theories is that significant social movement in the direction of peaceful cooperation and equality is impossible because it is alleged to go against *human nature.* Clearly, those in power benefit from such an assumption and are likely to encourage the development of such theories.

Behaviorism: Another Form of Post-Darwinian Reductionism

The Western materialist or naturalist tradition has not always moved in a biological determinist direction. It also includes thinkers who claim that environmental or cultural factors are the primary determinants of the human mind or behavior. The philosopher John Locke (1632–1704) saw the human mind as a kind of blank tablet to be written upon by sensory impressions, while Enlightenment figures like Helvétius assumed that education could shape human beings into almost any form.

In the first part of the twentieth century, environmentalist ideas became popular in the United States through a psychological movement known as behaviorism. John B. Watson (1878–1958), who first systematically developed the theory, insisted that in order for psychology to become a rigorous experimental science, it must give up its introspective orientation. It should no longer take its task to be analyzing private mental states, such as feelings, desires, and thoughts, but instead should study the relation between publicly observable behavior and the environment. For Watson, the two basic forms of this relation were the *unconditioned* and the *conditioned reflex.* The former was the basic human physiological endowment, consisting of automatic responses

to environmental stimuli, such as salivating in the presence of food and contracting pupils in the presence of light. Watson based his analysis of the conditioned reflex on the work of the Russian experimental psychologist Ivan Petrovich Pavlov (1849–1936), who had demonstrated that a hungry dog, repeatedly presented with both food and the ringing of a bell, would eventually salivate at only the bell-ringing. The sound of the bell had become a *substitute stimulus,* and the salivation was now a *conditioned response.* For Watson, all human behavior could be reduced to these two kinds of reflexes.

Watson's version of behaviorism was superseded by that of B. F. Skinner (1904–1990), who argued that reflex action could account for only a small part of human behavior. For Skinner, human behavior was primarily shaped by what he called *operant conditioning,* which *reinforced* certain spontaneous movements of the organism. For example, when a pigeon raised its head above a certain height and food was released into its cage, the result was a higher frequency of that behavior. Unlike the stimulus in Watson's model, the "reinforcer" (the food) was introduced *after* the "response" (the raising of the head to the desired height) occurred. For Skinner, most human behavior other than automatic reflex action, even human language, could be explained as the result of *positive* or *negative reinforcement,* which, by adding something to the situation (food, sex, money, praise, etc.)—or by removing something from it—increased the frequency of some behavior. While not denying that feelings and thoughts existed, Skinner refused to characterize them as residing in a special mental domain, consciousness, and claimed that they had no causal effect on human behavior (Skinner, 1953).

Both Watson and Skinner believed that human beings could be conditioned to develop almost any pattern of behavioral responses. Watson boldly declared that he could take almost any infant "at random and train him to become … doctor, lawyer, artist, merchant-chief, and, yes, even a beggar man and thief." Skinner insisted that operant conditioning "shapes behavior as a sculptor shapes a lump of clay." One evident consequence of the behaviorist program was that human freedom was an illusion. For Skinner, in particular, such concepts as freedom, moral responsibility, and human dignity were the conceits of a prescientific age (Skinner, 1973).

Behaviorism, just as much as biological determinism, is heir to the evolutionary paradigm because human behavior is still explained in terms of genetic dispositions regarded as having survival value. For behaviorism, however, these predispositions are not instincts or drives. Instead, specific unconditioned reflexes have evolved in the human species because they have survival value, while the human organism's susceptibility to conditioning helps it survive by allowing it to adapt to environmental changes more rapidly than its genetic structure could.

There are a number of difficulties with the behaviorist conception of human nature. First are the primary data of consciousness, such as desires, feelings, reflection, and decision making; it is hard to believe that these do not have at least some causal influence on human activity. Second, the fact that pigeons, rats, and human beings can sometimes be controlled by operant conditioning does not mean that all human behavior can be understood in this way. Linguist Noam Chomsky (1928–), for example, has argued against Skinner that linguistic competence requires creativity that goes beyond responses to prior conditioning because we are constantly constructing sentences that we have never before encountered. Finally, there is no room in the behaviorist model for human agency: The environment acts, human beings merely react. In this, behaviorism may be seen as ideologically reflecting a world in which people are continually managed and manipulated by technocratic and bureaucratic elites.

Social and Historical Conceptions of Human Nature

Social and historical conceptions of human nature offer an alternative to seeing human beings either as primarily determined by their biological drives or as passive clay to be molded by their physical and social environment. These approaches, while not ignoring human biology or the role of social conditioning, emphasize the importance of human social activity within specific historical contexts. The work of the revolutionary social theorist Karl Marx, together with his collaborator Friedrich Engels (1820–1895), and of the U.S. pragmatist philosopher John Dewey, provides two examples of this approach.

Marx and Engels's view of human nature (Schmitt) was embedded in their more general theory of human history, *historical materialism.* Human history, they contended, began with humans' attempt to satisfy their basic biological needs through producing their means of subsistence, so that human beings were, first and foremost, producers. Human production differed from that of nonhuman animals in that it was deliberate rather than instinctive, involving imagination, planning, and tool use. It was also inherently social, not only in requiring the coordination of human effort but also in utilizing skills and knowledge transmitted from one individual, group, or generation to another. In societies producing a surplus beyond that needed for immediate survival, human production typically involved a division of

labor going beyond a division into separate tasks, to a division between intellectual and physical work and between work considered appropriate for men and for women. Most important for Marx and Engels was the class division of labor between those groups who owned the means of production and those who had to work for them, a division generating the class struggles regarded by Marx and Engels as the motor force in history.

Different economic systems, or what Marx and Engels called modes of production, established forms of social life through which human beings individuated and understood themselves. Peasants and artisans, ladies and gentlemen, merchants and professionals, corporate capitalists and industrial workers would tend to think and act differently from each other. Changes in the mode of production would generate new forms of social life, new ways of understanding the world, and new ways of thinking and acting—in effect, new kinds of *individuals.* Thus, human nature itself would change. Since human beings were active in the class struggle that caused these social and economic changes, however, it could also be said that human beings actively changed their own natures over the course of history.

For John Dewey, as for Marx and Engels, human beings were neither governed by instincts nor passive recipients of environmental forces; rather, they were social agents who changed their own natures in the process of changing their societal conditions. However, in contrast to Marx and Engels, Dewey regarded the motor force of social change not as class struggle but as the product of reflective intelligence.

Dewey acknowledged that human beings had instincts—or impulses, as he preferred to call them in order to discourage associations of inflexibility. Impulses, in his view, were extremely flexible in that they could take on a variety of meanings, depending on the social context. Thus, the impulse of fear might become cowardice, caution, reverence, or respect; while the impulse of anger might become rage, sullenness, annoyance, or indignation. Impulses took on these meanings as habits, predispositions to certain kinds of thinking and acting, ultimately embodied in social customs and institutions. The content of these habits constituted our historical nature. However, when the habits proved inadequate to new social problems, humans could employ their reflective intelligence to redirect their impulses into new habits. For example, as war became increasingly problematic or as certain economic institutions become increasingly outmoded, human impulses could be rechanneled, creating new institutions embodying new habits.

To make sense of the claim that human nature changes, we need to remember the distinction between transhistorical and historical conceptions of human nature. For both Dewey and Marx, it is precisely because a certain transhistorical human nature exists—socially productive and reflectively intelligent—that the content of human nature can be changed historically. To put this point in a more contemporary idiom: Our distinctively human capacity to transform social institutions transforms social roles and, in so doing, transforms historically specific character structures.

Giving more weight to the social and historical aspects of human nature offers a new model of the relation between genetic determination and social conditioning, on the one hand, and social behavior, on the other. What is determined by our genes is our capacity to learn, reflect, and work for change. Humans can, thus, be agents of their own history. Biology determines certain potentialities, but it is only through concrete historical activities that humans develop certain specific cultural and psychological characteristics. Genes dictate the ability to develop general modes of response, such as learning languages, engaging in productive labor, and developing forms of social relatedness; but they do not dictate that humans learn English, produce nuclear weapons, or become selfish and competitive as opposed to altruistic and cooperative. Thus, historical and social conceptions of human nature do not deny biology but refuse to privilege it as the primary cause of human action. Similarly, they do not deny conditioning but equally refuse to privilege it in explaining human action. Certain social conditions undoubtedly encourage the development of certain habits, but these are not merely behavioral responses; instead, they are social patterns of meaning that connect thought to action. Furthermore, human beings do not merely react to social conditions but individuate themselves within them and can reflect intelligently on them. Thus, both individually and collectively humans can decide to change their habits and work to transform the social conditions from which they arose.

A Social and Historical Conception of the Human Body

Although many theorists are willing to acknowledge that people's character or personality or behavior is socially shaped, at least to some degree, the biological constitution, the body, is often viewed as a presocial given, the universal and unchanging foundation on which elaborate cultural edifices are erected. According to this way of thinking, the body constitutes the most natural aspect of human nature. Itself a product of natural selection, the body sets the *natural,* that is, biologically determined, limits of social variability.

While it may be true that there is less systematic cross-cultural and transhistorical variation in people's bodies than

there is in their personalities and social institutions, it is too simple to regard the human body as a presocial given. Although the human body may sometimes be experienced as a given, in fact, like the mind or the personality, bodies are socially and historically shaped on several levels.

It is not difficult to recognize some of the ways in which human bodies are influenced by their social context. Different kinds of work and living conditions develop or distort the body in various ways. For instance, scarcity of food results in stunted growth, so that body size and development vary systematically not only between cultures but often also between social classes. While many of these bodily marks are unintended side effects of social practices, others are deliberately induced. Social norms are consciously inscribed on the body in a variety of ways, ranging from foot-binding and circumcision to diet clinics and cosmetic surgery. The varying social meanings assigned to bodily characteristics and functions influence a person's experience of his or her body, which, depending on the social context, may become a source of pride, joy, pain, or embarrassment.

Social influences on the human body operate not only on the level of observable physical structure, the phenotype; in the past, they have also influenced the genotype, our genetic inheritance, and they continue to do so. While human prehistory is highly speculative, it seems likely that some genetically heritable characteristics have been selected not only *naturally,* as adaptive to such nonsocial circumstances as climate and food availability; but also socially, as adaptive to certain forms of social organization or perhaps even as the results of conscious social preferences. For instance, the average size difference between human males and females may have been a consequence as much as a cause of male dominance: If the dominant males fed first and most, only smaller-framed women could survive on the leftover food. Even today, the human gene pool continues to be influenced by social factors. For instance, exposure to environmental pollutants sometimes leads to genetic mutations, and modern medicine now makes it possible for people to survive and reproduce with genetic conditions that otherwise would have led to their early deaths. Finally, genetic engineering is rapidly becoming a real possibility.

The recognition that even the genetic constitution is influenced by social factors has far-reaching consequences for understanding human nature. The point is not simply that most versions of biological determinism are false because they fail to give sufficient weight to the social determinants of human characteristics. It is, rather, that the usefulness of the whole nature-culture distinction as an analytical framework for understanding human beings comes into question. Just as we cannot identify any cultural or social phenomena uninfluenced in some way by human biology, neither can we identify any human biological or *natural* features that are independent of social influence. The biological and the social are so intertwined in the human past and present that it becomes impossible in principle to distinguish the natural from the social or cultural components in the constitution of human beings. As far as human beings are concerned, the relation between nature and culture is mutually constitutive: To oppose one to the other is incomprehensible. Everything that we are and do is revealed as simultaneously cultural and natural.

Ethical Implications for the Life Sciences: A Cautionary Tale

What are the bioethical implications of these various conceptions of human nature? First, a cautionary note. Practical ethics reflects on a host of considerations in practical contexts and cannot simply deduce specific moral conclusions from general ethical principles, let alone from some general conception of human nature. Thus, the relation between the various conceptions of human nature and any specific bioethical position is unlikely to be one of logical entailment. This does not mean, however, that concepts of human nature have no relevance to bioethical issues. They may serve as starting points for bioethical analysis, raise suspicions about certain bioethical claims, or even rule out certain bioethical positions. In general, certain conceptions of human nature may be said to cohere, or provide a better *fit,* with certain bioethical stances than with others.

The dominant pre-Darwinian conceptions of human nature view physical nature, including the human body, as the realm of the material, the immanent, and the profane, and identify God with the spiritual, the transcendent, and the sacred. It is only because human beings are endowed with a soul that they are regarded as capable of partaking in the sacred, and their mission is to transcend their bodies and realize their spiritual nature. Insofar as they are part of God's creation, nonhuman animals are sometimes assigned a degree of moral worth, but the view that they lack souls typically rationalizes the claim that nonhuman animals are merely resources to serve human purposes. Saint Francis of Assisi notwithstanding, the dominant view of the Judeo-Christian tradition is that God created nonhuman animals and, indeed, all of nonhuman nature, primarily for the use of human beings. This sharp bifurcation between human and nonhuman nature not only permits but even legitimates the human subjugation and exploitation of all nonhuman nature, and may therefore contribute to the contemporary ecological crisis.

Within this ontology, the human body occupies a unique and somewhat ambiguous moral status. Although

material, and therefore a source of temptation, the body is nevertheless sacrosanct because it is indispensable to human life. God is thought to have a divine plan for humanity, and any attempt to subvert this plan by tinkering with the human body is regarded as at least prima facie wrong. When applied to humans as opposed to nonhuman animals, therefore, reproductive technology, genetic engineering, and euthanasia are viewed with suspicion, if not censure; and *brain death* may not be considered sufficient reason to switch off a life-support system, depending on when the soul is believed to leave the body. If, for example, the soul is thought to remain in the body until the last breath of life, then euthanasia can never be justified: Even the suffering and dying body must be revered as the house of the soul. Finally, because humans are morally distinguished by the possession of a soul, abortion is condemned at whatever point the fetus is believed to acquire a soul. It is interesting to note that the Catholic Church has not always held that fetal ensoulment occurs at the moment of conception: Saint Thomas Aquinas, for instance, argued as an Aristotelian that the fetus did not have a soul until it assumed human form, which he thought occurred after three months' gestation for the male fetus and six months' for the female.

In contrast with the pre-Darwinian dichotomies between human and nature, spiritual and material, sacred and profane, post-Darwinian conceptions of human nature posit an evolutionary continuity between human and nonhuman animals. This continuity is sometimes used as a basis for moral challenges to the human exploitation and domination of animals, especially animals that are close to human beings in evolutionary terms. It is precisely those nonhuman animals most like humans, however, that are most useful for many purposes, such as medical experiments and organ transplants; in consequence, some philosophers have sought to undercut moral challenges to the human exploitation of nonhuman animals by arguing that beings *lower* on the evolutionary scale may be sacrificed for the good of *higher* species. Opposing this position is a growing minority in the bioethics community that argues that such a position is an example of unwarranted human chauvinism or *speciesism,* a term invoked to suggest parallels with racism and sexism.

Although post-Darwinian assumptions of an evolutionary continuity between humans and nonanimals may be used to challenge the view that animals are simply a resource for human use, they have also been used to justify radical interventions in human life processes. If it is legitimate to experiment on nonhuman animals, for instance, it may be equally legitimate to experiment on human beings. If *Homo sapiens* is the accidental outcome of natural selection, if there is no inherent purpose for which we are created, then there is no a priori reason to assume that further modifications in human biological processes should not be made via reproductive technologies or even genetic engineering. Since the human nervous system is a defining component of human life, the fetus at an early stage of brain development is likely to have a different moral status than it does once the brain has developed. Certainly, the post-Darwinian conception of human nature would generally assume that *brain dead* means dead.

These conclusions reflect the absence of the concept of a soul in post-Darwinian views of human nature, since it was the soul that, in earlier conceptions, provided the philosophical grounding for human dignity. Unless an adequate substitute for the concept of the soul can be found, post-Darwinian conceptions of human nature may permit the drastic manipulation of human beings. Behavior regarded as undesirable may be treated either as a biological abnormality or as a failure of social conditioning. Biological determinists may regard alcoholism, addictive gambling, violent criminal behavior, schizophrenia, depression, and even homosexuality as candidates for treatment with a variety of biological techniques: psychosurgery, shock therapy, hormonal therapy, psychopharmacological interventions, and perhaps, in the future, even genetic manipulation. Behaviorists, of course, emphasize the use of various conditioning techniques to modify human behavior, raising the prospect of a *Clockwork Orange* world. Skinner, in fact, wrote a utopian novel, *Walden Two* (1948), in which behavioral managers conditioned people from birth to make choices in accord with the goals and institutions of that society. Both biological and behavioral interventions often work toward the same goal—direct control of human behavior.

But who will control the controllers, and how far will such control be allowed to extend? There are already biological determinists who advocate the use of genetic manipulation to raise IQ or to alter certain *undesirable* tendencies in the human species, perhaps to create a Superman. Others would clone the embryo and store it for future use, perhaps in case of some failure of the original stock. Brave New World may be just around the corner unless we can reclaim the concept of human dignity. Social and historical conceptions of human nature offer a secular basis for doing so.

Although people who accept a social and historical conception of human nature may still utilize some concept of naturalness in describing various human activities, such as conceiving or giving birth, they recognize that what is taken to be natural or unnatural changes historically and culturally, so that ethical decisions cannot be grounded in some unchangeable concept of human nature. However, this does not prevent us from ethically evaluating various attempts to manipulate and control human nature. Indeed, those who

accept social and historical conceptions of human nature are likely to urge caution in the use of biological interventions and conditioning techniques for the purposes of altering human behavior. They will be suspicious of all treatment and research modalities that fail to respect human agency, reflective intelligence, and decision-making capabilities, since it is precisely these transhistorical capacities that make possible the continuous transformation of our historical natures. In short, social and historical conceptions of human nature will tend to reaffirm the concept of human dignity. In the sphere of medicine, for instance, they are likely to insist on the dignity of medical subjects and emphasize informed consent and coparticipation in physician-patient relationships.

The recognition that human beings individuate themselves within and through social processes may also have implications for the abortion controversy; at the very least, it suggests that women and fetuses cannot have the same moral status. Moreover, social and historical conceptions of human nature emphasize that consideration of bioethical problems must be sensitive to concrete social and political contexts; in a society with an expressed commitment to human equality, for example, questions like procreative technology or contract parenting must be evaluated with special reference to their implications for people of different classes, genders, abilities, races, and ethnicities. Finally, social and historical conceptions regard human beings as transhistorically creative, productive, social, and capable of reforming their habits through reflective intelligence; and people who accept these conceptions are likely to valorize those capacities and seek to develop social institutions—including healthcare, psychiatric, and research institutions—through which they would be enhanced.

The open-ended nature of these last implications serves as a reminder that ethical conclusions are not strictly entailed by any general conception of human nature, especially by social and historical conceptions. In addressing particular bioethical problems, therefore, the values implicit in these conceptions must be supplemented by explicitly ethical criteria, such as historically specific understandings of justice, freedom, and human well-being.

HUMAN RIGHTS

• • •

Human rights constitute a set of norms governing the treatment of individuals and groups by states and nonstate actors on the basis of ethical principles incorporated into national and international legal systems. Because the subject matter of the norms in question relate to the treatment of human beings, human rights overlap to a considerable degree with ethics, but they nevertheless should not be confused with ethics. Similarly, because human rights include the right to health and refer to essential social determinants of health and well-being of people, they overlap with many principles and norms of bioethics. Human rights and bioethics differ, however, in scope, sources, legal nature, and the mechanisms of monitoring and applying the norms.

The *scope* of bioethics is the ethical issues arising from healthcare and biomedical sciences, whereas that of human rights embraces the claims individuals and groups can legitimately make against states and nonstate actors to respect their dignity, integrity, autonomy, and freedom of action as defined in an officially endorsed set of standards or norms. Bioethics regulates clinical encounters with patients on the basis of principles; human rights, by contrast, are the special rules agreed upon in a given society to achieve justice and well-being.

The *source* of human rights is the norm-creating process of national and international legal systems, whereas that of bioethics is the deliberations and published opinions of leading thinkers, constituted review boards, and professional associations on the health-related ethical issues they address. Bioethics and human rights share an ethical concern for just behavior, built on empathy or altruism. The proximate formal source of human rights is typically an international human rights treaty or declaration while that of bioethics is a professional code or review board guidelines. The proximate source occasionally is identical, as when an instrument of international law directly addresses an issue of bioethics and human rights, for example, in the United Nations Educational, Scientific and Cultural Organization's (UNESCO) Universal Declaration on the Human Genome and Human Rights or the Council of Europe's Convention for the Protection of Human Rights and Dignity of the Human Being with Regard to the Application of Biology and Medicine, both of which were adopted in 1997.

The *legal nature* of human rights norms ranges from merely aspirational claims to justiciable and enforceable legally binding obligations. An important distinction is made between *rights* and *human rights.* In ethics a right refers to any entitlement, the moral validity or legitimacy of which depends on the mode of moral reasoning the ethicist is using. In law, a right is any legally protected interest. In human rights discourse, a human right is a higher-order right authoritatively defined using the expression *human rights* with the expectation that such a right carries a peremptory character and thus prevails over other (ordinary) rights. Another distinction is between the natural law and

positive law foundations of human rights. The former refers to rights deriving from the natural order or divine origin, which are inalienable, immutable, and absolute, whereas in positive law rights are recognized through a political and legal process that results in a declaration, law, treaty, or other normative instrument. These may vary over time and be subject to derogations or limitations designed to optimize respect for human rights rather than impose an absolute standard. Human rights emerge from claims of people suffering injustice and thus are based on moral sentiment, culturally determined by contextualized moral and religious belief systems. They become part of the social order when an authoritative body proclaims them, and they attain a higher degree of universality based on the participation of virtually every nation in the norm-creating process, a process that is law-based but that reflects compromise and historical shifts. The International Bill of Human Rights (consisting of the Universal Declaration of Human Rights [UDHR] of 1948 and the International Covenant on Civil and Political Rights and the International Covenant on Economic, Social and Cultural Rights, both of 1966), along with the other human rights treaties of the United Nations (UN) and of regional organizations, constitute the primary sources and reference points for what properly belongs in the category of human rights.

The *methods of monitoring compliance* with human rights include moral judgments made with reference to recognized human rights, quasi-judicial procedures of investigation and fact-finding leading to official pronouncements of political bodies, and enforceable judicial decisions. The parallel methods of bioethics focus more on codes of bioethics and official pronouncements of professional bodies that may result in altering research design or the behavior or liability of health professionals in their relations with patients or in policies affecting the health of populations.

The overlap of human rights and bioethical discourse and the differences between the two become clearer as one clarifies the following: the emergence of human rights in political and legal discourse, the content of the right to health as defined in human rights instruments, the other human rights as they relate to health and well-being, and the role and means of promotion and protection of human rights.

Emergence of Human Rights

The early formulation of the norms that are characterized today as human rights is inseparable from historical and philosophical manifestations of human striving for justice. Ultimately, human rights certainly derive from basic human instincts of survival of the species and behavior of empathy and altruism that evolutionary biology is only beginning to understand. Since human evolution is driven by reproductive selfishness, one could wonder why the human species would develop any ethical system, like that of human rights, according to which individuals manifest feeling for the suffering of others (empathy) and—even more surprising—act in self-sacrificing ways for the benefit of others without achieving any noticeable reproductive advantage. And yet, as Paul Ehrlich notes in *Human Natures*, "empathy and altruism often exist where the chances for any return for the altruist are nil" (p. 312). Natural selection does not provide the answer to moral behavior as "there aren't enough genes to code the various required behaviors" but rather "cultural evolution is the source of ethics" (p. 317) and therefore of human rights.

Religion and law have an ambiguous role in this historical process. The history of religions is replete with advances in the moral principles of behavior—many of which directly influenced the drafting of human rights texts—but also in crimes committed in the name of a Supreme Being. Similarly, the emergence of the rule of law has been critical both to advancing justice and human rights against the arbitrary usurpation of power in most societies and to preserving the impunity of oppressors.

Scholars trace the current configuration of international human rights norms and procedures to the revolutions of freedom and equality that transformed governments across Europe and North America in the eighteenth century and that liberated subjugated people from slavery and colonial domination in the nineteenth and twentieth centuries. Enlightenment philosophers derived the centrality of the individual from their theories of the state of nature. Social contractarians, especially the eighteenth-century French philosopher Jean-Jacques Rousseau, predicated the authority of the state on its capacity to achieve the optimum enjoyment of natural rights, that is, of rights inherent in each individual irrespective of birth or status. Rousseau wrote in *A Discourse on the Origin of Inequality* (1755) that "it is plainly contrary to the law of nature … that the privileged few should gorge themselves with superfluities, while the starving multitude are in want of the bare necessities of life" (p. 117). Equally important was the concept of the universalized individual ("the rights of Man"), reflected in the political thinking of Immanuel Kant, John Locke, Thomas Paine, and the authors of the French and American declarations. Much of this natural law tradition is secularized in contemporary human rights.

World War II was the defining event for the internationalization of human rights, with the latter anticipated by Roosevelt's "Four Freedoms" speech (1941), confirmed by the inclusion of human rights in the UN Charter (1945), and applied at the trial of Nazi doctors, leading to the

Nuremberg Code (1946). In the war's immediate aftermath, bedrock human rights texts were adopted: the Genocide Convention and the UDHR in 1948 and the Geneva Conventions in 1949, followed in 1966 by the two international covenants. Nongovernmental organizations (NGOs) played a role in all these developments and in subsequent drafting of treaties, as well as in the creation of investigative and accountability procedures at the intergovernmental level and at the national level. These processes were instrumental in bringing down South African apartheid, transforming East-Central Europe, and restoring democracy in Latin America. Human rights NGOs are now active on all continents.

The Normative Content of Human Rights: The Right to Health

The current catalogue of human rights consists of some fifty normative propositions. They are enumerated in the international bill of human rights, extended by a score of specialized UN treaties, a half-dozen regional human rights treaties, and hundreds of international normative instruments in the fields of labor, refugees, armed conflict, and criminal law.

The meaning, scope, and practical significance of the right to health are particularly relevant for bioethics. The right to health as understood in international human rights law is defined in article 25 of the 1948 Universal Declaration of Human Rights ("Everyone has the right to a standard of living adequate for the health of himself and of his family, including food, clothing, housing and medical care and necessary social services.") and in article 12 of the 1966 International Covenant on Economic, Social and Cultural Rights (ICESCR) ("the right of everyone to the enjoyment of the highest attainable standard of physical and mental health"). Variations on these definitions are found in most of the core UN and regional human rights treaties. In 2000 the Committee on Economic, Social and Cultural Rights (CESCR), which was created to monitor the ICESCR, analyzed the normative content of the right to health in terms of availability, accessibility, appropriateness, and quality of care and specified the duties of the state to respect, protect, and provide this right. The committee also listed fourteen human rights as "integral components of the right to health." These related rights define to a large extent the determinants of health.

The right to health does not mean the right to be healthy, because being healthy is determined only in part by healthcare; it is also determined by genetic predisposition and social factors. The field of social epidemiology has excelled at establishing correlations between discrimination based on race, class, or gender, denial of education and of decent working conditions, as well as other factors that contribute directly to increased rates of mortality and morbidity. These social determinants may also be defined in human rights terms as deprivation of these health-related rights, which are among the most salient social factors that contribute to healthy lives. The summary below seeks to underscore the function of human rights as determinants of health by highlighting their normative content and their relation to health.

Health-Related Human Rights

Health is profoundly related to human rights both because human right violations have health impacts—such as those on torture survivors—and because human rights concern the dignity, integrity, autonomy of action, and conditions of social functioning of people. Some examples will be provided in each of these areas.

Foremost among the human rights relating to physical and mental integrity is the right not to be arbitrarily deprived of life, which does not rule out death resulting from lawful acts of warfare or capital punishment, although international humanitarian law limits the former, and newer protocols and regional conventions, supported by UN resolutions and social movements, define the latter as a violation of human rights. Special treaties and procedures exist for prevention and repression of torture, disappearance, summary and extrajudicial execution, crimes against humanity, genocide, slavery, racial discrimination, and various forms of terrorism. Most of these are also dealt with in international humanitarian law, which was established to protect victims of armed conflict (injured and shipwrecked combatants, prisoners of war, and civilian populations notably under occupation) and codified in the four Geneva Conventions of 1949 and the Additional Protocols of 1977.

The right to "a standard of living adequate for the health and well-being" of oneself and one's family was defined in the UDHR as including "food, clothing, housing and medical care and necessary social services" as well as "the right to security in the event of unemployment, sickness, disability, widowhood, old age or other lack of livelihood in circumstances beyond [one's] control." Subsequently, the rights to health, work, safe and healthy working conditions (occupational health), adequate food and protection from malnutrition and famine, adequate housing, and social security (that is, a regime covering long-term disability, old age, unemployment, and other conditions) have been further elaborated by the International Labour Organisation, the UN Commission on Human Rights, and the work of special rapporteurs and treaty bodies.

Dignity tends to be mentioned as both the basis for all human rights and a right per se. The great civil liberties—freedom of oral and written expression, freedom of conscience, opinion, religion, or belief—as well as freedom from arbitrary detention or arrest, rights to a fair hearing and an effective remedy for violations of human rights, and protection of privacy in domicile and correspondence, all support the autonomy of individuals to act without interference from the state or others. A separate but related human right is that of informed consent to medical experimentation, which was included in post-1945 enumerations of rights because of the extensive abuse of that right during World War II.

Equality and nondiscrimination are human rights that are at the same time principles for the application of all other human rights, because they require that all persons be treated equally in the enjoyment of their human rights and that measures be taken to remove discriminatory practices on prohibited grounds. Freedom of movement means the right to reside where one pleases and to leave any country, including one's own, and to return to one's country. The right to seek and enjoy asylum from persecution is also a human right, which has been developed and expanded by international refugee law, the practice of the UN High Commissioner for Refugees, and recent codes relating to internally displaced persons. This right, like many others, is not absolute; limitations may be imposed, for example, in time of epidemic, as long as certain safeguards, defined in human rights law, are observed.

Social well-being depends in large measure on group identity, education, family, culture, political and cultural participation, gender and reproductive rights, scientific activity, the environment, and development, all of which are the subject of specific human rights. The basic human rights texts affirm a limited number of group rights, notably the rights of *peoples* to self-determination, that is in the terms of the ICCPR and the ICESCR, to "determine their political status and freely pursue their economic, social and cultural development" and to permanent sovereignty over natural resources. They also enumerate the rights of persons belonging to minorities to practice their religion, enjoy their culture, and use their language. Indigenous peoples have defined rights that take into account their culture and special relation to the land.

The right to education is defined in the ICESCR and by the CESCR, as well as specialized instruments of UNESCO. Other rights of the child have been codified in the 1989 Convention on the Rights of the Child. Political rights include the right to run for office and to vote in genuine and periodic elections. Cultural rights refer primarily to the right to participate in the cultural life of the community; the protection of writers, artists, and performers; and the preservation of cultural heritage.

Health issues loom large in human rights standard-setting and policy determination regarding gender and sexual and reproductive rights. The basic human rights texts have been supplemented by a specialized Convention on the Elimination of All Forms of Discrimination against Women (CEDAW) of 1979. Considerable advances in mainstreaming women's rights as human rights were made at international conferences, a 1993 Declaration on Violence against Women, the work of a special rapporteur on this problem, and statements and programs on traditional practices harmful to health, such as female genital mutilation. Reproductive rights include the right of "men and women … to decide freely and responsibly on the number and spacing of their children" (CEDAW, article 16) and "to be informed and to have access to safe, effective, affordable and acceptable methods of family planning of their choice" (ICPD 1994). Various internationally approved programs and plans of action have set out in considerable detail the specific ways in which this right can be realized.

Bioethical concerns overlap with human rights with respect to the right to enjoy the benefits of scientific progress and rights in scientific research. The former refers to the positive and equitable use of scientific advances, while the latter protect freedom to conduct research and disseminate results and the requirement of informed consent of human subjects.

Occasionally, scholars refer to solidarity or third-generation rights to certain global values such as peace, a healthy environment, development, communication, and humanitarian intervention or assistance. Two rights in this category have become more systematically developed and enshrined in authoritative texts: the rights to a healthy environment and to development. The former has been recognized in many national constitutions and in the regional human rights texts. The latter has been recognized in numerous UN resolutions and specifically in a 1986 declaration, as well as in the African Charter on Human and Peoples' Rights. The 1986 Declaration on the Right to Development defines the right to development as "an inalienable human right by virtue of which every human person and all peoples are entitled to participate in, contribute to, and enjoy economic, social, cultural and political development, in which all human rights and fundamental freedoms can be fully realized."

Finally, article 28 of the UDHR proclaims the right of everyone to "a social and international order in which the rights and freedoms set forth in this Declaration can be fully realized." This right is perhaps the broadest but also the most

significant in making human rights the ordering criterion for national societies and international relations. The required social order suggests a democratic constitutional regime in which human rights of all categories are recognized in law and effectively observed in practice. It also suggests that international relations provide support for global efforts to further human rights and to establish means of accountability for persons and groups to obtain redress from countries that fail to fulfill their human rights obligations.

The Enforcement and Implementation of Human Rights

The term *enforcement* refers to coerced compliance, whereas *implementation* refers to supervision, monitoring, and the general effort to hold duty-holders accountable. Implementation is further subdivided into promotion—preventive measures to ensure respect for human rights in the future—and protection—responses to violations that have occurred in the past. The means and methods of implementation may be summarized in three forms of promotion and five forms of protection.

Promotion of human rights is achieved through developing awareness, standard-setting and interpretation, and creating national institutions. Awareness of human rights is a precondition to acting on them and is advanced though dissemination of knowledge and human rights education at all levels, for which the UN proclaimed a decade of action for the period from 1995 to 2004. Standard-setting means the drafting of human rights texts, for which the UN Commission on Human Rights, established in 1946, plays a central role, along with other UN and regional organizations. These norms are interpreted by various international courts and treaty-monitoring bodies. The third preventive or promotional means of implementation is national institution-building, which includes improvements in the judiciary and law enforcement institutions and the creation of specialized bodies such as national commissions for human rights and offices of an ombudsman.

The *protection* of human rights involves a complex web of national and international mechanisms to monitor, judge, denounce, and coerce states, as well as to provide relief to victims. Monitoring compliance with international standards is carried out through the reporting and complaints procedures of the UN treaty bodies and regional human rights commissions and courts. Special procedures of working groups and special rapporteurs study countries or issues, taking on cases of alleged violations, reporting back on their findings, and requesting redress from governments. Among the *thematic* rapporteurs, one is specifically mandated to study the right to health, and others deal with a variety of health-related issues. The second means of protection is adjudication of cases by fully empowered human rights courts, the main ones being the European Court of Human Rights of the Council of Europe, the American Court of Human Rights of the Organization of American States (OAS), and the African Union's African Court of Human and Peoples' Rights, which was not yet functioning in mid-2003.

Political supervision refers to resolutions judging the policies and practices of states adopted by the Commission on Human Rights, the UN General Assembly, the Committee of Ministers of the Council of Europe, the Assembly of OAS, and other political bodies that denounce governments for violations of human rights and demand that they redress the situation or provide compensation to the victims.

The use of coercion is available only to the UN Security Council, which can use its powers under Chapter VII of the UN Charter to impose sanctions, cut off communications, create ad hoc criminal tribunals, and authorize the use of force by member states or the deployment of UN troops to put an end to a threat to international peace and security, which it has on occasion interpreted to include human rights violations (e.g., Haiti, Somalia, Bosnia, Iraq). This forceful means of protecting human rights is complex and dangerous and can have harmful health consequences, as has been the case with sanctions imposed on Haiti and Iraq. If used properly it can be a modern and legitimate form of the nineteenth-century doctrine of humanitarian intervention, according to which states use armed force to halt atrocities committed in another state while respecting the principles of necessity, proportionality, disinterestedness, and collegiality. The North Atlantic Treaty Organization (NATO) sought to employ such a doctrine in Kosovo in 1999 but without the necessary authorization from the Security Council engaged in what most scholars consider a legitimate but illegal use of force. Each case of action (e.g., no-fly zones over Iraq imposed in 1991) or inaction (e.g., Rwanda in 1994) regarding the use of armed force for human rights purposes has complex ethical and legal difficulties.

The final means of responding to human rights violations is through humanitarian relief or assistance. Provision of food, blankets, tents, medical and sanitary assistance, and other forms of aid saves lives and improves the health of persons forcibly displaced often as a result of large-scale human rights violations. Refugees and internally displaced persons come under the protection of the UN High Commissioner for Refugees (UNHCR), which deploys massive amounts of aid, along with the International Committee of the Red Cross, UNICEF, World Food Program (WFP), United Nations Development Programme (UNDP), the

UN Office for the Coordination of Humanitarian Affairs, and other agencies, as well as major NGOs such as Oxfam International, CARE, and the International Rescue Committee.

Conclusion

Every country in the world has accepted that human rights are universal, but all are challenged, in one way or another, to achieve progress with respect to those rights they neglect, however proud they may be of achievements with respect to other rights. Thus Cuba may be rightfully proud of its record on rights to health and education but is challenged to do more for political and civil rights; the United States may pride itself on the degree to which freedom of expression or civil rights are guaranteed but is challenged to take seriously economic, social, and cultural rights, including universal access to healthcare. The normative content of the corpus of human rights standards is probably the most complete catalogue of the determinants of physical, mental, and social well-being. The methods of implementation or intervention to ensure compliance are not directly linked to medical and health practice or to health policy, as is the case with bioethics. They nevertheless constitute a potentially rich framework for the improvement of health policy and practice, which is the objective of the emerging subfield of health and human rights.

IMMIGRATION, ETHICAL AND HEALTH ISSUES OF

As of March 2000 it was estimated that approximately 10.4 percent of the United States population, or 28.4 million individuals, were immigrants. Prior to 1965 the majority of immigrants came from European countries, such as the United Kingdom, Greece, Poland, Portugal, Germany, and Ireland. Since then, however, an increasing number of immigrants has come from Latin American, Asian, and Caribbean countries, including El Salvador, Colombia, Vietnam, China, Haiti, and the Dominican Republic.

Individuals may seek to enter the United States for any number of reasons, including a desire to reunite with family members, the acceptance of a new employment opportunity, or a need to leave one's country of origin due to persecution. The majority of individuals entering the United States from other countries do so legally, through established immigration procedures. Others enter illegally, oftentimes in search of a safe haven from persecutors.

Findings relating to the health of immigrants have been inconsistent, in part due to reliance on different definitions of *immigrant.* For instance, some studies consider the health or illness of all foreign-born individuals, regardless of the legality or duration of their residence in the United States, while others may examine either the health of those who are here legally or of those who are here illegally (Loue and Bunce). Some studies have utilized the term *newcomers* to encompass those who are here permanently and temporarily, as well as those who are here legally and illegally (Smith). Refugees who are seeking safety from persecution within their own countries may be considered separately, or they may be included in broader discussions relating to immigrants.

Morbidity and Mortality

The risk of morbidity and mortality varies by immigrant group and by disease. In general, the health problems of immigrant populations mirror those that are prominent in the countries from which they have come. For instance, between 14 percent and 20 percent of Indo-Chinese refugees carry hepatitis B, and up to 15 percent of Southeast Asian refugees may be chronic carriers of the infection. This is not surprising in view of the fact that hepatitis B virus is endemic in many Asian countries (Tong and Hwang). During the period from 1986 through 1994, the rate of mycobacterium tuberculosis was four times higher among foreign-born individuals than among those born in the United States. Because more than half of the cases among the foreign-born were diagnosed less than five years after their arrival in the United States, it appears that imported tuberculosis is responsible for the majority of tuberculosis cases among immigrants in the United States (Zuber, McKenna, Binkin, et al.).

However, a number of studies have found that immigrants to the United States may experience lower rates of mortality than persons who remain in the sending countries. In addition, immigrants' risks of smoking, substance use, obesity, hypertension, and some forms of cancer are lower than the risks experienced by United States-born individuals of equivalent demographic and socioeconomic backgrounds. It has been hypothesized that this health advantage may result from a self-selection for immigration by healthier individuals (Swallen). However, for a number of immigrant groups, the risk of these illnesses appears to increase with increasing

length of residence in the United States (Frisbie, Cho, and Hummer).

Immigrants may be at particularly high risk for a variety of occupationally related illnesses. Many may be able to find employment only in sweatshop-like conditions or in agricultural work where they may face continuous exposure to pesticides and herbicides, generally without adequate protection (Stephenson).

Women who immigrate to the United States may experience a number of gender-related health problems. Women may suffer significant trauma during their transit to the United States, including sexual assaults and forced labor (sometimes in the form of sexual slavery). Once they arrive in the United States, they may confront additional gender-related problems. For instance, many immigrant women are more willing than their male partners to accept low-paying jobs in order to support themselves and their families. Once they become wage earners, they may be introduced to North American conceptualizations of gender roles. Their male partners may, as a result of their own unemployment, feel threatened by what appears to be a shift in the power structure within the family due to their inability to earn a living and their partners' newfound independence. For some women, these changes in family structure have been associated with an increase in domestic violence. Still other immigrant women may become subject to abuse by spouses or boyfriends who are United States citizens or legal permanent residents. These men may have promised to file immigration papers on the women's behalf, but failed to do so. The women may be afraid to leave their abusive partners or to report their abusers to law enforcement authorities because of their own illegal status and the consequent fear of deportation. Often, the women may be financially, as well as legally, dependent on their abusers, so that it becomes difficult for them to leave these situations. Specific provisions in U.S. immigration law now permit abused immigrant women in such situations to file petitions on their own behalf so that they will not have to remain captives in abusive relationships.

Barriers to Care

Immigrants may be reluctant to rely on Western-style medicine due to differing traditions of symptom identification, diagnosis, and healing. Additional barriers are presented by language differences and the relative unavailability of competent interpreters, by transportation difficulties, and by providers' lack of familiarity with the healing beliefs and practices of their immigrant patients. For example, a study of the utilization of mental health services by a sample of Mexican Americans in Fresno County, California, found that those who were born outside of the United States had a utilization rate that was only two-fifths that of the Mexican Americans born in the United States (Vega, Kolody, Aguilar-Gaxiola et al.). This differential utilization rate may have been attributable to the nonexistence of Spanish-speaking mental health professionals, a lack of insurance, the lack of a regular doctor or course of care, or to physical isolation in rural areas.

Southeast Asian immigrants have been found to have the lowest levels of Pap testing of any racial or ethnic group in the United States. A recent study of Cambodian immigrants found that barriers to the use of the Pap test included a traditional orientation to the prevention, causation, and treatment of disease; a lack of familiarity with Western concepts of early disease detection; low levels of knowledge about cervical cancer; concerns about the Pap test procedure; and difficulties with transportation and language interpretation (Jackson, Taylor, Chitnarong et al.).

Immigrants, both those who are in the United States legally and those who are not, must often confront a patchwork of federal programs that, despite their number and complexity, often do not assure access to necessary care. The Centers for Disease Control and Prevention (CDC) oversee specific programs for infectious diseases. The CDC is also responsible for the review of applications for waivers from those immigrants seeking legal entry who may be excludable from the United States pursuant to legal provisions prohibiting the entry of those with specified diseases, such as active tuberculosis, various sexually transmitted diseases, and various forms of mental illness. The Office of Refugee Resettlement of the U.S. Department of Health and Human Services provides funds to the CDC to oversee the infectious disease programs. The Migrant Health Program also provides some funding for preventive services and immunizations.

Numerous federal and state laws place restrictions on immigrants' ability to access care that is publicly funded. In 1994, for instance, California's Proposition 187 severely curtailed the ability of individuals who were in the United States illegally to obtain publicly funded care and required that specified agencies and healthcare professionals report these individuals' presence to the Immigration and Naturalization Service. Although numerous portions of the law were ultimately found by the courts to be unconstitutional, researchers noted a 5 percent decrease in the number of clients appearing at clinics for the diagnosis and treatment of sexually transmitted disease immediately following the law's passage (the law was not implemented because it was immediately enjoined by the court). Approximately 25 percent of these individuals indicated that they were in the country illegally (Hu, Donovan, Ford, et al.). A similar

decrease was noted in the number of individuals presenting for other medical services (Marx, Thach, Grayson, et al.). The possibility that physicians and other healthcare professionals would report their patients' illegal presence to government authorities raised significant ethical concerns about the imposition of conflicting loyalties, the breach of physician–patient confidentiality that would attend such reporting, and the potential threat to public health as a result of delays in seeking care due to fear of disclosure (Ziv and Lo).

Despite several amendments since their original passage, the provisions of the 1996 Personal Responsibility and Work Opportunity Reconciliation Act (commonly known as the Welfare Reform Act) and the Illegal Immigration Reform and Immigrant Responsibility Act (IIRAIRA) continue to severely restrict the ability of even legal immigrants to rely on publicly funded medical services, apart from emergency medical needs and the diagnosis and treatment of specified infectious diseases. The legislation has engendered significant controversy because many of the immigrants who are denied publicly funded care, such as Medicaid, actually pay into the system through their taxes. In addition, many states have not adopted state legislation that would permit immigrants to rely on publicly funded care when they do not have privately funded health insurance. This is particularly problematic for women of childbearing age, who may not have the funds or the private insurance to cover the costs of prenatal care, labor and delivery services, or care for their newborns.

Within those states that have implemented legislation permitting immigrants to receive publicly funded care, many may still be denied access to recommended treatments. In New York, which has been one of the most forward-thinking states in the provision of publicly funded health services to immigrants, a panel consisting of physicians, medical ethicists, and AIDS advocates charged that physicians are withholding certain HIV-related treatment regimens from immigrant patients in the belief that they will not adhere to the recommended regimen (Newsline People AIDS Coalition New York).

Both the Welfare Reform Act and IIRAIRA limit the ability of immigrants, whether legal or not, to utilize other types of publicly funded services, such as food stamps. The impact of welfare reform has thus disproportionately affected immigrant groups. For instance, although noncitizens represented only 9 percent of the households receiving welfare, they accounted for 23 percent of the total decline in welfare caseloads following the enactment of these laws (Fix and Passel).

Healthcare providers also face difficulties due to the limitations imposed on access to public funds by federal laws. Hospitals are required by the federal Emergency Medical Treatment and Active Labor Act (1986) to provide emergency medical care to those presenting for such care, regardless of their legal status in the United States (Galloro). There may be an ethical, as well as a legal, responsibility to care for those presenting at emergency departments with life-threatening situations. The hospitals are not reimbursed by the federal government for the full cost of these services, although the federal government is responsible for the enforcement of the immigration laws, and many of the injuries that are treated result directly from dangerous attempts to cross the border. As a result, many hospitals in border areas are experiencing critical losses in revenue due to uncompensated care (Galloro). Of the five states that are most impacted by illegal immigration (California, New York, Texas, Florida, and Illinois), two have unsuccessfully sued the federal government in an effort to obtain reimbursement for the costs incurred in providing uncompensated care to illegal entrants.

Negotiating the Provider–Patient Relationship

Numerous issues may arise in the context of the provider–patient relationship due to differing beliefs regarding, and experiences with, such relationships, concepts of autonomy, and understandings about disease and illness. Some patients may have come from countries in which medical practitioners functioned as agents of the government, reporting to law enforcement officers the names of patients whose illnesses may have been related to illegal activities (e.g. sexually transmitted diseases that may have resulted from extramarital sexual relations or commercial sex activities, or pelvic infections resulting from illegal abortions). Others may have experienced torture at the hands of government-employed medical professionals. Not surprisingly, such experiences may hinder the patient's willingness and ability to divulge sensitive information to a healthcare provider. A lack of provider sensitivity to this possibility may inadvertently exacerbate the difficulty of communication. Even patients who have not experienced such trauma may feel reticent to discuss deeply sensitive issues due to perceived disparities in power between the healthcare provider and the patient.

Western medicine emphasizes the importance of self-determination and autonomous decision making in the context of medical care. However, some immigrant patients, and particularly those from non-Western cultures, may conceive of the individual not as an autonomous and disconnected entity, but rather as a function of the roles that one maintains in relation to those around one, such as extended family members and community members. In

such instances, the patient may want the healthcare provider to discuss the details of his or her situation in as much, or even more, detail with the family or community members as with the patient. For instance, the patient may believe that the entire family should be involved in a decision to undergo chemotherapeutic treatment for cancer. Other patients may not want to know their own diagnosis, but may want family members to be fully informed.

The use of interpreters may also present challenges. At the most basic level, English phrases or terms may not be easily translatable into the language used by the patient. Other aspects of the interpreting function, however, may be more subtle and, consequently, more difficult to remedy. Differences in social status between the interpreter and the patient may influence the quality of the communication in ways that are not obvious to the healthcare provider. Interpreters may also incorporate their own beliefs and agendas into the communication. For instance, family members who serve as interpreters may inadvertently or intentionally minimize or exaggerate aspects of the information to be communicated.

Providers cannot realistically be expected to understand and be familiar with every possible culture and language. Providers may find it helpful, however, to consult with professionals in community-based organizations and agencies who have experience working with particular cultures. Family members of patients may be willing and able to provide additional background, particularly when it is clear that the provider is making a sincere effort to understand his or her patient.

Issues in Health Research

Immigrants may also face significant difficulties in the context of health research. For instance, many clinical trials do not provide care to trial participants. In such cases, examinations are provided only for the purpose of the trial and individuals are advised that they must consult with their own physicians for any necessary medical attention. In some cases, individuals are excluded if they do not have health insurance of some sort or if they do not have a regular provider of care. As a result, many immigrants may be ineligible for participation in a research study because they do not have employment-based health coverage, because they do not earn a salary that is sufficient to cover the costs of health insurance, or because they do not have a regular provider of care. In addition, many studies may limit participation to speakers of English, and those immigrants who have not yet mastered the language may be excluded from participation. Individuals may also be excluded due to the instability of their legal status and residence, in part because of the possibility that follow-up with them during the course of the study will be difficult and costly.

As in the clinical context, the development of a satisfactory informed-consent process for use with immigrant participants may require significant attention to ensure that the information provided to participants is understandable, both in terms of the language used and the sophistication of that language. An appropriate process may require, depending upon the culture of the participants, that the participant's family members or community members be engaged at some level. For example, information may be provided to the male head of the household, in addition to the prospective participant, so that the prospective participant can discuss the study with him. This does not, however, obviate the need for the individual consent of the participant.

As noted above, many immigrants may face extraordinary obstacles in attempting to obtain medical care. As a result, the offer of financial compensation or medical care in conjunction with participation in research may inadvertently place undue pressure on immigrants to agree to participate.

In the United States, immigrants have not traditionally been conceived of as constituting an especially vulnerable class of persons in need of special protections in the context of research. However, many of the characteristics of at least some members of this population may render them especially vulnerable. Poverty, lack of access to care, illiteracy, traumatic experiences, language, and illegal status can all have an effect in this regard. It is significant that Uganda has taken official note of these circumstances and has designated refugees as a class as being especially vulnerable and in need of special protections in the context of research. To address this situation, Ugandan institutional review committees reviewing proposed research that will involve refugees must include in its membership at least one individual from an agency whose primary responsibility is attention to refugee concerns, as well as a representative from a human rights organization.

IMPAIRED PROFESSIONALS

• • •

Impairment is a widespread problem of professional life. An impaired member of any profession creates legal and ethical difficulties for himself or herself, and can cause harm to others as well. For these reasons, the impaired professional merits serious attention (Boisaubin and Levine; Allan).

Defining the Problem

In common usage, the word *impair* connotes worsening or deterioration. An impairment diminishes the value or excellence of an individual or item. An impaired person has deteriorated significantly enough to endanger his or her capacity to function adequately.

When impairment refers to a professional, its meaning becomes more technical and restrictive. Because professions are self-regulating and resist external oversight, professionals largely determine for themselves what impairment means. Things that might impair an individual in the eyes of the lay community might not be defined as impairments within the professional community.

Typically, the impaired professional is one whose ability to function in his or her professional capacity has deteriorated because of a physical or mental difficulty. Impairing conditions traditionally have included drug dependency, alcohol dependency, illness, and disability (physical as well as mental). The American Medical Association (AMA), for example, defines the impaired physician as one "unable to practice medicine with reasonable skill and safety to patients because of physical or mental illness, including deteriorations through the aging process or loss of motor skill, or excessive use or abuse of drugs including alcohol" (La Puma and Schiedermayer, p. 91). A professional also may be regarded as impaired if abilities are significantly compromised as the result of stress or other factors (Nelson and Jennings).

While impairment raises concerns about an individual's professional competence, being impaired is not necessarily the same as being incompetent. An incompetent professional lacks the minimally acceptable levels of knowledge and skill needed to practice within a field. Such a person once may have been competent, then fails to maintain adequate knowledge and skill. One can be incompetent without being impaired.

Impairment's Social and Professional Implications

The impaired professional poses a serious problem to self and others. An impairment may adversely affect the professional's relationships with colleagues, patients and families, and the professional's institution or workplace. It can affect a professional's relationship with friends and family. An impaired professional may engage in self-destructive behavior.

Impairment is a grave problem to those who put trust in professionals and expect them to be competent and to protect the public against impaired practitioners. Members of the public seldom possess the expertise needed to evaluate the quality of services being provided to them. Their potential vulnerability becomes even more significant when other factors (e.g., being sick or injured, being in an unfamiliar setting, or being a member of a different socioeconomic class) make it difficult for a layperson to question a professional's assistance. People have a right to expect competent help from an unimpaired professional.

If severe, unrecognized and unaddressed professional impairment can spell disaster. The impaired professional can cause severe harm, even death, to others. This can give rise to legal liability for the professional, colleagues, coworkers, and the institution in which the impaired professional works.

The Persistence of Impairment

For many reasons, impairment is an enduring, ubiquitous phenomenon of professional life. First, instead of responsibly discharging the responsibility of self-regulation, professionals sometimes abuse their power or office. Second, professionals may protect inept colleagues. Third, professional impairment does not receive much attention in the education and training of those who are entering a profession. While medical students may be quick to identify and chastise a patient who has a serious emotional or drinking problem, they are less likely to learn how to recognize or respond constructively to self-impairment or impairment in a colleague. Fourth, some professions foster impairment. The idealized image of the competitive, self-reliant practitioner drives professionals to succeed and to work in isolation, patterns of behavior that are conducive to impairment.

Even a medical professional who knows about professional impairment may not recognize it (Boisaubin and Levine). Medical professionals still are relatively autonomous practitioners, which means that they tend to be self-supervising. When contact is occasional, they may neither have the opportunity to discern that a colleague is impaired nor feel responsible for doing something if they suspect it. When contact is frequent, they may cover for an impaired colleague. To the extent that medical professionals practice as independent contractors without supervision or sustained periods of collaboration and regular contact, the ability to recognize that a professional is impaired is impeded. To the extent that medical professionals work together, collegiality may supplant professional concern.

Initial signs of impairment are frequently subtle, not obvious. Moreover, just as few individuals are looking for impairment, few wish to discover that someone is impaired. The ability to recognize impairment is affected by the willingness to see it. Missed appointments, tardiness, or sloppiness in one's work might be attributed to a passing stress and not taken as signs of something seriously wrong. A friendly inquiry met with a plausible response may be enough to assuage concern about a colleague.

Professionals may sympathize or identify with a troubled colleague. Given how much time, money, and effort professionals invest to establish their careers, the potential consequences of finding impairment can be enough to cause a professional to accommodate rather than report a colleague who is in trouble. The tendency of professionals to protect an inept colleague limits society's ability to respond to the impaired professional.

Fear of possible recrimination from the individual and one's peers also affects the professional's response to the suspicion or recognition that a colleague is impaired. The professional may worry that reporting or taking action on another's impairment may cause exposure to civil liability. Even if reporting a colleague poses no genuine threat of legal action, peers may de facto punish an individual for initiating the process of exposing a colleague to shame and institutional or legal action. These and other anxieties may make even conscientious professionals reluctant to report an apparently impaired colleague.

The professional and institutional response to professional impairment may be significant. A reported impaired professional is likely to encounter problems at the place of employment and difficulties regarding licensure (see below) and obtaining liability insurance. Depending on the nature and severity of the impairment, rehabilitation and recovery may not resolve these difficulties.

Confronting or reporting an impaired professional may be more difficult when that person is unable or unwilling to recognize the impairment. Admitting an impairment may damage one's image and reputation in the community and be fatal to a career.

The risk an impaired professional poses does not disappear or diminish if the impairment is ignored or unaddressed. On the contrary, it is likely to worsen. To ignore or dismiss

the signs of impairment creates and sustains a potentially tragic situation. When the professional's impairment manifests itself, it is likely to be severe. At that point, those around the impaired professional are likely to be asked why no one intervened sooner, when the harm done could have been avoided or minimized.

Legal Implications

In every state, professional practice Acts specify as a grounds for professional discipline (including suspension or revocation of the license to practice) the inability to practice one's profession according to acceptable and prevailing standards of care by reason of mental or physical illness or habitual or excessive use or abuse of drugs, alcohol, or other substances that impair the ability to practice (Sanbar). In many states, professional boards operate treatment programs for impaired professionals (Ameringer; Talbott). Generally, successful participation in an approved treatment program is a prerequisite to licensure reinstatement for a rehabilitated, previously impaired professional (Spoon).

In many states, professionals are required by law to report impaired colleagues to relevant state professional boards and pertinent healthcare facility/agency administrators. Professionals are granted immunity from liability when they make such reports. When the reporting of impairment is mandatory under state law, failure to report is grounds for disciplinary action, although the actual enforcement of such statutes remains lax. Because the purpose of the law is prophylactic and arises out of the state's interest in protecting the public against harm, actual harm to a patient need not occur in order for a physician to be considered impaired. Because professional regulation is a matter of state law and is in constant flux, specific requirements, immunities, and programs vary considerably over place and time (Walzer).

Legal and ethical issues regarding informed consent arise in the case of impaired professionals who care for patients or clients. It has been suggested, for example, that the professional has an affirmative obligation to notify a patient/client about any impairment of that professional that might influence the decision to receive care from that professional, and that failure to share such information is a violation of the professional's fiduciary obligations (Furrow). Other commentators argue that information about specific professionals' impairments should be listed on publicly available data bases, raising a tension between the public's right to know and the professional's personal interest in privacy (Pape).

The Americans with Disabilities Act, 42 U.S.C. §§ 12101–12213, and §504 of the Rehabilitation Act, 29 U.S.C. § 794, prohibit discrimination against persons with physical and mental disabilities in such areas as employment and public accommodations These statutes affect, among other things, the licensing, discipline, institutional privileges, and insurability of impaired professionals (Rothstein, Piltch et al.).

INFANTICIDE

• • •

Infanticide is the practice of intentionally killing human newborns. Because the term *infant* descends from a Latin word that means *not speaking,* infanticide should be distinguished from feticide, or abortion, intentionally killing fetuses, on the one hand, and felicide, intentionally killing children who are mature enough to speak, particularly one's own, on the other.

Infanticide has been practiced all over the world throughout the whole of human history. Newborns who have not yet learned to talk have been intentionally killed because they were thought to be:

1. terminally ill;
2. experiencing unbearable pain or suffering;
3. born with unacceptable anomalies;
4. of the wrong gender, race, class, maternity, or paternity;
5. political threats;
6. economic threats;
7. fitting sacrifices in religious rituals; and
8. embarrassing, frustrating, or inconvenient.

The single most common reason for the practice of infanticide in the past and present has been the desire to be rid of female newborns. The histories of infanticide and gender bias are interwoven. Not to study them together is to overlook their interdependence.

Human newborns, particularly females, have been intentionally killed in many ways. They have been incinerated, decapitated, and suffocated. They have also been sundered, stabbed, stoned, shot, hung, drowned, struck, shaken, stomped, crushed, raped, poisoned, buried, starved, fed to animals, and exposed to the elements. They have been denied air, food, water, warmth, and protection from diseases. Their blood vessels have been injected with toxic substances and bubbles of air. It is impossible to understand the history of infanticide without taking into account its diverse and often cruel methods.

In many societies infanticide was not only tolerated but also sometimes promoted as a solution to the problem of unwanted infants, whether deformed or healthy. This entry provides a historical account of infanticide in Western societies, beginning with its practice in Graeco-Roman antiquity and concluding with modern evidence.

Infanticide in Antiquity

In Greek society, an infant's worth was measured by its potential to fulfill a useful function in society. Thus Plato, in his *Republic,* maintained that society was better served if deformed newborns were "hidden away, in some appropriate manner that must be kept secret," a practice that likely included infanticide (460). Similarly Aristotle wrote in *Politics*: "As to the exposure and rearing of children, let there be a law that no deformed child shall live." Aristotle also condoned abandonment as a method of population control, although he recommended early abortion in regions where the "regular customs hinder any of those born being exposed" (1335b). In Sparta, where military strength was highly valued, infanticide may have reached its zenith. In *Life of Lycurgus,* Plutarch gives an account of the Spartan custom: "But if it was ill born and deformed they sent it to … a chasm-like place at the foot of Mount Taygetus, in the conviction that the life of that which nature had not well-equipped at the very beginning for health and strength, was of no advantage, either to itself or to the state" (16).

It is difficult to distinguish between infanticide, with the intent to kill the infant, and abandonment, which may or may not have involved this intention. Failure to distinguish between the two has made accurate assessment of each difficult (Boswell). Historians have generally interpreted the Greek word for abandonment, translated as "exposure, putting out, or hiding away," as equivalent to infanticide. However, the Greek terms for abandonment do not convey the sense of injury or harm associated with infanticide. Historical evidence is not clear as to whether abandoned infants usually died or if those who abandoned them intended their death. Often abandonment was viewed as an alternative to infanticide. Nevertheless it is reasonable to infer that some deformed and healthy infants, particularly females, were exposed with the intent that they would not survive. Further it is likely that direct infanticide was practiced for both eugenic purposes and population control. Laws neither prohibited the killing of defective infants nor protected healthy infants from death by exposure.

Evidence from classical sources suggests that infanticide was practiced widely and with impunity in Roman society. While Romans continued the practice of disposing of defective infants for eugenic and economic reasons, an additional

motivation stemmed from the Roman belief in the phenomenon of unnatural events, or *prodigia* (Amundsen). The Greeks saw deformities in newborns as natural occurrences. In contrast the Romans viewed *portentosi,* meaning *unnatural* or *monstrous* births, as ominous or numinous signs that needed to be destroyed in order to rid the community of guilt and fear. The historian Livy of the first century B.C.E. wrote, in *Histories,* about the birth of an infant who was both unusually large and of indeterminate gender:

> [M]en were troubled again by the report that at Frusino there had been born a child as large as a four year old, and not so much a wonder for size as because … it was uncertain whether male or female. In fact the soothsayers summoned from Etruria said it was a terrible and loathsome portent; it must be removed from Roman territory, far away from contact with earth, and drowned in the sea. They put it alive into a chest, carried it out to sea and threw it overboard. (37.27)

Roman literature is rife with testimony to such killings. According to the Laws of the Twelve Tables (fifth century B.C.E., considered to be the basis of Roman law), deformed children, *puer ad deformitatem,* were to be killed quickly. Historians disagree whether the law required that these infants be killed or whether it merely allowed infanticide. In any case Roman society appears to have accepted infanticide as a reasonable solution to the problem of deformed infants both for eugenic and superstitious motives. In a gynecological treatise entitled "How to Recognize a Newborn Worth Rearing," the Graeco-Roman physician Soranus (first–second century C.E.) specifies that such an infant "immediately cries with proper vigor, is perfect in all its parts, members and senses [and] has been born at the due time, best at the end of nine months. And by conditions contrary to those mentioned, the infant not worth rearing is recognized" (*Gynecology,* p. 79–80).

In his *Moral Essays,* Seneca argued that the practice of infanticide is rationally motivated: "Mad dogs we knock on the head; the fierce and savage ox we slay; sickly sheep we put to the knife to keep them from infecting the flock; unnatural progeny we destroy; we drown even children who at birth are weakly and abnormal. Yet it is not anger, but reason that separates the harmful from the sound" (1.15). Even if it were not legally mandated, it is unlikely infanticide was penalized in Roman society given the tradition of *patria potestas,* which granted fathers absolute authority over other members of the family. Roman fathers had power of life and death over their children and were allowed to execute even a grown son (Boswell). The most likely victims, however, were infants, especially deformed ones *and* female children who—even when healthy—were considered of little social value.

Some Roman philosophers objected to abandonment and infanticide. Musonius Rufus, writing in the first century C.E., opposed infanticide because it reduced the population. Epictetus, a Stoic philosopher and a contemporary of Musonius, condemned abandonment as a violation of the natural affection that parents should have for their offspring. Such apparent concern for the infant was not based on a belief in the child's intrinsic right to life, but was motivated by the desires to follow natural law and to increase the population. Thus, although evidence for the practice of infanticide under the Roman empire is somewhat inconclusive, Roman law and custom apparently did not prohibit parents from killing their children.

Early Jewish and Christian Traditions

The people of ancient Israel were acquainted with infanticide, particularly as it was practiced in the religious rituals of their neighbors. As evidenced by the frequency and vigor with which infanticide was denounced by their leaders, it appears that some Israelites were attracted to it. The ancient story of Abraham's apparent willingness to sacrifice his son Isaac, who was not an infant but a young man, only to be instructed by a heavenly messenger to kill a ram instead, was told and retold over the centuries (Genesis 22). Among other things, the recitation of this story reiterated a preference for animal sacrifices in Israel's religious rituals, at least until the some of Israel's prophets condemned that practice too.

Jewish scholars were thus among the first to clearly condemn the killing of infants. Jews believed that humans were created in the image of their creator, Yahweh. Hence all human life was sacred from the moment of birth. The Torah speaks of defective individuals as Yahweh's creations and it mandates protection to the blind, the deaf, the weak, and others who are needy (Leviticus 19:14). Human life had intrinsic value by virtue of divine endowment, not merely instrumental value by virtue of social utility, as in classical Greek and Roman society.

The first-century Jewish philosopher Philo denounced infanticide and emphasized adults's duties toward children. His account equated abandonment with infanticide:

> Some [parents] do the deed with their own hands; with monstrous cruelty and barbarity they stifle and throttle the first breath which the infants draw or throw them into a river or into the depths of the sea, after attaching some heavy substance to make them sink more quickly under its weight. Others take them to be exposed in some desert place, hoping, they themselves say, that they may be

> saved, but leaving them in actual truth to suffer the most distressing fate. For all the beasts that feed in human flesh visit the spot and feast unhindered on the infants, a fine banquet provided by their sole guardians, those who above all others should keep them safe, their fathers and mothers.

Philo further condemned the practice, in *Works,* by claiming, "Infanticide undoubtedly is murder, since the displeasure of the law is not concerned with ages but with a breach to the human race" (Vol. 7).

However, it was the advent of Christianity, rooted in Judaism, that significantly altered public attitudes toward the practice of infanticide. Christians inherited the Jewish doctrine that humans were divinely created, including the emphasis on the sanctity of all human life. They also recalled with horror the New Testament report that King Herod had slaughtered many infants in his attempts to exterminate the infant Jesus (Matthew 2). Believers were urged to emulate Christ's self-sacrificing love through benevolence and charity, providing a new rationale for philanthropy (Ferngren, 1987a). The consequences of this philanthropy were seen in Christian charities and endeavors for the poor, the sick, and the needy. Rescue and care of exposed infants was viewed as a special Christian duty. During the medieval period through the nineteenth century, Christians established foundling hospitals, and institutions for abandoned and unwanted children.

Two other Christian concepts important for their effect on the practice of infanticide were original sin and its correlative ritual of infant baptism, thought to have become common during the third century. Christians believed that infants who died without baptism were condemned to eternal hell. Because baptisms were performed only on holy days, not necessarily soon after birth, many parents already were committed to raising the child by the time of the ritual. Thus baptism served as an important deterrent to both abandonment and infanticide.

Although Jews and Christians vigorously opposed infanticide, their opposition had little impact until Christianity became widespread and officially recognized in the fourth century. A church council in Spain issued the first canon against infanticide in 305 C.E., and soon after, both local and ecumenical councils throughout Europe took similar actions. The penalty prescribed by the church for infanticide was either penance or excommunication.

The first secular law concerning the killing of children was issued in 318 C.E. by Constantine, the first Christian emperor. However, the law mentions children killing parents as well as parents killing children and thus was not directed specifically against infanticide. In 374 C.E. Valentinian enacted legislation declaring infanticide to be murder and punishable by law. Soon after a statute was issued that appears to have prohibited exposure of infants. Although Christian emperors promulgated many laws reflecting Christian morality, fear of losing salvation made the penitential system of the churches far more effective in influencing moral behavior than did state legislation. Church leaders continued to put pressure on the state, bringing about a series of legal codes aimed at protecting newborn children.

Although the laws did not distinguish between healthy and defective infants, one may assume that Christian condemnation of infanticide extended to all infants. Early Christian apologists reflect this position. In *City of God,* Saint Augustine (354–430) argued that differences between healthy and deformed people should be seen in the same light as racial and ethnic diversity:

> If whole peoples have been monsters, we must explain the phenomenon as we explain the individual monsters who are born among us. God is the Creator of all; He knows best where and when and what is, or was, best for Him to create, since He deliberately fashioned the beauty of the whole out of both the similarity and dis-similarity of its parts.… It would be impossible to list all the human offspring who have been very different from the parents from whom they were certainly born. Still all these monsters undeniably owe their origin to Adam. (16.8)

Augustine's writings show a concern for children unusual in his time, placing the infant and the child under the protection of the Lord.

Despite decisive changes in attitudes and laws, infanticide persisted even after the official triumph of Christianity as the imperial religion. While the practice may have diminished, episodic killing of infants continued throughout Western history. What changed in subsequent periods were the motivations, methods, and penalties associated with infanticide as well as the options available to parents of unwanted children.

Medieval Period

Christianity's beliefs mixed with pagan myth, superstition, and folklore during Europe's medieval period. This commingling had significant implications for deformed infants and the practice of infanticide. Some thought, for example, that parental sexual behavior or *ill-timed passions* generated abnormal births or that sexual relations during menstruation, pregnancy, or lactation resulted in dire consequences

for the unborn. In addition the birth of an anomalous infant was sometimes attributed to demonic intervention: Such births were seen as the product of either a sexual liaison between the mother/witch and the devil or a changeling left by the devil as punishment for parental sins. Parents, particularly mothers, were held morally responsible for their infants's abnormalities.

The changeling myth, derived from pagan sources, maintained that fairies, motivated by jealousy, substituted an elf child for the real child (Haffter). This version did not impute guilt to the parents; instead, blame was placed on demon fairies of the underworld and their envy of humans. Once the myth was Christianized, however, it became the devil who stole the real child and left a demon-child in its place. Thus God allowed parents to be punished for impiety or for bearing children outside matrimony. This change transformed the rationalization for the birth of defective infants from external forces to parental responsibility. Brutal and frequently lethal methods were employed either to exorcise the devil from the child or to compel the devil to return the normal child. Few infants survived the ordeal. However violent infanticide of this sort was probably the exception rather than the rule, even during the Middle Ages.

There was some secular legislation against infanticide, particularly in the later medieval period, and the crime was usually considered to be homicide. But overlaying (suffocation in the parental bed), the most frequent cause of infanticide, was easy to conceal and intent was nearly impossible to establish, thus making prosecution extremely difficult. When cases of infanticide did reach secular courts, the accused were readily acquitted on pleas of insanity or poverty. Secular authorities displayed remarkable ambivalence toward the killing of infants. By law it was considered a serious crime, yet in practice it was generally excused (Damme).

Throughout most of the medieval period, infanticide was regulated largely by church courts rather than civil courts. Ecclesiastical penalties for married women convicted of infanticide were also remarkably light, considering the Church's position. Punishment involved penance and was comparable to that imposed for sexual offenses such as adultery and fornication. Once the penance had been performed, the guilty person was not prosecuted in civil courts. The relatively light penance and the failure of secular authorities to prosecute cases of infanticide suggests that the crime was considered something less than homicide (Helmholz). Cases involving unwed mothers, however, were treated differently. Unmarried mothers who killed their infants were often accused of being witches. In fact, infanticide was the most common charge brought against *witches* during the Middle Ages. Unlike their married counterparts, alleged witches were punished severely, usually by drowning, burial alive, or impalement.

The only reference to the status of infants under medieval secular laws was a civil law definition of a freeman (in the law "Of Different Kinds of Children"), which appears to have excluded both illegitimate and seriously deformed infants from what little protection the law offered: "Among freemen there may not be reckoned those who are born of unlawful intercourse … nor those who are created pervertedly, against the way of human kind, as for example, if a woman bring forth a monster or a prodigy" (Fleta 1.5). As legal historian Catherine Damme comments, "Clearly, these pitiful non-persons were vulnerable to the murderous attacks of their progenitors" (p. 7).

Although direct infanticide was practiced to some extent, the more common and insidious cause of infant death during the Middle Ages was abandonment. The distinction between infanticide and abandonment became increasingly important because abandonment was generally regarded as a venial offense, punishable only if the child died. In the early-Middle Ages, abandonment was widespread, motivated primarily by poverty and illegitimacy. Although a few churchmen believed it was equivalent to infanticide, two forms of abandonment were virtually institutionalized: oblation (or donating infants to the Church) and leaving infants at foundling hospitals. From a Christian point of view, both were improvements over the morally objectionable practices of exposure and infanticide. A canonical decree of the tenth century urged women to leave their illegitimate infants at the church rather than kill them (Boswell). Although oblates were tied irrevocably to the Church for life, the Church provided food, clothing, and a secure monastic life.

Foundling homes were established to diminish the practice of exposure and to provide a humane solution to infanticide. In reality, however, the foundling home often was equivalent to consigning the child to death through neglect, disease, and sometimes more direct action. Once infants arrived at a foundling home, they frequently were sent to the country with a wet nurse who was likely to be negligent and more interested in a steady flow of babies than in nurturing. Death rates were high, especially for female infants (Trexler). Markedly high demographic ratios of males to females throughout Europe during this period suggest that selective female infanticide may have been widely practiced. The disparity between male and female deaths was probably due to greater social value for males and a greater likelihood that, when put into foundling homes, they would be reclaimed by their parents. Thus such institutions did little to secure the lives of unwanted infants. They

were successful only in transferring the problem of unwanted infants from a public arena to an institutional one, shielding society from the realities of abandoned children and possibly encouraging the very practice they were intended to alleviate.

Renaissance and Reformation

During the sixteenth and seventeenth centuries there was a concerted effort to stem the practice of infanticide throughout Europe. Despite a dramatic surge in reported cases, it is not clear whether or not the increase meant more frequent practice; urbanization undoubtedly made it more difficult to destroy infants secretly. Authorities were more successful at promulgating harsh legislation aimed at ending the practice and were also increasingly vigilant in prosecuting murdering mothers. An intense focus on the problems of poverty and sexual promiscuity and their purported ties to infanticide led to laws that were strongly moral in tone and selective against unmarried mothers.

The first attempt to strengthen and unify infanticide laws under the Holy Roman Empire was a statute known as the Carolina, issued in 1532 by Emperor Charles V. The law decreed that those found guilty were to be buried alive, or impaled, or drowned. The law also made concealment of pregnancy a crime, as it was presumed that such secrecy indicated infanticidal intentions. Many judges, under the pretext of the Carolina, "engaged in a policy of terror," the most notorious being the Saxon jurist Benedict Carpozof, who claimed that he assisted in the executions of 20,000 women (Piers, p. 69). The Carolina was only the first in a series of laws over the next few centuries that dealt severely with alleged infanticidal mothers.

In England Henry VIII's split from the Roman Catholic church resulted in increased secular control. Growing concern about sexual immorality and criminality among the swelling numbers of urban poor led to the enactment of several social control laws. The Poor Law of 1576 (18 Eliz. I, c.3) made bearing bastard children a crime. The fact that punishment was severe and involved substantial social disgrace for the mother increased the incentive for these women to commit infanticide. It is not surprising, therefore, that English criminal court records show that the number of indictments and guilty verdicts for infanticide rose dramatically after 1576. Most cases involved bastard children, and concealment of pregnancy was mentioned frequently (Hoffer and Hull).

The reasons for the increased zeal in punishing illegitimacy are somewhat obscure, but Puritan interests seem to have played a role. The 1623 Jacobean infanticide statute (21 Jac. I, c.27), influenced by the Puritan element in parliament, allowed courts to convict on the basis of circumstantial evidence of concealment and prior sexual misconduct. The law presumed that the child was born alive and then killed unless the mother could prove otherwise. Prosecutions of infanticide showed a fourfold increase immediately following its enactment (Hoffer and Hull).

Ideas about the role of witches in the death of infants, even the deaths of children in foundling hospitals, persisted. Infanticide and witchcraft were so strongly interrelated during this period that their rates of indictments rose and fell in parallel. Witchcraft continued to play a major part in the drama of infanticide until the early 1800s.

Foundling hospitals continued to remove unwanted and abandoned children from public view throughout the sixteenth and seventeenth centuries. As in earlier centuries, the fate of these children was precarious. Overcrowded conditions, disease, lack of enough wet nurses, and general neglect continued to claim the lives of many of the institutions's charges.

The overwhelming majority of the victims of infanticide during this period were children born out of wedlock. Demographic information does not show the strong gender bias seen in the medieval years, nor is there evidence that defective newborns were consistently selected out. Apparently the shame associated with immoral sexual behavior was the primary selective force associated with the killing of infants.

Eighteenth and Nineteenth Centuries

In the eighteenth century, a steep decline occurred in indictments for infanticide; the courts showed greater leniency toward those accused of killing their children. In addition illegitimacy was more common; as a result the stigma associated with it lessened and its strong correlation to infanticide began to diminish. Attitudes toward parenting changed as well, with a new emphasis on the emotional nurturing of children. Wet-nursing lost popularity, and it became more common for children to spend their early months with their mothers. The greater value placed on children resulted in increased beneficence in child rearing, and so parents were probably less likely to kill their offspring. In any case juries were less willing to convict parents of infanticide solely on the basis of concealment.

New defenses for the suspected infanticidal mother were developed and more readily accepted by juries. One of the first of these defenses, known as *benefit of linen,* was based on evidence that the mother had made linen for the

baby before its birth and therefore had no intention to kill it. This line of argument became very popular after 1700 and virtually guaranteed acquittal. Another major defense commonly used was the *want of help* plea. Various accidents and calamities, such as failure to tie the umbilical cord, falls of either the mother or baby, illness of the mother, and unheeded cries for help, all effectively helped to sway jurors.

Efforts to reform the English infanticide statute of 1624 began in 1773 but were not successful until 1803. In the ambivalence of eighteenth-century English society, infanticide was considered homicide yet somehow not quite the equivalent of killing an adult. Despite the failure of reform resolutions until the nineteenth century, juries tended to ignore the severe infanticide law aimed selectively at unwed mothers.

A similar trend occurred in Prussia during the reign of Frederick the Great. In his *Dissertation sur les raisons d'établir ou d'abroger les lois* (1756), Frederick argued that the prevalence of infanticide was due to the harsh penalties for illegitimacy. He therefore abolished laws penalizing pregnancies out of wedlock and eventually provided legal protection for unwed mothers. Scholars throughout Europe, including Cesare Beccaria, Voltaire, Johann Heinrich Pestalozzi, and Johann Wolfgang von Goethe, also called for legal reform and urged authorities to prevent the circumstances leading to infanticide.

Despite moderately successful reform efforts, however, infanticide did not disappear. During the nineteenth century high rates of illegitimate births continued; so, consequently, did infant killing. Corpses of infants found in privies, parks, rivers, and other public places fueled the perception that infanticide was reaching intolerable proportions. This perception may or may not have represented an actual increase in the incidence of the crime, but it did serve to stimulate an unprecedented public outcry. By the mid-nineteenth century, the concern over the *slaughter of innocents* appeared in the press (Behlmer). The British newspaper *Morning Star* (June 23, 1863) declared, "This crime is positively becoming a national institution"; and the *Pall Mall Gazette* (April 30, 1866) protested, "It is exceedingly unpleasant to find ourselves stigmatized in foreign newspapers … as a nation of infanticides.… 13,000 children are yearly murdered by their mothers in heretical England." *The Saturday Review* (1865, p. 161–162) asserted that infanticide "is the characteristic at once of the rudest barbarism and of that more terrible epoch of national life when the wheel has gone its full circle, and society falls to pieces by the vices of civilization."

Physicians were among those who led reform efforts. In his essay on infanticide in 1862, William Burke Ryan wrote passionately against the horrors of infant murder; he and several colleagues formed the Infant Life Protection Society. By 1870 the group had achieved many of its goals, including mandatory registration of all births. In 1872 Parliament passed the first Infant Life Protection Act requiring registration of all *baby farms,* houses with more than one child under the age of one.

Legal prosecution of infanticide also underwent significant changes. Ellenborough's Act of 1803, which replaced the Infanticide Act of 1623, reinstated the common-law presumption of stillbirth, shifting the burden of proof from the defendant (mother) back to the prosecutor. In 1828 the law was expanded to include legitimate as well as illegitimate births, removing the obvious selection against unwed mothers. The fact that courts consistently acquitted the accused or mitigated penalties on the basis of insanity is testimony to the court's continued hesitancy to consider infanticide the moral equivalent of murder. There was a "visceral feeling that such a crime simply could not be a rational act.… [t]he minds of the jury and jurist could not accept that such a heinous act could be committed by a rational person—the accused's mind had to be deranged, if only temporarily" (Damme, p. 14).

Twentieth Century

The most notorious instances of infanticide in the twentieth century were committed secretly in Nazi Germany, under the auspices of the Committee for the Scientific Treatment of Severe, Genetically Determined Illness. Doctors, nurses, and teachers were required to register all children with congenital abnormalities or mental retardation. Failure to comply meant civil penalties or imprisonment. Defective children were removed from their homes and routinely euthanized at hospitals by morphine injection, gas, lethal poisons, or sometimes starvation. To ensure secrecy, the bodies were cremated immediately. Parents who protected their children were sent to labor camps and their children were taken from them. Documents reveal substantial public support for the euthanasia of defective children, even from parents with abnormal children (Proctor).

Calls for legalized euthanasia also arose from the United States, where it was justified primarily as a way of limiting the social costs associated with defective infants. W. A. Gould, writing in the *Journal of the American Institute of Homeopathy,* cited the "elimination of the unfit" in ancient Sparta as a defense of the economic arguments for euthanasia in the twentieth century (Gould). In 1938 W. G. Lennox advocated the "privilege of death for the congenitally mindless and for the incurable sick who wish to die" because

saving these lives "adds a load to the back of society" (Lennox, p. 454). But as the realities of the Nazi extermination programs began to surface in the United States in the 1940s, promotion of euthanasia in general began to decline.

Yet in 1942, Foster Kennedy, professor of neurology at Cornell Medical College, wrote an article entitled "The Problem of Social Control of the Congenital Defective" advocating "euthanasia for those hopeless ones who should never have been born—Nature's mistakes." Kennedy believed "we have too many feebleminded people among us," and it was most humane to relieve defective individuals of their tortured and useless existence (Foster). Furthermore, he maintained that in diagnosis and prognosis there could be no mistakes in this *category* of children. A Gallup poll conducted twelve years earlier indicated that Kennedy's position probably was not without support within the American community. According to the poll, 45 percent of Americans in 1930 favored euthanasia of anomalous infants (Proctor, p. 180).

Toward the end of the twentieth century, the possibility of killing newborns with anencephaly in the course of acquiring transplantable organs from them was debated in professional circles. Babies with this condition are born without cerebral hemispheres, with an open skull that is empty except for the top of the spinal cord. They are wholly and permanently unconscious. Some viewed the possibility of acquiring rare transplantable organs from such infants as a way to squeeze something of value out of a tragic set of circumstances. This option was restricted by the convergence of two widely accepted norms, however. The first was that vital organs must be acquired only from dead donors. The second was that death must mean either the irreversible loss of spontaneous circulation and respiration or the irreversible loss of the functioning of the whole brain, including the brain stem. Several attempts at Loma Linda University in Southern California to acquire transplantable organs from babies born with anencephaly within the constraints of these two norms established that either the dead donor rule or the usual definition of death must first be changed. Several years later, The Council on Judicial and Ethical Opinions of the American Medical Association (AMA) proposed that in cases of anencephaly the requirement that donors of vital organs must be dead be relaxed. Shortly thereafter it withdrew this proposal in deference to intensely negative reactions. Some believed that the Council had put the wrong foot forward while attempting to move in a helpful direction. They thought that when babies are born with anencephaly it would have been less controversial to allow parents to opt for a *higher brain* rather than a *whole-brain* definition of death. If this change had been made, babies born with accurately confirmed cases of the anomaly would have been declared legally dead before transplantable organs were acquired from them. Some held that this would have honored the important ethical conviction that no one of any age or condition should be killed merely to provide transplantable organs for someone else.

The practice of infanticide was debated in the popular culture of the United States and elsewhere when Peter Singer of Australia joined the faculty of Princeton University one year before the end of the twentieth century. An accomplished utilitarian moral philosopher who was well known beyond academic circles for his advocacy of animal liberation, Singer troubled many. He contended that in general it is ethically permissible to treat human newborns in ways that parallel the ways we are morally permitted to treat other animals with approximately the same traits and abilities. He held that it is ethically acceptable to kill infants born with some serious anomalies. He also suggested that there is a sense in which parents are free to kill a handicapped infant and rear a healthier one instead. His point was that in infancy the value or interests of one newborn can often be interchanged with those of another with little or no overall loss of value, and sometimes with a gain.

These issues proved difficult to resolve in academic and popular settings in the last part of the twentieth century. This was partly because, even in many of the most widely used English dictionaries, the ability to distinguish between the basic meanings of *possible* and *potential* had all but vanished. The claim that a human infant is a potential embodiment of value, interests, or rights weighty enough to protect him or her from death at the sheer discretion of others was typically understood to mean that for a newborn this eventual state is merely possible. Common although it was, this understanding of potential failed to capture and convey the senses of inner *power, capacity,* and *endowment* in its root meaning, as was still sensed in related terms like *potent, potentiate,* and *potentate.* Wider recognition of the differences in basic meaning between potential and possible would not have settled the debates about infanticide in the last part of the twentieth century; however, it would have enabled these exchanges to proceed with greater precision and plausibility.

Conclusion

Authors who have explored the ethical dimensions of infanticide have frequently prefaced their discussions with surveys of its practice throughout history. The ostensible purpose of these discussions generally has been to provide a broader, less culturally bound perspective. However, Stephen Post argues that many writers selectively present "a one-sided and

reductionist view of the history of infanticide to support their position … that active killing of neonates is morally acceptable" (Post, p. 14). He contends that the extent of infanticide has been misrepresented and overstated. The argument is that commentators on the history of infanticide have drawn, at least to some extent, from historical surveys plagued by interpretations that tend to view history in a positivist or linear fashion. The French historian Phillipe Ariès maintains that the idea of a separate childhood was unknown until the later Middle Ages (Ariès). Similarly Lloyd DeMause contends: "The further back in history one goes, the lower the level of child care, and the more likely children are to be killed, abandoned, beaten, terrorized, and sexually abused" (DeMause, p. 1).

Revisionist historians, focusing on social, economic, and cultural forces, offer a significantly altered perspective on infanticide. While infanticide has been practiced continuously throughout Western history, it is not obvious that filicidal tendencies are widespread among parents. On the contrary, parents have usually resorted to infanticide only in exceptional circumstances. Although accurate estimates of the frequency of infanticide are almost nonexistent (largely due to inadequate and inconsistent record keeping), the prevalence of infanticide throughout Western history seems to have been episodic. Rates of infant killing have shown a tendency to rise and fall depending on prevailing economic and social forces. There have been striking discrepancies between the official position of the law, the frequency of the crime, the rate of prosecutions, the severity of punishment, and public sentiment concerning infanticide. Although the law has been relatively consistent in prohibiting its practice, the law has not always been an accurate gauge of societal values. Finally the availability of alternatives to infanticide—including abandonment, foundling hospitals, oblation, contraception, and abortion—appears to have had more impact on its practice than have official prohibitions.

INFANTS, ETHICAL ISSUES WITH

• • •

The birth of a baby can be one of the most satisfying, fulfilling experiences of a parent's life or a couple's marriage. After months of *infanticipating,* the experiences connected with the first few hours and days of the baby's life can be intensely rewarding for the parents, providing them with joy, gratitude, and perhaps humility as they contemplate the new life that is now entrusted to them for care and support. If they are religious believers, they may be inclined to think of the baby's life as a divine gift and to regard their parental role as involving responsible stewardship over that gift. At the very least, they will probably be thankful that the baby has a normal brain, the correct number of fingers and toes, and the rest of a physical endowment that would suggest normal human development.

Unfortunately, in a small minority of cases the months of parental dreams and plans for a normal baby turn out to be false hope. In some instances, even when prenatal diagnosis has already indicated that the baby will not be normal, there may still be parental surprise and disappointment at the range of medical problems and the degree of neurologic impairment the child has. In other instances, when prenatal diagnosis was not done and the potential parents had no opportunity for anticipatory grief over the loss of a normal baby, the birth of a premature and/or congenitally disabled infant can have an enormous emotional impact on the parents that severely tests their most deeply held beliefs, values, and hopes for the future.

The birth of such a baby can also reflect the diversity of ethical perspectives that exist among parents, physicians, and other persons regarding the value of infants with life–threatening medical conditions, especially when the projected future lives of these children are filled with a mixture of neurologic impairments, mental and physical disabilities, and, sometimes, considerable medical uncertainty regarding the degree of those disabilities. For many persons, such cases raise important substantive questions: What is the moral status of infants with mental and physical disabilities? Should all of these infants receive life-sustaining medical interventions regardless of the severity of their medical conditions? What should be the ethical standard according to which a few infants would not receive life-sustaining efforts? Is there any moral difference between withholding and withdrawing life-sustaining treatments? Are there important moral differences between decisions about life-sustaining treatment in cases of severely disabled infants compared with cases of adults who have never been autonomous because of severe mental retardation? Would it be justifiable, in rare cases, intentionally to kill any of these infants?

Cases of premature and disabled infants also raise important procedural questions: Who should have the authority to make these life-and-death decisions? Should physicians, and in particular neonatologists, make these decisions because of their greater technical knowledge and experience with similar cases? Should the infant's parents decide because of their roles in conceiving and caring for the child, and because of their greater emotional and financial stake in the child's death or disabled life? Should a collective body (e.g., a pediatric ethics committee) make the borderline decisions?

In addition, important questions are sometimes raised about contextual and methodological matters related to decisions about the care of infants: What lessons can we learn about caring and nurturing from parents who have learned to cope with and transcend one of life's personal tragedies? Is a philosophical approach that focuses on principles, rights, interests, and obligations the correct model for ethical analysis? Do theological claims about the sanctity of life, the meaning of suffering, and the importance of stewardship over life have a significant place in decisions about the appropriate level of care for infants, whether normal or abnormal in some way? To what extent should the realities of medical economics influence the decision about whether a premature and severely disabled infant lives or dies? How

much should decision makers in individual cases consider the implications of their decisions in terms of public policy?

This article has five parts: (1) a brief historical overview; (2) international perspectives among pediatricians; (3) alternative perspectives on the moral status of infants; (4) perspectives on abating life-sustaining treatment; and (5) the emerging mainstream ethical perspective. Additional information on some of these points is found in the other articles in this entry.

Historical Overview

Throughout history, as at the present time, the birth of a baby has often been the occasion for joy, celebration, and thanksgiving. In earlier centuries, the birth of a healthy, normal baby was frequently the occasion for celebration because the baby, especially if the infant was male, offered future promise for the family: another hunter for food supplies, another worker for the field or factory, another opportunity for continuing the family lineage. The birth of a baby was often an occasion for celebration for another reason: the mother had survived the dangers inherent in pregnancy and childbirth, dangers that posed a significant risk to maternal health and life in every pregnancy before the advent of modern medicine.

However, not all births were celebratory occasions. In many societies and in virtually all historical periods, very young infants, female infants, bastards, and infants and older children believed to be *defective* in some way were frequently killed. The intentional destruction of infants and children through starvation, drowning, strangulation, burning, smothering, poisoning, exposure, and a variety of lethal weapons was a tragically common practice. Such practices were widely accepted ways of dealing with unwanted children, with the responses of governments varying from required infanticidal practices (e.g., in Sparta), to acceptance of or at least indifference to the killing of female infants (e.g., in China and India), to considerable uncertainty as to how to punish parents who may have committed an illegal act by killing one of their children under questionable circumstances.

Mothers and fathers have historically had several possible reasons for killing one or more of their children. Some of them have killed for economic reasons: A dead child would mean one less mouth to feed. Others have killed their infants because of social customs and pressures: An illegitimate child, an *extra* child beyond a certain number, or another female child was especially vulnerable. Still other parents have killed their children because the infants were physically or mentally abnormal, with their congenital abnormalities being interpreted as works of the devil, signs of fate, punishment for the sins of the parents, or tricks played by witches (Weir).

Some of these older explanations of congenital disabilities seem strange now, but two features of traditional infanticidal practices remain a part of the modern world. First, infants are still sometimes killed by their parents or, perhaps more commonly, abandoned without food, shelter, or parental protection. No society is exempt from such events, with media reports of dead or abandoned babies coming from China, India, Brazil, the United States, Romania, and other countries. Second, even for parents who cannot imagine killing their own children, the birth of an extremely premature and/or severely disabled infant is a mixed blessing. For that reason, parental decisions about medical efforts to prolong a child's life frequently involve concerns about the future of the family as well as considerations about the welfare of the child.

In many parts of the world, such decisions, whether made by a child's parents or physicians, are strikingly similar to decisions made about sick and disabled children in earlier historical periods because many countries still lack the medicines, the medical and nursing personnel, and the medical technology that are common to the rest of the world. In technologically developed countries, by contrast, the development of neonatal intensive-care units (NICUs), neonatologists and other pediatric subspecialists, sophisticated medical technology, new medicines, and new surgical techniques has brought unprecedented opportunities and challenges to physicians, parents, nurses, and all other persons interested in prolonging the lives and improving the health of critically ill children. Likewise, changes in neonatal medicine since the 1970s have meant that physicians, parents, or some combination of health-care professionals in a hospital can sometimes decide that the appropriate course of moral action in a case is not to initiate or continue life-sustaining treatments, given the child's severe neurologic impairments and likelihood of continued suffering.

Such decisions—not to use medical technology to sustain an extremely premature or severely disabled infant's life—are usually difficult and sometimes controversial. In the United States, public and professional responses to publicized pediatric cases in the 1980s generated two efforts at regulating selective nontreatment decisions. The two attempts at regulation, while not always in conflict, reflected two quite different ethical perspectives regarding how and by whom selective nontreatment decisions should be made.

One effort at regulation took the form of two sets of published federal regulations during the administration of President Ronald Reagan. The *Baby Doe* regulations, first

proposed in 1983, and the subsequent childabuse regulations, established in 1985, differed in legal philosophy, implementation, and influence. Yet both agreed on the ethical perspective that should govern life-and-death decisions made in NICUs and pediatric intensive-care units (PICUs): Every infant, unless permanently unconscious, irretrievably dying, or salvageable only with treatment that would be "virtually futile and inhumane," should be given life-sustaining treatment, no matter how small, young, or disabled the infant might be.

The other effort at regulation was made by the U.S. President's Commission for the Study of Ethical Problems in Medicine (1983), the American Academy of Pediatrics, and numerous writers on ethics in pediatric medicine. Given the complexity of some pediatric cases and the life-and-death nature of selective nontreatment decisions, the common recommendation was to have an ethics committee consult on the cases and give advice to the physicians in the cases. The ethical perspective at the heart of this recommendation was straightforward: In truly difficult cases, the most prudent procedure for decision making is the achievement of consensus by a multidisciplinary committee that is knowledgeable, impartial, emotionally stable, and consistent from case to case.

Similar efforts at regulating selective nontreatment decisions in NICUs and PICUs have not occurred in other countries having technological medicine. In Britain and Australia, for example, governments interested in regulating assisted reproduction technologies to protect pre-embryos have not had a similar interest in regulating selective nontreatment decisions to protect young infants, either from premature deaths or from profoundly impaired lives. Likewise, neither the governments nor the medical societies in these countries have chosen to establish pediatric ethics committees, preferring instead to leave decisions to abate life-sustaining treatment for young infants to the discretion of the physicians and parents of the children.

Nevertheless, some themes and problems are common as decision makers in technologically advanced countries confront the difficult choices presented by premature and disabled infants. First, the ongoing technological development of pediatrics (e.g., the use of exogenous surfactants and high-frequency oscillatory ventilation for treating pulmonary problems) has resulted in improved mortality and morbidity rates for numerous infants and young children. Second, unprecedented surgical techniques (e.g., surgery for short-bowel syndrome and for hypoplastic left ventricle) have resulted in the prolongation of life for many infants who would have died without surgery only a few years ago. Third, these technological and surgical achievements have created a trend in some pediatric subspecialties toward overtreatment of premature and disabled infants, a trend that seems to be contrary to the best interests of some of these children (Caplan et al.). Fourth, even with the technological progress in pediatrics, neonatologists and the parents with whom they work in individual cases are still frequently confronted with an inescapable problem: medical uncertainty regarding the degree and range of disability a neurologically impaired child will have, if the child survives with medical treatment (Hastings Center).

Compared with earlier historical periods, the period of technological medicine has produced unprecedented changes and challenges for parents, physicians, and other persons concerned about the care of infants. The rapidity and extent of the change is noticeable in the types of cases that now present the greatest ethical challenges for parents and physicians in NICUs. In the 1970s and 1980s, considerable debate centered on whether infants with Down's syndrome plus complications and infants with myelomeningocele should receive surgical correction of their physical abnormalities. In the 1990s these types of cases have largely been replaced as ethical challenges by other kinds: (1) cases of extremely premature neonates with birth weights below 600 grams, gestational ages of approximately twenty-four weeks, and severe cardiac, pulmonary, and neurologic impairments; (2) cases of very small and disabled neonates whose low birth weights and disabilities are the result of factors during pregnancy, such as maternal malnutrition, infection (e.g., HIV and AIDS), smoking, consumption of alcohol, or use of cocaine and other drugs; and (3) cases of neonates with anencephaly whose organs could be transplanted into other infants, if the parents of the anencephalic infants were to consent and the law were to permit the transplantation (Walters).

International Perspectives among Pediatricians

The roles of physicians, parents, and nurses in the care of premature and disabled infants vary significantly from country to country. In general, pediatricians in countries that in recent decades have been characterized by authoritarian or totalitarian political regimes tend to take a similar approach to decisions made in NICUs: The decisions to treat or not to treat are made by physicians with only minimal participation by parents, nurses, or other health professionals. By contrast, pediatricians in democratic societies tend to have a more democratic attitude toward decisions made in NICUs: With some variation from physician to physician, the decisions to treat or not to treat are often made in consultation

with the parents of the imperiled infants, with some physicians also finding merit in having pediatric ethics committees consult on some of the truly difficult decisions.

For example, one study indicated significant differences between pediatricians in Poland and pediatricians in Australia. The majority of both groups of physicians indicated that they had been confronted with the necessity of making decisions regarding the withholding or withdrawing of life-sustaining treatment from severely disabled infants. However, their views regarding the substantive and procedural features of such decisions were quite different. Whereas virtually all the pediatricians surveyed in Australia (98.2 %) indicated that they did not believe that "every possible effort" should be made to sustain life in every case, half of the pediatricians surveyed in Poland (50 %) stated that they thought that all possible efforts at sustaining life should be made in every case. Regarding specific diagnostic cases, significant numbers of Australian pediatricians thought that life-sustaining treatment could be withheld or withdrawn in cases of anencephaly and microcephaly (29.7 % of the responding physicians), spina bifida and myelomeningocele (25.2 %), extreme prematurity (9.0 %), Down's syndrome with complications (16.2 %), and brain damage with projected mental retardation (26.1 %). By contrast, the pediatricians in Poland, while agreeing with the Australian physicians regarding cases of extreme prematurity and brain damage, were much more reluctant to abate life-sustaining treatment for infants having microcephaly, spina bifida, or Down's syndrome (Szawarski and Tulczynski).

The differences between the Australian and Polish pediatricians were even more significant when they were asked about the procedural aspects of decisions that would probably result in an infant's death. The majority of responding Australian pediatricians indicated that they discussed such decisions with other physicians (90.9 %), the parents of the infant (90.1 %), and nurses (84.7 %). The Polish pediatricians, by contrast, almost always consulted with other physicians (99.0 %) but rarely discussed the decisions with the parents (8.1 %) or nurses (4.3 %).

Another study suggested that there are differences among pediatricians in the United States, Sweden, Britain, and Australia on both substantive and procedural aspects of selective nontreatment decisions. According to this interpretive study, the dominant practice among American pediatricians, especially neonatologists, is to initiate aggressive life-sustaining treatments early, continue those medical interventions while diagnostic tests are being done and various pediatric specialists are consulted, and talk with parents about the alternative of abating treatment only when the parents bring up the subject or when a grim prognosis becomes increasingly clear. This perspective is described as a "wait until certainty" approach, an approach involving a clear ethical choice: Saving an infant who will have severe-to-profound disabilities is preferable to permitting the death of an infant who could have lived a tolerable life. This strategy ensures that all errors are in one direction: the promotion of the infant's life, even a severely disabled life. Treatment that sustains the infant's life can therefore be terminated only when death or profoundly impaired life is inevitable (Rhoden).

This study suggests that pediatricians in Sweden have a different perspective, one that is described as a "statistical prognostic" strategy. This approach seeks to minimize the number of infants whose deaths would come slowly as well as those whose lives would be characterized by profound disabilities. At the risk of sacrificing some potentially normal infants to avoid prolonging the lives of severely impaired infants, this approach uses statistical data, like birth weight, gestational age, and early diagnostic tests, to make selective nontreatment decisions. This strategy also ensures that all errors are in one direction: the promotion of healthy life, even at the cost of allowing some infants to die who could have lived with disabling conditions.

Pediatricians in Britain and Australia are described in the study as having medical and ethical perspectives that frequently differ from those of their American and Swedish counterparts. In contrast to many pediatricians in the United States, pediatricians in Britain and Australia are willing to withhold or withdraw treatment with much less prognostic certainty. Yet in contrast to many pediatricians in Sweden, British and Australian pediatricians are willing to engage in time-limited trials to give various treatments a chance to work, even when the child being treated is likely to have ongoing disabilities. Called an "individualized prognostic" strategy, this approach reflects an ethical perspective that realizes the inherent uncertainty in medicine, permits some role for parental discretion, and affirms the appropriateness of selective nontreatment decisions once a child's prognosis appears poor (Rhoden).

In much of the world, the ethical perspectives among physicians are quite different from the approaches described above because the provision of care to infants takes place outside the confines of technological medicine. In the People's Republic of China, India, the countries of the former Soviet Union, and many of the other countries in the world, the differences in medical management that have just been described have no significance. The shortages of medicine, the obsolescence of medical equipment, the inadequacies of prenatal care, the limited number of pediatricians, and the ongoing problems of malnutrition and infectious disease contribute to a social context in which the lives of

infants are frequently short and often characterized by disease and disability.

Alternative Perspectives on the Moral Status of Infants

Ethical perspectives on the care of infants are significantly influenced by views that are held regarding the ontological status and moral standing of infants, whether premature, disabled, or normal. What kind of entity is it whose life, health status, or death is at stake in the decisions made by physicians and/or parents? Is a neonate, in terms of ontological status, the same as an older child and an adult? Does an infant count as a person, in the same way that you and I count as persons? Or are questions about personhood irrelevant in terms of the moral standing that adults choose to grant infants? In terms of moral standing, what kinds of moral rights do infants possess? Do human infants possess full moral standing, making them morally equal to adult persons? Is the moral standing of neonates to be understood as somehow less than that of human adults but more than of human fetuses, or are fetuses, neonates, and adults to be understood as morally the same?

For many philosophers in recent years, questions related to the moral standing of infants have been addressed in the broader context of a discussion about ontological status and, more specifically, the meaning of personhood. One approach is to define *person* as meaning *a living being with full moral standing.* According to this definition, all persons have such standing, leaving open the question of just which characteristics give that standing.

Given this general philosophical perspective on personhood, at least three positions can be identified that link the ontological status of neonates with the moral standard granted to infants. The first position holds that all neonates, whether normal or neurologically impaired, count as actual persons in the same way that you and I count as persons. According to this view, the personhood of neonates is merely an extension of the personhood possessed earlier by fetuses. With this ontological status, neonates, like all other actual persons, have the moral right not to be killed or prematurely allowed to die, since the possession of personhood entails full moral standing, regardless of the age of the person. Personhood, according to this view, is based on genetic code or some other characteristic possessed at conception, not on possession of consciousness, self-awareness, rationality, or any other neurological characteristic.

The second position holds that in order to count as persons, infants (and other beings, whether human or nonhuman) must possess the intrinsic qualities or traits often defined by philosophers as being the threefold combination of consciousness, self-awareness, and at least minimum rationality (Feinberg). If infants lack these core properties, they have an ontological status that is more similar to the status of human fetuses than to the status of older children or adults. Holders of this view claim that all neonates, including normal babies, fail to pass the neurologic tests for personhood and are thus to be classified as nonpersons. In this view, all neonates lack the cognitive qualities that make a human into a person. In addition, the notion of potential personhood is discarded as flawed, largely because the advocates of this second position argue that personhood cannot be possessed in varying degrees. Holders of this second view also claim that only those who have the neurological characteristics of persons possess the rights of persons, including the right not to be killed or prematurely allowed to die. The result, in terms of the moral standing of neonates, is straightforward: Neonates do not possess the moral rights of persons, leaving them at risk of being killed or prematurely allowed to die unless their parents and physicians are motivated by psychological or legal considerations to sustain their lives (Tooley).

The third position stands between the other positions. It identifies the same neurological characteristics of personhood, but according to this view, most neonates (those lacking severe neurologic impairment) are to be regarded as potential persons, not yet possessing the ontological status of actual persons but on the way to the possession of the core properties of personhood through the normal course of human development. Agreeing with advocates of the first two positions on the linkage between ontological status and moral standing, philosophers holding the third position maintain that when infants develop and subsequently become persons, they will acquire full moral standing. Until that time, including during the neonatal period, they are regarded as having a prima facie claim not to be killed, prematurely allowed to die, or significantly harmed in some other way, precisely because they will subsequently and naturally become actual persons.

The differences in these philosophical views have practical consequences in terms of the ways that adults value the lives of infants, including infants who may be extremely premature or severely disabled. Advocates of the first position tend to call for life-sustaining treatment to be administered to all infants in NICUs regardless of birth weight, gestational age, or neurological status, because all infants are actual persons in possession of the full panoply of moral rights common to persons. By contrast, any parents or physicians in NICUs who regard neonates as nonpersons (and who believe that only persons bear the rights borne by

persons) are likely to be ready to withhold or withdraw treatment much more quickly, if the law permits them to do so, because the infant lives that are lost do not yet count for much morally. For advocates of the third position, the concept of potential personhood provides an intellectual framework in which difficult prognostic judgments make some sense. In this view, at least part of the difficulty in making decisions to provide life-sustaining treatment or to abate treatment, especially in cases of severe neurologic impairment, has to do with judgments about whether a particular baby has the potential even to become a person in the normal course of his or her development.

Other perspectives on the moral status of infants, some of which are grounded in theological ethics, suggest that the philosophical debate about the personhood of infants is intellectually restrictive and of little practical significance. For example, one fairly common view is that the moral standing of infants cannot depend on whether they meet a philosophically strict definition of personhood, because all infants fail to meet that standard. Rather, what is important is a social understanding of *person* according to which infants are regarded by their parents, physicians, and others *as if* they were persons. This social sense of personhood involves the imputing of personlike rights to infants because of their special roles in families and in society. The practical consequence of this view is that infants, who are given the imputed status of *person* in a social sense, have the same kind of moral standing as older human beings who are persons in a more formal sense (Engelhardt).

Another widely held view is that the personhood question simply does not apply to infants, either in a strict sense or in a social sense. Rather, what is important is that infants are understood to have moral standing as *fellow human beings*. Advocates of this view may regard fetuses and infants as having equal moral standing as human beings, or they may have a developmental view in which viable fetuses and infants, but not nonviable fetuses, have equal moral standing as human beings. Either way, infants are regarded as having the same kinds of moral rights that older human beings have, including the right not to be killed or allowed to die prematurely unless, in unusual cases, the burdens of continued life are regarded as outweighing the benefits of that life to the child (Fletcher). Holders of this view give the same moral standing to infants and fetuses as do holders of the first position above, but deny that these beings have to be called persons.

The personhood approach to the moral status of infants, according to another theological view, is unrelated to the possession of the neurological characteristics identified with personhood discussed above for another reason. The limiting of an infant's value to the question of whether that infant possesses the intrinsic properties of personhood entirely omits another approach to the understanding of the value that infants have: namely, a relational view of value that results from interpersonal bonding, affection, and care by parents and other adults. Even when an infant has a future that will, because of neurologic impairments, be characterized by developmental delay and mental retardation, the parents of the child still usually go through a process of bonding with the child. That process of bonding, which involves the replacement of a hoped-for child with a healthy attachment to the child one has been given, results in a valuing of the child by parents that is surely equal to the valuing of normal children by their parents (May).

A related view is that philosophical arguments about the moral status of infants need to be supplemented, if not replaced, by an experiential ethic of care. This view emphasizes the importance of the various perspectives that parents, physicians, nurses, and other persons bring to pediatric cases. Rather than focusing on the ontological and moral status of infants, most commonly with questions related to the possession of personhood and moral rights, this approach concentrates on the various values and virtues present, or possible, in the context of decision making about an infant's impending death or projected life with disabilities. The practical result is that questions in difficult cases are raised not only about what should be done for the patient but also about what kinds of moral agents the parents, physicians, and nurses should be as they provide care for an imperiled infant (Reich).

Ethical Perspectives on Abating Life-Sustaining Treatment

The ethical perspective that became enacted into the *Baby Doe* regulations and child abuse regulations was only one of the ethical perspectives on the medical care of infants that received considerable attention in the United States in the 1970s–1990s. Other ethical perspectives have also been widely held, both before and after the federal regulations became policy.

For example, for some persons the important ethical question is not whether a given infant can be salvaged through medical treatment. Rather, the important question is what quality of life the child will probably have later, especially if the child's future is predicted to be dominated by severe-to-profound neurologic impairments, multiple surgeries, and numerous other medical problems. The question is sometimes posed in terms of the future relational

potential possessed by a child with severe neurologic impairments, with the moral judgment being that an infant who lacks relational capacity will never have the quality of life that would justify the continuation of the child's life (McCormick).

A closely related ethical perspective focuses on a child's best interests. For persons holding this position, the important question is whether the life-sustaining treatment that could be given to imperiled newborns will, on balance, provide the infants with more benefits than burdens. Since quality-of-life projections can sometimes extend to include persons other than the patient, this position's strength is in framing the ethical debate primarily in terms of the patient's best interests, not the interests of the family or society (U.S. President's Commission).

Another ethical perspective emphasizes procedural issues. According to this view, the most important aspect of decisions not to sustain some infants' lives is the question of who should make these difficult decisions. Advocates of this position maintain that in most cases, the parents of a premature or disabled infant are the appropriate decision makers.

A very different ethical perspective on selective treatment decisions also has some advocates. As described in the previous section, some philosophers hold that life-sustaining treatment can morally be withheld or withdrawn from any infant, regardless of birth weight or disability, because the only deaths that matter are the deaths of persons, and no infants meet the requirements of personhood.

Three of these ethical perspectives continue to play major roles in selective nontreatment decisions, with the dominant perspective in individual cases varying from hospital to hospital, physician to physician, parent to parent, case to case. The perspective that calls for life-sustaining treatment to be administered to all infants who are conscious, not dying, and for whom treatment is not "virtually futile and inhumane" remains influential, even if the federal regulations that reflect this perspective have been largely unenforced throughout the country. The reasons for its continuing influence are twofold. First, this perspective is consistent with the reasons that motivate neonatologists to do the work they do: to prolong and enhance the lives of the youngest, smallest, most disabled, and most vulnerable human beings among us. Second, this perspective offers the simplest way of dealing with the multiple problems that constitute the *ethics lab* known as the NICU: It minimizes the factor of medical and moral uncertainty in cases, the role of parents as decision makers, and any considerations of the harm that may be done through prolonged, aggressive efforts to salvage imperiled young lives.

The second perspective that remains influential is the position that emphasizes the role of parents as decision makers. Advocates of this view rarely suggest that parents alone should make the selective nontreatment decisions that could result in the deaths of their children, or that parents should be given unlimited discretion in making such decisions. Rather, the claim that is often made is that parents should, in response to appropriate medical information and advice, have reasonable discretion in making a life-and-death decision regarding their child in the NICU, subject to certain ethical and legal constraints. They are the ones, after all, who may be saddled with the enormous financial costs of neonatal intensive care. They are the ones, in addition to the child, who will have to deal with the child's ongoing medical problems, repeated hospitalizations and surgeries, neurologic abnormalities, and developmental delays. They are the ones who will have to struggle to sustain their marriage, their family life, their careers, and their own physical and mental health.

The third perspective that remains influential is the patient's-best-interests position. Advocates of this position acknowledge the medical and moral uncertainty inherent in many cases, affirm an important role for parents as decision makers, and recognize that the same medical and surgical interventions that produce great benefit for some patients can produce undue harm for others. In contrast to the parental perspective, proponents of this view emphasize that the focal point of decision making in neonatal and pediatric cases should be the best interests of the patient, even when the patient's interests conflict with the interests of the parents. In this manner, the patient's-best-interests position emphasizes the linkage between life-sustaining medical treatment and patient-centered considerations regarding the quality of life—without broadening quality-of-life judgments to include the family, the society, or arbitrary standards for normalcy and acceptability, as quality-of-life projections sometimes do.

The Emerging Mainstream Perspective

If any of these positions can be correctly designated as the mainstream ethical position, at least in the United States, it is the patient's-best-interests position. Advocates of this position are concerned about the treatment-related harms that sometimes occur when neonatologists and other pediatric subspecialists persist, perhaps under the influence of the federal regulations, in overtreating infants who have extremely low birth weights and severe disabling conditions but who are neither unconscious nor dying. At the same time, proponents of the best-interests view are reluctant to

grant the parents of premature and disabled infants as much discretion in deciding to abate life-sustaining treatment as some parents would like to have.

In clinical cases, the best-interests position relies on eight variables that help to determine whether to initiate, continue, or abate life-sustaining treatment: (1) the severity of the patient's medical condition, as determined by diagnostic evaluation and comparison with (a) all infants and (b) infants having the same medical condition; (2) the achievability of curative or corrective treatment, in an effort to determine what is meant by *beneficial* treatment in a given case; (3) the important medical goals in the case, such as the prolongation of life, the effective relief of pain and other suffering, and the amelioration of disabling conditions; (4) the presence of serious neurologic impairments, such as permanent unconsciousness or severe mental retardation; (5) the extent of the infant's suffering, as determined by the signs of suffering that infants send by means of elevated blood pressure, elevated heart rate, degree of agitation, and crying; (6) the multiplicity of other serious medical problems, with the most serious cases usually involving a combination of neurologic, cardiac, pulmonary, renal, and other medical complications; (7) the life expectancy of the infant, because some of the severe congenital anomalies involve a life expectancy of only a few weeks or months; and (8) the proportionality of treatment-related benefits and burdens to the infant, a medical and ethical "bottom line" for determining whether life-sustaining treatment or the abatement of such treatment is in a particular infant's best interests (Weir and Bale).

Even with these variables, the ethical analysis of cases involving neonates or other young pediatric patients is anything but easy. Although there are numerous cases about which almost everyone agrees, there continue to be many cases that combine unprecedented medical and moral territory, advances in medical management and technology, medical uncertainty, and ethical conflicts between physicians and parents in such a way as to present serious ethical challenges to all the parties involved in the cases. In such instances, the discernment of the infant's best interests can be a challenging and humbling experience.

INFANTS, MEDICAL ASPECTS AND ISSUES IN THE CARE OF

• • •

Overall, there are three relatively distinct groups of babies who are admitted to neonatal intensive care units (NICUs). These groups are different in ways that are ethically relevant. The first group consists of full-term or near-term babies with acute illnesses such as pneumonia or sepsis, as well as babies with surgically correctable anatomic abnormalities. The second group comprises babies with congenital anomalies, including chromosomal anomalies, which are not correctable at the present time. Many of these babies have problems that can be ameliorated but not corrected with surgical or medical treatment. The final group of babies includes those born prematurely who are otherwise physically normal—that is, they have no acute illness or congenital anomaly except their prematurity. The first two groups raise problems that are essentially similar to those that arise in other patient groups. They are different from other patients only in that they are babies. The third group is entirely unique. There are no other clinical populations in which the primary clinical problem arises from an arrested developmental process, and in which the clinical problem will correct itself if development is allowed to continue. This entry describes, in separate sections, the three groups and the different ethical issues associated with them.

Acute Illnesses

Acute illnesses in full-term babies are usually the least morally controversial of the clinical problems that arise in neonatology. Most acute illnesses can be treated if they are accurately diagnosed. The problems that arise in babies are

similar to the problems in other high-risk populations. Diagnosis must be made quickly and treatment initiated expeditiously. The babies generally either get better quickly or they die quickly.

Rarely, treatment is only partially successful, and the babies survive but with severe long-term complications of their acute illness. For example, term babies might develop meningitis. The disease can be diagnosed and treated, but some babies are left with severe neurological impairment. In situations where treatment is only partially successful, the babies become similar to babies with uncorrectable congenital anomalies. The only difference is that, in these cases, the anomaly was acquired after birth rather than before. The process of decision-making, however, will be similar to that outlined below.

In general, the issues that arise in this group of NICU patients are not unique to NICU patients. The primary concerns are accurate diagnosis and appropriate treatment. If there is a treatment that works, it should be provided. There is rarely disagreement between doctors and parents in these cases. The ethical issues are driven almost entirely by the medical indications for treatment. Ethics simply dictates that doctors should be competent and should communicate well with parents.

Congenital Anomalies

Congenital anomalies were the primary focus of legal and moral controversy in the 1970s regarding treatment decisions for newborns (Lantos). The key cases focused on syndromes such as trisomy 21 (Down syndrome), spina bifida, and cases of multiple congenital malformations. Generally, the issue that arose was whether or not to attempt surgical treatment to correct some but not all of the congenital anomalies. Thus, for babies with Down syndrome, the issue was whether to correct an associated intestinal or cardiac malformation. In babies with spina bifida, the issue was whether to treat the hydrocephalus by placing a shunt in the brain, or whether to close an open lesion of the spinal canal.

It is understood that, in these situations, the underlying syndromes themselves cannot be treated. Babies with Down syndrome will still have Down syndrome, even if their intestinal or cardiac anomalies are repaired. Babies with spina bifida will still have the long-term neurological problems associated with the spinal cord injury, even if their hydrocephalus is treated. Thus, the issues that drive these decisions are fundamentally different from those in cases of acute illness. The primary focus in these cases is on long-term quality of life for survivors.

Congenital anomalies focus discussion on anticipated quality of life as opposed to prognosis for survival. The discussions often involve the ethical implications of active intervention as opposed to "letting nature take its course." In many of the discussions, there is a sense of fatalism in the face of what are seen as mistakes of nature. Perhaps, the thought goes, these babies were somehow meant to die, and interventions are both unnatural and inhumane.

Many congenital malformations that were once thought to be incompatible with life can now be treated. Given the capabilities of modern intensive care, there are very few congenital anomalies that are truly incompatible with life. Babies with severe congenital heart disease can have open-heart surgery, babies with no intestines can be given total parenteral nutrition, and babies with minimal brain function can be kept alive on ventilators. Unlike cases of acute illness, decisions in these cases are not driven primarily by the medical indications for treatment. Those are usually straightforward. Instead, the decisions are driven by judgments about whether the results of successful treatment will be acceptable. In other words, will the consequential quality of life be sufficient to make the life worth living? In analyzing such decisions, it is necessary to have a nuanced understanding of the different components of "quality of life."

QUALITY OF LIFE COMPONENTS. Quality of life can be broken down into a number of ethically relevant components, each of which must be considered in these cases. These components include the anticipated cognitive or neurological function, the anticipated physical disabilities, the pain and suffering that is associated with the disease itself, and the burdens of the treatments that will be necessary in the future.

Most people today hold that a certain minimal level of cognitive or neurological function is essential for a life to be considered worth living. This was one of the rare areas of consensus in the 1980s controversy about federal regulation of nontreatment decisions for newborns. The agreement, in principle, that cognitive function is an important consideration begs the question of appropriate thresholds. Babies with no cortical function at all, such as babies with anencephaly or babies with prolonged cortical unresponsiveness as a result of anoxic (oxygen-deficiency) injuries, define one extreme. Babies with syndromes such as Down syndrome that lead to mild mental retardation are at the other end of the spectrum. In between are babies with other chromosomal or genetic anomalies, babies with intraventricular hemorrhages, or babies with neurological damage as an aftereffect of treatment for an acute illness.

The process for decision making in such cases requires recognition of a real but constantly shifting boundary or

threshold that has clearly defined extremes and a well-recognized "gray zone" in the middle. Today, as a matter of societal consensus, the quality of life in Down syndrome is considered to be above the threshold, so these babies, and babies like them, must be treated. The quality of life in anencephaly is considered to fall below the threshold, so babies with this syndrome generally ought not be treated. There are, occasionally, exceptional cases of anencephaly in which treatment is provided at the parents' insistence, but they are noteworthy because they are exceedingly rare. Exceptions to the rule do not undermine the validity of the rule, they simply highlight the difficulty of imposing universal compliance with the rule. Cases in between these extremes are still difficult and controversial.

The physical disabilities associated with a condition must be addressed separately from the cognitive or neurological disabilities. Often, babies have an intact brain but have other physical disabilities. In severe spina bifida, for example, the spinal cord damage may make it impossible for a person to move about independently. Generally, physical disabilities, by themselves, cannot justify a decision to withhold life-sustaining treatment. It is clear from studies of adults with spinal cord injuries that it is possible for a person with severe physical disabilities to lead a rich and satisfying life. Thus, in such cases, the focus of discussion is usually on developing an adequate support system and insuring access to rehabilitation services so that function can be maximized.

A third part of any assessment of quality of life has to do with the pain and suffering associated with the disease. Some diseases lead to unrelenting pain and suffering. For example, severe epidermolysis bullosa is a disease that causes blistering of the skin over the entire body, including the oral cavity and intestinal tract. Swallowing is impossible. Scarring of the skin leads to contractures (permanent shortenings) of all the joints. Even comfort care is difficult because merely handling babies with this syndrome causes pain and exacerbates the condition. In such a case, an attempt to prolong life inevitably prolongs the suffering. It is appropriate in such cases, or in cases like them (though there are not many other syndromes that are relevantly similar to epidermolysis bullosa), to withhold life-sustaining treatment based solely on the pain and suffering associated with the disease.

Another component of quality of life has to do not with the pain and suffering of the underlying condition but with the pain and other burdens associated with the necessary treatments. Babies with short gut syndrome, for example, can survive, but only with indwelling venous catheters placed into large veins in the chest or neck. These central lines often become infected and must be replaced. When they become infected, patients must be admitted to the hospital for intravenous antibiotics. Parenteral nutrition often causes secondary problems such as liver failure. In extreme cases, patients are frequently hospitalized to deal with the complications of the treatment, and further treatment predictably exacerbates these complications in ways that cannot be prevented. Another example of excessively burdensome treatment is the provision of mechanical ventilation for babies with progressive and degenerative motor neuron disease. Some such babies are unable to eat, breathe, or talk, but their cerebral cortex is intact, so that they can think. Prolonged mechanical ventilation can prolong life for such babies, but the burdens of the treatment are thought to be high enough that a decision not to initiate mechanical ventilation, or to discontinue it once started, is usually considered acceptable. In such cases, the burdens of treatment drive the decision.

Any adequate discussion of quality of life must separate the components. Nevertheless, in most cases, a combination of these components exists. Generally, the task of moral reasoning about any unique individual case requires doctors and parents to analogize the case with better known paradigm cases. For doctors and parents, the question may be whether a particular case is more like Down syndrome than it is like anencephaly, or whether a burdensome treatment is more like lifetime mechanical ventilation than it is like lifetime dependence on insulin.

Extreme Prematurity

Babies with extreme prematurity comprise the third group of babies admitted to the NICU. The moral considerations involved with these babies include not only all of the considerations in the other two groups but also an important new one—long-term prognostic uncertainty.

Prematurity is both an acute crisis and a chronic condition. The acute crisis requires an emergency response driven by medical indications, just as in the cases of full-term babies with acute medical problems. At the time treatment is initiated, however, the baby's prognosis is usually uncertain in a different way than in the other two situations. With acute pneumonia, treatment usually either succeeds, in which case the problem is completed resolved, or it fails, in which case the baby dies. There is almost no middle ground. With congenital anomalies and syndromes, treatment cannot cure the underlying disease. So a baby with Down syndrome will still have Down syndrome, even if the congenital heart disease is repaired. The long-term prognosis for survivors is clearly predictable. Again, there is almost no middle ground of uncertainty. With extremely premature babies, by contrast, the prognosis is radically uncertain. It ranges from early death through later death to survival with severe disabilities, moderate disabilities, or no disabilities.

The disabilities can be cognitive, pulmonary, or involve virtually any other organ system. When treatment must be initiated, nearly all babies are in a prognostic gray zone. The outcome for any particular baby simply cannot be known, and it can range across the entire spectrum of possibilities from the very best to the very worst. This raises a whole different set of ethical considerations.

PROGNOSIS FOR SURVIVAL AND THE BIRTHWEIGHT FACTOR. At the time of birth, it is difficult to say whether a particular baby will live or die. It is difficult to predict how long life can be prolonged in cases where death will ultimately ensue. And it is difficult to predict whether survivors will have mild, moderate, or severe chronic problems or no problems. Obviously, an accurate prognosis for a particular baby would be essential to making the best ethical decision for that baby. If survival is impossible, then treatment should not be provided. If intact survival is likely, then treatment is morally obligatory. To a certain extent, clinical research in neonatal intensive care since the early 1980s has helped bring about a greater understanding of these issues and helped to refine, though not perfect, doctors' prognostic abilities.

The goal of this research has been to develop a method to precisely predict the anticipated outcome for each premature baby. The most powerful prognostic measure has always been birthweight. Overall, bigger babies do much better than smaller babies. Almost no babies who weigh less than 500 grams at birth survive, whereas nearly all babies who weigh more than 875 grams at birth survive. The zone of controversy is in between these two birthweights. The weights correspond, roughly, to the time between about twenty-three weeks of gestation and twenty-six weeks of gestation, or between the fifth and sixth months of pregnancy.

One plausible response to these data would be to suggest that only babies over 850 grams should be treated. If this course were taken, however, there would be many babies in the 500- to 850-gram birthweight range who might have survived but who would be allowed to die. Another response might be to treat all babies over 500 grams. With this option, however, treatment is provided to many babies whose death is likely. One way to refine the prognostic estimates is to look a little more closely at the clinical course of these babies.

It turns out that most premature babies who are going to die do so in the first few days of life. The sickest babies are very sick. Because the sickest babies die quickly, the babies who survive for even three days are, by definition, much more likely to survive than other babies of the same birthweight. In fact, by seventy-two hours of age, birthweight virtually disappears as a relevant predictor of survival. The 600-gram babies who survive do just as well as the 1,000-gram babies who survive (Meadow, Reimshisel, and Lantos).

These clinical epidemiological facts have shaped the moral responses of NICU professionals. Prior to the 1980s, discussions about the appropriateness of decisions involving whether or not to treat premature babies presumed that the decision should be made at birth and in the delivery room. It was seen as a one-time, either/or decision. The newly understood clinical realities show why that did not make sense. Among all babies born at less than 750 grams today, half can be saved and half cannot. At the time of birth, however, it is almost impossible to tell which baby will be in which group. The only way to separate the two groups is to initiate treatment on all of them. The sickest babies then *declare themselves* by getting sicker in spite of medical treatment, and the healthier babies *declare themselves* by improving.

NEUROLOGICAL OUTCOMES. Determining the prognosis for neurological outcome is even more difficult than determining the prognosis for survival. Clearly, premature babies have worse neurological outcomes than full-term babies. Numerous studies have shown a higher incidence of cerebral palsy, seizures, chronic lung disease, and educational problems among premature babies than among their full-term peers. Nicholas S. Wood and colleagues summarized outcomes for tiny babies in a 2000 issue of the *New England Journal of Medicine* (see Figure 1).

These statistics, however, are like the statistics showing poor survival for tiny babies. The relevant question for clinicians and parents is not whether, overall, a group of babies has a worse prognosis but whether for any particular baby the likely outcome can be predicted. There are predictors of bad outcomes, but they are imperfect.

As they reported in 2002, Carl T. D'Angio and colleagues studied long-term neurologic, cognitive, and educational outcomes for babies born at less then twenty-nine weeks of gestation. They showed that the only predictors of bad neurologic outcomes were neonatal intraventricular hemorrhage, severe lung disease, and low socioeconomic status. Betty R. Vohr and colleagues found similar results in a 2000 study. Interestingly, the first two factors are physiological while the third is social, but each is independently associated with bad outcomes. At the very least, this suggests a complex interplay between physiological and sociological factors. Importantly, neither birthweight nor gestational age is, by itself, associated with poor neurological outcomes for these babies. This again suggests that, in the clinical setting, a simple criterion for treatment or nontreatment based on birthweight alone is likely to be relatively inaccurate in tailoring treatment decisions in an ethically appropriate way.

Implications of Clinical Knowledge for Ethical Decision Making

These epidemiological facts help define the zone of parental discretion. In order for a decision to withhold life-sustaining treatment to even be considered, doctors must first determine that a baby has an appropriately severe condition. Thus, doctors initiate most discussions of treatment withdrawal. Sometimes, parents will initiate the discussions but when they do, the doctor's task is the same—deciding whether or not the baby fits into one of the categories in which treatment withdrawal is permissible. If not, the doctor must rebuff the parents' request. If so, the doctor should facilitate the process in a way similar to the way she would if she had initiated it herself.

Over the years, different schools of thought have evolved about the proper tone and structure for such discussions. These might be characterized as the *objective information* approach and the *broad shoulders* approach.

In the objective approach, doctors see it as their responsibility to give parents information in the most nondirective way. They simply provide the facts and try to empower parents to understand those facts and to come to a decision that reflects the parents' personal moral or spiritual values. In this approach, the doctor does not make a recommendation about the appropriate course of treatment. If they are asked what they would do, they refuse to answer. The moral psychology of this approach is based upon a fear of being coercive. It views doctors as inappropriately empowered and parents as problematically vulnerable to being overpowered. Given that sociological background, doctors have a moral obligation to restrain their own implicit dominating impulses. Sociologists, who examine the power structures of human communities, often see this sort of pattern of interaction. Some philosophers, especially those for whom individual autonomy is a paramount moral principle, are the most articulate defenders of this approach.

The broad shoulders approach takes a different tack. By this view, parents' particular vulnerabilities require doctors to take some of the burden of decision making upon themselves. Instead of simply giving parents the facts, doctors are obligated to make a recommendation. Advocates of this approach point out that the circumstances of serious illness are circumstances of personal moral and psychological crisis in which ordinary moral principles may not be applicable. Individuals may not be capable of the same sort of autonomy in such situations as they are in other situations. They may need subtle and often implicit assistance to understand their own wants, needs, and values, and they may have trouble owning the decision that flows from these values.

In spite of these radical differences in understandings of the moral underpinnings of the conversations that lead to decisions, in practice, the structure of conversations between doctors and parents look similar in both. The first discussion is one of facts and possibilities. The clinical facts are explained. The possibilities for treatment or nontreatment or presented. Questions are answered. Usually, this first discussion is then adjourned, and parents are allowed time to think. In most cases, they seek outside support—from extended family, from clergy, or from mental health professionals.

A second discussion, during which a decision is reached, usually follows within a few days. Three sorts of conclusions can be reached. In the first, parents decide that they do not want to stop treatment and do not want to reconsider their decision in the future. They want *everything done* to keep their baby alive. Generally, this leads to a discussion of the ambiguity of the term *everything done* in today's medical environment. The second sort of conclusion that can be reached is for a *time-limited trial* of continued treatment. By this approach, doctors agree to continue treatment for a defined period and to set certain parameters or endpoints that they might then look for to see if the treatment is leading to anticipated goals. For example, doctors might offer to continue mechanical ventilation for another week and if, at that point, the ventilator can be safely discontinued, then it will be. If not, however, it will be discontinued anyway in a manner that will likely lead to the death of the baby. The final sort of conclusion that can be reached is a decision to withdraw life-sustaining treatment immediately.

In these situations, a standard set of rituals, familiar to the staff in most NICUs, ensue. The baby is moved to a separate room, the parents are called in, the ventilator or the intravenous fluid pumps are removed, and the parents are allowed time alone to hold their dying baby.

These approaches reflect the inherent uncertainty of the process. When death is inevitable, there is no moral decision to be made. In those circumstances, heroic efforts are often made to prolong life and those efforts fail. A moral statement has been made, a moral commitment fulfilled. Moral decisions arise only when there is ambiguity or uncertainty about the prognosis and about the efficacy of treatment. As has been shown above, however, there is almost always uncertainty. Uncertainty creates the necessity for moral, as opposed to simply clinical, decision making.

Conclusion

The current state of ethical decision making for infants in neonatal intensive care units involves several tasks. The first task is to correctly categorize the clinical indication for intensive care treatment. The second is to determine, as accurately as possible, the baby's prognosis for survival. Finally, doctors must estimate the prognosis for long-term outcome among survivors in terms of neurologic disability and quality of life. These facts ground discussions of the proper ethical course of action. In most cases, they lead quickly to a consensus about the proper course of action.

INFANTS, PUBLIC POLICY AND LEGAL ISSUES

• • •

Medical decisions regarding infants vary in the seriousness of their consequences for infants, families, health providers, and society. They range from decisions about home birth and male circumcision—debatable but generally agreed to be matters of private choice—to vaccination, genetic screening, female genital mutilation, and high technology interventions for critically ill newborns. In the United States, parents' legal right to select even the most invasive treatment—or to refuse lifesaving measures—was nearly unquestioned until late in the twentieth century. From the early 1980s into the early twenty-first century, this right became a focal point of litigation, extensive scholarly comment, and public concern. Because much of the legal and public policy debate has focused on infants who require life support, decision making will be discussed here in that context.

The Infant's Interests

The increasing complexity of decisions about the treatment and nontreatment of infants has exacerbated the struggle over who may make these decisions. Advances in medical technology, surgical procedures, and pharmaceuticals allow severely compromised infants to survive. These new technologies frequently entail painful procedures for the infant and the possibility of adverse effects that further attenuate

the infant's already fragile hold on life. For example, resuscitation techniques allow many more premature infants to survive; but these infants frequently need prolonged ventilatory assistance and invasive diagnostic and treatment procedures. They are also at increased risk both for cerebral hemorrhages, which create severe neurological deficits, and for significant treatment-related adverse effects, such as blindness and deafness.

Decisions on treatment have traditionally rested with parents, healthcare providers, or some combination of the two. Since the 1980s, the decision-making powers of these parties have been challenged. In the United States, the older body of law has been partially eroded by legislative enactments and court decisions that highlight the rights of the infant (Cooper). Indeed, recognition of the infant's individual rights arising from the celebrated 1982 Baby Doe case became the basis for substantial federal intervention in medical practice and family life.

Baby Doe was afflicted with Down syndrome, a chromosomal abnormality resulting in mental retardation and a propensity for cardiac and other congenital malformations. The infant had such a congenital defect, a tracheoesophageal fistula (an abnormal passage connecting the trachea and esophagus), which if not surgically corrected results in death. The parents, after consultation with and with the concurrence of their attending physician, refused to consent to the surgery, primarily on the grounds that a child with Down syndrome could not attain a "minimally acceptable quality of life." That conclusion was, and continues to be, strongly disputed. A trial court, however, ruled that the parents had the right to refuse surgery for their child (*In re Infant Doe,* 1982).

Immediately after the infant's death, President Ronald Reagan directed the U.S. Department of Health and Human Services (DHHS) to issue regulations protecting infants with disabilities from treatment discrimination by parents, healthcare providers, or both. Through the regulations, issued in March 1983, DHHS claimed authority under the Rehabilitation Act of 1973 to order healthcare facilities receiving federal assistance to provide sustenance and aggressive medical treatment to infants with disabilities. The regulations required posting signs announcing the new federal protection in treatment areas of hospitals; established "Baby Doe Squads" to investigate alleged instances of treatment discrimination; and provided for a toll-free hot line to facilitate the reporting of discrimination (Lawton, Carder, and Weisman). Most healthcare providers, as well as many members of the public and of Congress, reacted negatively. A prestigious national group studying healthcare decisions—the U.S. President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research (hereafter, U.S. President's Commission)—and the American Academy of Pediatrics (AAP) both vehemently criticized the regulations. The U.S. President's Commission argued for a standard that would focus on the "best interests" of the infant. The AAP, along with several other parties, sought help from the federal courts, which invalidated the regulations only a few weeks after they became final (*American Academy of Pediatrics v. Heckler,* 1983).

DHHS next produced the "Baby Doe II" regulations, modifying the requirements for signs and providing for an infant-care review committee in each hospital rather than an outside investigative team. These regulations too were rejected—ultimately by the U.S. Supreme Court—on the grounds that the Rehabilitation Act did not give DHHS any authority to regulate parental decisions about infant treatment (*Bowen v. American Hospital Association,* 1986).

In a final effort to influence the care of newborns, Congress enacted the Child Abuse Amendments of 1984, which directed DHHS to develop regulations governing infant care and guidelines for hospital infant-care review committees. As of 1985, federal funding for state child-abuse prevention and treatment efforts was conditioned on compliance; only a few states chose to decline the funding. Under the amendments, the child protective service agency of a state is the only party that may initiate an action of neglect. Nevertheless, the act broadened the definition of child abuse to include "withholding of medically indicated treatment," thereby affecting physician practice standards. The amendments require that an infant with a disability receive appropriate nutrition, hydration, medication, and the "most effective" treatment according to the reasonable judgment of the treating physician. In only three situations may treatment be withheld: (1) when the child is chronically and irreversibly comatose; (2) when treatment could not save the child's life for any substantial length of time; or (3) when the treatment would be inhumane and "virtually futile" with respect to survival. The distinction between inability to save the life (situation 2) and "virtually futile" (situation 3) lies in the "degree of probability or uncertainty in determining the futility of treatment" (Boyd and Thompson). This distinction has become increasingly difficult to draw, in the context of both withdrawal and continuation of treatment.

In the wake of the Child Abuse Amendments, the U.S. President's Commission continued to advocate that the standard for infant treatment or nontreatment be based on the "best interests" of the infant. This standard draws on the standard of "substituted judgment" that is often applied to incapacitated, but once competent, patients. In such cases, a proxy attempts to make treatment decisions, as she or he

believes the patient would, if able. For newborns, the commission recommended that decision makers attempt to assess the best interests of the infant "by reference to more objective, societally shared criteria." In sum, the commission recommended that decision makers "choose a course that will promote the patient's well-being as it would be conceived by a reasonable person in the patient's circumstances" (U.S. President's Commission, pp. 135–136). Numerous courts have since adopted the "best interests" standard in making infant treatment decisions, and it has become the prevalent standard.

Ascertaining the infant's best interests generally falls to the primary caregivers—in most cases, the parents, who, although assisted by numerous directors, nurses, and social workers, must make and bear the brunt of these difficult decisions. Unfortunately, the guidelines available to decision makers from the U.S. President's Commission and subsequent case law are far from concrete. In describing the "best interests" standard, the commission stressed that normal adults must not impose their values or external concerns upon the beleaguered infant. In its guidelines, the commission stated that futile treatment for severely compromised infants with a lifespan of hours or days need not be provided; at the other end of the spectrum, the commission condemned the withholding of treatment for a correctable problem when the infant was afflicted with an unrelated, non-life-threatening disorder, such as Down syndrome (U.S. President's Commission, 1983). For the vast territory in between, however, there is little guidance.

Determining the best interests of a compromised infant using the commission's guidelines presents considerable problems of interpretation (Rhoden, 1985). Some believe that the best interests of the infant require providing maximum treatment in virtually all cases (Smith; Wells; Wells, Alldridge, and Morgan). Under this construction, infants express their interest in surviving by responding positively to treatment (Cooper). Others believe that nontreatment may be justified when the infant's life can be viewed as an injury rather than as a gift to the infant; an *injury* is inferred when there is no prospect of meaningful life, which might occur because: life expectancy is very short, there are severe mental deficits, or no curative or corrective treatments are available (Weir).

Some argue that the rational interests of the infant in treatment or nontreatment should not be limited to avoiding suffering (including the pain of treatment) and to minimizing physical and mental deficits, but should also include factors such as the burden on the family and society (Wells, Alldridge, and Morgan; Smith). Such a view holds that when an infant's condition lacks any "truly human qualities" or "relational potential," the best decision is not to treat (Smith, p. 56). One can presume that an infant has an interest in his or her "standing and memory within the family" (Mitchell, p. 341). If so, the infant's best interests cannot be determined in isolation from the feelings and concerns of others. Although such "quality of life" considerations are given short shrift under the current federal law and under the U.S. President's Commission's best-interests standard, they are an inevitable subtext to the debate (Rhoden).

Parents' Interests

U.S. jurisprudence still strongly favors parents as decision makers for children's medical care, although it does not accord constitutional status to this preference (*Cruzan v. Director, Missouri Department of Health,* 1990). Though some dispute the basis for a parental preference—asking whether it is for the parents' sake, the children's, or society's (Schneider)—the law is willing to assume that parents, with physicians' help, generally can best judge the child's interest and will best protect it. Moreover, it seems fair to defer to those who will live intimately with the results of the decisions.

Nevertheless, the wisdom of this presumption is challenged on many fronts, both from within and outside the legal establishment. Parental authority is not absolute, but rather conditional. It is settled law that the state may intervene if necessary, superseding parents' authority by proving them unable or unwilling to safeguard the child's welfare. In the late 1990s and early 2000s, there was increasing willingness to resort to child-endangerment provisions to subvert parental decision making with respect to critically ill infants (*Tabatha R. v. Ronda R.,* 1997; *In re K.I.,* 1999; *In the Matter of D.R.,* 2001). Some scholars have posited that paradoxically greater deference is given to parental authority when an adolescent is involved as compared to when an infant is involved, with parents of compromised infants frequently being referred to child protection authorities for questioning or opposing the recommendations of physicians (Rosato). In extreme cases, parents may be criminally prosecuted for failing to fulfill their responsibility to provide ordinary care (*Lundman v. McKown,* 1995).

Many scholars and practitioners question how well parents are able to judge the needs of a critically ill infant. The task is daunting, because the medical specialists on whom parents depend often cannot predict a child's chances of survival or normality with any certainty at the point when decisions must be made, nor adequately warn of the suffering that treatment may eventually entail (Bouregy). In addition, parents come to the task exhausted by childbirth and the child's medical crisis, grief-stricken, and in near shock (Jellinek et al.). Physicians do not always share essential information with parents, and parents often absorb

poorly the limited information they receive (Perlman et al.). Even observers who find parents the best possible decision makers speak of their vulnerability during the crisis, especially to manipulation by physicians and others (Rushton and Glover).

On the other hand, parents may wholly reject medical guidance. Parents have sought to prevent necessary medical treatment of their infants despite entreaties of medical professionals (*In the Matter of D.R.,* 2001; *HCA, Inc. v. Miller,* 2000). Conversely, parents have fought to continue extraordinary medical intervention for infants and children, despite physicians considering such treatment virtually futile in terms of ultimate survival (*In the Matter of Baby "K",* 1994; *Rideout v. Hershey Medical Center,* 1995; *In re K.I.,* 1999). Several have protested the removal of a *legally* dead infant from life support, insisting on continued treatment (*In the Matter of Long Island Jewish Medical Center,* 1996). In other cases, parents have commandeered treatment; in one notorious incident, a father, Rudy Linares, disconnected his infant son's respirator and held off nurses at gunpoint until the boy died (Gostin).

A second criticism of giving parents authority is that they may deliberately elect not to satisfy an infant's dire needs. In this view, it is naive to posit an identity of interest between infant and parent. Parents guard their own interests, those of the family as a unit, and those of current and future siblings—all of which may be gravely threatened by the sick newborn. Some observers of such behavior describe it neutrally. To a sociobiologist, "individual infants may attempt to extract greater investment from their parents than the parents have been selected to give," causing parents to reduce their investment in the child (Hrdy, p. 410). A philosopher writing on the subject actively encouraged parents to weigh the child's interests, including life itself, against others' needs: "The neonate is not born into the family circle so much as outside it, awaiting inclusion or exclusion. The moral problem the parents must confront is whether the child should become a part of the family unit" (Blustein, p. 166). But other commentators condemn any deviation on the part of parents from pursuit of the child's interest. Among these were the proponents of the Baby Doe regulations and, later, a majority of the U.S. Supreme Court, which noted that family members "may have a strong feeling—a feeling not at all ignoble or unworthy, but not entirely disinterested either—that they do not wish to witness the continuation of the life of a loved one which they regard as hopeless, meaningless, and even degrading" (*Cruzan v. Director, Missouri Department of Health,* p. 286). Echoing this view, in a case from 2000 (*HCA, Inc. v. Miller*), a couple sued their healthcare providers for having resuscitated their prematurely born infant, against the parents express wishes, when all agreed that the infant would be severely impaired if she survived.

Practitioners—doctors, lawyers, and social workers—observe parents acting from mixed motives in accepting or rejecting medical care. By forgoing treatment, they may hope to spare the infant suffering and lessen their own, avoid financial and other burdens on the family, and/or prevent the child's eventual institutionalization (Newman). They may instinctively fear the damage to parent-child relations created by medicine's lifesaving technology (Boyce; Kratochvil, Robertson, and Kyle).

Not infrequently, the parents' religious beliefs discourage medical intervention. When the infant is in peril and medical attention will ameliorate or cure the illness or disability, there is an increasing tendency to seek a court order to terminate parental rights to further the best interests of the child. In a case from 2001 (*In the Matter of D.R.*), the parents were followers of the Church of Truth, which rejects medical treatment of all illnesses in favor of spiritual healing. Their infant was beset with developmental delays and numerous disabilities, including a severe seizure disorder. Unmedicated, the seizure disorder was likely to cause additional neurological injury to the infant, worsening her already poor prognosis. At the insistence of the paternal grandparents, the child came to the attention of physicians and child protection authorities. The parents steadfastly refused to comply with the infant's medication regimen, and ultimately the court deemed the child deprived and neglected, awarding custody to the paternal grandparents. The court professed respect for the parents' religious preferences and their right to raise their child in concert with those preferences but was bound to take action to preserve the child's health and welfare. The court noted that the statutory requirements for deeming the infant *deprived* had little to do with the parents' religious beliefs, but rather turned on the child's need of special medical care and the parents' willful failure to provide such care.

This increasingly protective posture toward the infant is evident even before birth. In the case of a pregnant Jehovah's Witness with a dangerously low blood count, a court asserted custody over the thirty-four-week-old fetus and mandated blood transfusion against the mother's will to safeguard the fetus. An appeals court subsequently held that the unconsented-to blood transfusion was an invasive medical procedure and a violation of the mother's rights to bodily integrity (*In re Fetus Brown,* 1997). This case demonstrates the willingness of the courts to favor the alleged best interests of the child, or even fetus, over the well-enunciated religious beliefs of the parent.

Parents also may insist on extraordinary measures in an attempt to be faithful to their understanding of their religion's tenets, as well as to assuage perceived guilt; or to please the other parent, friends, and family; or from selfless devotion to the child that the parent cannot reconcile with consenting to death (Nelson and Nelson). In such cases, ultimately, the best interests of the child are likely to be valued above the parents' beliefs and needs. Before a decision is made to cease extraordinary life-support measures in opposition to the parents' wishes, however, the parents must be afforded appropriate due process to argue for continuation of therapy (*Rideout v. Hershey Medical Center,* 1995). Although parental rights are not absolute, they are a formidable factor in medical decision making for infants and children and remain so even if the parents are not *model parents* (*Tabatha R. v. Ronda R.,* 1997).

The law is relatively clear in its expectation of parents, though the mandate may be excruciatingly difficult to follow. Federal and state constitutions, as well as statutory and decisional law, accord equal status to all living human beings. Parents must act in their child's interest, weighing the immediate physical and long-term emotional suffering for the infant to be expected from aggressive treatment against the consequences of no or lesser treatment. Thus, while some object to consideration of the infant's quality of life in these decisions, such factoring is central to the parents' legal duty.

Healthcare Providers' Interests

Historically, treatment decisions rested with the midwife or physician caring for the newborn and its mother. Although parents ostensibly *owned* their children, they routinely ceded control to the healthcare provider. During the twentieth century, the decision-making model shifted to one in which the parent and the provider jointly decided on medical intervention for the infant. In recent decades, the parents' role has markedly increased as a result of a greater number of treatment options, increased parental knowledge and awareness, and greater respect for patient autonomy (Cooper).

Organized medicine has not opposed this development. A 1975 AAP survey indicated broad support among pediatricians for the proposition that infant treatment decisions should be made jointly by the parents and physician, with the parents taking the pivotal role. In a 1990 report, the Society of Critical Care Medicine's Task Force on Ethics recommended that parents set priorities for the treatment of critically ill pediatric patients. The American Medical Association also defers to parents but emphasizes use of the best-interests standard proposed by the U.S. President's Commission.

Physicians readily acknowledge the frequent conflicts between their dual commitment to save lives and to alleviate suffering. In reality, these factors are rarely the only ones that affect the physician treating a critically ill infant. Healthcare providers may have varying philosophies with respect to treatment of infants afflicted with certain disabilities; they may also be influenced by their research agendas, possess insufficient knowledge to assess accurately the infant's disability and prognosis, or be influenced by real or perceived risk of legal liability (Rushton and Glover; Rosato). In addition, physicians focus on the diagnosis rather than on the prognosis and long-term care of their infant patients (Perlman et al.). As a result of all these factors, physicians may not be optimally effective partners for the parents in the decision-making process. For example, an obstetrician may act in a paternalistic fashion toward a patient, a mother, seeking to protect her from the tragedy of dealing with the fate of an impaired infant. Alternatively, a neonatologist may be overly optimistic in judging and discussing with the parents the infant's potential for meaningful life (Cooper).

Frequently, nurses serve as the primary information conduit between doctors and parents, and naturally there are biases inherent in their perspective, too. Because they are the healthcare providers who care for patients most intimately, they may personalize severely disabled infants beyond reality in order to deal with the burden of nursing them on a day-to-day basis. As a result, nurses may be incapable of advocating against treatment when it is futile and thus be unable to serve as effective advocates for either the infant or the family. In addition, they are limited by the practical realities of their role in the employment hierarchy of the hospital (Mitchell).

In some cases, healthcare facilities and providers may overtreat a severely compromised infant to avoid legal liability. The Linares case, while an extreme example, arose from tensions that are often present. The healthcare providers in that case, despite their acknowledged sympathy and agreement with the father's desire for his son's death, insisted for many months on treating the infant. They did so, they said later, because they believed that state law required continued life support. Critics alleged that individual healthcare providers and the facility (through its lawyer) had abandoned the best interests of both the child and the family to protect themselves. Indeed, some see an "overwhelming fear of possible, indeed theoretical, adverse legal repercussions" among healthcare providers (Nelson and Cranford, p. 3210). This fear is not unfounded; as mentioned earlier, in the 2000 *HCA, Inc. v. Miller* case, healthcare providers were sued, albeit unsuccessfully, for wrongful resuscitation of a severely premature infant. On the other side of the treatment coin, the 1994 Baby "K" case, in which healthcare providers were forbidden to refuse to provide

treatment they considered futile, also speaks to the risk of legal reprisal. There is no safe harbor that ensures freedom from liability for healthcare providers in these difficult, emotionally charged situations.

Society's Interests

A society such as that of the United States has numerous, sometimes contradictory, interests in the healthcare of infants. These include preservation of the life and health of the next generation; the guarantee of the rights of individuals; the support of families; the conservation and wise expenditure of economic resources; the maintenance of a just and predictable legal system; and the compromise between—or at least the orderly expression of—clashing values of groups within society. Two of these issues, cost and the social effect of litigating treatment decisions, are discussed below.

Concern for the cost of neonatal intensive care—the most expensive element in the care of infants—preceded the currently intense focus on health costs in general. This treatment is the exception to the rule that the United States directs resources disproportionately to adults, especially the elderly. Technological advances in the treatment of newborns halved the neonatal death rate between 1970 and 1980 (U.S. President's Commission, 1983). Since then, the extraordinary cost of the technology has helped to focus attention on how many and which infants should be treated.

Many families cannot cover the cost, and there is debate over whether the resources available for a particular infant should be taken into account by decision makers. Most commentators share the view expressed in a seminal article from 1975 on the subject: "Just as a parent is not obligated to attempt to save a drowning child if the parent cannot swim, neither is he obligated to incur enormous expense in providing treatment with a slight chance of success" (Robertson, p. 236; see also Newman). No judicial decision, however, accepts the proposition that personal resources should dictate life or death. Usually, the issue is avoided in litigation. When it is specifically cited, a typical court reply is that the "cost of care in human or financial terms is irrelevant" (*In re Care and Protection of Beth,* p. 1383).

Whether or not cost should affect decisions on treatment, there is evidence that it does. Although providers may not abandon a patient without incurring liability, a study comparing medical need to the services sick newborns receive indicates that healthcare providers do not allocate services solely according to need, but are instead influenced by the newborn's insurance coverage—private, governmental, or none (Braveman et al.). Governmental insurance is less attractive to providers than private insurance because government does not reimburse the full cost of care. Thus, at times it appears that while society insists on extending the life of premature and seriously ill infants, it simultaneously refuses to absorb the cost of their immediate and long-term care—a result described as "political hypocrisy in its cruelest form" (Holder, p. 113).

A second salient issue for society is whether it has erred by assigning this category of treatment decisions increasingly to the courts. Criticism of the failure to treat Baby Doe was widespread and severe, but the legal processes that ensued were also criticized. Numerous objections are raised to the removal of medical decisions from the private sphere. The judicial system may be too cumbersome and costly and may further traumatize family members and invade their privacy. The publicity surrounding infant-care cases may prevent other parents from exercising their right to forgo treatment. In addition, the practice of medicine is negatively affected. Explicit direction from some courts to extend life whenever possible and the implicit threat of litigation reinforce U.S. medicine's alleged tendency to overtreat (Newman). For example, one in three neonatologists state that the Baby Doe regulations require treatment *not* in an infant's best interest (Fost). Finally, in investigating and deciding these cases, judges and other officials must choose among competing moral and religious philosophies, a problematic choice in a society that values diversity (Newman).

Obviously, the law is disadvantaged in attempting to supervise medical care for particular infants. In most jurisdictions, understanding of the legal requirements for forgoing treatment is imperfect, even among lawyers (Gostin). The scarcity of prosecutions and precedents suggests a high degree of social ambivalence on this subject—leading, according to Carl Schneider, to "a troubling disjunction between the law on the books, which seems to make neonatal euthanasia criminal, and the law in action, which does not punish it" (p. 152). Schneider further contends that there is no social consensus on the central questions: What is human life? When is death preferable to life? What do parents owe their children? What does society owe the suffering? As a result, he and others see a tendency to abandon the search for substantive principles in the law and instead adopt procedures for reviewing individual cases (Schneider).

One such procedure is the assignment of a role in decision making to institutional ethics committees. Virtually unknown before 1983 (fewer than 1 percent of U.S. hospitals had such committees at that time), they came to prominence through two avenues. First, the influential U.S. President's Commission report in 1983 recommended their use; second, the establishment of committees became a major point of compromise in negotiations between the

government and healthcare providers over the Baby Doe regulations (Lawton, Carder, and Weisman). By 1986 the AAP, which had strongly endorsed the committees, found them in 60 percent of hospitals.

In some instances, the committees have functioned as it was hoped they would. For example, in the case of Baby "L," a physician applied to the hospital's ethics committee for permission to cease extraordinary treatment of an infant who was capable only of pain perception and to transfer the infant to another facility and provider. The parent opposed this action and sought an opinion from the courts. The court upheld the decision of the hospital and the physician and allowed the transfer of the child to a facility willing to continue treatment (Paris, Crone, and Reardon). In other cases, however, a hospital's ethics committee failed to persuade either the parent or the trial court that treatment was futile (*In the Matter of Baby "K",* 1994; *Rideout v. Hershey Medical Center,* 1995). Although concerns are expressed about the committees' role, makeup, criteria for decision making, influence, results, and effectiveness, ethics committees appear entrenched as a visible, albeit not dispositive, representative of society in controversies over care for infants.

Long-standing respect for the discretion of parents and healthcare providers in making infant treatment decisions appears to be gradually giving way to greater emphasis on the rights of the infant. Debate is ongoing as to whether this emphasis has been overaccentuated, to the detriment of parents and critically ill infants alike. Parents and healthcare providers continue to look to the courts and society at large for guidance, finding precious little consensus.

INFORMATION DISCLOSURE, ETHICAL ISSUES OF

• • •

Since 1970, ethically recommended healthcare practice in the United States has increasingly supported a high level of information disclosure to patients. This article reviews the change, notes some reasons for it, and explores several concerns about disclosure and its implications for particular information types.

Philosophical Background of Current Opinion

Generally, philosophical discussion has supported veracity as a moral principle, obligation, or virtue. Veracity draws its strength from the complex support it provides to diverse values—respecting others, avoiding coercion and manipulation, supporting community, maintaining reciprocity in relationships, supporting the value of communication generally, eliminating the costs and complexities of deception, refraining from unduly assuming responsibility, and maintaining trust.

Philosophers have generally treated veracity as an obligation flowing from more fundamental theoretical principles, such as utility, religious duty, respect for persons, or

some combination of beneficence, fidelity, and autonomy. John Stuart Mill, for instance, regarded truth-telling as justified by utilitarian considerations, and W. D. Ross included honesty among the duties of fidelity. A few have given it more basic status. Some theologians, such as Dietrich Bonhoeffer, have set truth telling in the context of greater religious truths and treated false doctrines as forms of deception. Aristotle described falsehood as "in itself mean and culpable" (Bok, p. 24); G. J. Warnock listed veracity as a major virtue with the same status as beneficence and justice. Immanuel Kant and Augustine are notable for having defended truth-telling most strongly. In a brief article, Kant argued that it would be wrong to lie even to a murderer seeking the hiding place of an intended victim.

However, not all theorists have defended veracity; Henry Sidgwick denied that it could stand as a "definite moral axiom" because of its variable applications and numerous exceptions (Bok, p. 293). David Nyberg argued that trusting relationships among people normally require "the adroit management of deception" (Nyberg, p. 24). Moreover, most philosophers have defended deception in at least some cases. Plato defended lying to the public for the sake of society as a whole, and many philosophers have warranted deception when truthfulness might result in serious harm (Bok).

Application to Healthcare

Until the late twentieth century, philosophers often regarded a physician's withholding a fatal diagnosis from a patient as a stock exception to general precepts of veracity. Philosophers and physicians regarded the distress expected from such news as sufficiently harmful to outweigh the presumption favoring disclosure. Withholding a fatal diagnosis functioned as a paradigm for sharing other medical information with patients. The ethical tradition concerning the doctor-patient relationship thus tended, with some notable exceptions such as Worthington Hooker and Richard Cabot, to emphasize the obligations of confidentiality and to ignore and even deprecate disclosure (Radovsky). Oaths and codes omitted truth telling, and precepts and discussions of talking with patients tended to recommend caution in revealing information. Ethicists perceived the doctor-patient relationship as oriented to therapy, reassurance, and avoiding harm; physicians were to provide lies and truth instrumentally only insofar as they aided therapy.

Since the 1960s, opinion on the role of disclosure in healthcare has changed rapidly in the United States. The patients' rights movement and the rise of bioethics have created a climate of opinion supporting honest disclosure of medical information. The affirmation in 1972 of "A Patient's Bill of Rights" by the Board of Trustees of the American Hospital Association notably marked this shift in opinion. The bill stated, "The patient has the right to obtain from his physician complete current information concerning his diagnosis, treatment, and prognosis in terms the patient can be reasonably expected to understand" (Lee and Jacobs, p. 41).

These changes in opinion developed in concert with the spread of informed consent as standard practice in research and therapy. Informed consent derived from a view of respect for persons that emphasized an individual's power to make decisions adequately. This view required honest disclosure. Thus, most ethicists in the 1970s and 1980s supported fuller disclosure as a means of respecting patient autonomy (Katz).

The patients' rights movement favored empowering patients and increasing their control over medical care. As Howard Waitzkin argued in his observations of physicians' communications with patients, the traditional pattern of withholding information reflected a habit of dominating patients and keeping the course of therapy firmly under professional control (Waitzkin). Reformers saw a wider patient understanding of care as supporting a less paternalistic and more contractual relationship, as well as empowering particular classes of patients, such as women and people of color. Susan Sherwin, for example, identified one of the main tasks of feminist healthcare ethics as being to increase equity "by distributing the specialized knowledge on health matters in ways that allow persons maximum control over their own health" (Sherwin, p. 93).

The codes of ethics of the health professions began to reflect this important shift in opinion. The American Nurses' Association's Code for Nurses linked disclosure with truth-telling and self-determination: "Clients have the moral right … to be given accurate information, and all the information necessary for making informed judgments." The code counseled nurses to avoid "claims that are false, fraudulent, misleading, deceptive, or unfair" in their relations with the public (American Nurses' Association, p. 2). The 1980 revision of the American Medical Association's "Principles of Medical Ethics" included the principle, "A physician shall deal honestly with patients and colleagues, and strive to expose those physicians deficient in character or competence, or who engage in fraud or deception" (Council on Ethical and Judicial Affairs, p. ix). The American College of Physicians' (ACP) Ethics Manual recommended that patients be "well informed to make health care decisions and work intelligently in partnership with the physician." The manual advised that communication can "dispel uncertainty and fear and enhance healing and patient satisfaction." In

general, the ACP held, "disclosure to patients is a fundamental ethical requirement" (p. 950). Subspecialty ethics codes—such as those of the American Academy of Orthopaedic Surgeons, the World Psychiatric Association, and the American College of Obstetricians and Gynecologists—also began to include recommendations supporting veracity.

Changing Contexts for Veracity in Healthcare

While a high level of disclosure became the recommended practice, cross-currents of thought emerged regarding the motivations for informing patients. First, observers discussed the psychological benefits and risks of giving patients bad news. Second, the increasingly institutional setting of healthcare practice influenced patterns of disclosure. Third, discussion distinguished the obligation to disclose information from the obligation to refrain from lying. Fourth, the uncertainty of medicine modulated the obligation to disclose. Finally, an increasing philosophical emphasis on relational aspects of practitioner-patient ethics broadened the foundations for veracity beyond the single element of respect for autonomy.

HEALTHY DISCLOSURE. Medical works prior to the 1970s tended to assume that revealing a fatal diagnosis would cause patients to experience painful emotions, commit suicide, refuse needed care, or give up hope and die more swiftly. In her important work *Lying: Moral Choice in Public and Private Life,* Sissela Bok argued that traditionalists exaggerated such problems. Patients generally want to be informed, and the benefits to a well-informed and cooperating patient outweigh the risks of disclosure (Bok). Others supplied case histories illustrating the emotional perils of withholding a terminal diagnosis from vulnerable and trusting patients (Dunbar; Sherwin).

Elisabeth Kübler-Ross provided crucial support for the psychological benefits of disclosure by her research on the emotional processes of coming to terms with expected death. In extensive interviews with dying cancer patients, she observed that patients' initial negativity was normally followed by a staged sequence of feelings resolving in acceptance with hope. She regarded disclosure as part of the healthy process of maintaining ongoing communication with dying patients, and her stage theory permitted clinicians to engage in a therapeutic process around disclosure of a fatal diagnosis. The hospice movement accepted this perspective as key to humane care of the dying. Kübler-Ross nevertheless strongly opposed disclosing detailed predictions of life expectancy.

Patients' powerful emotional reactions and personal transformations during grave illnesses involve caregivers in intimate, significant connections with patients. The belief that knowledge of death is healthy has changed the image of the clinician from that of maintaining a cool distance to one of performing emotional work with patients (Hochschild). Ethicists often suggested that health professionals who withheld information from patients reflected several concerns: denial of their own and the patient's fear of dying, unconscious wishes to foster dependency in their clients, concern that discussing death constituted admitting failure, and manipulation of hope to encourage more extensive treatment choices.

Some commentators have challenged the positive emotional benefits of discussing death. Ernest Becker argued that the fear of death is too powerfully terrifying to permit most people to accept it (Becker). Some studies have found at least a few patients showing regret over being informed (Temmerman). Others have criticized the cold delivery of information, the image of the physician "bearing down" on the patient with bad news (Byrne). But in most of the literature, the question has become not whether to tell but how to tell; sharing bad news involves timing and a commitment to continuing empathy, compassion, reassurance, and conversation (Buckman and Kason; Kessel; Kübler-Ross; Radovsky).

THE INSTITUTIONAL CONTEXT. Expanding healthcare delivery organizations and complex technologies have multiplied the number of personnel providing patient care. These changes have magnified the obstacles to easily orchestrated and effective deception; a physician must not only deceive the patient and family but also involve dozens of other staff in the process. Institutional growth has also increased the need for accurate recordkeeping to cope with the expanding quantity of information.

Although information flow to patients has traditionally been the responsibility of physicians, other healthcare team members spend more time with patients, have the knowledge and opportunity to disclose information to patients and their families, and belong to professions assuming responsibility for educating patients. Coordinating communication has become an organizational challenge as hospital staffing has become more efficient, patient acuity greater, and lengths of stay shorter (Zussman). Who should talk with the patient when the physician is absent poses ethical questions for staff members, who may feel reluctant to provide information without explicit delegation even though disclosure may be timely for the patient. Nurses experience ethical conflicts when physicians order them to withhold information to which patients are entitled (Chadwick and

Tadd). Staff members may make promises to patients and their families about disclosure, promises that other staff members cannot keep.

Legally, the information in the hospital record belongs to the patient (Annas), but patients are not employees, and so patients' rights are hard to define procedurally. Patients' responsibility to provide honest disclosure to healthcare staff similarly lacks explicit definition. Thus, although large healthcare institutions have fostered a need for improved communication with patients and made systematic deception difficult, smoothing the flow of appropriate information to patients presents a daunting institutional task.

DISCLOSURE AND DECEPTION. The principle of veracity suffers ambiguity; it may simply prohibit lying and deception, or it may express a broader obligation to disclose information. Ethicists have tended to deploy arguments against lying and deception to support a high level of disclosure in healthcare, because lying and deception have often accompanied withholding information in maintaining illusory hopes. But, one can avoid lies and deception and yet disclose scant information. Since the obligation of full disclosure is role-dependent, supporting it involves considerations beyond criticizing deception. Arguments for full disclosure require normative arguments concerning appropriate relationships of healthcare professionals and institutions to patients in their service.

In healthcare, the principle of full disclosure stands in a reciprocal relationship to the obligation to keep confidentiality. Clinicians often have an obligation to disclose information to the patient, and at the same time, keep the same information from others. Moral judgment requires appreciating the range of application of both principles, that is, knowing which information should be disclosed or withheld in what circumstances (Jonsen and Toulmin). The more formal arguments justifying disclosure parallel the arguments for informed consent by appealing to autonomy, but broader notions of serving patient psychological good and building relationships provide less clear guidance as to the full extent of disclosure. Although favoring disclosure of a fatal diagnosis, as the worst possible news, has tended to encourage wide disclosure of less frightening information, it is still unclear what patients should or should not be told about hospital procedures, student participation in procedures, financial information, names of manufacturers, opinions on the skills of clinicians, personal information about practitioners, mistakes, and so on.

DOUBTS AND UNCERTAINTIES. The phrase "information disclosure" connotes a level of certainty absent from many diagnoses, prognoses, and therapeutic options. Do guesses and projections *belong* to the patient as much as the contents of the case record? Kathryn Taylor observed that physicians diagnosing cancer often exaggerate their uncertainty in order to soften the blow of a diagnosis or suppress it in order to hide feelings of doubt (Taylor). Physicians diagnosing symptoms often consider unlikely possibilities, which would frighten patients if shared unnecessarily with them. Nurses may discover or obtain information about which they are uncertain or lack authority to know and wonder whether or not to share it with patients.

Prevailing uncertainty has motivated some physicians to argue that the truth is so uncertain and variable that veracity is irrelevant to patient care. They argue that prospects and options can be framed in so many ways that clinicians inevitably control patient decisions. Even in the relatively well-studied area of informed consent, what to tell about unlikely dangers remains a contested area. Although some physicians have chosen to limit disclosure on the grounds of uncertainty, David Hilfiker characterized giving false reassurances and concealing uncertainty as forms of dishonest misrepresentation.

BUILDING RELATIONSHIPS. Although bioethics in the 1970s and 1980s rooted disclosure in autonomous decision making, the practice of disclosure has become so widespread in the United States that it has received support on broader grounds. Feminist ethics began to shift the basis of philosophical discussion from the language of autonomy to the language of caring and community. This trend, by diminishing the use of rights language, might have relaxed the new emphasis on disclosure; however, the trend expanded grounds for it, and a conception of the practitioner-patient relationship developed that sees disclosure as a key element in a good professional-patient relationship, apart from its role in decision making.

Lorraine Code, for instance, noted that there is "no stark dichotomy between interdependence and autonomy" (p. 74). Howard Brody recommended that as part of the ongoing "conversation" between physicians and patients, physicians should "think out loud" (Brody, p. 116) in order to share medical reasoning more fully with patients. Charles Lidz and his colleagues found that patients generally wanted procedures explained to them, not to participate in decision making, but as a sign of respect and to assist in therapy. Annette Baier advocated the necessity of going beyond the contract model and of appreciating disclosure in a context in which power relationships are unequal. Baier emphasized trust in relationships as a priority over decision making. Trust thrives most readily in relationships free of deception and where good mutual communication maintains connections between people.

Specific Concerns in Disclosure

Although terminal diagnoses have served as the paradigm for exploring disclosure, they cover only a portion of the possible concerns involving communication with patients. This section briefly describes a few of the other concerns. Many can arise, such as using placebos; therapeutic privilege; giving patients information about the costs of care; disclosing brain death to the family; lying to an insurance company to obtain coverage for a treatment or diagnostic test; falsifying records to help patients escape war service or school busing; reporting an accidentally discovered serious condition to the patient when the doctor-patient relationship is undefined; offering information to patients concerning futile therapeutic options; deceptively introducing medical students to patients as *doctor*; concealing the histocompatibility (mutual tolerance of tissues or organs to be grafted) of an unwilling potential organ donor; revealing to patients that a caregiver has tested positive for the human immunodeficiency virus (HIV); revealing HIV diagnoses to patients; encouraging patients to disclose HIV diagnoses to sexual partners; communicating psychiatric interpretations to patients; expecting disclosure by patients to health professionals; and disclosing genetic information to patients.

DISEASES LACKING EFFECTIVE TREATMENT. When a diagnostic test can predict a dread and incurable disease—such as Huntington or Alzheimer's disease—some physicians consider the possibility of withholding the diagnosis. An instrumental view of communication tends to support the view that the burden to the patient of knowing outweighs the value of disclosure. This concern arose with regard to Huntington disease when a levodopa test became available in the early 1970s; the concern was renewed when genetic marker tests became available in 1983. Although some critics continued to express reservations, genetic counselors tended to find that disclosure helped both patient and family to make long-range plans. Gwen Terrenoire emphasized that a consensus favoring testing and disclosure resulted from counselors working with organized patient groups involved with Huntington disease (Terrenoire). In 1989, the Huntington Disease Society of America published guidelines for testing for the condition. They recommended counseling patients prior to the screening decision and before disclosing results. They also recommended against screening patients who have conditions that diminish judgment, while thoroughly evaluating them for suicide risk (DeGrazia).

DISCLOSING DIAGNOSTIC TESTS. Hospitals and clinics often screen patients upon admission for a wide range of conditions without informing them of the reasons for testing. Services may standardly screen for HIV, sexually transmitted diseases, or pregnancy without informing the patient. They may also wish to make surreptitious tests when they believe a patient is claiming false symptoms. One case study described a patient as suffering from mysterious bruising, which could most probably be explained by drug abuse; she denied taking drugs and refused to permit a blood test. Physicians considered whether to administer the diagnostic test without informing her of its purpose. The discussants of the case argued that a contractual model of the doctor-patient relationship is inadequate because patients frequently lie to physicians and are poor historians. They suggested also that such tests need not be disclosed since they yield such diverse results; they are often based on guesses; and their interpretation depends on patient histories (Vanderpool and Weiss).

REVEALING MISTAKES TO PATIENTS. Surely, practitioners should tell patients of mistakes pertinent to their welfare or requiring changes in treatment plans. However, the possibility of lawsuits, the fear of losing patient confidence, painful feelings of incompetence, and solidarity between healthcare team members often outweigh patient benefits in frankness regarding errors. Charles Bosk observed that discussion of medical errors tends to be highly ritualized, confined to well-defined hospital subgroups, and used to reaffirm a strong collective sense of competence. Hilfiker, however, in a remarkably frank discussion of his own errors, recommended that patients can be accepting of physician limitations, that maintenance of illusions about competence tends ultimately to undermine trust in physicians, and that hiding mistakes tends to alienate caregivers from the healing process of confessing and handling mistakes. The ACP Ethics Manual also recommends disclosing significant "procedural or judgment errors" (American College of Physicians, p. 950).

PATIENT REFUSAL OF INFORMATION. The bioethics literature has debated the proper handling of patient refusals of information (Ost; Strasser). On the one hand, the literature usually has regarded refusing information as an autonomous choice and therefore has supported it: A caregiver may ethically choose to respect a patient's wish to rely more heavily on the caregiver. Raanan Gillon argued that "forcing" information on a patient is both harmful and disrespectful of autonomy. The issue can also be regarded as a feature of relational style; Edmund Pellegrino noted that "some patients need a more authoritative approach than others" (p. 1735).

On the other hand, autonomy is not the only basis for disclosure; caregivers have some role-dependent duties to

disclose information to the reluctant; and patients have responsibilities as well as rights to use information on their own behalf. Some information may be so surprising and crucial for patients or so necessary for a working partnership that caregivers have an obligation to disclose despite patient protests. Caregivers may feel that a patient's denial is slowing recovery, or that patients may have a duty to act on information, such as that they are HIV-positive, in order to protect others. It is thus doubtful that the question of refusals can be answered generally.

DISCLOSURE TO FAMILY MEMBERS. Kübler-Ross suggested entrusting some information to family members rather than the patient; this has also been the pattern reported in several countries, such as Hungary, Italy, Japan, and China. This approach may result from seeing the patient as "an extension of the family" (Christakis and Fox, p. 1101), respecting the family as a strongly interdependent unit, or wishing others to carry the burden of knowledge. Yoshitomo Takahashi reported that some Japanese practitioners consider talking about death as threatening family relationships and separating the patient from others (Takahashi), and Eric Feldman noted that many Japanese practitioners perceive disclosing terminal diagnoses as "a callous practice" (p. 21). However, supporters of patient autonomy have expressed concern that leaving the patient uninformed is more likely to isolate the patient psychologically (Quill and Townsend). From both perspectives, the main concern appears to be to include the dying patient in the community, but it is difficult to make reliable cross-cultural generalizations because recommended practices, actual practices, and patient attitudes often vary widely within each culture.

Difficult questions balancing disclosure and confidentiality arise in keeping family members appropriately informed along with the patient. The family may be the recipient of disclosure when an unconscious patient is admitted to the hospital; when the patient recovers competency, the pattern of leaving the family in charge may continue or the family may become excluded from communication. Or family members may give clinicians important information about the patient and ask that the patient not be told; however, the ACP Ethics Manual holds that practitioners are "not obliged" to keep such secrets and should "use sensitivity and judgment" in disclosing such information (American College of Physicians, p. 949).

DISCLOSURE IN THE SOCIAL ARENA. Although bioethical discussion has focused primarily on disclosure and honesty at the bedside, similar issues arise in the larger healthcare arena. For instance, a study of advertising in medical journals showed that a high proportion of pharmaceutical advertisements failed to meet U.S. Food and Drug Administration standards for honesty (Wilkes et al.). Many physicians rely on advertisements and pharmaceutical representatives for their information. Consequently, deceiving physicians leads to misinformed patients.

Occupational and public-health physicians face conflicts affecting disclosure. For instance, some clinicians and medical researchers cooperated for many years in industry suppression of information on the carcinogenicity of asbestos (Lilienfeld); other health professionals have been active in political struggles over posting health warnings on cigarette and alcohol labels. In recent years, the U.S. Occupational Safety and Health Administration has expanded workers' rights to know about their exposure to toxic materials in the workplace, although the complexity of state and federal regulations makes application difficult. Pressures arising from fear of litigation, protection of trade secrets, and concern for individual confidentiality create tensions in pursuing public-health goals of improving public health by keeping workers and the public better informed of their exposure (Ashford and Caldart).

Conclusion

Beneath this sketch of disclosure lie a number of ethical concerns of great subtlety and depth. Brief reflection on honesty links veracity primarily to telling others what one believes. But the complex interactions between clinicians and patients require clinicians to consider carefully how patients interpret their words; skill in listening to patients has often been identified as the key element in effective patient teaching. Moreover, health professionals bear serious duties to service and science that require them to examine honestly the limits of their knowledge, the help they can promise, and their insights into the meanings of illness and death. Thus, accepting honest disclosure calls upon professionals to reflect deeply on the relationship of medical science to health, the consequences of individual service to public health, and the impact of healthcare institutions and practices on the public's understanding of health, illness, and death.

INFORMED CONSENT

• • •

I. HISTORY OF INFORMED CONSENT

Informed consent is not an ancient concept with a rich medical tradition. The term *informed consent* first appeared in 1957, and serious discussion of the concept began only around 1972. As the idea of informed consent evolved, discussion of appropriate guidelines moved increasingly from a narrow focus on the physician's or researcher's obligation to disclose information to the quality of a patient's or subject's understanding of information and right to authorize or refuse a biomedical intervention.

Early History of Associated Ideas

Prior to the late 1950s, there was no firm ground in which a commitment to informed consent could take root. This is not to say, however, that there is no relevant history of the physician's or researcher's management of information in the encounter with patients and subjects. The major writings of prominent figures in ancient, medieval, and modern medicine contain a storehouse of information about commitments to disclosure and discussion in medical practice. But it is a disappointing history from the perspective of informed consent. Beginning with the classic text of ancient medicine, the Hippocratic Corpus, the primary focus of medical ethics became the obligation of physicians to provide medical benefits to patients and to protect them from harm. The purpose of medicine as expressed in the Hippocratic oath was to benefit the sick and keep them from harm and injustice. Managing information in interactions with patients was portrayed as a matter of prudence and discretion. The Hippocratic writings did not hint even at obligations of veracity.

Throughout the ancient, medieval, and early modern periods, medical ethics developed predominantly within the profession of medicine. With few exceptions, no serious consideration was given to issues of either consent or self-determination by patients and research subjects. The proper principles, practices, and virtues of truthfulness in disclosure were occasionally discussed, but the perspective was largely one of maximizing medical benefits through the careful management of medical information. The central concern was how to make disclosures without harming patients by revealing their condition too abruptly and starkly. Withholding information and even outright deception were regularly justified as morally appropriate means of avoiding such harm. The emphasis on the principle "First, do no harm" even promoted the idea that a healthcare professional is obligated not to make disclosures because to do so would be to risk a harmful outcome.

Eighteenth and Nineteenth Centuries

Benjamin Rush and John Gregory are sometimes cited for their enlightened views about disclosure and public education in the eighteenth century. However, neither was advocating informed consent; they wanted patients to be sufficiently educated so that they could understand physicians' recommendations and therefore be motivated to comply. They were not even optimistic that patients would form their own opinions and make appropriate medical choices. For example, Rush advised physicians to "yield to [patients]

in matters of little consequence, but maintain an inflexible authority over them in matters that are essential to life" (p. 323). Gregory (1772) was quick to underscore that the physician must be keenly aware of the harm that untimely revelations might cause. There is no assertion of the importance of respecting rights of self-determination for patients or of obtaining consent for any purpose other than a medically good outcome. Gregory and Rush appreciated the value of information and dialogue from the patient's point of view, but the idea of informed consent was not foreshadowed in their writings.

Thomas Percival's historic *Medical Ethics* (1803) continues in this same tradition. It makes no more mention of consent solicitation and respect for decision making by patients than had previous codes and treatises. Percival did, however, struggle with the issue of truth-telling. He held that the patient's right to the truth must yield to the obligation to benefit the patient in cases of conflict, thereby recommending benevolent deception. Percival maintained that

> [T]o a patient … who makes inquiries which, if faithfully answered, might prove fatal to him, it would be a gross and unfeeling wrong to reveal the truth. His right to it is suspended, and even annihilated; because its beneficial nature being reversed, it would be deeply injurious to himself, to his family, and to the public. And he has the strongest claim, from the trust reposed in his physician, as well as from the common principles of humanity, to be guarded against whatever would be detrimental to him …. The only point at issue is, whether the practitioner shall sacrifice that delicate sense of veracity, which is so ornamental to, and indeed forms a characteristic excellence of the virtuous man, to this claim of professional justice and social duty. (pp. 165–166)

Percival was struggling against the arguments of his friend, the Rev. Thomas Gisborne, who opposed practices of giving false assertions intended to raise patients' hopes and lying for the patient's benefit: "The physician … is invariably bound never to represent the uncertainty or danger as less than he actually believes it to be" (Gisborne, p. 401). From Percival's perspective, the physician does not lie or act improperly in beneficent acts of deception and falsehood, as long as the objective is to give hope to the dejected or sick patient.

The American Medical Association (American Medical Association) accepted virtually without modification the Percival paradigm in its 1847 "Code of Medical Ethics." Many of the above passages appear almost verbatim in this code as the AMA position on the obligations of physicians in regard to truth-telling (American Medical Association, 1847). This code and most codes of medical ethics before and since do not include rules of veracity although many codes today do contain rules for obtaining an informed consent. For more than a century thereafter, American and British medical ethics developed under Percival's vision.

There was, however, a notable nineteenth-century exception to the consensus that surrounded Percival's recommendations. Connecticut physician Worthington Hooker was the first champion of the rights of patients to information, in opposition to the model of benevolent deception that had reigned from Hippocrates to the AMA (Hooker). He and Harvard professor of medicine Richard Clarke Cabot were the best known among physicians who championed this model prior to the second half of the twentieth century. Moreover, there may never have been a figure who, in regard to truth-telling, swam so much against the stream of indigenous medical tradition as Hooker.

Hooker's arguments are novel and ingenious but do not amount to a recommendation of informed consent. Hooker was concerned with "the general effect of deception" on society and on medical institutions. He thought the effect disastrous. But in Hooker no more than in the AMA Code is there a recommendation to obtain the permission of patients or to respect autonomy for the sake of autonomy. Hooker's concerns were with expediency in disclosure and truth-telling rather than with the promotion of autonomous decision making or informed consent. The idea that patients should be enabled to understand their situation so that they are able to participate with physicians in decisions about medical treatment was an idea whose time was yet to come.

Although the nineteenth century saw no hint of a rule or practice of informed consent in clinical medicine, consent practices were not entirely absent. Evidence exists in surgery records of consent-seeking practices and rudimentary rules for obtaining consent since at least the middle of the nineteenth century (Pernick). However, the consents thus obtained do not appear to have been meaningful informed consents, because they had little to do with the patient's right to decide after being appropriately informed. Practices of obtaining consent in surgery prior to the 1950s were pragmatic responses to a combination of concerns about medical reputation, malpractice suits, and practicality in medical institutions. It is at best physically difficult and interpersonally awkward to perform surgery on a patient without obtaining the patient's permission. Such practices of obtaining permission, however, do not constitute practices of obtaining informed consent, although they did provide a modest nineteenth-century grounding for this twentieth-century concept.

The situation is similar in research involving human subjects. Little evidence exists that, until recently, requirements of informed consent had a significant hold on the practice of investigators. In the nineteenth century, for example, it was common for research to be conducted on slaves and servants without acquiescence or consent on the part of the subject. By contrast, at the turn of the century, American army surgeon Walter Reed's yellow-fever experiments involved formal procedures for obtaining the consent of potential subjects. Although deficient by contemporary standards of disclosure and consent, these procedures recognized the right of the individual to refuse or authorize participation in the research. The extent to which this principle became ingrained in the ethics of research by the mid-twentieth century is a matter of historical controversy. Although it has often been reported that the obtaining of informed and voluntary consent was essential to the ethics of research and was commonplace in biomedical investigation, it is unclear that consent seeking on the part of investigators was standard practice. Anecdotal evidence suggests that biomedical research often proceeded without adequate consent at least into the 1960s.

Early Twentieth-Century Legal History

The legal history of disclosure obligations and rights of self-determination for patients evolved gradually. It is the nature of legal precedent that each decision, relying on earlier court opinions, joins a chain of authority that incorporates the relevant language and reasoning from the cited cases. In this way, a few early consent cases built on each other to eventuate in a legal doctrine. The best known and ultimately the most influential of these early cases is *Schloendorff* v. *New York Hospital* (1914). *Schloendorff* used rights of *self-determination* to justify imposing an obligation to obtain a patient's consent. Subsequent cases that followed and relied upon *Schloendorff* implicitly adopted its justifactory rationale. In this way, self-determination came to be the primary rationale or justification for legal requirements that consent be obtained from patients.

In the early twentieth century, the behavior of physicians was often egregious, and courts did not shrink from using ringing language and sweeping principles to denounce it. The same language was then applied as precedent in later cases in which physicians' behavior was less outrageous. As the informed-consent doctrine developed and problems grew more subtle, the law could have turned away from the language of self-determination but instead increasingly relied on this rationale as its fundamental premise. The language in the early cases suggests that rights of freedom from bodily invasion contain rights of medical decision making by patients.

The 1950s and 1960s: Law and Medicine

The emerging legal doctrine of informed consent first brought the concept of informed consent to the attention of the medical community. "The doctrine of informed consent" is a legal doctrine; and informed consent has often been treated as synonymous with this legal doctrine. A remarkable series of cases in the second half of the twentieth century brought informed consent to the attention of lawyers and physicians alike.

During the 1950s and 1960s, the traditional duty to obtain consent evolved into a new, explicit duty to disclose certain types of information and then to obtain consent. This development needed a new term; and so *informed* was added onto *consent,* creating the expression *informed consent,* in the landmark decision in *Salgo* v. *Leland Stanford, Jr. University Board of Trustees* (1957). The *Salgo* court suggested, without accompanying analysis, that the duty to disclose the risks and alternatives of treatment was not a new duty but a logical extension of the already established duty to disclose the treatment's nature and consequences. Nonetheless, *Salgo* clearly introduced new elements into the law. The *Salgo* court was not interested merely in whether a recognizable consent had been given to the proposed procedures. Instead, *Salgo* focused strongly on the problem of whether the consent had been adequately informed. The court thus created not only the language but the substance of informed consent by invoking the same right of self-determination that had heretofore applied only to a less robust consent requirement.

Shortly thereafter, two opinions by the Kansas Supreme Court in the case of *Natanson* v. *Kline* (1960) pioneered the use of the legal charge of negligence in informed-consent cases, rather than that of battery. The court established the duty of disclosure as the obligation "to disclose and explain to the patient in language as simple as necessary the nature of the ailment, the nature of the proposed treatment, the probability of success or of alternatives, and perhaps the risks of unfortunate results and unforeseen conditions within the body" (*Natanson* v. *Kline,* 1960). Thus, the *Natanson* court required essentially the same extensive disclosure—of the nature, consequences, risks, and alternatives of a proposed procedure—as had *Salgo.* After *Natanson,* battery and negligence appeared virtually identical in their disclosure requirements for informed consent.

Not surprisingly, the number of articles in the medical literature on issues of consent increased substantially following these and other legal cases. Typically written by lawyers,

these reports functioned to alert physicians both to informed consent as a new legal development and to potential malpractice risk. How physicians reacted to these legal developments in the 1950s and 1960s is not well documented, but a handful of empirical studies of informed consent in clinical medicine provides some insights. A study done in the early to mid-1960s indicates that a preoperative consent form was not yet a ubiquitous feature of the practice of surgery. Surgeons at several hospitals refused to participate in this study precisely because they were not using a consent form for surgery.

This indifference to consent procedures seems to have changed by the late 1960s, when most physicians appear to have come to recognize both a moral and a legal duty to obtain consent for certain procedures and to provide some kind of disclosure. There is also evidence, however, that physicians' views about proper consent practices even in the late 1960s differed markedly from the consensus of opinion and convention today. For example, in one study, half of the physicians surveyed thought it medically proper, and 30 percent ethically proper, for a physician to perform a mastectomy with no authorization from the patient other than her signature on the blanket consent form required for hospital admission; more than half the physicians thought that it was ethically appropriate for a physician not to tell a cancer patient that she had been enrolled in a double-blind clinical trial of an experimental anti-cancer drug.

On the basis of the volume of commentary in the medical literature, many physicians before the 1970s were at least dimly aware of informed consent. Empirical studies conducted at the time suggest that there was at least enough documentable consent seeking in such areas as surgery, organ donation, and angiography to warrant empirical investigation. Also during this period, the procedure-specific consent form was gaining acceptance, although it was not yet universally in use. Whether in the 1960s physicians generally regarded informed consent as a legal nuisance or as an important moral problem is unclear, but an explosion of commentary on informed consent emerged in the medical literature in the early 1970s. Much of this commentary was negative: Physicians saw the demands of informed consent as impossible to fulfill and—at least in some cases—inconsistent with good patient care. In tone the articles ranged from serious critique to caustic parody. Predictions were voiced that fearful patients would refuse needed surgery after disclosure. In much of this literature, only the legal, not the moral dimensions of informed-consent requirements were recognized. This began to change in the 1970s, with the ascendancy of an interdisciplinary approach to medical ethics. Gradually, informed consent became a moral as well as a legal issue.

The 1950s and 1960s: Biomedical Research

The histories of informed consent in research and in clinical medicine have developed largely as separate pieces in a larger mosaic of biomedical ethics, and these pieces have never been well integrated even when they developed side by side. Research ethics prior to World War II was no more influential on research practices than the parallel history of clinical-medicine ethics was on clinical practices. But one event that unquestionably influenced thought about informed consent was the Nuremberg trials. The Nuremberg military tribunals unambiguously condemned the sinister political motivation of Nazi experiments in their review of "crimes against humanity." A list of ten principles constituted the Nuremberg Code. Principle One of the code states, without qualification, that the primary consideration in research is the subject's voluntary consent, which is "absolutely essential" (Germany [Territory Under Allied Occupation], 1947).

The Nuremberg Code served as a model for many professional and governmental codes formulated in the 1950s and 1960s, but several other incidents involving consent violations subsequently moved the discussion of post-Nuremberg problems into the public arena. Thus began a rich and complex interplay of influences on research ethics: scholarly publications, journalism, public outrage, legislation, and case law. In the United States, one of the first incidents to achieve notoriety in research ethics involved a study conducted at the Jewish Chronic Disease Hospital (JCDH) in Brooklyn, New York. In July 1963, Dr. Chester Southam of the Sloan-Kettering Institute for Cancer Research persuaded the hospital's medical director, Emmanuel E. Mandel, to permit research involving injection of a suspension of foreign, live cancer cells into twenty-two patients at the JCDH. The objective was to discover whether a decline in the body's capacity to reject cancer transplants was caused by the cancer or by debilitation. Patients without cancer were needed to supply the answer. Southam had convinced Mandel that although the research was nontherapeutic, such research was routinely done without consent. Some patients were informed orally that they were involved in an experiment, but it was not disclosed that they were being given injections of cancer cells. No written consent was attempted, and some subjects were incompetent to give informed consent. The Board of Regents of the State University of New York later censured Southam and Mandel for their role in the research. They were found guilty of fraud, deceit, and unprofessional conduct (*Hyman v. Jewish Chronic Disease Hospital,* 1964).

Another major controversy about the ethics of research in the United States developed at Willowbrook State School, an institution for "mentally defective" children in Staten Island, New York. Beginning in 1956, Saul Krugman and

his associates began a series of experiments to develop an effective prophylactic agent for infectious hepatitis. They deliberately infected newly admitted patients with isolated strains of the virus based on parental consents obtained under controversial circumstances that may have been manipulative. The issues in the Willowbrook case are more complex than those in the Jewish Chronic Disease Hospital case, and today there are those who still defend, at least in part, the ethics of these experiments. Krugman's research unit was eventually closed, but closure on the debate about the ethics of the studies conducted in the unit was never achieved (New York University).

The most notorious case of prolonged and knowing violation of subjects' rights in the United States was a Public Health Service (PHS) study initiated in the early 1930s. Originally designed as one of the first syphilis-control demonstrations in the United States, the stated purpose of the Tuskegee syphilis study, as it is now called, was to compare the health and longevity of an untreated syphilitic population with a nonsyphilitic but otherwise similar population. These subjects, all African-American males, knew neither the name nor the nature of their disease. That they were participants in a nontherapeutic experiment also went undisclosed. They were informed only that they were receiving free treatment for "bad blood," a term local African-Americans associated with a host of unrelated ailments, but which the white physicians allegedly assumed was a local euphemism for syphilis (Jones).

Perhaps the most remarkable thing about Tuskegee was that, although the study was reviewed several times between 1932 and 1970 by PHS officials and medical societies as well as reported in thirteen articles in prestigious medical and public-health journals, it continued uninterrupted and without serious challenge. It was not until 1972 that the U.S. Department of Health, Education and Welfare (DHEW) appointed an ad hoc advisory panel to review the study and the department's policies and procedures for the protection of human subjects. The panel found that neither DHEW nor any other government agency had a uniform or adequate policy for reviewing experimental procedures or securing subjects' consents.

The 1970s and 1980s

Although the Jewish Chronic Disease Hospital case, the Willowbrook study, and the Tuskegee study had a profound effect on public consciousness with respect to the ethics of research and medicine, these events are insufficient to explain why informed consent became the focus of so much attention in both case law and biomedical ethics between the late 1960s and the late 1980s. Many hypotheses can be invoked to explain this phenomenon. Perhaps the most accurate explanation is that law and ethics, as well as medicine itself, were all affected by issues and concerns in the wider society about individual liberties and social equality, made dramatic by an increasingly technological, powerful, and impersonal medical-care system. It seems likely that increased legal interest in the right of self-determination and increased philosophical interest in the principle of respect for autonomy and individualism were instances of the new rights orientation that various social movements had introduced. The issues raised by civil rights, women's rights, the consumer movement, and the rights of prisoners and the mentally ill often included healthcare components and helped reinforce public acceptance of rights applied to healthcare. Informed consent was swept along with this body of social concerns, which propelled the new bioethics throughout the 1970s.

Three 1972 court decisions are widely recognized as informed consent landmarks: *Canterbury* v. *Spence, Cobbs* v. *Grant,* and *Wilkinson* v. *Vesey. Canterbury* had a massive influence. In its most significant and dramatic finding, the *Canterbury* court moved in the direction of a more patient-oriented standard of disclosure:

> The patient's right of self-decision can be effectively exercised only if the patient possesses enough information to enable an intelligent choice. The patient should make his own determination on treatment. Informed consent is a basic social policy for which exceptions are permitted (1) where the patient is unconscious or otherwise incapable of consenting, and harm from failure to treat is imminent; or (2) when risk-disclosure poses such a serious psychological threat of detriment to the patient as to be medically contraindicated. Social policy does not accept the paternalistic view that the physician may remain silent because divulgence might prompt the patient to forego needed therapy. Rational, informed patients should not be expected to act uniformly, even under similar circumstances, in agreeing to or refusing treatment. (*Canterbury* v. *Spence,* 1972)

As the impact of *Canterbury* filtered down to medical practice, the U.S. National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research began in 1974 what would be a four-year struggle with a variety of concerns about informed consent in research involving human subjects. The commission developed an abstract schema of basic ethical principles for research ethics that gave informed consent a major role (U.S. National Commission, 1978):

Principle of	*applies to*	*Guidelines for*
Respect for Persons		Informed Consent
Beneficence		Risk/Benefit Assessment
Justice		Selection of Subjects

Under this schema, the purpose of consent provisions is not protection from risk, as some earlier federal policies had implied, but rather the protection of autonomy and personal dignity, including the personal dignity of incompetent persons incapable of acting autonomously (for whose involvement a third party must consent). This conclusion develops an explicit philosophical position on informed consent for the first time in a government-sponsored document.

Among the most important publications in the medical literature to appear during this period was a statement by the Judicial Council of the American Medical Association in 1981. For the first time, the AMA recognized informed consent as "a basic social policy" necessary to enable patients to make their own choices even if the physician disagrees. The AMA's statement is a testament to the impact of the law of informed consent on medical ethics: The AMA's position closely followed the language of *Canterbury* v. *Spence* (Judicial Council, 1981).

The U.S. President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research provides further evidence regarding the status informed consent had achieved by the 1980s. The commission was first convened in January 1980, with informed consent as a main item on its agenda. In 1982 it produced a three-volume report that dealt directly with informed consent: *Making Health Care Decisions: The Ethical and Legal Implications of Informed Consent in the Patient-Practitioner Relationship.* The commission argued that although informed consent has emerged primarily from a history in law, its requirements are essentially moral and policy-oriented. It held that informed consent is ultimately based on the principle that competent persons are entitled to make their own decisions from their own values and goals, but that the context of informed consent and any claim of "valid consent" must derive from active, shared decision making. The principle of self-determination was described as the "bedrock" of the commission's viewpoint.

In addition to the efforts of the U.S. President's Commission and the statement of the AMA, the 1980s saw the publication of several books devoted to the subject of informed consent, as well as hundreds of journal articles, and the passage of procedure-specific informed-consent laws and regulations. These events provide powerful testimony of the importance of informed consent in moral and legal thinking about medicine in the United States. By themselves, however, they tell us little about physicians' or researchers' actual consent practices or opinions or about how informed consent was viewed or experienced by patients and subjects.

As might be expected, the empirical evidence on this subject is mixed, although it is clear that procedures of informed consent have taken a firm hold in some parts of medical practice. For example, routine practice encourages the obtaining of signatures on consent forms and the disclosing of information about alternative treatments, risks, and benefits. The best data on this subject are the findings of a national survey conducted for the U.S. President's Commission by Louis Harris and Associates in 1982. Almost all of the physicians surveyed indicated that they obtained written consent from their patients before in-patient surgery or the administration of general anesthesia. At least 85 percent said they usually obtained some kind of consent—written or oral—for minor office surgery, setting of fractures, local anesthesia, invasive diagnostic procedures, and radiation therapy. Only blood tests and prescriptions appear to have proceeded frequently without patient consent, although about half of the physicians reported obtaining oral consent (1982).

The overall impression conveyed by this survey is that the explosion of interest in informed consent in the 1970s had a powerful impact on medical practice. However, evidence from the Harris survey and other sources questions the meaningfulness of the increase in consent-related activity. The overwhelming impression from the empirical literature and from reported clinical experience is that the actual process of soliciting informed consent often falls short of a serious show of respect for the decisional authority of patients. As the authors of one empirical study of physician-patient interactions put it, "despite the doctrine of informed consent, it is the physician, and not the patient, who, in effect, makes the treatment decision" (Siminoff and Fetting, p. 817).

The history of informed consent, then, indicates that medicine has undergone widespread changes under the influence of legal and moral requirements of informed consent, but it also remind us that informed consent is an evolving process, not a set of events whose history has passed.

II. MEANING AND ELEMENTS

Appropriate criteria must be identified to define and classify an act of informed consent properly. If overdemanding criteria such as "full disclosure and complete understanding" are adopted, an informed consent becomes impossible to obtain. Conversely, if underdemanding criteria such as "the patient signed the form" are used, an informed consent becomes too easy to obtain and the term loses all moral significance. Many interactions between a physician and a patient or an investigator and a subject that have been called informed consents have been so labeled only because they rest on underdemanding criteria; they are inappropriately referred to as informed consents. For example, a physician's truthful disclosure to a patient has often been declared the essence of informed consent, as if a patient's silence following disclosure could constitute an informed consent. The existence of such inadequate understandings of informed consent can be explained in part by empirical information about physicians' beliefs about informed consent.

Contemporary Assumptions in Medicine

Data about the relevant beliefs of physicians in the United States were gathered in a 1982 survey of physicians conducted by Louis Harris and Associates. One question of this survey asked physicians, "What does the term informed consent mean to you?" In their answers, only 26 percent of physicians indicated that informed consent has something to do with a patient's giving permission, consenting, or agreeing to treatment. In a related question, only 9 percent

indicated that it involves the patient's making a choice or stating a preference about his or her treatment (Harris and Associates; U.S. President's Commission, 1982). Similar results were found in a survey of Japanese physicians (Hattori et al.).

The majority of these physicians appear to regard disclosure as the primary (and perhaps sole) element of informed consent. That is, they conceive of informed consent as explaining to patients the nature of their medical conditions together with a recommended treatment plan. But if physicians regard informed consent as nothing more than an event of conveying information to patients, rather than a process of discussion with and obtaining permission from the patient, then claims that they regularly "obtain consents" from their patients before initiating medical procedures are both vague and unreliable.

Other polls conducted in the United States indicate that the majority of physicians understand an informed consent to be either a signed consent form or a disclosure. Some also conclude that no evidence exists that informed-consent practices are widespread in clinical medicine and that many agreements by patients that are called informed consents in some clinical settings fall far short of being meaningful informed consents (Lidz and Meisel).

The Elements of Informed Consent

Literature of bioethics often analyzes informed consent in terms of the following elements: (1) disclosure; (2) comprehension; (3) voluntariness; (4) competence; and (5) consent (see U.S. National Commission, 1978, U.S. President's Commission, 1982; Meisel and Roth, 1981). This analysis is sometimes joined with a corresponding thesis that these elements collectively define informed consent. The postulate is that a person gives an informed consent to an intervention if and only if the person receives a thorough disclosure about the procedure, comprehends the disclosed information, acts voluntarily, is competent to act, and consents.

This definition is attractive because of its consistency with standard usage of informed consent in medicine and law. However, medical convention and malpractice law have special orientations that tend to distort the meaning of informed consent in ways that need correction. Analyses that use the five elements listed above, as well as conventional usage in law and medicine, are best suited for cataloguing the analytical parts of informed consent and for delineating moral and legal requirements of informed consent, not for conceptually analyzing the meaning of informed consent. Neither requirements nor parts amounts to a definition.

The U.S. Supreme Court addressed the definition of informed consent in *Planned Parenthood of Central Missouri* v. *Danforth* as follows: "One might well wonder … what 'informed consent' of a patient is.… We are content to accept, as the meaning, the giving of information to the patient as to just what would be done and as to its consequences …" (*Planned Parenthood of Central Missouri* v. *Danforth,* 1976, p. 67). The essential element or part of informed consent, as described here, is disclosure, an analysis that recalls the assumptions made by physicians in the Harris poll (Harris and Associates). However, as we will see, nothing about an informed consent requires disclosure as part of its meaning, and this element does not amount to a definition. Moreover, to make disclosure the sole or even the major condition of informed consent incorporates questionable assumptions about medical authority, physician responsibility, and legal liability. These norms delineate an obligation to make disclosures so that a consent can be informed, rather than a meaning of informed consent. Even all five of the above elements merged as a set do not satisfactorily capture the meaning of informed consent.

Both the elements and the meaning of informed consent, then, need a more comprehensive treatment. The following seven categories express the analytical components of informed consent more adequately than the above five categories—although this sevenfold list does not adequately express the meaning of informed consent either (Beauchamp and Childress):

I. Threshold elements (preconditions)
   1. Competence (to understand and decide)
   2. Voluntariness (in deciding)

II. Information elements
   3. Disclosure (of material information)
   4. Recommendation (of a plan)
   5. Understanding (of terms 3 and 4)

III. Consent elements
   6. Decision (in favor of a plan)
   7. Authorization (of the chosen plan)

The language of material information in (3) is pivotal for an adequate analysis of the elements of disclosure (3) and understanding (5). Critics of legal requirements of informed consent have often held that procedures sometimes have so many risks and benefits that they cannot be disclosed and explained in a reasonable period of time or in an understandable framework. The demands in this misreading of the nature and requirements of informed consent must be pruned, as many courts have pointed out. Material risks are the risks a reasonable patient needs to understand in order to decide among the alternatives; only these risks and benefits need to be disclosed and understood.

Corresponding to each of the above elements, one could construct informed-consent requirements. That is, there could be disclosure requirements, comprehension requirements, noninfluence requirements, competence requirements, authorization requirements, and so forth. These requirements would specify the conditions that must be satisfied for a consent to be valid.

Two Meanings of Informed Consent

Translating the above seven elements directly into a definition or meaning of informed consent invites confusion, because the term *informed consent* has subtleties not captured by these elements. A subtlety that has generated considerable misunderstanding is that two very different meanings of informed consent operate in current literature and social practices.

In the first meaning, an informed consent is an autonomous authorization of a medical intervention or of involvement in research by individual patients or subjects. An autonomous authorization requires more than merely acquiescing in, yielding to, or complying with an arrangement or a proposal made by a physician or investigator. A person gives an informed consent in this first sense if and only if the person, with substantial understanding and in substantial absence of control by others, intentionally authorizes a health professional to do something. A person who intentionally refuses to authorize an intervention but otherwise satisfies these conditions gives an informed refusal. This first sense derives from the philosophical premises that informed consent is fundamentally a matter of protecting and enabling autonomous or self-determining choice by patients and subjects and that final authority for making decisions about medical treatment or research participation properly rests with patients and subjects, not physicians or research scientists.

In the second meaning, informed consent is analyzed in terms of institutional and policy rules of consent. This sense expresses the mainstream conception in the regulatory rules of federal agencies and in healthcare institutions. Here *informed consent* refers only to a legally or institutionally effective approval by a patient or subject. An approval is therefore effective or valid if it conforms to the rules that govern specific institutions, whatever the operative rules may be. In this sense, unlike the first, conditions and requirements of informed consent are relative to a social and institutional context and need not be autonomous authorizations. This meaning is driven by demands in the legal and healthcare systems for a generally applicable and efficient consent mechanism by which responsibilities and violations can be readily and fairly assessed (Faden et al.).

Under these two contrasting understandings of informed consent, a patient or subject can give an informed consent in the first sense, but not in the second sense, and vice versa. For example, if the person consenting is a minor and therefore not of legal age, he or she cannot give an effective or valid consent under the prevailing institutional rules; a consent is invalid even if the minor gives the consent autonomously and responsibly. ("Mature minor" laws do sometimes make an exception and give minors the right to authorize medical treatments in a limited range of circumstances.)

The Relationship between the Two Meanings

Rules governing effective authorization have often not been premised on a carefully delineated conception of autonomous decision making, but current literature in bioethics suggests that any justifiable analysis of informed consent must be rooted in autonomous choice by patients and subjects. An act is increasingly recognized in this literature as an informed consent only if (1) a patient or subject agrees to an intervention based on an understanding of material information; (2) the agreement is not controlled by influences that engineer the outcome; and (3) an authorization for an intervention is given by the patient or subject with the understanding that it is an authorization.

In principle, although less clearly in practice, these conditions of informed consent (in the sense of an individual's autonomous authorization) can function as model standards for fashioning the institutional and policy requirements for effective consent. The model of autonomous choice would then serve as the benchmark against which the moral adequacy of prevailing rules and practices should be evaluated. The postulate that policies governing informed consent in the second sense should be formulated to conform to the standards of informed consent in the first sense is grounded in the premise that the primary goal of informed consent in medical care and in research is to enable potential subjects and patients to make autonomous decisions about whether to grant or refuse authorization for medical and research interventions (Katz).

It does not follow that institutional policies regarding informed consent are justifiable only if they rank the protection of decision making above all other values. Consent requirements imposed by institutions should be formulated and evaluated against a range of social and institutional considerations. The preservation of autonomous choice is the first but not the only consideration. For example, a patient's need for education and counseling in order to achieve a substantial understanding of a medical situation

must be balanced against the interests of other patients and of society in maintaining a productive and efficient healthcare system. Accordingly, institutional policies must consider what is fair and reasonable to require of healthcare professionals and researchers and what the effect would be of alternative consent requirements on efficiency and effectiveness in the delivery of healthcare and the advancement of science.

III. CONSENT ISSUES IN HUMAN RESEARCH

"The voluntary consent of the human subject is absolutely essential." This, the first sentence of the Nuremberg Code,

signals the centrality of the consent requirement in research involving human subjects (Germany [Territory under Allied Occupation], p. 181). Before the Nuremberg Code was written in 1947 as a response to the atrocities committed in the name of science by Nazi physician-researchers, statements of medical and other professional organizations apparently made no mention of the necessity of consent. Ironically, the only nations known to have promulgated regulations that established a requirement for consent to research were Prussia and Germany (Perley et al.). Subsequently, the tendency to focus on informed consent has been reinforced by public outcry over the inadequacy of consent in certain landmark cases in the United States, such as the Willowbrook Studies (1963–1966), Jewish Chronic Disease Hospital Study (1963), Tea Room Trade Study (1970), and Tuskegee Syphilis Study (1932–1972) (Katz, Capron, and Swift; Levine). Indeed, the issue of informed consent has so dominated recent discussion of the ethics of research that one might be led to think erroneously that other ethical issues (e.g., research design, selection of subjects) are either less important or more satisfactorily resolved.

This entry is concerned with the conceptual aspects of informed consent. For an extensive review of empirical studies of informed consent, see the 1999 article written by Jeremy Sugarman and Douglas C. McCrory.

Grounding of Informed Consent

The requirement for informed consent has philosophical, religious, and legal foundations.

PHILOSOPHICAL BASIS. The philosophical foundations of the requirement for informed consent may be found in several lines of reasoning (Veatch 1981; Faden, Beauchamp, and King; Brock 1987). Based on the Hippocratic admonition "to help, or at least, to do no harm," one can justify seeking consent for the benefit of the patient; to do so provides a mechanism for ascertaining what the patient would consider a benefit. Allowing individuals to decide what they consider beneficial is consistent with the perspective affirmed in U.S. public policy that competent persons are generally the best protectors of their own well-being (Brock 1987). A focus solely on patient benefit, however, would allow physicians and scientists not to seek consent when they judge that doing so might harm patients or subjects. Thus this justification alone does not suffice to establish a requirement to seek consent.

The requirement can also be justified on grounds of social benefit: The practice of seeking consent may contribute to producing the "greatest good for the greatest number" by forestalling suspicion about research, thus ensuring a subject population and increasing the efficiency of the research enterprise. Again, however, the justification fails to stand alone, because it can also be used to justify not seeking consent; the social good might be better served by avoiding the inefficient and frequently time-consuming consent process. Some commentators express concern that, carried to its extreme, the social-benefit argument might support the use of unwilling subjects, as in Nazi Germany; such a position would necessarily rest on a very limited vision of the relevant social consequences.

The firmest grounding for the requirement to seek consent is the ethical principle *respect for persons,* which according to the U.S. National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research (hereafter, U.S. National Commission) "incorporates at least two basic ethical convictions: first, that individuals should be treated as autonomous agents, and second, that persons with diminished autonomy and thus in need of protection are entitled to such protection" (U.S. National Commission, p. 4). Although this term suggests a Kantian or deontological (a foundational ethical principle holding that the moral rightness of an action resides in the action itself without regard to its consequences) grounding of the principle, this was not the intent of the commission; a substantially similar principle, self-determination, may be grounded in rule utilitarianism deontological (a foundational ethical principle holding that the moral rightness of an action must be evaluated in terms of its consequences) (Brock, 1987). In a legal context, American jurist Benjamin Cardozo stated in 1914 that "every human being of adult years and sound mind has a right to determine what shall be done with his own body" (Katz, p. 51). To return to the Kantian approach that will be used often in this entry, this principle of respect for persons, autonomy or self-determination ensures that the research subject will be treated as an end and not merely as a means to another's end (Beauchamp and Childress). Thus the purpose of the consent requirement is not only to minimize risk but also to give persons the right to choose.

RELIGIOUS BASIS. Several fundamental tenets of the Judeo-Christian and other traditions also provide grounding for the requirement to seek consent. This tradition affirms that each human life is a gift from God and is of infinite and immeasurable worth (the "sanctity of life"). The infinite worth of the individual requires that persons treat each other with respect and not interfere in each other's lives without consent. The consent requirement can also be grounded explicitly in the notion of covenant. Seeking consent is an affirmation of the basic faithfulness or care required by the fundamental covenantal nature of human existence (Ramsey, 1970).

LEGAL BASIS. The legal grounding for the requirement for consent to research (Annas, Glantz, and Katz) is based on the outcome of litigation of disputes arising almost exclusively in the context of medical practice. There is virtually no case law on which to define the basis of the legal standards for consent to research, as distinguished from consent to practice (there is one Canadian case, *Halushka v. University of Saskatchewan* [1965]). The law defines, in general, the circumstances under which a patient, or by extension, a subject, may recover damages for having been wronged or harmed as a consequence of failure to negotiate adequate consent.

The legal bases for the consent requirement—which also shed light on the ethical dimensions of consent—are twofold (Annas, Glantz, and Katz). First, failure to obtain proper consent was traditionally treated as a battery action. Closely related to the principles of respect for persons and self-determination, the law of battery makes it wrong to touch, treat, or do research upon a person without the person's consent. Whether or not harm befalls the patient/subject is irrelevant: It is the unconsented-to touching that is wrong.

The modern trend in malpractice litigation is to treat cases based on failure to obtain proper consent as negligence rather than battery actions. The negligence doctrine combines elements of patient benefit and self-determination. To bring a negligence action, a patient/subject must prove that the physician had a duty toward the patient, that the duty was breached, that damage occurred to the patient, and that the damage was caused by the breach. In contrast to battery actions, negligence actions remove as a basis for the requirement for consent the simple notion that unconsented-to touching is a wrong. Rather, such touching is wrong (actionable) only if it is negligent and results in harm; otherwise, the patient/subject cannot recover damages. Under both battery and negligence doctrines, consent is invalid if any information is withheld from the patient/subject that might be considered material to the decision to give consent.

Functions of Informed Consent

In their 1975 book, *Catastrophic Diseases: Who Decides What?* Jay Katz and Alexander Morgan Capron identified the following functions of informed consent: promoting individual autonomy, encouraging rational decision making, avoiding fraud and duress, involving the public, encouraging self-scrutiny by the physician-investigator, and reducing the civil and/or criminal liability of the investigator and her institution.

In general, the negotiations for informed consent are designed to safeguard the rights and welfare of the subject, while documentation that the negotiations have been conducted properly safeguards the investigator and institution (Levine). The net effect of the documentation may, in fact, be harmful to the interests of the subject. Retaining a signed consent form tends to give the advantage to the investigator in any adversarial proceeding. Moreover, the availability of such documents in institutional records may lead to violations of privacy and confidentiality. Consequently, federal regulations permit waivers of the requirement for consent forms when the principal threat to the subject would be a breach of confidentiality and "the only record linking the subject and the research would be the consent document" ("Documentation of Informed Consent," pt. 46.117c).

Those who are interested in making operational the requirement for consent have a tendency to focus nearly all of their attention on the consent form. Federal regulations prescribe what information must be included in and excluded from these forms. Members of institutional review boards and researchers collaborate in a struggle to create reproachless forms. This seems to reflect an assumption that the consent form is an appropriate instrumentality through which researchers might fulfill their obligation not to treat persons merely as means. Most commentators on informed consent disagree, however, seeing consent as a continuing process rather than an event symbolized by the signing of a form; for example, Robert J. Levine (1986) characterized informed consent as a discussion or negotiation, while Katz (1984) envisioned consent as a searching conversation.

Whether or not negotiations for informed consent to research should be conducted according to different standards than consent to practice is controversial. In a 1974 article, Alvan R. Feinstein observed that it is the custom to adhere to a double standard: "An act that receives no special concern when performed as part of clinical practice may become a major ethical or legal issue if done as part of a formally designed investigation" (p. 331). In his view there is less need for formality in the negotiations for informed consent in a relationship in which the interests of research and practice are conjoined—for example, as in research conducted by a physician-investigator who has the aim of demonstrating the safety and/or efficacy of a nonvalidated therapeutic maneuver—than when the only purpose of the investigator–subject relationship is to perform research. Capron, on the other hand, asserted in a 1972 publication: "Higher requirements for informed consent should be imposed in therapy than in investigation, particularly when an element of honest experimentation is joined with therapy" (p. 574). Levine (1986) concluded that patients are entitled to the same degree of thoroughness of negotiations for informed consent as are subjects of research. Patients, however, may be offered the opportunity to delegate some (but

not all) decision-making authority to a physician, whereas subjects should rarely be offered this option. The most important distinction is that the prospective subject should be informed that in research, in contrast with practice, the subject will be at least in part a means and perhaps primarily a means to an end identified by someone else.

Two Interpretations of the Consent Requirement

Interpretations of the meaning and application of informed consent reflect a tension between respecting the autonomy of persons and protecting them from harm. Hans Jonas (1970) and Paul Ramsey (1970) have developed a covenantal model in which subjects are respected and protected by ensuring that they give truly informed consent. Benjamin Freedman (1975) stressed the legally competent individual's freedom of choice, whether or not the choice is informed.

For Jonas and Ramsey, the consent requirement is derived from the duty to treat persons as ends, not merely as means. In research, subjects are *used* as means to the end of acquiring knowledge. (In Jonas's terms, they are "sacrificed" for the collective good.) Such *use* of persons is justified only if the subjects so identify with the purposes of the research that they will those purposes as their own ends. Only then are they not being *used,* but instead they have become, in Ramsey's term, "co-adventurers." The consent requirement thus affirms a basic covenantal bond between the researcher and the subject and ensures respect for the subject as an end, not merely a means.

To establish a true covenant, the subject's consent must be informed. Only subjects who genuinely know the purposes and appreciate the risks of research can assume those risks and adopt those purposes as their own ends. Ideal subjects, therefore, would be researchers themselves (Jonas). The less one understands the risks and identifies with the purposes of research, the less valid is one's consent. Jonas therefore established a "descending order of permissibility" for the recruitment ("conscription") of volunteers. Both Ramsey and Jonas restrict the use of subjects unable to consent or to understand what is involved, permitting the use of such subjects only in research directly related to their own condition (Jonas) or their own survival and well-being (Ramsey).

This interpretation reflects certain assumptions that can be challenged. First, while neither Jonas nor Ramsey focused exclusively on patients as subjects, their approach appears to be influenced largely by the medical practice model. That approach may not be adequate to deal with research not based on the medical practice model—for example, social-science research.

Second, while Ramsey argued that it is wrong to use a person in research without consent irrespective of risk (because one can be *wronged* without being *harmed*), he nonetheless appears to share with Jonas the assumption that most research is risky and involves *sacrifice* on the part of the subject. In fact, most research does not present risk of physical or psychological harm; rather, it presents inconvenience (e.g., of urine collection) and discomforts (e.g., of needle sticks) (Levine). Even Phase I drug testing, which involves the first administration of new drugs to humans and is usually assumed to be highly risky, has been estimated to present subjects with *risks* slightly greater than those involved in secretarial work and substantially less than those assumed by window washers and miners (Levine).

But the most important challenge is Freedman's (1975) alternative interpretation and use of the basic principles. Like Jonas and Ramsey, Freedman derived the consent requirement from the duty to have respect for persons. Unlike Jonas and Ramsey, however, he interpreted the requirement of respect for competent persons to allow the possibility of a "valid but ignorant" consent.

Freedman proposed that striving for *fully informed consent* is generally undesirable and that what is required is *valid consent,* not necessarily *informed consent.* To be valid, consent must be responsible and voluntary. Thus valid consent "entails only the imparting of that information which the patient/subject requires in order to make a responsible decision" (Freedman, p. 34). A choice based on less or other information than another responsible person might consider essential is not necessarily a sign of irresponsibility. Overprotection is a form of dehumanization and lack of respect; for example, to classify persons as incompetent to protect them from their own judgment is the worst form of abuse.

This approach also has several weaknesses. Much hinges on what is taken to be a responsible choice. Freedman suggested that responsibility is a dispositional characteristic and is to be judged in terms of the person, not in terms of a particular choice. There can be still, however, an element of paternalism introduced in judging another to be an irresponsible person. Moreover, this approach may not provide sufficient protection for those subjects who tend too readily to abdicate responsibility for choice, or who lack sufficient capacity or information to choose prudently.

It is clear that debates over the interpretation of informed consent depend on interpretations of the basic ethical principle of respect for persons and the extent to which that principle requires protection from harm or respect for autonomy.

Informed Consent: Conditions and Exceptions

According to the Nuremberg Code, to consent to participate in research one must:

1. be "so situated as to be able to exercise free power of choice";
2. have the "legal capacity" to give consent;
3. have "sufficient … comprehension" to make an "enlightened" decision; and
4. have "sufficient knowledge" on which to decide (Germany [Territory under Allied Occupation], p. 181).

More recent discussion emphasizes the knowledge or information component of consent—hence the term "*informed consent*" (Katz). The Nuremberg Code's focus on freedom of choice rather than on the quantity or quality of information transmitted is represented by its use of the term *voluntary consent,* instead of *informed consent.* It is worth recalling that a demand for informed consent at the expense of other styles of self-determination such as Freedman's responsible choice is not necessarily respectful of persons. Most commentators agree that compromise on any one of the four conditions specified by the Nuremberg Code jeopardizes the ethical acceptability of the consent.

"FREE POWER OF CHOICE." The Nuremberg Code proscribes "any element of force, fraud, deceit, duress, overreaching, or other ulterior forms of constraint or coercion" (Germany [Territory under Allied Occupation], p. 181) in obtaining consent. Any flagrant coercion—for instance, when competent, comprehending persons are forced to submit to research against their expressed will—clearly renders consent invalid. There may be more subtle or indirect "constraints" or "coercions" when prospective subjects are highly dependent, impoverished, ignorant, or "junior or subordinate members of a hierarchical group" (CIOMS, p. 65). Some argue that consent obtained from such persons violates the intent of the Nuremberg Code. This argument has been posed most sharply with respect to prisoners and other institutionalized populations, because institutionalization often involves both dependency and impoverishment. (Biomedical research involving prisoners as subjects has become quite rare since 1976 when the U.S. National Commission recommended very stringent standards for its justification [Dubler and Sidel 1989].) Some argue that consent to participate in research is not valid when it is given (1) to procure financial reward in situations offering few alternatives for remuneration; (2) to seek release from an institution either by evidencing "good behavior" or by ameliorating the condition for which one was confined; or (3) to please physicians or authorities on whom one's continued welfare depends (Branson).

But in his contribution to a 1976 U.S. National Commission report, Cornel R. West argued that such indirect forms of constraint do not constitute coercion in a strict sense and thus do not render consent involuntary. "Coercion," says West, consists in a threat to render one's circumstances worse if one does not do something. Hence, a threat to withdraw basic necessities of existence, or in some other way to render a prison inmate's situation worse if he declines to participate in research, would constitute coercion and render consent invalid. Similarly, to condition release from prison upon participation would constitute coercion, because it would make the inmate's situation worse by removing normal alternatives for seeking release. But the provision of better living conditions in exchange for participation in research does not constitute a threat to make conditions worse; rather, it is an enticement to make conditions better. While enticement and bribery can invalidate consent by undermining the rational grounds for choice, they do not undermine the voluntariness of the choice (Cohen). Similarly, a desire to *get well* or to favorably influence institutional authorities is not an *ulterior* constraint in the strict sense of the Nuremberg Code, though it may be a very real psychological constraint.

Other commentators, however, are less concerned with a sharp distinction between coercion and other forms of constraint or undue influence (Levine; CIOMS). Even outside such total institutions as prisons there are many situations in which junior or subordinate members of hierarchical groups may be exploited or manipulated. Such persons may assume that their willingness to consent to research may be rewarded by preferential treatment or that their refusals could provoke retaliation by those in positions of authority in the system. Whether or not such assumptions are justified, it is the assumptions themselves that make such persons susceptible to manipulation. Examples of such persons are medical or nursing students, subordinate hospital and laboratory personnel, employees of pharmaceutical firms, and members of the military services. Other persons whose dependency status can be exploited include residents of nursing homes, people receiving welfare benefits, patients in emergency rooms, and those with incurable diseases.

Apart from those populations identified by regulations and ethical codes as requiring *special protection*—fetuses, children, prisoners, and those who are incompetent by reason of mental incapacity—there is no clear consensus about how to respond to the problems presented by those whose capacity to consent may be limited by virtue of their dependency status. For example, whereas some medical schools have policies that forbid the involvement of medical

students as research subjects, others have required investigators to invite them to participate in certain complex projects, reasoning that their highly sophisticated understanding of the risks, benefits, and purposes of such projects ensures a high quality of consent (Levine). Involvement of medical students, it is further argued, is consistent with Jonas's "descending order of permissibility" and contributes to their socialization into the medical profession.

While most regulations and ethical codes proscribe undue material inducements, there is no consensus on what this means. Some commentators argue that in most cases in which competent adults are recruited to serve as subjects in research that presents only slight increases above minimal risk, the role of the research subject is similar to that of an employee (Levine). Consequently, the amounts of cash payments or other material inducements can be determined by ordinary market factors. Others protest that because participation in research entails *selling one's body* as opposed to *selling one's labor* the role of the research subject might be considered more akin to commercial sex work than to any other type of employment (Wartofsky). According to this view, research subjects should not be paid at all; rather, they should be motivated by altruism.

Attempts to regulate the amounts of permissible material inducements are inevitably problematic (Levine). Setting the rates at a low level results in inequitable distribution of the burdens of participation among those who have no opportunities to earn more money for each unit of their time. Higher rates may overwhelm the capacity of the impoverished to decline participation.

In multinational research it is essential to evaluate the ethical acceptability of material inducements in the light of the gift-exchange traditions of the culture or community in which the research is to be carried out (CIOMS).

COMPETENCE AND COMPREHENSION. The Nuremberg Code requires both "legal capacity" to consent (often called *competence*) and "sufficient understanding" to reach an "enlightened" decision. Definitions of competence often include elements of comprehension, for example, to evaluate relevant information, to understand the consequences of action, and to reach a decision for rational reasons (Stanley and Stanley).

ASSESSMENTS OF INCOMPETENCE. The various standards employed for assessing competence are variations of four basic themes (Appelbaum, Lidz, Meisel):

1. *Reasonable outcome of choice.* This is a highly paternalistic standard in that the individual's right to self-determination is respected only if she makes the "right" choice—that is, one that accords with what the competency reviewer either considers reasonable or presumes a reasonable person might make.
2. *Factual comprehension.* The individual is required to understand, or at least be able to understand, the information divulged during the consent negotiation.
3. *Choice based on rational reasons.* Individuals must demonstrate a capacity for rational manipulation of information. They may, for example, be required to show that they not only understand the risks and benefits but also have weighed them in relation to their personal situations.
4. *Appreciation of the nature of the situation.* Individuals must demonstrate not only comprehension of the consent information but also the ability to use the information in a rational manner. Furthermore, they must appreciate that they are being invited to become research subjects and what that implies.

While there is disagreement as to the grounds for assessing incompetence, most commentators agree that such assessments are limited in several ways (Faden, Beauchamp, and King). First, a judgment of incompetence may apply to only certain areas of decision making, for example, to one's legal but not to one's personal affairs. Second, confinement to a mental institution is not in itself equivalent to a determination of incompetence. Third, some people are legally competent but functionally incompetent, whereas others are legally incompetent but functionally competent.

The Nuremberg Code does not permit the use of subjects lacking legal capacity or comprehension. Most subsequent codes and discussions allow their use with certain restrictions: for example, that mentally competent adults are not suitable subjects, that the veto of a legally incompetent but minimally comprehending subject is binding, and that consent or permission of the legal guardian must be obtained (Levine).

In its 1982 report, *Making Health Care Decisions,* the U.S. President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research (hereafter, U.S. President's Commission) wrote that "decisionmaking capacity requires, to a greater or lesser degree: (1) possession of a set of values and goals; (2) the ability to communicate and understand information; and (3) the ability to reason and deliberate about one's choices" (p. 57). Moreover, individuals may have sufficient capacity to make some decisions but not others (Brock; Kopelman). In the words of the U.S. President's Commission:

> Since the assessment [of capacity] must balance possibly competing considerations of well-being

> and self-determination, [one should] take into account the potential consequences of the patient's decision. When the consequences for well-being are substantial, there is a greater need to be certain that the patient possesses the necessary level of capacity.… Thus a particular patient may be capable of deciding about a relatively inconsequential medication, but not about the amputation of a gangrenous limb. (U.S. President's Commission, p. 60)

PROXY CONSENT. The debate between Paul Ramsey and Richard A. McCormick over the legitimacy of proxy consent to authorize the participation of an incompetent person in research is one of the classics in the brief history of bioethics. Adopting the battery argument, Ramsey claimed that the use of a nonconsenting subject is wrong whether or not there is risk, simply because it involves an unconsented touching. Unconsented touching is not wrongful, however, when the guardian judges it is for the good of the incompetent individual. Hence, proxy consent may be given for the use of nonconsenting subjects in research only when it includes therapeutic interventions related to the subject's own recovery (Ramsey, 1970).

Ramsey acknowledged, however, that benefit does not always justify unconsented touching; such touching of a competent adult is wrong even if it benefits that person. Why, then, can benefit be presumed to justify such touching for a child (or other subject unable to give consent)? McCormick proposed that the validity of such interventions rests on the presumption that the child, if capable, would consent to therapy. This presumption in turn derives from a child's obligation to seek therapy, an obligation that the child possesses simply as a human being (McCormick, 1974). Because children have an obligation to seek their own well-being, it is presumed that they would consent if they could, and thus presumed also that proxy consent on their behalf would not violate respect for them as persons.

By analogy, McCormick suggested that, as members of a moral community, children have other obligations to which one would presume their consent and give proxy consent on their behalf. One such obligation is to contribute to the general welfare when such contribution requires little or no sacrifice. Hence, nonconsenting subjects may be used in research not directly related to their own benefit so long as the research fulfills an important social need and involves no discernible risk. Ramsey countered this argument with respect to children, claiming that McCormick's position fails to recognize that children are not adults with a full range of duties and obligations. Instead, they have rights that must be protected by adults (Ramsey, 1976).

Adopting this premise about the nature of the child as a moral being, Freedman drew different conclusions. Because a child is not a moral being in the same sense as an adult, he argued, the concept of wrongful touching does not apply. The child has no right to be left alone but only a right to be protected. Hence, Freedman concluded that the only relevant moral issue is the risk involved in the research, and, like McCormick, that children could be used in research unrelated to their therapy, provided it presents them no discernible risk. Thus, the debate centers on the status of the child (a paradigmatic incompetent) as a moral being and on interpretations of the requirements of respect for persons.

Although disagreements persist over both standards of competence and the use of incompetent subjects, one issue seems to have been settled by the U.S. National Commission in several of its reports (Levine). Parents, guardians, and, in some cases, other *responsible relatives* may give *permission* (a term that often replaces "proxy consent") to involve an incompetent in research if there is no more than minimal risk, if incompetents who are capable of giving their *assents* (knowledgeable agreements that do not meet the legal standards for informed consent) do so, and if certain other criteria are satisfied. If there is more than minimal risk, the standards for ethical justification of the involvement of incompetents are more stringent.

DISCLOSURE OF INFORMATION. The Nuremberg Code requires that the subject be told "the nature, duration, and purpose of the experiment; the method and means by which it is to be conducted; all inconveniences and hazards reasonably to be expected; and the effects upon his health or person which may possibly come (Germany, [Territory under Allied Occupation], p. 182)." These requirements have been modified by subsequent codes and regulations. U.S. federal regulations require:

1. a statement of the purpose of the research and a description of its procedures;
2. a description of foreseeable risks and discomforts;
3. a description of benefits;
4. disclosure of appropriate alternatives, if any;
5. a statement of the extent of confidentiality;
6. an explanation of the availability of medical treatment for injury and compensation for disability;
7. an explanation of whom to contact for answers to questions; and
8. a statement that participation is voluntary and that neither refusal to participate nor withdrawal at any time will result in a loss of benefits to which the subject is otherwise entitled ("General Requirements" 1993).

The regulations further specify six additional elements of information to be provided when appropriate:

1. additional risks to the subject or to the fetus if the subject becomes pregnant;
2. circumstances in which a subject's participation may be terminated without his consent;
3. additional costs to the subject that may result from participation;
4. the consequences of a subject's decision to withdraw and procedures for orderly termination of participation;
5. a commitment to divulge significant new findings developed during the research that may relate to the subject's continued willingness to participate; and
6. the approximate number of subjects in the study.

Finally, the regulations forbid use of any exculpatory language through which the subject or her representative is made to waive any of their legal rights or that releases of the investigator, sponsor, or institution from liability for negligence.

While these requirements have the force of law, they are by no means exhaustive of possible standards for disclosure. To them one might add the following: a clear invitation to participate in research, distinguishing maneuvers required for research purposes from those necessary for therapy; an explanation of why the particular person is invited (selected); a suggestion that the prospective subject might wish to discuss the research with another person; and an identification of the source of funding for the research. Robert M. Veatch (1978) would add the names of members of any review boards that had approved the research and an explanation of the right, if any, to continue receiving treatments found useful. In short, there is no universal agreement on standards for disclosure of information or on what it takes for a person to have *sufficient knowledge* to give *informed* consent.

Those who agree on the need for disclosure of information in a particular category—the risks, for example—often disagree on the nature of the information that must be made known. The Nuremberg Code requires explication of hazards "reasonably" to be expected. Does this include a very slight chance of a substantial harm, or a substantial chance of a very slight harm? Neither the quality nor the probability of the risks to be divulged has been clearly determined legally.

Disagreements over particulars arise in part from disagreements about underlying standards: Is disclosure to be determined by (1) general medical practice or opinion, (2) the requirements of a *reasonable person,* or (3) the idiosyncratic judgment of the individual? While the legal trend may be shifting from the first to the second, it may be argued that only the third, the *subjective standard,* is truly compatible with the requirement of respect for the autonomy of the individual person (Faden, Beauchamp, and King; Veatch, 1978).

Yet even those who adopt the subjective standard disagree as to its implications. As noted earlier, Freedman (1975) held that the idiosyncratic judgment of the individual is overriding, to the point that the prospective subject can choose to have less information than a "reasonable" person might require. Veatch (1978), however, argued that anyone refusing to accept as much information as would be expected of a "reasonable person" should not be accepted as a subject.

In the context of medical practice, two exceptions to the requirement for informed consent are recognized—*emergency exception* and *therapeutic privilege.* The former, which permits the doctor to proceed without delay to administer urgently required therapy in emergencies, is reflected in a limited form in two provisions of the regulations of the U.S. Food and Drug Administration: (1) In some "life-threatening" emergencies in which informed consent is "infeasible," physician-investigators are authorized to employ investigational drugs and devices for therapeutic purposes (Levine). (2) In carefully defined circumstances, research designed to evaluate the safety and efficacy of investigational drugs or devices in emergency conditions may be carried out without the consent of the patient-subjects or the permission of their representatives. In such protocols either consent or permission must be obtained within a reasonable period of time after the initiation of the research; this entails authorization of the research participation already completed as well as the continuing participation of the subject in the research (Biros et al.).

The therapeutic-privilege exception to the informed-consent rule permits the doctor to withhold information when, in her judgment, disclosure would be detrimental to the patient's interests or well-being (Levine). Most commentators agree that invoking the doctrine of therapeutic privilege to assure a subject's cooperation in a research project is almost never appropriate; it gives the investigator entirely too much license to serve vested interests by withholding information that might be material to a prospective subject's decision. U.S. federal regulations do not explicitly endorse the use of the therapeutic-privilege exception in research, although some authors have suggested that they could be interpreted as an implicit endorsement (Levine).

The success of some research activities is contingent upon withholding from the subjects information about the purposes or procedures of the activities or, in some cases, upon deliberate deception (providing false information).

U.S. federal regulations permit *waivers and alterations* of consent requirements if there is no more than minimal risk; if the waiver or alteration will not adversely affect subjects' rights or welfare; if without the waiver or alteration the research "could not practicably be carried out"; and if the subjects will be debriefed (given a full and accurate explanation afterward) when appropriate ("General Requirements," pt. 46.116d).

There are some categories of research which, until recently, have been customarily carried out without individual informed consent; waiver of the requirement for informed consent in these categories was generally considered justified according to the *waivers and alterations* provisions of the regulations. Such activities included most research involving medical records and "leftover" specimens of tissues and body fluids obtained for either clinical or research purposes. Institutional patient information brochures generally contained notices of such routine research activities (Levine). Such routine uses of medical records without consent have had to be reconsidered in the light of the requirements of the Health Insurance Portability and Accountability Act of 1996 (DHHS). Similarly, routine use by researchers of specimens of tissue, without informed consent, have had to be reevaluated in the light of rapidly evolving standards (Clayton et al.); there is general agreement that such research is permissible without informed consent if the specimens are anonymous.

In a 1979 article, Diana Baumrind expressed her opposition to deceptive practices, arguing not only that they violate the principle of respect for persons but also that in the long run they will invalidate research on scientific grounds. Various proposals have been made to minimize the need for and harmful effects of deceptive practices: Subjects might be invited to consent to incomplete disclosure with a promise of full disclosure at the termination of the research; subjects might be told as much as possible and asked to consent for specified limits of time and risk; or approval of the plans to withhold information from or to deceive subjects might be sought from *surrogate* populations that resemble the actual intended subject populations in relevant respects (Levine).

"Secondary" Research Subjects

U.S. federal regulations define a human subject as "a living individual about whom an investigator … conducting research obtains (1) data through intervention or interaction with the individual, or (2) identifiable private information." (45 CFR 46.102f). Until 1999 it was generally assumed that this definition applied only to those individuals who were the targets of the researcher's interest and that part (2) of the definition was intended to cover the use of records and specimens of tissue and body fluids. In 2000, however, the federal Office for Protection from Research Risks (now the Office for Human Research Protections, part of the Department of Health and Human Services) issued a novel interpretation: Questions asked of research subjects calling upon them to report on private information of their relatives, friends, or associates had the effect of turning these friends, relatives, and associates into *secondary* research subjects. If the private information solicited could be considered *sensitive,* then it would be required that the informed consent of the *secondary* subjects be obtained. This is a highly controversial matter, a full discussion of which is beyond the scope of this entry (Botkin).

Conclusions

The use of a person as a research subject can be justified only if that person, or one authorized to speak on the person's behalf, consents to such use. The legal and ethical requirement for consent is grounded in fundamental tenets of the Judeo-Christian religious tradition as well as in basic ethical principles that create the universal obligation to treat persons as ends and not merely as means to another's end. The consent requirement also reflects the perspective that competent persons are generally the best protectors of their own well-being. Most major disagreements over the form and substance of the consent requirement derive from conflicting interpretations of one or more of the basic principles.

A widespread tendency among researchers to focus on consent forms seems to reflect an assumption that the consent form is an appropriate instrumentality through which they might fulfill their obligation not to treat persons merely as means. Most commentators on informed consent disagree, however, seeing consent as a continuing process rather than a single event consummated by the signing of a form. Moreover, whereas the primary purposes of informed consent are to foster self-determination and to empower prospective subjects to protect their own well-being and other interests, the primary purpose of its written documentation is to protect the investigator, the institution, and the research sponsor from legal liability.

IV. CLINICAL ASPECTS OF CONSENT IN HEALTHCARE

Decision making is an everyday event in healthcare, not only for doctors and patients, but also for nurses, psychologists, social workers, emergency medical technicians, dentists, and other health professionals. Since the 1960s, however, the cultural ideal of how these decisions should be made has changed considerably. The concept that medical decision making should rely exclusively on the physician's expertise has been replaced by a model in which healthcare professionals share information and discuss alternatives with patients who then make the ultimate decisions about treatment.

The concept of informed consent gained its initial support as part of the general societal trend toward broadening access to decision making during the 1960s. Thus, the initial support for informed consent came from legal and philosophic circles rather than healthcare professionals. In the legal arena, informed consent has been used to develop minimal standards for doctor–patient interactions and clinical decision making (Berg et al.). Although there are some differences by jurisdiction, widely accepted legal standards require that healthcare professionals inform patients of the risks, benefits, and alternatives of all proposed treatments, and then allow the patient to choose among acceptable therapeutic alternatives.

In academia, informed consent has served as a cornerstone for the development of the discipline of bioethics. Based on the importance of autonomy in moral discourse, philosophers have argued that healthcare professionals are obligated to engage patients in discussions regarding the goals of therapy and the alternatives for reaching those goals, and that patients are the final decision makers regarding all therapeutic decisions.

While many physicians would express some support to the concept of shared decision making, this support is largely theoretical and does not seem to have made its way into routine medical practice. Physicians typically think of informed consent as a legal requirement for a signed piece of paper that is at best a waste of time, and at worst a bureaucratic, legalistic interference with their care for patients. Rather than seeing informed consent as a process that promotes good communication and patient autonomy, many healthcare professionals view it as a complex, legally prescribed recitation of risks and benefits that only frightens or confuses patients.

Objections to Informed Consent

There are various objections to informed consent that clinicians often make, and it will be useful to review those objections here.

CONSENT CANNOT BE TRULY "INFORMED." Many practicing clinicians report that their patients are unable to understand the complex medical information necessary for a fully rational weighing of alternative treatments. There is considerable research support for this view. A variety of studies document that patients recall only a small percentage of the information that professionals present to them (Meisel and Roth); that they are not as good decision makers when they are sick as at other times (Sherlock; Cassell, 2001); and that they often make decisions based on medically trivial factors. Informed consent thus appears either to promote uninformed—and thus suboptimal—decisions, or to encourage patients to blindly accept healthcare professionals' recommendations. In either case informed consent appears to be a charade, and a dangerous one at that.

However, the fact that patients often do have difficulty understanding important aspects of medical decisions does not mean that healthcare professionals are the best decision

makers about the patient's treatment. Knowledge about medical facts is not enough. Wise house buyers will have a structural engineer check over an old house, but few would be willing to allow the engineer to choose their house for them. Just as structural engineers cannot decide which house a family should buy—because they lack knowledge about the family's pattern of living, personal tastes, and potential family growth—healthcare professionals cannot scientifically deduce the best treatment for a specific patient simply from the medical facts. What matters to individuals about their health depends on their lifestyles, past experiences, and values, so choosing the *optimal therapy* is not a purely objective matter (U.S. President's Commission). Thus, patients and healthcare professionals both contribute essential knowledge to the decision-making process: patients bring their knowledge of their personal situation, goals, and values; and healthcare professionals bring their expertise on the nature of the problem and the technology that may be used to meet the patient's goals (see Brock).

Informed-consent disclosures, even if they are well done, may not lead to what clinicians might consider optimal decisions. Most people make major life decisions, such as whom to marry and which occupation to take up, based on faulty or incomplete information. Patients' lack of understanding of medical information in choosing treatment is probably no worse than their lack of information in choosing a spouse, nor are medical decisions more important than spousal choice. Respecting patient autonomy means allowing individuals to make their own decisions, even if the healthcare professional disagrees with them. The informed-consent process can improve patient decisions, but it cannot be expected to lead to perfect decisions.

Moreover, although sick persons have defects in their rational abilities, so do healthcare professionals. In fact, some of the most famous research on the difficulties individuals have with the rational use of probabilistic data involves physicians (Dawson and Ackes). Health professionals must be careful not to be too pessimistic about patients' ability to become informed decision makers. Patients may not be able to become as technically well-informed as professionals, but they clearly can understand and make decisions based on relevant information. One study, for example, showed that patients' decisions regarding life-sustaining treatment changed when they were given accurate information about the therapy's chance of success and that patients, when given increased information about screening tests for prostate cancer, were less likely to have the test change their decision on having the test (Murphy et al.). Moreover, what seems to be an irrational decision may turn out to be, from the patient's point of view, rational. Thus, a patient may turn down a recommended treatment because of personal experience with surgery or because the long-term benefit is not seen as being worth the short-term risk.

Most important, the difficulty of educating sick persons does not justify unilateral decision making. Rather, it places a special obligation on healthcare professionals to communicate clearly with patients. Using technical jargon, trying to give all of the available information in one visit, and not asking what the patient wants to know is a recipe for confusing even the most intelligent patient. A growing literature deals with informational aides—ranging from question prompt-sheets to giving patients audiotapes of the interaction and formal decision aides—that can be used to promote patient understanding and shared decision-making. New technologies like interactive DVD offer patients the opportunity to participate more fully in shared decision making at their own rate. A limitation of many of these aides is that they are limited helping with specific decisions and need to be updated frequently (Barry). Healthcare professionals also need to become more familiar with different cultural patterns of communication in order to talk with patients from different cultural backgrounds. For example, although a simple, factual discussion of depression and its treatment may be acceptable to most middle-class Americans, it would be seen as inappropriate by a first-generation Vietnamese male, whose culture discourages viewing depression as a disease (Hahn). There is no reason, in principle, why a person who makes decisions at home and work cannot, with help, understand the medical data sufficiently to become involved in medical decisions. Healthcare professionals must learn how best to present that help and involve patients in the decision-making process.

PATIENTS DO NOT WISH TO BE INVOLVED IN DECISION MAKING. Many healthcare professionals believe that it is unfair to force patients to make decisions regarding their medical care. After all, they argue, patients pay their healthcare professionals to make medical decisions. The empirical literature partially supports the view that patients want professionals to make treatment decisions for them (Steel et al.). For example, in a study of male patients' preferences about medical decision making regarding hypertension, only 53 percent wanted to participate at all in the decision-making process (Strull et al.). More recent data suggest that sicker patients are less interested in information about their disease and more willing to have doctors make decisions (Butow 1997; 2002).

There is no reason to force patients to be involved in decisions if they do not want to be. However, unless the health professional asks, he or she cannot know how involved a patient wants to be. Studies suggest that doctors' ability to predict their patients' interest in information, or

their desire to be involved in decision making, is no better than flipping a coin (Butow 1997, 2002). In addition, roughly two-thirds of patients want to be involved in decision making, either by being the primary decision maker (the minority) or in shared decision making with the physician.

Patients may not always want to be involved in decision making, since many have been socialized into believing that "the doctor knows best." This is particularly true for poorer patients. Studies have shown that physicians wrongly assume that because patients with fewer socioeconomic resources ask fewer questions, they do not want as much information. These patients may in fact want just as much information, but they have been socialized into a different way of interacting with healthcare professionals (Waitzkin, 1984).

Patients may choose to allow someone else to make the decision for them. However, when a patient asks, "What would you do if you were me?" the underlying question may be, "As an expert in biomedicine, what alternative do you think will best maximize my values or interest?" If this is the case, the healthcare professional should respond by making a recommendation and justifying it in terms of the patient's values or interests. More frequently, the patient is asking, "If you had this disease, what therapy would you choose?" This question presumes that the professional and patient have the same values, needs, and problems, which is often not the case. Healthcare professionals should respond by pointing this out and emphasizing the importance of the patients' values in the decision-making process.

Although many patients do not want to be actively involved in decision making, they almost always want more information concerning their illness than the healthcare professional gives them. Healthcare professionals should not assume that just because patients do not wish to choose their therapy, they do not want information. Patients may desire information so as to increase compliance or make modifications in other areas of their lives, as well as to make medical decisions.

THERE ARE HARMFUL EFFECTS OF INFORMING PATIENTS. Healthcare professionals often justify withholding information from patients because of their belief that informing patients would be psychologically damaging and therefore contrary to the principle of nonmaleficence. Many healthcare professionals, however, overestimate potential psychological harm and neglect the positive effects of full disclosure (Faden et al.). Some discussions that physicians assume are stressful, such as advance care-planning, have been shown to decrease patient anxiety and increase the patient's sense of control. Moreover, bad news can often be communicated in a way that ameliorates the psychological effects of the disclosure (Quill and Townsend). Truth-telling must be distinguished from "truth dumping." Explanation of the care that can be provided, and empathic attention to the patient's fears and uncertainties can often prevent or mitigate otherwise more painful news. Finally, sometimes the harm associated with bad news is unavoidable. It is normal to be sad after finding out that one has an incurable cancer, for example. That does not mean that one should not convey the information, only that it should be done in as sensitively and supportively as possible.

INFORMED CONSENT TAKES TOO MUCH TIME. Respecting autonomy and promoting patient well-being—the values served through informed consent—are fundamental to good medicine. However, adhering to the ideals of medical practice takes time—time to help patients understand their illness and work through their emotional reactions to stressful information, to discuss each party's preconceptions and to clarify the therapeutic goals, to decide on a treatment plan, and to elicit questions about diagnosis and treatment.

In U.S. healthcare, time is money. As many commentators have noted, physicians are less well reimbursed for talking to patients than for performing invasive tests. This may discourage doctors from spending enough time discussing treatment options with patients. This, along with the pressures of managed care has decreased the average outpatient encounter, allowing even less time for doctor–patient communication. The ultimate justification for spending time to facilitate patient decisions is the same as that for spending any time in medical care: that patients will be better cared for. Moreover, some of the new decision aides, such as question prompts, may in fact decrease the time spent in the patient visit, while simultaneously increasing patient understanding.

Clinical Approaches to Informed Consent

Many of the problems in implementing informed consent result, at least in part, from the way informed consent has been implemented in clinical practice. Informed consent has become synonymous with the *consent form,* a legal invention with a legitimate role in documenting that informed consent has taken place, but hardly a substitute for the discussion process leading to informed consent (Andrews).

A PRO FORMA APPROACH: AN EVENT MODEL OF INFORMED CONSENT. In many clinical settings, consent begins when *it is time to get consent,* typically just prior to the administration of treatment. The process of getting the patients' consent consists of the recitation by a physician or nurse of the list of material risks and benefits and a request

that the patient sign for the proposed treatment. This "conversation" is a very limited one that emphasizes the transfer of information from the physician or nurse to the patient. While it does meet the minimal legal requirements for informed consent efficiently, it does not meet the higher ethical goal of informed consent, which is to empower patients by educating and involving them in their treatment plans. Instead, it imposes an almost empty ritual on an unchanged relationship between provider and patient (Katz).

The procedure just described assumes that care involves a series of discrete, circumscribed decisions. In fact, much of clinical medicine consists of a series of frequent, interwoven decisions that must be repeatedly reconsidered as more information becomes available. When "it is time to get consent," there may be nothing left to decide. Consider the operative consent form obtained the evening prior to an operation. After patients have discussed with their families whether to be admitted to the hospital, rearranged their work and child-care schedules, and undergone a long and painful diagnostic workup, the decision to have surgery seems preordained. The evening before the operation, patients do not seriously evaluate the operation's risks and benefits, so consent is pro forma. No wonder some healthcare professionals feel that *consent* is a waste of time and energy.

The event model for gathering informed consent falls far short of meeting the ethical goal of ensuring patient participation in the decision-making process. Rather than engaging the patient as an active participant in the decision-making process, the patient's role is to agree to or veto the healthcare professionals' recommendations. Little attempt is made to elicit patient preferences and consider how treatment might address them.

A DIALOGICAL APPROACH: THE PROCESS MODEL OF INFORMED CONSENT. Fortunately, it is possible to fulfill legal requirements for informed consent while maximizing active patient participation in the clinical setting. An alternative to the event model described above, which sees informed consent as an aberration from clinical practice, the process model attempts to integrate informed consent into all aspects of clinical care (Berg et al). The process model of informed consent assumes that each party has something to contribute to the decision-making process. The physician brings technical knowledge and experience in treating patients with similar problems, while patients bring knowledge about their life circumstances and the ability to assess the effect that treatment may have on them. Open discussion makes it possible for the patient and the physician to examine critically their views and to determine what might be optimal treatment.

The process model also recognizes that medical care rarely involves only one decision made at a single point in time. Decisions about care frequently begin with the suspicion that something is wrong and that treatment may be necessary, and they end only when the patient leaves follow-up care. Decisions involve diagnostic as well as therapeutic interventions. Some decisions are made in one visit, while others occur over a prolonged period of time. Although some interactions between provider and patient involve explicit decisions, decisions are made at each interaction, even if the decision is only to continue treatment. The process model also recognizes that various healthcare professionals may play a role in making sure that the patients' consent is informed. For example, a woman deciding on various breast cancer treatments may talk with an oncologist and a surgeon about the risks of various treatments, with a nurse about the side effects of medication, with a social worker about financial issues in treatment, and with a patient-support group about her husband's reaction to a possible mastectomy.

Ideally, then, informed consent involves shared decision making over a period of time; it a dialogue throughout the course of the patient's relationship with various healthcare professionals. Such a dialogue aims to facilitate patient participation and to strengthen the therapeutic alliance.

Tasks Involved in Informed Consent

Consent is a series of interrelated tasks. First, the patient and professional must agree on the problem that will be the focus of their work together (Eisenthal and Lazare). Most nonemergency consultations involve complex negotiations between healthcare professional and patient regarding the definition of the patient's problem. The patient may see the problem as a routine physical examination for a work release, the need for advice, or the investigation of a physical symptom. If professionals are to respond effectively to the patients' goals, they must find out the reason for the visit. Whereas physicians typically focus on biomedical information and its implications, patients typically view the problem in the context of their social situation (Fisher and Todd). The differences between the patient's perceptions of the problem and the professional's perceptions must be explicitly worked through, since agreement regarding the focus of the interactions will lead to increased patient satisfaction and compliance with further treatment plans (Meichenbaum and Turk).

Even when the professional and patient have agreed on what the problem is, substantial misunderstandings may arise regarding the treatment goals. Patients may expect the medically impossible, or they may expect outcomes based on

knowledge of life circumstances about which the physician is unaware. Since assessing the risks and benefits of any treatment option depends on therapeutic goals, the professional and patient must agree on the goals the therapy aims to accomplish.

Finding out what the patient wants is more complicated than merely inquiring, "What do you want?" A patient typically does not come to the professional with well-developed preferences regarding medical therapy except "to get better," with little understanding of what this may involve (Cassell, 1985). As a patient's knowledge and perspective change over the course of an illness, so too may the patient's views regarding the therapeutic goals.

Because clinicians provide much of the medical information needed to ensure that the patient's preferences are grounded in medical possibility, healthcare professionals play a significant role in how a patient's preferences evolve. It is important that they understand that patients may reasonably hold different goals from those their practitioners hold. This is particularly true when they come from different economic strata. For example, a physician's emphasis on the most medically sophisticated care may pale in the light of the patient's financial problems. Therapeutic goals, like the definition of the problem, require ongoing clarification and negotiation.

After agreeing upon the problem and the therapeutic goals, the healthcare professional and the patient must choose the best way to achieve them. If patients have been involved in the prior two steps, the decision about a treatment plan will more likely reflect their values than if they are merely asked to assent to the clinician's strategy.

Healthcare professionals often ask how much information they must supply to ensure that the patient is an informed participant in the decision-making process (Mazur). There is, however, a more important question: Has the information been provided in a manner that the patient can understand? While the law only requires that healthcare professionals inform patients, morally valid consent requires that patients understand the information conveyed. Ensuring patient understanding requires attention to the quality as well as the quantity of information presented (Faden).

A great deal of empirical data has been collected concerning problems with consent forms. These forms have been criticized, for example, as being unintelligible because of their length and use of technical language (Berg et al.) Healthcare professionals thus need to be aware of, and facile in using, a variety of methods to increase patients' comprehension of information, including verbal techniques, written information, and interactive videodiscs (Stanley et al.).

Still, the question of how much information to present remains. The legal standards regarding information disclosure—what a reasonable patient would find essential to making a decision or what a reasonably prudent physician would disclose—are not particularly helpful. Howard Brody has suggested two important features: (1) the physician must disclose the basis on which the proposed treatment or the alternative possible treatments have been chosen; and (2) the patient must be encouraged to ask questions suggested by the the physician's reasoning—and the questions need to be answered to the patient's satisfaction (Brody). Healthcare professionals must also inform patients when controversy exists about the various therapeutic options. Similarly, patients should also be told the degree to which the recommendation is based on established scientific evidence rather than personal experience or educated guesses.

Two other factors will influence the amount of information that should be given: the importance of the decision (given the patient's situation and goals) and the amount of consensus within the healthcare professions regarding the agreed-upon therapy. For example, a low-risk intervention, such as giving influenza vaccines to elderly patients, offers a clear-cut benefit with minimal risk. In this case, the professional should describe the intervention and recommend it because of its benefits. A detailed description of the infrequent risks is not needed unless the patient asks or is known to be skeptical of medical interventions. Interventions that present greater risks or a less clear-cut risk-benefit ratio require a longer description—for example, the decision to administer AZT to an HIV (human immunodeficiency virus)-positive, asymptomatic woman with a CD4 cell count of 350. In this situation, the data regarding starting medications are unclear and a patient's preference is critical. In this situation, one would need to talk about the major side effects of the medicines, the burden of taking medicines daily, the immunological benefit of anti-virals, etc. In neither case is a discussion of pathophysiology or biochemistry necessary. It must be emphasized that there is no formula for deciding how much a patient needs to be told or the length of time this will take. The amount of information necessary will depend on the patient's individual situation, values, and goals.

Finally, an adequate decision-making process requires continual updating of information, monitoring of expectations, and evaluation of the patient's progress in reaching the chosen or revised goals. Thus, the final step in informed consent is follow-up. This step is particularly important for patients with chronic diseases for which modifications of the treatment plan are often necessary.

The process model of informed consent has many advantages. Because it assumes many short conversations over time rather than one long interaction, it can be more

easily integrated into the professional's ambulatory practice than the event model. It also allows patients to be much more involved in decision making and ensures that treatment is more consistent with their values. Furthermore, the continual monitoring of patients' understanding of their disease, the treatment, and its progress is likely to reduce misunderstandings and increase their investment in, and adherence to, the treatment plan. Thus, the process model of informed consent is likely to promote both patient autonomy and well-being.

Unfortunately, there are situations in which this approach is not very helpful. Some healthcare professionals, anesthesiologists, or emergency medical technicians, for example, are not likely to have ongoing relationships with patients. In emergencies, there is not time for a decision to develop through a series of short conversations. In these cases, informed consent may more closely approximate the event model. However, since most medical care is delivered by primary-care practitioners in an ambulatory setting, the process model of informed consent is more helpful.

V. LEGAL AND ETHICAL ISSUES OF CONSENT IN HEALTHCARE

This article, by Jay Katz, is reprinted from the first edition, where it carried the title "Informed Consent in the Therapeutic Relationship: II. Legal and Ethical Aspects." It is followed immediately by a "Postscript," prepared by Angela R. Holder for purposes of updating the original article.

The doctrine of informed consent, introduced into U.S. case law in 1957, represents judges' groping efforts to delineate physicians' duties to inform patients of the benefits and risks of diagnostic and treatment alternatives, including the consequences of no treatment, as well as to obtain patients' consent (*Salgo v. Stanford University,* 1957). The doctrine's avowed purpose was to protect patients' right to "thoroughgoing self-determination" (*Natanson v. Kline,* 1960). The legal implications of informed consent, however, remain unclear. The doctrine is in fact more of a slogan, which judges have been too timid or too wise to translate into law, at least as yet. It has been employed with little care but great passion to voice a dream of personal freedom and individual dignity. Though its legal impact in protecting patients' right to self-decision making has been scant, the threat of informed consent has opened profound issues for the traditional practice of medicine.

The Medical Framework

It has been insufficiently recognized, particularly by judges, that disclosure and consent, except in the most rudimentary fashion, are obligations alien to medical practice. Hippocrates' admonitions to physicians are still followed today: "Perform [these duties] calmly and adroitly, concealing most things from the patient while you are attending to him. Give necessary orders with cheerfulness and serenity, turning his attention away from what is being done to him; sometimes reprove sharply and emphatically, and sometimes comfort with solicitude and attention, revealing nothing of the patient's future or present condition." Thus it is not surprising that the Hippocratic oath is silent on the duty of physicians to inform, or even converse with, patients. Similarly Dr. Thomas Percival, whose 1803 book *Medical Ethics* influenced profoundly the subsequent codifications of medical ethics in England and the United States, commented only once on the discourse between physicians and patients, restricting his remarks to "gloomy prognostications." Even in that context he advised that "friends of the patient" be primarily informed, though he added that the patient may be told "if absolutely necessary" (Percival, p. 91). The Code of Ethics of the American Medical Association, adopted in 1847, and the Principles of Medical Ethics of the American Medical Association, adopted in 1903 and 1912, repeat, in almost the same words, Percival's statement. The AMA Principles of Medical Ethics, endorsed in 1957, delete Percival's wording entirely and substitute the vague admonition that "physicians … should make available to their patients … the benefits of their professional attainments." The pertinent sections of the *Opinions of the Judicial Council* of the AMA, interpreting the principles, note only the surgeon's obligation to disclose "all facts relevant to the need and performance of the operation" and the experimenter's obligation, when using new drugs and procedures, to obtain "the voluntary consent of the person" (American Medical Association Judicial Council). Nine years later, the AMA House of Delegates in endorsing, with modifications, the Declaration of Helsinki, asked that investigators, when engaged "in clinical [research] primarily for treatment," make relevant disclosures to and obtain the voluntary consent of patients or their legally authorized representative.

Thus in the context of therapy no authoritative statement encouraging disclosure and consent has ever been promulgated by the medical profession. The AMA's tersely worded surgical exception was compelled by the law of malpractice. Its experimental exception represented primarily an acquiescence to the U.S. Public Health Service and the U.S. Department of Health, Education, and Welfare requirements, which in turn were formulated in response to congressional concerns about research practices. When disclosure and consent prior to the conduct of therapeutic research were endorsed by the AMA, it did not extend those requirements to all patient care but limited the exception to "clinical [research] primarily for treatment."

Two significant conclusions can be drawn: (1) *Informed consent* is a creature of law and not a medical prescription. A duty to inform patients has never been promulgated by the medical profession, though individual physicians have made interesting, but as a rule unsystematic, comments on this topic. Judges have been insufficiently aware of the deeply ingrained Hippocratic tradition against disclosure and, instead, seem to have assumed that individual physicians lack of disclosure was aberrant with respect to standard medical practice, and hence *negligent,* in the sense of *forgetful* or *inadvertent,* conduct. (2) When judges were confronted with claims of lack of informed consent, no medical precedent, no medical position papers, and no analytic medical thinking existed on this subject. Thus physicians were ill prepared to shape judges' notions on informed consent with thoughtful and systematic positions of their own.

The Legal Framework

With the historical movement from feudalism to individualism, consent, respect for the dignity of human beings, and the right of individuals to shape their own lives became important principles of English common law and, in turn, of American common law. Yet, as these principles gained greater acceptance, questions arose in many areas of law about the capacity of human beings to make their own decisions and about the need to protect them from their own "folly." The tug of war between advocates of thoroughgoing self-determination and those of paternalism has continued unabated. The informed-consent doctrine manifests this struggle. While in physician-patient interactions the legal trend during the past two decades has been to increase somewhat the right of patients to greater freedom of choice, the informed-consent doctrine has not had as far-reaching an impact on patients' self-determination as many commentators have assumed. This fact has been insufficiently appreciated and has led to confusion, further compounded by the courts' rhetoric that seemed to promise more than it delivered.

Consent to medical and surgical interventions is an ancient legal requirement. Historically an intentional touching without consent was adjudicated in battery. The law has not changed at all in this regard, and a surgeon who operates on a patient without permission is legally liable, even if the operation is successful. In such instances any inquiry into medical need or negligent conduct becomes irrelevant, for what is at issue is the disregard of the person's right to exercise control over his body. The jurisprudential basis of these claims is personal freedom:

> … under a free government at least, the free citizen's first and greatest right, which underlies all others—the right to himself—is the subject of universal acquiescence, and this right necessarily forbids a physician or surgeon, however skillful or eminent … to violate without permission the bodily integrity of his patient by … operating on him without his consent.… (*Pratt v. Davis,* 1906)

But what does consent mean? In battery cases it means only that the physician must inform the patient what he proposes to do and that the patient must agree. Medical emergencies and patients' incompetence are the only exceptions to this requirement.

In mid-twentieth century, judges gradually confronted the question whether patients are entitled not only to know what a doctor proposes to do but also to decide whether the intervention is advisable in the light of its risks and benefits and the available alternatives, including no treatment. Such awareness of patients' informational needs is a modern phenomenon, influenced by the simultaneous growth of product liability and consumer law.

The law of fraud and deceit has always protected patients from doctors' flagrant misrepresentations, and in theory patients have always been entitled to ask whatever questions they pleased. What the doctrine of informed consent sought to add is the proposition that physicians are now under an affirmative duty to offer to acquaint patients with the important risks and plausible alternatives to the proposed procedure. The underlying rationale for that duty was stated in *Natanson v. Kline*:

> Anglo-American law starts with the premise of thorough-going self-determination. It follows that each man is considered to be master of his own body, and he may, if he be of sound mind, expressly prohibit the performance of life-saving surgery, or other medical treatment. A doctor might well believe that an operation or form of treatment is desirable or necessary but the law does not permit him to substitute his own judgment for that of the patient by any form of artifice or deception. (*Natanson v. Kline*)

The language employed by the *Natanson* court in support of an affirmative duty to disclose derives from the language of the law of battery, which clearly makes the patient the ultimate decision maker with respect to his body. Thus the courts reasoned, with battery principles very much in mind, that significant protection of patients' right to decide their medical fate required not merely perfunctory assent but a truly *informed consent,* based on an adequate understanding of the medical and surgical options available to them.

Yet in the same breath judges also attempted to intrude as little as possible on traditional medical practices. In doing so their impulse to protect the right of individual self-determination collided with their equally strong desire to maintain the authority and practices of the professions. Law has always respected the arcane expertise of physicians and has never held them liable if they practiced "good medicine." The law of consent in battery represented no aberration from this principle since most physicians agree that patients at least deserve to know the nature of the proposed procedure. However, the new duty of disclosure that the law, in the name of self-determination, threatened to impose upon physicians was something quite different. For the vast majority of physicians significant disclosure is not at all part of standard medical practice. Most doctors believe that patients are neither emotionally nor intellectually equipped to be medical decision makers, that they must be guided past childish fears into *rational* therapy, and that disclosures of uncertainty, gloomy prognosis and dire risks often seriously undermine cure. Physicians began to wonder whether law was now asking them to practice "bad" medicine.

In the early informed-consent cases, judges simply did not resolve the conflict between self-determination and professional practices and authority. The result was distressing confusion. In obeisance to the venerable ideal of self-determination, courts purported to establish, as a matter of law, the physician's

> … obligation … to disclose and explain to the patient in language as simple as necessary the nature of the ailment, the nature of the proposed treatment, the probability of success or of alternatives, and perhaps the risks of unfortunate results and unforeseen conditions within the body. (*Natanson v. Kline*)

The threat of such an obligation greatly disturbed the medical profession. It recognized that serious implementation of such a standard would significantly alter medical practice. Physicians argued that in order fully to serve patients' best interests, they must have the authority to exercise medical judgment in managing patients. Courts likewise bowed to this judgment. In the very sentence that introduced the ambiguous but exuberant new phrase "informed consent," the court showed its deference to medical judgment and its hesitancy to disturb traditional practice:

> … in discussing the element of risk a certain amount of discretion must be employed consistent with the full disclosure of facts necessary to an informed consent. (*Salgo v. Stanford University*)

Thus the extent to which evolving case law, under the banner of individualism, was challenging traditional medical practice—which for millennia has treated patients paternally as children—remained confusing. In those earlier cases (*Salgo v. Stanford University, Natanson v. Kline*) judges were profoundly allegiant to both points of view, but the balance was soon tipped decisively in favor of protecting medical practices.

BATTERY OR NEGLIGENCE. The striking ambivalence of judges toward the doctrine of informed consent manifested itself in the competition between battery and negligence doctrines as a means of analyzing and deciding the claims of lack of informed consent. Battery offered a more rigorous protection of patients' right to self-determination. The inquiry into disclosure and consent would not be governed by professional practices but instead would rest on the question: Has the physician met his expanded informational responsibility so that the patient is able to exercise a choice among treatment options? A negative answer to this question would show that the physician's actions constitute trespass, rendering him liable for an unauthorized and *offensive* contact (*Dow v. Kaiser Foundation*).

However, in virtually every jurisdiction judges resolved the competition in favor of negligence law. In doing so, judges were able to defer to medical judgment by evaluating the adequacy of disclosure against the medical professional standard of care, asserting that this standard will govern those duties as it does other medical obligations. As a consequence, physicians remain free to exercise the wisdom of their profession and are liable only for failure to disclose what a reasonable doctor would have revealed. Furthermore, negligence theory does not redress mere dignitary injuries, irrespective of physical injuries, and requires proof that the patient, fully informed, would have refused the proposed treatment. Interferences with self-determination, standing alone, are not compensated.

In rejecting battery, judges made much of the fact that such an action required *intent,* while negligence involved *inadvertence*; it was the latter, they believed, that accounted for the lack of disclosure. They overlooked that the withholding of information on the part of physicians is generally quite intentional, dictated by the very exercise of medical

judgment that the law of negligence seeks to respect. In stating that the nondisclosures were *collateral* to the central information about the nature of the proposed procedure and hence not required for a valid consent, judges discarded the very idea of informed consent—namely, that absence of expanded disclosure vitiates consent. They refused to extend the inquiry to the total informational needs of patients, without which patients' capacity for self-decision making remains incomplete. At bottom, the rejection of an expanded battery theory and of its proposed requirement of informed consent followed from the threat they posed to the authority of doctors and traditional medical practice.

Thus informed consent, based on patients thoroughgoing self-determination, was a misnomer from the time the phrase was born. To be sure, a new cause of action has emerged for failure to inform of the risks of, and in most jurisdictions alternatives to, treatment. Some duty to disclose risks and alternatives, the courts were willing to say, exists; the extent of that duty is defined by the disclosure practice of a reasonable physician in the circumstances of the case. The new claim is firmly rooted in the law of negligent malpractice, in that plaintiffs are still required to prove the professional standard of care by means of medical expert witnesses. In these, the majority of jurisdictions, traditional medical practice—which generally opposes disclosure—has scarcely been threatened at all in legal reality. The legal life of informed consent, except for dicta about self determination and the hybrid negligence law promulgated in a handful of jurisdictions, was almost over as soon as it began. Judges had briefly toyed with the idea of patients' self-determination and then largely cast it aside. Good medicine, as defined by doctors, remains good law almost everywhere.

MODIFICATIONS IN PROFESSIONAL STANDARD OF CARE. In a few jurisdictions, beginning in 1972 in the District of Columbia with the decision in *Canterbury v. Spence,* the new cause of action for failure to inform combined elements of battery with negligence, creating a legal hybrid. The court purported to abandon the professional standard of care with respect to disclosure, asserting that

> … respect for the patient's right of self-determination on particular therapy demands a standard set by law for physicians rather than one which physicians may or may not impose upon themselves. (*Canterbury v. Spence*)

Thus the court laid down a judge-made rule of disclosure of risks and alternatives, which for all practical purposes resembled an expanded battery standard of disclosure.

The preoccupation with risk disclosure, however, continued unabated. From the very beginning, despite all the talk about *informed consent,* judges did not lay down any rules for a careful inquiry into the nature and quality of consent, which on its face any meaningful implementation of the doctrine required. Instead major emphasis was placed on risk disclosures. Since in the cases before courts plaintiff-patients only complained of the injurious results of treatment, this emphasis is understandable. Yet to focus solely on risks is to bypass the principal issue of self-determination—namely, whether the physician kept the patient from arriving at his own decision. The *Canterbury* court, too, restricted its concerns largely to risk disclosures and added the requirement that

> an unrevealed risk that should have been made known must materialize for otherwise the omission, however, unpardonable, is legally without consequence. (*Canterbury v. Spence*)

Thus the court foreclosed legal redress for the patient who, fully informed of the potential effects of, for example, a maiming operation, would have chosen an alternative medical course, even though some of the risks did not materialize.

But to the extent these jurisdictions have abandoned the professional standard of disclosure, traditional medical practice has been challenged; "good medicine," in the eyes of the profession, may no longer be a sufficient defense. Seemingly, in these jurisdictions self-determination has begun to encroach upon the province of medical paternalism. That encroachment, however, may be substantially an illusion, for the touted abandonment of the professional standard of disclosure in *Canterbury* was far from complete. Medical judgment to truncate full disclosure must be "given its due," the court said, when "it enters the picture." The court left ambiguous when the plaintiff must establish the appropriate standard of disclosure by an expert witness, or when he must produce such a witness in order to rebut a defendant-physician's claim that good medical judgment was exercised.

What is clear is that the physician has a *therapeutic privilege* not to disclose information where such disclosure would pose a threat to the *well-being* of the patient. But the ambit of this privilege as well as the relationship of its invocation to a directed verdict is not clear, and this for "good" reasons: Even in these most liberal jurisdictions with respect to patients' rights, courts still cannot face squarely the question of how much they are willing to challenge the traditional medical wisdom of nondisclosure. The law remains ambiguous with respect to this, the core issue of informed consent.

TENSIONS BETWEEN SELF-DETERMINATION AND PATERNALISM. Beyond its allegiance to medical paternalism,

noted above, the *Canterbury* court showed its preference for paternalism in another way. Under negligence law, the courts have stated that lack of disclosure cannot be said to have caused the patient's injury unless the patient, if adequately informed, would have declined the procedure; this is the crucial problem of causation in informed-consent cases. Such an approach to causation is quite appropriate where law seeks not to compensate interference with self-determination, but only physical injuries resulting from inadequate disclosure. Yet the *Canterbury* court, and every court that has considered the matter subsequently, held that the decision whether or not to undertake therapy must be examined not from the point of view of the patient-plaintiff but from that of a "prudent person in the patient's position," limiting the inquiry to whether a "reasonable patient" would have agreed to the procedure. This substitution of a community standard of a "reasonable" person cuts the heart out of the courts purported respect for individual self-determination. Questions of the influence of hindsight and bitterness are familiar to juries, as is the problem of self-serving testimony generally. While those are delicate problems, they do not justify abrogating the very right at issue in cases of informed consent: the right of individual choice, which may be precisely the right to be an "unreasonable" person.

EPILOGUE ON LAW. Thus law has proceeded feebly toward the objective of patients' self-determination. While a new cause of action, occasionally hybridized with battery, has emerged for the negligent failure to disclose risks and alternative treatments, it remains a far cry from the avowed purpose of the informed-consent doctrine, namely, to secure patients' autonomy and right to self-determination. In not tampering significantly with the medical wisdom of nondisclosure, yet creating a new cause of action based on traditional disclosure requirements, courts may have accomplished a different result, very much in line with other purposes of tort law—namely, to provide physically injured patients with greater opportunities for seeking compensation whenever it can be argued that disclosure might have avoided such injuries. In doing so judges may have hoped, through the anticipatory tremors of dicta, to urge doctors to consider modifying their traditional disclosure practices. But judges have been unwilling, at least as yet, to implement earnestly patients' right to self-determination.

Whither Informed Consent?

The disquiet that the doctrine of informed consent has created among physicians cannot be fully explained by the small incremental step courts have taken to assure greater patient participation in medical decision making. More likely it was aroused by the uncertainty over the scope of the doctrine and by an appreciation that medical practice, indeed all professional practice, would be radically changed if fidelity to thoroughgoing self determination were to prevail. In what follows, some of the issues raised by the idea of an informed-consent doctrine, based on a premise of self-determination, will be discussed.

PATIENTS. Traditionally patients have been viewed as ignorant about medical matters, fearful about being sick, childlike by virtual of their illness, ill-equipped to sort out what is in their best medical interest, and prone to make decisions detrimental to their welfare (Parsons). Thus physicians have asserted that it makes little sense to consult patients on treatment options: far better to interact with them as beloved children and decide for them. In the light of such deeply held convictions, many physicians are genuinely puzzled by any informed-consent requirement. Moreover, its possible detrimental impact on compassion, reassurance, and hope—ancient prescriptions for patient care—has raised grave ethical questions for the medical profession.

Those concerns should not be dismissed lightly. What may be at issue, however, is not an intrinsic incapacity of patients to participate in medical decision making. For not all patients, and probably not even most, are too uneducated, too frightened, or too regressed to understand the benefits and risks of treatment options available to them. Moreover, their capacities for decision making are affected to varying degrees, for example, by the nature of the disease process, its prognosis, acuteness, painfulness, etc., as well as by the personality of patients. The medical literature is largely silent on the question of who—under what circumstances and with what conditions—should or should not be allowed to participate fully in medical decision making.

But why has not the sorting-out process, distinguishing between those patients who do and those who do not have the capacity for decision making, been undertaken long ago? One answer suggests itself: Once those patients have been identified who, in principle, can make decisions on their own behalf, physicians would be compelled to confront the questions of whether to interact with them on a level of greater equality; whether to share with them the uncertainties and unknowns of medical diagnosis, treatment, and prognosis; and whether to communicate to them their professional limitations as well as the lack of expert consensus about treatment alternatives. Such an open dialogue would expose the uncertainties inherent in most medical interventions; and to the extent medicine's helpful and curative power depends on the faith and confidence which the physician projects, patients may be harmed by disclosure and consent.

Physicians' objections to informed consent, therefore, may have less to do with the incompetence of patients as such than with un unrecognized concern of the doctrine's impact on the dynamics of cure. Put another way, the all too sweeping traditional view of patients has misled doctors into believing that medicine's opposition to informed consent is largely based on patients' incompetence, rather than on an apprehension, however dimly perceived, that disclosure would bring into view much about the practice of medicine that physicians seek to hide from themselves and their patients; for example, the uncertainties and disagreements about the treatments employed; the curative impact of physicians' and patients' beliefs in the unquestioned effectiveness of their prescriptions rather than the prescriptions themselves; the difficulty in sorting out the contributions that *vis medicatrix naturae* ("the healing power of nature") makes to the healing process; the impact of patients' suggestibility to cure, etc. Thus the question: When does informed consent interfere with physicians' effectiveness and with the dynamics of cure?

Little attention has been paid to the fact that the practice of Hippocratic medicine makes patients more incompetent than they need be. Indeed patients' incompetence can become a self-fulfilling prophecy as a consequence of medical practices. That the stress of illness leads to psychological regression, to chronologically earlier modes of functioning, has been recognized for a long time. Precious little, however, is known about the contributions that physicians' attitudes toward and interactions with their patients make to the regressive pull. Also, little is known about the extent to which regression can be avoided by not keeping patients in the dark, by inviting them to participate in decision making, and by addressing and nurturing the intact, mature parts of their functioning. This uncharted territory requires exploration in order to determine what strains will be imposed on physicians and patients alike, if Anna Freud's admonition to students of the Western Reserve Medical School is heeded:

> … you must not be tempted to treat [the patient] as a child. You must be tolerant toward him as you would be toward a child and as respectful as you would be towards a fellow adult because he has only gone back to childhood as far as he's ill. He also has another part of his personality which has remained intact and that part of him will resent it deeply, if you make too much use of your authority. (quoted in Katz, p. 637)

PHYSICIANS. Traditionally physicians have asserted that their integrity, training, professional dedication to patients' best medical interests, and commitment to "doing no harm" are sufficient safeguards for patients. The complexities inherent in medical decision making, physicians maintain, require that trust be patients' guiding principle. The idea of informed consent does not question the integrity, training, or dedication of doctors. Without them, informed consent would be of little value. What the idea of informed consent does question is the necessity and appropriateness of physicians' making all decisions for their patients; it calls for a careful scrutiny of which decisions belong to the doctor and which to the patient.

Physicians have preferences about treatment options that may not necessarily be shared by patients. For example, no professional consensus exists about the treatment of breast cancer. The advantages and disadvantages of lumpectomy, simple mastectomy, radical mastectomy, radiation therapy, chemotherapy, and various combinations among these are subject to much controversy. Dr. Bernard Fisher, chairman of the National Surgical Adjuvant Breast Cancer Project, has said that we simply do not know which method is best (Fisher). Thus the question must be answered: How extensive an opportunity must patients be given to select which alternative? Informed consent challenges the stereotypical notion that physicians should assume the entire burden of deciding what treatment *all* patients, *whatever* their condition, should undergo. Indeed, can the assumption of this burden be defined purely on medical grounds in the first place? Is not the decision in favor of one treatment for breast cancer over another, like many other treatment decisions, a combination of medical, emotional, aesthetic, religious, philosophical, social, interpersonal, and personal judgments? Which of these component judgments belong to the physician and which to the patient?

Much needs to be investigated in order to learn the practical human limits of any new obligations to disclose and to obtain consent:

1. Informing patients for purposes of decision making requires learning new ways of interacting and communicating with patients. Such questions as the following will have to be answered: What background information must patients receive in order to help them formulate their questions? How should physicians respond to *precipitous* consents or refusals? How deeply should doctors probe for understanding? What constitutes irrelevant information that only tends to confuse? What words and explanations facilitate comprehension? Physicians have not been in the habit of posing such questions.
2. Underlying informed consent is the assumption that physicians have considerable knowledge about their

particular specialties, keep abreast of new developments, and are aware of what is happening in other fields of medicine that impinge on their area of professional interest. This is not so; indeed, it may be asking too much. Moreover, since physicians have their preferences for particular modes of treatment, can they be expected to present an unbiased picture of alternative treatments?

3. Physicians have consistently asserted that informed consent interferes with compassion (Silk). Doctors believe that, in order to maintain hope or to avoid the imposition of unnecessary suffering, patients in the throes of a terminal illness, and other patients as well, should not be dealt with honestly. But the evidence for such allegations is lacking. When physicians are asked to support them with clinical data, they are largely unable to do so (Oken). Indeed, the few studies that have been conducted suggest that most patients do not seem to yearn for hope based on deception, but for hope based on a reassurance that they will not be abandoned, that everything possible will be done for them, and that physicians will deal truthfully with them. Moreover, evidence is accumulating that informed patients become more cooperative, more capable of dealing with discomfort and pain, and more responsible. Whether the often alleged conflict between *compassionate* silence and *cruel* disclosure is myth or reality remains to be seen. Disclosure may turn out to be a greater burden to those who have to interact with patients than to the patients themselves.
4. Informed consent confronts the role of faith in the cure of disease and the complex problems created by the uncertainties inherent in medical practice. To some extent the two issues are intertwined. The effectiveness of a therapeutic program, it has often been said, depends on three variables: the "feeling of trust or faith the patient has in his doctor and therefore in his therapy … the faith or confidence the physician has in himself and in the line of therapy he proposes to use … and the therapy [itself]" (Hoffer, p. 124). Informed consent could interfere with the first two variables and thus undermine the effectiveness of treatment. Precisely because of the uncertainties in medical decision making, the physician, to begin with, defends himself against those uncertainties by being more certain about what he is doing than he realistically can be. There is perhaps some unconscious wisdom in what he has been doing since Hippocrates' days, for the unquestioned faith the doctor has in his own therapy is also therapeutic in its own right. Thus, to be a more effective healer, a physician may need to defend himself against his uncertainties by believing himself to be more powerful than he is. That defense will be threatened by informed consent, for it would now require him to be more aware of what he does not know, and therapeutic effectiveness in turn might suffer. Finally, patients' response to treatment also depends on faith in the physician and his medicines. Knowing of the *ifs* and *buts* may shake patients' faith and undermine the therapeutic impact of suggestibility, which contributes so much to recovery from illness.

Physicians' traditional counterphobic reaction to uncertainty, adopting a sense of conviction that what seems right to them is the only correct thing to do, has other consequences as well. Defensive reactions against uncertainty have led to overenthusiasm for particular treatments that have been applied much more widely than an unbiased evaluation would dictate. The ubiquitous tonsillectomies performed to the psychological detriment of untold children is a classical example. Moreover, by not acknowledging uncertainty to themselves, doctors cannot acknowledge it to their patients. Thus consciously and unconsciously physicians avoid the terrifying confrontation of uncertainty, particularly when associated with poor prognosis. As a result, communications with patients take the form of an evasive monologue. The dialogue that might reveal these uncertainties is discouraged (Davis).

While disclosure of information would reduce patients' ignorance, it would also diminish doctors' power within the physician-patient relationship. As Waitzkin and Stoeckle have observed, the "physician enhances his power to the extent that he can maintain the patient's uncertainty about the course of illness, efficacy of therapy, or specific future actions of the physician himself" (p. 187). Thus new questions arise: What consequences would a diminution of authority have on physicians effectiveness as healers? How would patients react to less powerful doctors? Would they accept them or turn to new faith healers?

LIMITS OF SELF-DETERMINATION. Patients' capacity for self-determination has been challenged on the grounds that neither total understanding nor total freedom of choice is possible (Ingelfinger). This of course is true. Any informed-consent doctrine, to be realistic, must take into account the biological, psychological, intellectual, and social constraints imposed upon thought and action. But those inherent constraints, which affect all human beings, do not necessarily justify treating patients as incompetents. Competence does not imply total understanding or total freedom of choice.

What needs to be explored is the extent to which medicine, like law, should presume competence rather than incompetence, in interactions with patients. Neither presumption comports fully with the psychobiology of human beings; both of them express value judgments on how best to

interact with human beings. Once the value judgment is made, one can decide on the additional safeguards needed to avoid the harm that any fiction about human behavior introduces.

The idea of informed consent asks for a presumption in favor of competence. If that is accepted, it may also follow that human beings should be allowed to strike their own bargains, however improvident. The then Circuit Judge Warren E. Burger, in commenting on a judicial decision to order a blood transfusion for a Jehovah's Witness, had this to say: "Nothing in [Justice Brandeis's `right to be let alone' philosophy, suggests that he] thought an individual possessed these rights only as to sensible beliefs, *valid* thought, *reasonable* emotions or *well-founded* sensations. I suggest he intended to include a great many foolish, unreasonable and even absurd ideas which do not conform such as refusing medical treatment even at great risk" (*Application of President of Georgetown College*). A physician may wish, and even should try, to persuade his patients to agree to what he believes would serve their medical interests best; but ultimately he may have to bow to his patients' decision, however "senseless" or "unreasonable," or withdraw from further participation. The alternatives, deception or coercion, may be worse, for either would victimize not only patients but physicians as well.

Conclusion

The narrow scope that courts have given to the informed-consent doctrine may reflect a deeply held belief that the exercise of self-determination by patients is often against the best interests of otherwise responsible adults and that those interests deserve greater protection than personal freedom. It may also reflect a judicial recognition of law's limited capacity to regulate effectively the physician-patient relationship. Therefore, once having suggested that patients deserve at least a little openness in communication, courts may have concluded that they had gone as far as they could. Judges, at least for the time being, have largely left it up to the medical profession to confront the question of patients' greater participation in medical decision making.

Despite their snail's pace, the courts' approach may have merit. Implementing a right of self-determination has tremendous consequences for medical practice. Many difficult problems, each with vast ethical implications, need to be considered by the medical profession. Thus introspection and education, responsive to the legal and professional problems that new patterns of physician-patient interaction will create, may ultimately provide firmer foundations for new patterns of physician-patient interactions than forced change through outside regulation. The latter, however, may increase if the profession does not rise to the challenge of addressing these long-neglected problems.

POSTSCRIPT

Courts have broadened the doctrine of informed consent well beyond its initial construct. For example, informed consent was, in a few states, applicable only to physical touching, as courts held that a failure to obtain informed consent was a claim for battery, not for negligence (e.g., *Morgan v. MacPhail,* 1997; *Gray v. Grunnagle,* 1966). This meant, for example, that a physician who failed to warn a patient about the risks of a prescribed medication before the patient had life–threatening consequences would not have violated the patient's right to informed consent. The clear trend by the beginning of the twenty–first century, however, was to treat any claim for informed consent as one in negligence, so no *touching* is required (*Matthies v. Mastromonaco,* 1999; Hanson). Of course, if a procedure is performed without any consent (i.e., a surgeon performs a different or additional procedure from the one to which the patient had consented while the patient is under anesthesia) an action for battery is still appropriate (*Montgomery v. Bazaz–Sehgal,* 2002).

Several court cases broadened the doctrine of informed consent, establishing that in order to give informed consent, the patient must understand the risks of refusing the proposed therapy (*Truman v. Thomas,* 1980; *Battenfield v. Gregory,* 1991; *Arato v. Avedon,* 1993).

Informed consent jurisprudence at the turn of this century also explored whether the patient is entitled to some information about the physician's abilities as well as about the contemplated procedure. Does the patient have a right to know that the surgeon has never performed the procedure on anyone else? Does the patient have the right to know that the Health Maintenance Organization to which she belongs will reward her physician economically at the end of the year if he does not refer patients to specialists, even if her disease should be treated by specialists? Most cases in which disclosure of fiscal issues have arisen have imposed liability, if at all, on the HMO and not on the physician (Kurfirst; Potter; Simmons).

In one case from Illinois, the intermediate appellate court held that the physician had breached his fiduciary duty when he did not disclose to the patient that he made more money if the patient was not referred to a specialist. The Illinois Supreme Court held that since the failure to refer the patient to a cardiologist constituted malpractice, the reason the physician did not do so was irrelevant (*Neade v. Portes,* 2000). If a physician knows or should have known that he should refer a patient to a specialist or other more qualified physician and does not do so, if the patient's condition becomes worse, the failure constitutes malpractice even if the patient never raises the issue of informed consent (*Johnson v. Kokemoor,* 1996). The earliest case to this effect was decided in 1898, decades before there was any concept of *informed consent* (*Logan v. Field,* 1898).

Other informed consent cases involved a physician's failure to disclose inexperience with performing the procedure. Most courts take the position that the doctrine of informed consent applies only to the risks of the procedure or treatment itself, and not to information about the physician (*Ditto v. McCurdy,* 1997; *Duttry v. Patterson,* 2001). This was even true in one case where the surgeon failed to inform a child–patient's parents that he was an alcoholic and unlicensed (*Kaskie v. Wright,* 1991). A 2002 decision by the New Jersey Supreme Court, however, held that outright misrepresentation of experience or credentials (as opposed to failure to disclose) does constitute failure to obtain informed consent (*Howard v. University of Medicine and Dentistry,* 2002).

Special Situations

Some situations involving particular groups of patients create unusually complex problems in providing information or obtaining consent.

PREGNANT PATIENTS. During the 1980s there was a series of cases in which pregnant women were subjected to blood transfusions to which they had religious and other objections and, in some cases, court–ordered cesarean sections when they had refused the procedure. In the infamous case of A.C. (*In re A.C.,* 1990), the woman and her premature infant both died following her court–ordered cesarean, and

professional organizations began to issue statements urging that such refusals be respected (George Washington University, 1991). Since that ruling, although there has been one reported case of a court–ordered cesarean (*Pemberton v. Tallahassee Memorial Regional Medical Center,* 1999), there have been many more cases in which the courts rejected such requests by hospitals (*In re Baby Boy Doe,* 1994; Levine, 1994; Oberman, 2000). Several states have also held that a pregnant woman may not be transfused against her will, even to save her fetus (*The Stamford Hospital v. Vega,* 1996; *Harrell v. St. Mary's Hospital,* 1996).

During the 1990s, several states attempted to decrease drug abuse among pregnant women by criminalizing it as *child abuse.* While these statutes are still being enforced in a few states, the Supreme Court has ruled that testing women for drugs without their knowledge or consent when they come to a clinic for prenatal care is a violation of their constitutional rights against search and seizure and, of course, in violation of any concept of informed consent (Barton; *Ferguson v. City of Charleston,* 2001). Moreover, many medical groups issued statements that they feared that the threat of prosecution would drive away from medical care the women who needed it most (see, for example, the 1990 statement of the American Medical Association's Board of Trustees; Annas).

Women have been increasingly successful in informed consent suits alleging that they were not told during prenatal care about diagnostic tests that would have revealed serious handicaps in time to abort their fetuses (*Quinn v. Blau,* 1997; *Kassama v. Magat,* 2001). Since many states refuse to permit *wrongful birth* cases, an action for failure to obtain informed consent may be the patient's only recourse (Gantz). In other cases, women have successfully sued when physicians refused to respect their wishes on such matters as Cesarean sections and the newborns had handicaps as the result. All of these cases allege obstetrical malpractice as well as an absence of informed consent (*Schreiber v. Physicians Insurance Co.,* 1998).

MINORS. Minors over age fourteen are increasingly able to make medical decisions for themselves, although many states in which a minor by herself could make decisions about major surgery or other serious interventions have abortion statutes that restrict the same young woman from deciding to have a first–trimester abortion. The standards of informed consent—the patient's capacity to understand the nature of the procedure and the risks (including foregoing treatment) and benefits—is the same for adolescent as it is for an adult (English).

Parents occasionally ask a physician not to tell their adolescent child his or her diagnosis. Although it may be negotiable in some illnesses, if an adolescent is HIV positive or has another serious communicable condition, the physician must tell him or her and make sure the patient understands safe sex and other means to keep others from contracting the infection. The physician can be found liable if the uninformed adolescent patient infects a third party (*Reisner v. Regents of the University of California,* 1995; Committee on Pediatric AIDS, American Academy of Pediatrics).

While minors may refuse treatment in many situations, courts rarely allow them to refuse life–saving therapies. In a few cases (*In re E.G.,* 1989, rehearing denied,1990 *Belcher v. Charleston Area Medical Center,* 1992), judges have allowed minors to refuse life–saving therapy, but most courts have ruled that minors do not have "the right to die." (*In re Application of Long Island Jewish Medical Center,* 1990; *Novak v. Cobb County–Kennestone Hospital Authority,* 1996). In no state is a minor permitted to create a valid Living Will or Durable Power of Attorney (Hawkins; McCabe). When the minor is dying, however, the fact that she or he cannot make a legally binding decision does not mean that the physician should not be the patient's advocate in arguing for that perspective if the parents wish to "try one more thing" (Leiken, 1993; Evans, 1995).

If the diagnosis and treatment of a minor is undertaken without the involvement or knowledge of the parent, the young patient is entitled to the same degree of confidentiality accorded an adult patient (Council for Scientific Affairs, American Medical Association; Sigman, Silber, English, et al.; American College of Obstetrics and Gynecology).

PSYCHIATRIC PATIENTS. Admission to a psychiatric hospital, even if a patient has been involuntarily committed, does not preclude a person's ability and right to consent to many aspects of his or her care, including agreeing to or refusing medication (Berg, Appelbaum, and Grisso; Wirshing, Wirshing, and Marder). In order to medicate a patient over his or her objections, the patient must be found incompetent to make that decision by a court (*In re Qawi,* 2001; *Hamilton County v. Steele,* 1999). Moreover, a psychiatric patient may consent to participate in research to the same extent that she or he may consent to treatment (Carpenter; Dunn and Jeste; Roberts; Capron, 1999).

Limits on Self-Determination

A patient is not always entitled to whatever care he or she wishes. A physician who does not think a therapy would be beneficial does not have to offer it to a patient, although if it is a treatment which a minority of physicians find acceptable, the physician may have the duty to refer the patient to

such a practitioner. Therapies which have no adherents in mainstream medicine—for example, laetrile to treat cancer—do not impose a requirement of referral.

The physician does not have the right to discontinue a therapy he or she believes is *futile* over a family's objection as long as a patient is not brain dead (Jecker and Schneiderman; Blake, Maldondo, and Reinhardt; Capron, 1991; Cantor; Council on Judicial and Ethical Affairs, American Medical Association). Conversely, if an adult patient has made clear to his or her physician that he or she wishes to forego further treatment, the physician has the obligation to support the patient's decision, even if the family objects.

VI. ISSUES OF CONSENT IN MENTAL HEALTHCARE

Since the 1970s informed consent has been at the center of an evolving doctor-patient relationship whose characterization has shifted from strict paternalism to information exchange, shared decision making, and patient-centered care. In research, informed consent operates in concert with research regulations to protect human subjects while enabling research participation that is regarded, alternatively, as a burden or potential benefit to subjects. Concerns about informed consent in mental health treatment and research touch upon all of these issues.

Informed Consent in Mental Healthcare

The dual ethical goals of informed consent are the protection of the welfare and promotion of the autonomy of patients. As a legal doctrine, informed consent guarantees certain rights of patients in determining their treatment. Informed consent's legal history can be traced to the Supreme Court case of *Schloendorff v. Society of New York Hospitals* (1914), in which Justice Benjamin Cardozo declared that "every human being of adult years and sound mind has a right to determine what shall be done with his body" (*Schloendorff,* p. 126). The questions of what constitutes a sound mind and the rights of those with *unsound* minds remain central to discussion of informed consent in the context of mental healthcare.

At the beginning of the twentieth century, in the earliest stage of what would become the informed consent doctrine, battery provided the legal theory for a cause of action; physicians were required to obtain consent to invasive treatment (Katz). Informed consent's second stage was marked by increasing judicial pressure for consent to be not only free, but also informed; physicians were to disclose treatment alternatives and the risks of the proposed treatment, and then to obtain consent. Still, the California court in *Salgo v. Leland Stanford Junior University Board of Trustees* (1957), which ushered in this second stage, failed to articulate precisely the type of information that was required by this duty to disclose. The decision in *Canterbury v. Spence* (1972) initiated the third stage of informed consent doctrine by articulating a patient-oriented standard of disclosure that required physicians to disclose to patients what a reasonable person would find material to making treatment decisions. Since 1972, the literature on informed consent has burgeoned (e.g., Appelbaum, Lidz, and Meisel; Berg, Appelbaum, and Lidz; Faden and Beauchamp; Meisel, Roth, and Lidz).

Informed consent serves to protect individual autonomy, respect the patient's status as a human being, avoid

fraud or duress, encourage doctors to carefully consider their treatment decisions, foster rational decision making by the patient, and involve the public in medicine (Capron). The law of informed consent is based on guaranteeing patients the right to receive sufficient information to make informed choices about treatment, and the right to accept or decline the physician's recommendations. As a process, informed consent involves active exchange of information between patient and physician. Elements fundamental to this process are *disclosure* of the risks and potential benefit of treatment options (or of participation in a research protocol), *comprehension* by the patient (or subject) of such information, *competence* of the decision maker, *voluntariness* of the decision, and the consent (or refusal) itself (Beauchamp and Childress). Competence and voluntariness have special import in the mental health context.

COMPETENCE. Determination of competence functions as a gatekeeping mechanism for informed consent in any healthcare context, because a decision maker's competence is a prerequisite for being able to give informed consent and thus have his/her treatment preferences or decisions respected. In bioethical analyses, competence pertains to a specific task (e.g., making a particular decision); it is not a general quality of persons (Buchanan and Brock). Conceived as decision-relative, competence is a variable or sliding-scale standard; in other words, the greater the degree of risk to patient welfare associated with a particular decision (e.g., to refuse likely life-saving treatment), the higher the standard of competence required of the patient choosing that option (Buchanan and Brock). Nevertheless, determination of competence is based on evaluation of the patient's process of decision making, not the acceptability or reasonability of its outcome. The capacities requisite for competent decision making are the ability to understand and appreciate the risks and benefits of treatment options, the ability to reason and deliberate about those options, and the ability to weigh options against a relatively stable set of values (Buchanan and Brock).

The difference between *competence* and *capacity* can be confusing, and the terms are often used interchangeably (Wolpe, Moreno, and Caplan). Medical or mental health professionals determine patient capacity, whereas incompetence is a legal construct, a legal determination that a patient is incapable of making decisions. The standards for determining incompetence are vague given the lack of judicial consensus. Although courts are available to make the determination, it is typically made by the attending physician. Whether the final determination of incompetence must be made by a court or in the clinical setting with judicial consideration remains unsettled (Berg, et al.; Berg and Appelbaum). Despite attempts to establish standardized means for assessing decisional capacity and competence, in clinical practice such judgments are still highly dependent on individual psychiatric evaluations (and attending physicians' judgments). Competence assessment remains difficult, especially when a patient's decision seems contrary to his/her ostensible best interests.

In mental health contexts, competence determinations may be especially complicated. Although an ethical, legal, and medical consensus now exists that a competent adult's voluntary informed choices must be respected in the course of treatment and research, it is not entirely clear how to proceed when a person's decision-making capacity may be compromised by mental illness. Historically there has been an erroneous presumption that mental illness obviates the patient's ability to make competent decisions and that either professional paternalism or surrogate decision making is therefore warranted. While some mental disorders may impair the cognitive faculties upon which the capacities for competent decision making rest, a blanket generalization regarding such an adverse effect of mental illness on decision-making capacity is unwarranted. A person with Alzheimer's disease or late life dementia, for example, may be incapable of making some decisions at some times, but at other times may ably comprehend information and weigh options; a patient with bipolar disorder may be quite capable of decision making while medication controls his/her illness, but be incapable if such medication becomes inadequately adjusted to control symptoms of depression or mania. In reality, many people with mental illness may be competent to make medical decisions at least much of the time (Buchanan and Brock; NBAC).

Responses to patient incompetence—specifically, decision making by a surrogate (or proxy) or by a court—serve as an exception to the usual process of informed consent. Nevertheless, surrogate decision making pursues the dual ethical goals of informed consent: the promotion of patient autonomy and protection of patient welfare. Customarily, the surrogate decision-making process involves obtaining informed consent for treatment (or its refusal) from a surrogate named by the patient in an advance directive, or in the absence of such a directive, by the patients' family members. In the absence of such family members, or in the case of irresoluble conflict among them, courts may appoint a guardian to make healthcare decisions on behalf of an incompetent patient. Advance directives for psychiatric treatment allow for a currently competent person to make plans for a future period during which he/she may lose decision-making capacity due to mental illness. These advance directives may include choices about treatment (including

electroconvulsive therapy and emergency interventions), medications, hospitalization, research participation (discussed below), and, through the vehicle of a durable power of attorney, the appointment of a surrogate decision maker. Persons who have reason to think they may lose decisional capacity or be subject to involuntary psychiatric commitment may complete such advance directives to guide their psychiatric care and even to help arrange such necessities as temporary custody for their children.

VOLUNTARINESS. In order to constitute an informed consent (or refusal), a competent patient's decision must be both informed and voluntary. Legal discussions of conditions that would impugn the voluntariness, and thus validity, of informed consent focus on undue pressures, threats, and coercion imposed by external factors. However, the medical setting is replete with pressures stemming from the experience of illness (e.g., pain, discomfort, and fear), as well as physicians' recommendations and family dynamics. These situational factors may be especially intense in mental health settings, especially inpatient psychiatric settings, and their effect on the voluntariness of patient decision making must be examined. Philosophical accounts of voluntariness differ, but for the purposes of the informed consent process, a decision is considered voluntary if it is made in the absence of substantially controlling influences (Faden and Beauchamp).

The practice of involuntary psychiatric commitment presents a unique challenge to the doctrine of informed consent, as it entails involuntary hospital admission, while consent to admission is usually sought in other (at least, nonemergency) contexts. The ethical and legal justification of the practice of involuntary commitment resides in balancing the patient's right of self-determination, the patient's well-being, and the protection of third parties from harm. Although statutes may differ, most states permit at least temporary involuntary commitment when there is reason to believe that a patient poses a danger to him/herself or to others, or is unable to take care of him/herself as a result of profound mental illness.

Historically, the involuntary commitment and treatment of mentally ill patients was an exception to the theory of informed consent (Appelbaum). Prior to the 1960s, involuntary commitment to psychiatric facilities on the basis of a mental disorder was considered *ipso facto* a determination of mental incompetence. As the grounds for psychiatric commitment evolved in the 1960 and 1970s from criteria based on the perceived need for treatment to criteria based on perceived dangerousness to self or others, the grounds for commitment came to be distinguished from the justification for treatment. Judicial scrutiny of involuntary hospitalization has led to the widespread opinion that institutionalization is not always in the service of treatment, that it is certainly not equivalent to a determination of incompetence, and that therefore at least some involuntarily committed patients have the right to refuse treatment (Berg, et al.). In short, some individuals who meet criteria for involuntary commitment—to prevent harm to themselves or others—may nevertheless be competent to refuse (or consent to) treatment for their symptoms and/or underlying condition. Even if competent to refuse treatment, however, involuntarily committed patients may feel substantial pressure to agree to the recommendations of healthcare providers. The context of their treatment may unduly pressure them to consent in the (sometimes accurate) belief that only by agreeing to and undergoing treatment will they be permitted to leave and remain outside the institution. Further complicating this issue is the fact that some courts recognize a state interest in reducing the danger a patient poses to others and in restoring a patient sufficiently to warrant his/her discharge from the hospital. In some jurisdictions, then, treatment may be imposed without the patient's consent, although some jurisdictions at least require legal review of the medical appropriateness of the proposed intervention or the patient's competence, or both (Berg, et al.).

Informed Consent for Research in the Mental Health Context

Reflecting the Belmont Report's 1979 articulation of the ethical principles underlying research ethics and human subjects' protections, as well as provisions of the Nuremberg Code (1947) and the Declaration of Helsinki (1964, subsequently revised), federal regulations governing federally-funded research with human subjects consistently give priority to research subjects' rights and welfare over the pursuit of scientific and social interests (Title 45, Code of Federal Regulations). Informed consent's goal of welfare protection assumes prominence in research, because the right to refuse participation functions as an ultimate line of (self-) protection, in concert with other human subjects protections, or in the event that other protections prove inadequate. "Legally effective informed consent" is required of all research subjects (or their legally authorized representatives [LAR]).

Eight informational elements must be disclosed: a statement that the study involves research, as well as a description of the research and its purposes; a description of reasonably foreseeable risks; a description of reasonably expected benefits; disclosure of appropriate alternatives; a statement about maintenance of confidentiality; for research involving more than minimal risks, an explanation about

possible compensation if injury occurs; information about how the subject can have pertinent questions answered; and a statement that participation is voluntary (i.e., the refusal to participate involves no penalties or loss of benefits). Subjects should also be given information regarding: unforeseeable risks; circumstances under which the subject's participation will be terminated; additional costs that the subject may incur; the consequences of a subject's decision to withdraw; the dissemination of findings developed during the study that relate to a subject's willingness to continue; and the approximate number of total subjects (Berg, at al.; Title 45, Code of Federal Regulations). Because the consent must be in writing, there has been a tendency to equate giving informed consent with signing a consent form; in reality, informed consent is a legally-mandated process that is merely documented by signing the consent form. During the informed consent process, care must be taken to prevent the therapeutic misconception (Appelbaum, Roth, and Lidz) or institutional and psychosocial factors from undermining subjects' understanding and voluntariness.

One of Belmont Report's principles is that individuals should be respected as autonomous agents and that those with diminished autonomy should be afforded additional protection in research. Mental health research is conducted on a diverse range of mental health conditions, and only some of these conditions diminish autonomy by impairing the decision-making capacity requisite for the informed consent process.

Guidelines that have been developed to protect *mentally or cognitively impaired* research participants—whether in mental health research projects or not—are relevant for understanding aspects of informed consent in mental health research. Simultaneously, the conflation of mental illness or impairment with incapacity or incompetence must be avoided, not only for conceptual clarity and ethical appropriateness, but also to avoid further stigmatizing those with mental illness. Indeed the 1998 report of the National Bioethics Advisory Commission (NBAC), "Research Involving Subjects with Mental Disorders That May Affect Decision-Making Capacity" has been criticized for perhaps perpetuating discriminatory attitudes by focusing on persons with mental disorders rather than selecting all incapacitated persons as the focus of concern (Oldham, Haimowitz, and Delano, 1999a).

Perhaps recognizing that special protections may themselves be stigmatizing, the Federal Code or "Common Rule" does not identify the mentally ill as a vulnerable group in need of such protections. Special guidelines do address research with children (considered a vulnerable group) and on substance abuse (Office for Protection From Research Risks). As part of the informed consent process, researchers must be prepared to address, perhaps with federal certificates of confidentiality (Title 42, Code of Federal Regulations), and at least in disclosure of the psychosocial and economic risks of participation (McEnvoy and Keefe), the stigma that attaches to mental illness and to substance abuse (Gorelick, Rickens, and Bonkovsky). Because substance abuse and mental illness may impugn both decisional capacity and behavior control (and thus voluntariness), researchers may need to turn to surrogate decision makers in the consent process. Further, researchers must be cognizant that parents of children with mental disorders are also frequently stigmatized (Jensen, Fisher, and Hoagwood).

Thus, informed consent for mental health research is complicated, first, by the need to determine when mental illness or impairment renders patients incapable of giving informed consent (or refusal) and when it does not; second, by the institutional contexts of much psychiatric research and the myriad pressures that may impugn the voluntariness of such decisions; third, by the need for research to develop effective treatment for mental illness to alleviate the suffering it causes; and finally, by the difficulty that surrogates might have in appreciating the situation of those with mental illness so that they may decide as prospective subjects would if they were competent to do so.

Recognizing that some research potentially benefiting the *mentally infirm* cannot be conducted with any other group, the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, created in 1974, sought ethical means to include in research subjects incapable of giving consent. In two reports (1977 and 1978), the Commission recommended that research involving children and the institutionalized mentally infirm be placed in three categories according to level of risk presented: minimal risk, minor increase over minimal risk, and more than a minor increase. Contrary to provisions in both the Nuremberg Code and the Declaration of Helsinki, the Commission concluded that subjects incapable of giving informed consent could be enrolled in both studies that offered the potential of direct benefit and studies that did not offer such a prospect, so long as the burdens and risks of participation did not exceed a certain level. Also proposed were provisions for incapable participants to assent or object to study participation (i.e., to say "yes" or "no" when asked about willingness to participate); such a recommendation is in keeping with the current Council for International Organizations of Medical Sciences (CIOMS) comment that incapable subjects' objections to participation must be respected except in the rarest instance involving direct therapeutic benefit to the subject and the absence of alternative therapy. The Commission also recommended that institutional review boards (IRBs) appoint an auditor to assure the

adequacy of the consent process for research involving more than minimal risk, and that informed consent be obtained from the incompetent patient's legal guardian, which parallels provisions of the current version of the Declaration of Helsinki. While a substantial number of the Commission's recommendations regarding research with children were adopted as part of the Common Rule, due to a lack of consensus and concerns about auditing the informed consent process, its recommendations regarding the *mentally infirm* were not adopted.

Concerns about review and audit of research also plagued reception of the 1998 NBAC report, including its recommendations that a qualified expert "independent of the research team" assess subjects' decision-making capacity and that an "independent consent auditor" observe and approve the informed consent process with decisionally-impaired subjects. Most contentious, however, was the NBAC's proposed categorization of research based on risk levels, coupled with its recommendation that a Special Standing Panel (SSP) be created at the Department of Health and Human Services to which IRBs could submit some protocols for prospective review and authorization.

NBAC proposed adhering to a two-tier categorization of risks for research involving decisionally-incapacitated subjects: (1) minimal risk and (2) greater than minimal risk. NBAC recommended that IRBs approve protocols involving minimal risk, or greater than minimal risk that is potentially beneficial to the subject, only if the subject gives informed consent, or has given prospective authorization and his/her LAR also gives permission, or if the subject's LAR gives permission, and if there is no dissent by the subject. (IRBs may also waive the consent requirement for some minimal risk protocols.) LARs are to make decisions about participation based on "a best estimation of what the subject would have chosen if capable of making a decision," and must monitor the subject's participation to make decisions about continuing or withdrawing from participation. Patients with mental illness or with other conditions that may at some time(s) impair their decision-making capacities may execute research advance directives giving *prospective authorization* to research participation and naming a LAR (Sunderland and Dukoff). Prospective authorization cannot be a *blanket* authorization and must be limited to specific classes of research about which the (then capable) subject understood the relevant risks, potential benefits, and other conditions (NBAC). The degree of specificity of the prior prospective authorization must increase as the risk presented by a particular protocol increases. For research presenting greater than minimal risk and not holding out the prospect of direct medical benefit, NBAC recommended that IRBs approve such protocols under the same conditions, or if the protocol is approved by the SSP or falls within its guidelines and the potential subject's LAR gives permission for participation. This final provision drew criticism from two sides.

Recognizing that research involving greater than minimal risk and not presenting the prospect of direct benefit to subjects may nevertheless promise "significant increases in understanding their conditions," and thus warrant further review, the NBAC envisioned that IRBs could refer such protocols to a SSP for case-by-case review through an *open consensus process* with the prospect that, over time, guidelines for conducting such research would emerge. NBAC viewed its recommendations as consistent with the two-tier risk-level scheme found in the majority of the Common Rule (and the National Institutes of Health Clinical Center Policy on the Consent Process in Research Involving Impaired Human Subjects), and stated that the SSP could evaluate research protocols that could not be approved otherwise under provisions of its 1998 report while providing patients, their families, and advocates with confidence that such protocols were receiving independent review (NBAC).

Some critics, however, argue that the NBAC's approach would greatly hamper valuable moderate-risk research that would otherwise be categorized as minor increase over minimal risk research (Miller and Fins; Oldham, et al., 1999a, 1999b). They argue that if federal regulations result from the NBAC recommendations, relatively low-risk research, including routine medical procedures such as positron emission tomographic scans and magnetic resonance imaging with sedation, would be subject to the same restrictions as research that is categorized at the highest level of risk (such as internal organ biopsies). In a statement appended to the NBAC report, similar concerns are voiced by two NBAC commissioners (Lo and Flynn). Some of these critics advocate a tri-level risk classification including an intermediary category of research presenting "a minor increase over minimal risk" derived from the National Commission's 1978 report and the Common Rule's regulations governing research involving children (Miller and Fins). Responding to these concerns, NBAC commissioners suggest that a SSP would only review those protocols involving persons incapable of giving informed consent and who have not provided advanced authorization (Childress and Shapiro). Yet, argue John M. Oldham and his coauthors, the number of protocols involving low-risk procedures that would require SSP review would be large, given the infrequency of advance directives for research and the inclusion of so many different protocols based upon the two-tier categorization of risk (1999b).

Although the majority of concerns expressed about the NBAC's recommendations take issue with allegedly unnecessary and cumbersome layers of oversight for research

involving subjects with impaired capacity, a second line of criticism urges the opposite. Beverly Woodward argues that human research subjects are now threatened by increased research-related risks as a result of pressures to reduce restrictions on research involving subjects with impaired decision-making capacity. She charges that by downplaying the conflict between the progress of science and the protection of human subjects, and in departing from protections afforded by the Nuremberg Code and the Declaration of Helsinki to those who cannot give informed consent, the NBAC has endorsed the primacy of scientific interests over human subject welfare. Woodward finds particularly troubling NBAC's recommendation that would "permit a waiver of the consent requirement for research involving greater than minimal risk" that is without the prospect of direct benefit, so long as the subject's surrogate consents and the SSP also "grants permission based on a finding that the research 'offers the possibility of substantial benefit to the population under study'" and that the risks presented to subjects are commensurate with this possible benefit (p. 1948). Woodward believes that in some of the NBAC's recommendations, the "rapid march of science" is being advanced over the interests of individual research subjects, which, if true, would constitute a serious departure from the consensus that has grounded research ethics and the requirements for informed consent in research since the Nuremburg Code. Much remains to be examined—both at the level of drafting regulations and at the point of their implementation—to determine whether any such shift is indeed occurring.

INJURY AND INJURY CONTROL

• • •

The factual assertions used to demonstrate the importance of injuries as a public-health problem are well known: Injuries are the leading cause of death for the majority of the human life span; injuries deprive people of more potential years of life than any single disease; and the cost of injuries, whether measured in dollars or in human suffering, is staggering (Rice et al.). Injuries are generally defined by those working in the field of injury prevention as human damage due to the acute transfer of energy or the lack of essentials such as oxygen (as in asphyxiation) or heat (as in hypothermic injuries) (National Committee for Injury Prevention and Control).

Actions taken to control injury provide prototypical clashes between the personal liberty of the individual and the goals of public health. These conflicts—referred to in ethical terminology as conflicts between paternalistic beneficence and individual autonomy—are experienced in such public interventions as those that mandate helmet use by motorcyclists or that require the wearing of seat belts by drivers and passengers in automobiles. However, injury control also illuminates how public health makes progress by redefining the nature of the problem—in this case, by shifting from the term *accident* (which points to the individual who is injured or an "act of God" as the responsible agent) to *injury* (which suggests that equipment, environment, and those responsible for equipment and environment share responsibility).

Historical Development

Although injuries have plagued the human race since its earliest times, it is only in the twentieth century that science has been applied to this public-health problem. For most of

history, and to some extent up to the present, injuries have been misperceived as the equivalent of accidents; that is, chance occurrences that are basically unpredictable, and therefore unpreventable. The notions that some people are accident-prone, and therefore we should expect them to be injured, and that people are injured as punishment for a prior moral offense, have substantially retarded the ability to approach injuries and injury prevention scientifically.

A turning point in the historical development of injury control occurred in the early 1960s, when scientists first recognized that injuries, like diseases, had agents that interacted with hosts in specific environments to produce human damage (Gibson; Haddon). By modifying the agent (which was recognized as transferred energy), the human host, or the environment, one could substantially reduce the likelihood and/or the severity of an injury. William Haddon is generally recognized as the individual who most clearly "moved injury prevention into the mainstream of public health research and policy" (Baker). He developed the conceptual tools for the analyses of injury etiology and prevention that form the foundation of modern injury control.

In the decades that followed, scientists applied epidemiologic methods to the investigation of injuries and developed a new body of knowledge on how, when, where, and to whom injuries occur. Data are now available to dispel definitively the notion that injuries occur at random. The clear patterns of injury, which include identified high-risk groups (e.g., elderly persons at risk for hip fractures), geographic patterns (e.g., the distribution of firearm fatalities in the United States), and temporal trends (e.g., the increasing rate of adolescent suicide), make injuries both predictable and, more important, preventable (Baker et al.). Interventions can be focused on high-risk persons and sites, and the effects of the interventions can be scientifically evaluated by comparisons of injury rates.

Shifting Conceptions: Environmental and Product Modification

Notwithstanding these significant advances in the science of injury control, the field remains troubled by popular misconceptions that impede effective prevention programs. The reduction of injuries is still considered a matter of common sense by many. Unlike disease prevention, which is generally recognized to depend upon expert knowledge, injury prevention is commonly misperceived as a matter of an individual's responsibility rather than of public policy, and the importance of expert advice in preventing injuries is often not acknowledged. Thus the false orientation that the only way to prevent injuries is to teach people to be careful remains a popular bias, even among key decision makers who are in a position to protect millions from injury. The exclusive focus on the behavior of individuals for the prevention of injuries characterizes what was once known as accident prevention. Accidents were understood as the result of imprudent behavior; the remedy was to teach people to be constantly careful and vigilant. An example of this is the early approach to reducing highway fatalities. The method relied upon was improvement of drivers' skills through education and frequent reminders to be careful delivered in public service announcements. By the mid-1960s, however, there was a growing awareness that lives could be saved by shifting the focus of attention from the driver to the highway and the automobile. Crashes were recognized as foreseeable events. By altering the construction of vehicles and highways, the human cargo of the vehicles would not have to suffer serious injuries if and when a crash occurred.

The U.S. Congress took notice of the increasing number of highway fatalities and the opportunity to reduce this toll by mandating "crashworthy" vehicles. In 1966, Congress passed the National Traffic and Motor Vehicle Safety Act, which provided for the creation of motor vehicle safety standards. These standards, which anticipated driver error and provided a more forgiving environment within the vehicle, have saved tens of thousands of lives (Robertson).

The idea of paying attention to products as well as behaviors has not been restricted to highway safety. Efforts to prevent childhood scald injuries from hot tap water provide an example of this trend toward product alteration. Hot water coming out of faucets in homes is often at a temperature that can cause a severe burn injury to a child's skin in a matter of a few seconds. Rather than relying on parents to keep young children away from faucets, efforts have been made to direct the parents to turn down the setting on their water heaters so that water will not be discharged at temperatures greater than 125°F (Katcher et al.). This prevention strategy, however, still relies upon motivating parents to reset the water heater. An even more effective strategy has been to influence appliance manufacturers to set the heaters at the proper level before they leave the factory, thus eliminating the need to modify parental behavior.

A general principle of injury control, illustrated by the prevention of scald injuries, is to shift the focus of prevention from the individual to the community (Beauchamp; Barry). Legislation and regulation that require safer products and environments are more effective in preventing injuries than are efforts to have individuals control their own behaviors. When safety legislation or regulation has been difficult to accomplish because of strongly resistant political influences, litigation has been used. An example of this is product

liability litigation, which transfers the cost of injuries from a dangerous product back to the manufacturer, thus giving the manufacturer a strong incentive to improve the safety aspects of its product (Teret).

Altering Behaviors: Paternalism and Prevention

Sometimes product modification is not available to achieve a desired prevention strategy, and reliance upon altering behaviors is necessary. Such is the case with motorcycle helmet use. The effectiveness of helmet use in preventing or reducing the severity of head injuries is well established, but helmet use is not universally accepted by motorcyclists. Legislation requiring helmet use is effective both in increasing the use rates and in decreasing motorcyclist death rates. These laws, however, have been bitterly fought by some motorcyclists, and most states have passed and then repealed mandatory helmet use laws.

The debate over motorcycle helmet laws has raised many issues that apply to other areas of mandating safe behaviors. The propriety of governmental paternalism, the relevance of who pays the costs of injuries, and the constitutionality of laws that interfere with personal decisions are all included in the helmet issue. Assuming a definition of paternalism as institutional interference with individual action for the sake of some greater good, motorcyclists question whether their enforced safety is a good substantial enough to deny them their freedom of choice to ride without a helmet.

Opponents of helmet laws categorize such laws as *hard* legal paternalism, in that the laws regulate voluntary behavior that can harm only the motorcyclist (see Feinberg, p. 12, for distinction between *hard* and *soft* legal paternalism). Proponents of the laws point out that the increased harm inflicted on a helmetless motorcyclist eventually affects the public as a whole. The public pays about 85 percent of the costs of motorcyclists' injuries; helmet laws would reduce the human capital costs by about $400 million per year in the United States (Rice et al.). Arguments have been raised that the solution to the cost-of-injury problem is to require adequate medical insurance of those who choose to assume risks, but the flaws of this argument are apparent. Some motorcyclists will not purchase insurance, through lack of money or indifference; and it would be unacceptable to have the injuries of these motorcyclists go without medical attention (Dworkin).

The motorcycle helmet issue illustrates a problem that permeates the field of injury prevention. As a society, Americans will still permit the manufacture and marketing of some inherently dangerous products, and then rely upon limited efforts to control the behavior of the individuals to whom these products are distributed. Guns provide a striking example. There are about 38,000 firearm fatalities each year in the United States, and most of the policy to reduce this toll focuses on modifying the behavior of the individual who possesses a gun. There are few effective regulations governing the number and types of guns that can be manufactured in the United States (Webster et al.).

The future success of injury prevention appears to be highly dependent upon the willingness of government to regulate business. The products people use and the built environments in which they place themselves are highly determinative of the risk of injury. Since people do not always act in a prudent fashion, and since government is unwilling and unable to mandate such behavior, the greatest opportunity to reduce the incidence and severity of injury rests in the regulation of products and environments.

INSANITY AND THE INSANITY DEFENSE

• • •

A defendant's legal responsibility for his or her criminal conduct is a controversial issue that continually draws public attention, particularly after highly publicized crimes. The insanity defense relates to the defendant's mental condition at the time of the crime rather than at the time of the trial. The latter issue, which is discussed as the defendant's competency to stand trial, is not the subject of this entry. The insanity defense deals with the criminal competency of an individual at a time in the past rather than at the time of the trial and sentencing.

Legal insanity is by definition a legal issue and should be distinguished from *clinical insanity,* which is not a term that is recognized by mental health professionals. The term *temporary insanity* sometimes is used by the general public to refer to a brief episode of mental illness and abnormal behavior that was present only at the time of the offense rather than before or after it. Legal insanity, however, is always temporary in the sense that it refers only to the defendant's behavior at the precise time of the alleged offense.

The insanity defense represents a special defense to a criminal offense. Although the prosecution generally has the responsibility of proving the defendant guilty beyond a reasonable doubt, a defendant is legally entitled to raise defenses to the charge, whether self-defense, alibi, misidentification, insanity, or another defense.

The insanity defense is one of many issues subsumed under the rubric of criminal responsibility. Although this entry reviews several of the important issues related to the special defense of insanity, it excludes several related issues, such as diminished mental capacity, diminished responsibility, guilty but mentally ill, and the sentencing of a mentally ill defendant after conviction.

There are public misperceptions about the insanity defense. That defense is used infrequently in criminal trials in the United States and is rarely successful. Empirical research has revealed that it is introduced in less than 1 percent of felony trials and is successful in fewer than one-quarter of those trials. Many insanity acquittals occur through a stipulation between the prosecution and the defense rather than as a result of a contested trial. There is substantial variation among the states in the use and success of the insanity defense, with some states having more than seventy-five acquittals each year and many others having fewer than five. After acquittal insanity acquittees can remain hospitalized longer than they would have been imprisoned if they had been convicted of the same criminal offense and incarcerated. Generally, the public is not sympathetic to defendants who use the insanity defense for serious violent crimes except in cases of infanticide by severely depressed or mentally ill women.

Purpose of the Insanity Defense

The contemporary insanity defense had its origins more than 2,500 years ago, when it was recognized that certain

categories of individuals, such as children, the mentally ill, and the developmentally disabled, could not be considered to be at fault for their offenses. A twentieth-century judge in the United States, David Bazelon, noted in the 1954 court decision *Durham v. United States,* "Our collective conscience does not allow punishment where it cannot impose blame." Generally, however, the criminal law posits that individuals act with *free will* should be held responsible for their behavior. Mentally ill individuals can be excused from moral, and sometimes legal, blameworthiness when they act in ignorance, under compulsion, or irrationally.

Many people in the lay community mistakenly believe that a crime is defined by the perpetrator's behavior so that a homicide is a homicide. In contrast, most criminal offenses require the presence of a physical element and a mental element. The physical element, the *actus rea,* refers to the actual behavior of the perpetrator, such as aiming and firing a weapon at the victim. The mental element, the *mens rea,* or guilty mind, addresses the state of mind of the perpetrator at the time of the offense. There are, for instance, several types and degrees of criminal homicide, and they usually are distinguished by the intent of the perpetrator, such as the presence of malice, criminal intent, or advance deliberation. In many states murder is charged in several degrees. Criminal homicides may be charged as involuntary manslaughter, voluntary manslaughter, third-degree murder, second-degree murder, or first-degree murder. The most serious homicide charge requires the presence of premeditation and deliberation by the defendant at the time of the crime. Each homicide crime has different mental elements, although all involve the killing of a victim by a defendant, and the punishments vary considerably among them.

The special defense of insanity builds on this inclusion of a mental element in the offense but advances it further to inquire about the defendant's state of mind beyond criminal intent. A defendant who makes detailed advanced preparations and then kills a person upon hearing voices from God commanding that act has criminal intent but may lack criminal responsibility for that offense, depending on the legal definition of insanity in the jurisdiction.

A handful of state jurisdictions in the United States have eliminated the legal defense of insanity. In those jurisdictions evidence regarding the defendant's mental illness at the time of the offense sometimes still can be introduced at trial to attempt to prove that the defendant did not have the requisite mental element or intent to commit the offense. Thus, if the defendant was so mentally ill that he or she could not have intended to commit the offense, then evidence of that illness and mental state is admissible at trial.

Legal Standards of Criminal Responsibility

Elements of the insanity defense are defined in different ways. The definition of the underlying mental disorder and the specific components of the defense are defined by state and federal statute but sometimes are defined by case (judge-made) law. The states vary widely in the definition, implementation, and outcome of the insanity defense.

Statutes and case law also describe the applicable procedural issues related to evaluations of criminal responsibility, such as the right of the defense and the prosecution to request an examination, the court appointment and payment of forensic experts to conduct the examination, and the extent of the waiver, if any, of the attorney client-privilege in conjunction with the examination.

For centuries courts, legislators, and policy makers have struggled to articulate an appropriate threshold and definition of legal insanity to exculpate a criminal defendant. The concept of a "wild beast" test was introduced centuries ago, excusing only individuals who did not know what they were doing because they resembled infants or wild beasts in their intellectual function. A New Hampshire court decision in 1868 (*State v. Pike,* 49 N.H. 399) offered the "product test" of insanity, stating, "No man shall be held accountable, criminally, for an act which was the offspring and product of mental disease." The product test subsequently was adopted in 1954 for the federal courts in the Washington, D.C., Federal Circuit. The product test was abandoned because of its breadth and concerns about abuse in light of the fact that symptoms of many mental disorders not deemed exculpatory can be expressed as criminal acts.

The contemporary legal standards for the insanity defense are composed of two principal factors: cognitive standards and volitional standards. Cognitive standards relate to the defendant's cognitive ability or actual knowledge of the criminality, illegality, or wrongfulness of his or her conduct at the time of the crime. Cognitive abilities include the ability to perceive reality accurately and make rational decisions that are based on that reality. Originating in the United Kingdom in 1843, the M'Naghten standard, for example, asks whether the defendant was suffering from a "defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing; or if he did know it, that he did not know he was doing what was wrong." *Wrong* is defined variously as legally wrong (the defendant knew his or her action to be illegal) or morally wrong (the defendant knew his or her action to be morally wrong in his or her own eyes or in those of the public). As a symptom of severe mental illness, a command hallucination from God instructing a defendant to kill someone could be accompanied by an impairment in the defendant's cognitive

ability or knowledge regarding wrongfulness. Cognitive tests of legal insanity are the most common test in the United States and characterize the legal insanity test used by the federal courts since 1984.

The alternative insanity defense standard is concerned with the defendant's ability to control his or her behavior at the time of the offense as a result of a mental disease or disorder. This volitional test asks whether the defendant lacked partial or total capacity to control the behavior that led to the offense independent of cognitive knowledge or appreciation of the offense and its wrongfulness. This standard originally was described as an "irresistible impulse test" in which the individual's desires were so strong that he or she could not help acting on them. The individual was in effect compelled to perform the criminal acts. Mental disorders such as bipolar disorder, with a euphoric mood, elevated energy, insomnia, impulsive behavior, and racing thoughts, can reduce an individual's ability to control his or her behavior.

There are several specific variations of the cognitive and volitional tests of insanity. A cognitive test that employs the language of the defendant's ability to appreciate the wrongfulness of his or her conduct is significantly different from one that relates to the defendant's ability to know its wrongfulness. Appreciation is a broader mental ability than simple knowledge and encompasses emotional as well as cognitive or intellectual abilities. Similarly, the test that asks whether a defendant lacks substantial capacity to conform her or his conduct to the requirements of the law is a looser or broader test than one that asks whether the defendant was unable to control herself or himself because of the mental illness.

The federal test of criminal responsibility, which was enacted by Congress in 1984 after the acquittal of John Hinckley, Jr., by reason of insanity for the attempted assassination of President Ronald Reagan, applies to federal crimes. It states: "It is an affirmative defense to a prosecution under any federal statute that, at the time of the commission of the acts constituting the offense, the defendant, as a result of severe mental disease or defect, was unable to appreciate the nature and quality or wrongfulness of his acts" (18 u.s.c. section 17a).

Some states use both a cognitive prong and a volitional prong. The American Law Institute (ALI) proposed a model test in 1962 through the Model Penal Code. The ALI test states: "A person is not responsible for criminal conduct if at the time of such conduct as a result of mental disease or defect he lacks substantial capacity either to appreciate the criminality of his conduct or to conform his conduct to the requirements of law." This test had been adopted by approximately half the states before the Hinckley trial and the subsequent reforms.

Post-Hinckley Reforms of the Insanity Defense

After John Hinckley, Jr.'s, acquittal by reason of insanity in federal court many states as well as the federal government enacted changes to the insanity defense. Those changes included altering the test by making it stricter and changing certain procedures for its use. Some states and the federal courts eliminated the volitional test. Some states and the federal courts shifted the burden of proof at trial from the prosecution having the burden of proving that the defendant was not legally insane (beyond a reasonable doubt) to the defense, which must prove that the defendant was legally insane (by clear and convincing evidence). Other states added a guilty but mentally ill verdict to their criminal laws, offering a jury an alternative verdict to the insanity acquittal for mentally ill defendants who failed to satisfy the insanity defense requirements at trial.

Other statutory changes implemented stricter controls and supervision over individuals acquitted by reason of insanity, such as initial automatic hospitalization at least for psychiatric evaluation, with tighter procedures to prevent the premature release of dangerous individuals. Connecticut and Oregon have established special security review boards that intensively monitor insanity acquittees even on an outpatient basis, similar to criminal probation. Acquittees can be rehospitalized involuntarily if they are deemed to be too mentally ill or dangerous to remain in the community.

Clinical Evaluation

Statutes and case law variously use and define the terms *mental disease, mental disorder, mental illness,* and *mental defect* as the condition underlying a defendant's loss of cognitive or volitional function. The evaluator must be familiar with the legal definition of the term *mental disease* and the precise language of the criminal responsibility test in the defendant's jurisdiction. Statutes may or may not clearly define a mental disease or defect and usually do not employ accepted psychiatric nomenclature. Severe mental disorders such as schizophrenia, schizoaffective disorder, bipolar disorder, and other mood disorders with psychotic features generally qualify as mental diseases or defects for purposes of the insanity defense. Impulse control disorders such as kleptomania, pyromania, paraphilia, and pathological gambling may or may not be grounds for an insanity defense under the law. Other conditions not formally recognized as

mental disorders by the mental health community, such as *battered woman syndrome,* may not constitute a mental disease or defect for purposes of the insanity defense.

The criminal responsibility evaluation is a retrospective evaluation of a defendant's criminal competency and is readily distinguished from an evaluation for treatment purposes. Therefore, forensic evaluators must have adequate training, experience, and forensic knowledge to conduct such evaluations properly. Evaluators typically attempt to interview the defendant about his or her thinking, behavior, and emotional controls at the time of the offense. However, evaluators cannot rely exclusively on the defendant's account of the crime because of the possibility of feigned mental illness and also must review crime scene data such as police reports, autopsies, witness accounts, and other information that can lead more objectively to an understanding of the events. Psychiatric treatment records of the defendant also are made available to the evaluator. Collateral interviews with family members or friends of the defendant, current treatment personnel, coworkers, and victims and witnesses also can be conducted. Psychological or neurological testing can be helpful in establishing a psychiatric diagnosis but cannot provide direct evidence that the defendant satisfies the insanity test standard. Evaluators may not be able to interview a defendant until months or years after the crime. Thus, reconstructing the defendant's mental state at that earlier time is a challenging task.

Clinical Issues

After the forensic mental health evaluator has obtained the necessary data regarding the defendant's mental health history and the defendant's state of mind at the time of the offense, the evaluator must provide to the retaining attorney or court an opinion about the defendant's psychiatric diagnosis and address the insanity defense standard. There are no biological tests that can prove directly whether a defendant had a mental disorder at the time of the crime or met the insanity defense standard, and the evaluator uses clinical judgment to reach conclusions in this regard. A defendant's assertion of a severe mental disorder at the time of the crime is more credible when there is a previous history of that disorder and documented treatment for it.

The evaluator must attempt to exclude mental conditions that are not deemed to be exculpatory by the applicable law. Personality disorders and intoxication by alcohol and drugs at the time of an offense are typically not exculpatory, and so the effects of those disorders on a defendant must be considered but separated from those of disorders that are potentially exculpatory. In other words, the evaluator must establish the relationship between the mental disorder present at the time of the offense and the criminal behavior.

There are many challenges in determining whether a defendant meets the legal insanity standard. The evaluator focuses on the defendant's thoughts, feelings, and behavior at the time of the crime but also inquires about those issues before and after the crime. If the defendant is charged with multiple crimes, the evaluator performs the analysis for each of those crimes. The evaluator must analyze the defendant's thoughts, feelings, and behavior carefully to determine whether the specific cognitive or volitional criteria for the applicable insanity defense are satisfied. It is likely that a defendant will satisfy the criteria for one insanity defense test but not for another.

If a jurisdiction uses a volitional insanity defense test, the evaluator must determine whether the defendant lacked the ability to control his or her behavior as a result of a severe mental disorder or simply failed to control his or her behavior because of anger, revenge, greed, envy, sexual arousal, or another condition unrelated to a severe mental disorder. The fact that a defendant acted on an impulse or desire does not mean that that impulse was irresistible; most, if not all, impulses can be resisted in certain circumstances. Volitional assessments involve a determination of whether the defendant attempted to delay or resist the impulse, pursued alternatives to gratifying the impulse, and planned or prepared for the crime while avoiding apprehension.

The insanity defense has been a complex yet compelling subject for centuries, attracting extraordinary public attention, especially after well-publicized crimes. The defense has survived many attempts to abolish it, with only a few states having done that. Although there are moral and legal bases for excusing an individual's criminal activity, most societies have struggled to adopt exculpatory rules that are politically acceptable and fair to mentally disordered individuals. Increasing attention has been paid in the United States to adopting postacquittal treatment and monitoring procedures to maximize the treatment of insanity acquittees while providing for the public safety.

INSTITUTIONALIZATION AND DEINSTITUTIONALIZATION

• • •

Deinstitutionalization, the mass exodus of mentally ill persons from state hospitals into the community, was accomplished in the United States during the seventh and eighth decades of the twentieth century. The process has taken away from persons with long-term, severe mental illness the almost total asylum from the pressures of the world and the care, however imperfect, that they received in these institutions. The central ethical question is: Does society not have an obligation to provide the care and treatment that they need in the community? The fact that a significant proportion of the severely and persistently mentally ill population is now living in the streets, in jails, and in other squalid conditions is evidence that adequate community care has not been provided. Moreover, it may be that some mentally ill persons who cannot be effectively treated in the community have been deinstitutionalized. Does society not have an obligation to correct this situation as well?

Before the current era of deinstitutionalization, persons with long-term, severe mental illness were usually institutionalized for life in large state mental hospitals. This institutionalization often began after a first acute mental breakdown in adolescence or early adulthood. Sometimes these patients went into remission in the hospital and were discharged, but at the point of their next psychotic episode were rehospitalized, often never to return to the community.

In the 1960s, British social psychiatrist John Wing and others observed that persons who spent long periods in mental hospitals developed what has come to be known as *institutionalism,* a syndrome characterized by lack of initiative, apathy, withdrawal, submissiveness to authority, and excessive dependence on the institution (Wing and Brown). Sociologist Erving Goffman argued that in what he called *total institutions,* such as state mental hospitals, impersonal treatment can strip away a patient's dignity and individuality and foster regression. The deviant person is locked into a degraded, stigmatized, deviant role. Goffman and others believed that the social environment in institutions could

strongly influence the emergence of psychotic symptoms and behavior.

Other investigators, however, observed that institutionalism may not be entirely the outcome of living in dehumanizing institutions; at least in part, it may be characteristic of the schizophrenic process itself. With deinstitutionalization, these researchers observed that many persons with long-term, severe mental illness who were liable to institutionalism seemed to develop dependence on any other way of life that provided minimal social stimulation and allowed them to be socially inactive. They gravitated toward a lifestyle that allowed them to remain free from symptoms and painful and depressive feelings.

Is this dependent, inactive lifestyle bad? For many deinstitutionalized persons, it may lead to unnecessary regression and impede their social and vocational functioning; thus, for these patients it should be discouraged. However, this restricted lifestyle may meet the needs of many deinstitutionalized individuals and help them stay in the community. Mental-health professionals and society at large need to recognize the crippling limitations of mental illness that do not yield to current treatment methods. They also need to be clear about the importance of providing adequate care for this vulnerable group of severely mentally ill persons so that the end result is not like the fate of the mentally ill in the back wards of state hospitals—neglect, abysmal conditions, extreme regression, and marked deterioration of their mental states. For those persons who can be restored to social and vocational functioning only to a degree, many mental-health professionals advocate lowered expectations and the provision of reasonable comfort and a dignified, undemanding life.

The Origins of Deinstitutionalization

In 1955, the number of persons in state hospitals in the United States reached its highest point: 559,000 persons were institutionalized in state mental hospitals out of a total national population of 165 million. In 1998, there were approximately 57,000 institutionalized persons out of a population of 275 million. In 43 years, the United States reduced its number of occupied state hospital beds from 339 per 100,000 population to 21 per 100,000. Some individual states have gone even further: in California in 2000, for example, there were 9 state hospital beds per 100,000 population, including forensic patients (committed through the legal system); nonforensic beds numbered only 3 per 100,000.

Until the deinstitutionalization movement, state mental hospitals had fulfilled the function for society of keeping the mentally ill out of sight and thus out of mind. At the same time, before the advent of modern psychoactive medications, the controls and structure provided by the state hospitals—as well as the granting of asylum—may have been necessary for many of the long-term mentally ill. Unfortunately, the ways in which structure and asylum were achieved, and the everyday abuses of state hospital life such as neglect, abysmal living conditions, and deterioration of the patients' mental states, left scars on the mental-health professions and on the reputation of state hospitals, as well as on the patients. Periodic public outcries about these deplorable conditions, documented by journalists such as Albert Deutsch in his influential book *The Shame of the States* (1948), set the stage for deinstitutionalization. These concerns, shared by mental-health professionals, led to the formation by Congress of the Joint Commission on Mental Illness and Health (1961), which issued recommendations for community alternatives to state hospitals. When psychoactive medications appeared in the 1950s, along with a new philosophy of social treatment, the majority of the long-term psychotic population seemed to have been left in an institutional environment that was no longer necessary or even appropriate.

Other factors also came into play. First, the conviction that mental patients receive better and more humanitarian treatment in the community than in state hospitals far away from home was a philosophical keystone of the community mental-health movement. Another motivating force was concern that the system of indefinite commitment and institutionalization of psychiatric patients deprived them of their civil rights. Finally, many financially strapped state governments wished to shift some of the fiscal burden for these patients to federal and local governments, that is, to federal Supplemental Security Income (SSI) and Medicaid, and to local law-enforcement and emergency-health and mental-health services.

Two developments at the federal level accelerated the process of deinstitutionalization in 1963. Under the provisions of categorical Aid to the Disabled (ATD), the Secretary of Health, Education, and Welfare issued an administrative order making the mentally ill eligible for federal financial support in the community. Moreover, Congress passed legislation to facilitate the establishment of community mental-health centers. With ATD, psychiatric patients and mental-health professionals acting on their behalf now had access to federal grants-in-aid, in many places supplemented by funding from the state. This enabled patients to support themselves or be supported either at home or in such facilities as board-and-care homes (boarding homes) or old hotels, at little cost to the state. ATD is now the Supplemental Security Income referred to above, and is administered by

the Social Security Administration. Instead of maintaining patients in a state hospital, the states, even those that provided generous ATD supplements, found the cost of maintaining these patients in the community to be far less than the cost of maintaining them in state hospitals. Although the amount of money available to patients under ATD was not a princely sum, it was sufficient to pay for a board-and-care home or to maintain a low standard of living elsewhere in the community.

Many individuals in the community discovered that they could earn substantial additional income by taking former mental patients into their homes, even at the rates allowed by the ATD grants. Some entrepreneurs set up board-and-care homes holding as many as one hundred persons or more in large, old houses and converted apartment buildings and rooming houses. Although these board-and-care-home operators were not skilled in the management of psychiatric patients, they were able to accommodate tens of thousands of persons who had formerly been in state hospitals and who did not now have major behavior problems (primarily because they were being treated with the antipsychotic drugs).

In 1963, too, Congress passed the Mental Retardation Facilities and Community Mental Health Centers Construction Act, amended in 1965 to provide grants for the initial costs of staffing newly constructed centers. This legislation was a strong incentive to the development of community programs with the potential to treat people whose main recourse previously had been the state hospital. However, although rehabilitative services and pre-care and aftercare services were among the ten services eligible for funding, an agency did not have to offer them in order to qualify for funding as a comprehensive community mental-health center. Many community mental-health centers chose to focus on persons with neuroses and problems of living—the healthy but unhappy. Persons with long-term, severe mental illness were often just as neglected in the community as they had been in the hospitals.

Sweeping changes in the commitment laws of the various states also contributed to deinstitutionalization. In California, for instance, the Lanterman-Petris-Short Act of 1968 provided further impetus for the movement of patients out of hospitals. Underlying this legislation was a concern for the civil rights of the psychiatric patient. (Much of this concern came from civil rights groups and individuals outside the mental-health professions.) The act made the involuntary commitment of psychiatric patients a much more complex process, and holding psychiatric patients indefinitely against their will in mental hospitals became much more difficult. Thus, the initial stage of what had formerly been the career of the long-term hospitalized patient—namely, an involuntary, indefinite commitment—became a thing of the past.

Deinstitutionalization in Practice

One of the most important lessons to be drawn from the experience with deinstitutionalization was almost totally unforeseen by its advocates. The most difficult problem is not the fate of those patients discharged into the community after many years of hospitalization. Rather, the problem that has proved most vexing and that has presented the most difficult ethical dilemmas has been the treatment of the generation that has grown up since deinstitutionalization. It is largely from this generation that the homeless mentally ill are drawn. The large homeless population with major mental illness—that is, schizophrenia, schizoaffective disorder, bipolar illness, and major depression with psychotic features—tends to be young.

Why is this so? In the older generation of long-stay, hospitalized patients, chances were that most of those who were least appropriate for discharge—because of their propensity to physical violence, very poor coping skills, or marked degree of manifest pathology—were not discharged, or if they were discharged and failed in the community, were be sent into the community again.

Those who have been hospitalized for long periods have been institutionalized to passivity. For the most part, they have come to do what they are told. This is not presented as a beneficial effect of long-term hospitalization, but simply as a clinical observation. When those for whom discharge from the hospital is feasible and appropriate are placed in a community living situation with sufficient support and structure, most (though by no means all) tend to stay where they are placed and to accept treatment.

Long-term, severely mentally ill persons of the new generation, however, have not been institutionalized to passivity. Not only have they not spent long years in hospitals, they have probably had difficulty just getting admitted to an acute hospital, whether or not they wanted to be admitted, and even greater difficulty staying there for more than a short period on any one admission. Acute psychiatric inpatient care is extremely expensive, and there is a great reluctance to use scarce mental-health funds to provide it.

Existential Problems in the Community

A young person just beginning to deal with life's demands struggles to achieve some measure of independence, to choose and succeed at a vocation, to establish satisfying

interpersonal relationships and attain some degree of intimacy, and to acquire some sense of identity. Lacking the abilities to withstand stress and to form meaningful interpersonal relationships, the mentally ill person's efforts often lead only to failure. The result may be a still more determined, often frantic effort with a greatly increased level of anxiety and desperation. Ultimately, this may lead to another failure accompanied by feelings of despair. For a person predisposed to retreat into acute mental breakdowns, the result is predictably stormy, with acute psychotic breaks, and repeated—and usually brief—hospitalizations often related to these desperate attempts to achieve. The situation becomes even worse when such persons are in an environment where unrealistic expectations emanate not just from within themselves, but also from families and mental-health professionals.

Before deinstitutionalization, these *new long-term patients* would have been institutionalized, often from the time of their first mental breakdown in adolescence or early adulthood. After their initial failures in trying to cope with the vicissitudes of life and of living in the community, such patients would have been exposed no longer to these stresses, but given a permanent place of asylum from the demands of the world.

Such an approach now tends to be the exception, not the rule; since large-scale deinstitutionalization began, hospital stays tend to be brief. In this sense, the majority of *new* long-term patients are the products of deinstitutionalization. To observe this is not to imply that society should turn the clock back and return to a system of total institutionalization for all persons with long-term, severe mental illness. In the community, most of these patients can have something very precious—their liberty, to the extent they can handle it. Furthermore, if the resources are provided, they can realize their potential to pass some of life's milestones successfully. Nevertheless, it is this new generation of long-term, severely mentally ill persons that poses the greatest ethical challenge to deinstitutionalization and the most difficult clinical problems in community treatment, and that has swelled the ranks of the homeless and the incarcerated mentally ill.

Problems in Treatment

As recently as 1950, there were no psychoactive drugs to bring long-term, severely mentally ill persons out of their world of autistic fantasy and help them return to the community. Even today, many patients fail to take psychoactive medications because of disturbing side effects, denial of illness, or, in some cases, the desire to avoid the depression and anxiety that result when they see their reality too clearly; grandiosity and a blurring of reality may make their lives more bearable than a drug-induced relative normality.

A large proportion of the new long-term patients tends to deny the need for mental-health treatment and to eschew the identity of the long-term mental patient. Admitting mental illness seems to many of these persons to be admitting failure. Becoming part of the mental-health system seems to them like joining an army of misfits. Many of these persons also have substance-abuse disorders and/or medicate themselves with street drugs. Another contributing factor is the natural rebelliousness of youth.

The problem becomes worse for those whose illnesses are more severe. These persons' problems are again illustrated by the problems of the homeless mentally ill. Evidence is beginning to emerge that the homeless mentally ill are more severely ill than the general mentally ill population. At Bellevue Hospital in New York City, for example, approximately 50 percent of inpatients who were homeless on admission are transferred to state hospitals for long-term care as a result of the severity of their illnesses, as opposed to 8 percent of other Bellevue psychiatric inpatients.

Functions of the State Hospital

Valid concerns about the shortcomings and antitherapeutic aspects of state hospitals in the United States often overshadowed the fact that the state hospitals fulfilled some crucial functions for persons with long-term, severe mental illness. The term *asylum* was in many ways appropriate: these imperfect institutions did provide asylum and sanctuary from the pressures of the world with which, in varying degrees, most of these persons were unable to cope. They also provided medical care, patient monitoring, respite for the patient's family, and a social network for the patient, as well as food, shelter, and needed support and structure.

Furthermore, in the state hospitals, the treatment and services that did exist were in one place and under one administration. In the community the situation is very different. Services and treatment are under various administrative jurisdictions and in various locations. Even the mentally healthy have difficulty dealing with a number of bureaucracies, both governmental and private, and having their needs met. Patients can easily get lost in the community. In a hospital, they may have been neglected, but at least their whereabouts were known.

These problems have led to the recognition of the importance of case management. Many of America's homeless mentally ill would not be on the streets if they were on the caseload of a professional or paraprofessional trained to deal with the problems of persons with long-term, severe

mental illness, monitor these persons (with considerable persistence when necessary), and facilitate their receiving services.

The fact that persons with long-term, severe mental illness have been deinstitutionalized does not mean they no longer need social support, protection, and relief, either periodic or continuous, from external stimuli and the pressures of life. In short, they need asylum and sanctuary in the community. Unfortunately, because the old state hospitals were called asylums, the word *asylum* took on an almost sinister connotation. Only in recent years has the word again become respectable, signifying the function of providing asylum, rather than asylum as a place.

The concept of asylum and sanctuary in the community becomes important in post-discharge planning because, while some long-term, severely mentally ill persons eventually attain high levels of social and vocational functioning, others have difficulty meeting simple demands of living on their own, even with long-term rehabilitative help. Whatever degree of rehabilitation is possible for each patient cannot take place unless support and protection in the community—from family, treatment program, therapist, family-care home, or board-and-care home—are provided at the same time. Moreover, if the need for asylum and sanctuary within the community is not taken into account, many persons with long-term, severe mental illness may find it impossible to live in the community.

Ingredients of a System of Community Care

Has community care in the United States been better than institutionalized care for persons with long-term, severe mental illness? The answer appears to be both yes and no. With deinstitutionalization, for instance, some long-term dysfunctional and mentally disordered individuals gradually, over a period of years, succeed in their strivings for independence, a vocation, intimacy, and a sense of identity. For them, deinstitutionalization has indeed been a success. The deinstitutionalization movement has also taught administrators much about what good community care should be: a comprehensive and integrated system of care, with designated responsibility, accountability, and adequate fiscal resources.

More specifically, such care requires an adequate number and ample range of graded, stepwise, supervised community-housing settings; adequate, comprehensive, and accessible psychiatric and rehabilitative services provided assertively and through outreach services when necessary; and available and accessible crisis services. A system of responsibility for persons with long-term, severe mental illness living in the community should ensure that each patient has one case manager, a mental-health professional or paraprofessional who is responsible for seeing that the appropriate psychiatric and medical assessments are carried out. This case manager should formulate, in collaboration with the patient, an individualized treatment and rehabilitation plan, including the proper pharmacotherapy; monitor the patient; and assist him or her in receiving services. Respite care, a period when families can be relieved of the responsibilities of caring for their mentally ill relatives, is needed for the more than 50 percent of the long-term, severely mentally ill population in the United States who live with their families, so that the family is better able to provide a support system. The entire burden of deinstitutionalization should not be allowed to fall on families, as it sometimes has.

Setting up such a comprehensive and integrated system of care for persons with long-term, severe mental illness in the United States has proven far more difficult to accomplish than was envisioned. A large proportion of the many hundreds of thousands of persons with long-term, severe mental illness has not been well served in the community. In addition, some patients who cannot be effectively treated in the community have been deinstitutionalized. Probably only a relatively small minority of long-term mentally ill persons requires a highly structured, locked, twenty-four-hour setting for adequate intermediate or long-term management. But for members of this small minority, such institutional management may be critical—for their sake and for the sake of the community. Attempts to treat persons characterized by such problems as assaultive behavior; severe, overt major psychopathology; grossly inappropriate social behavior; reluctance to take psychoactive medications; inability to adjust to open settings; problems with drugs and alcohol; and self-destructive behavior in the community have required an inordinate amount of time and effort from mental-health professionals, various social agencies, and the criminal-justice system. Many patients have been lost to the mental-health system because their treatment needs have not been met, and these people, for the most part, are on the streets or in jail.

The result has often been seen as a series of failures on the part of both mentally ill persons and mental-health professionals. As a consequence, a number of long-term mentally ill persons have become alienated from the system that has not met their needs, and some mental-health professionals have become disenchanted with the treatment of these persons. The heat of the debate in the United States over the issue of whether or not to provide intermediate and long-term hospitalization has tended to obscure the benefits of community treatment for the great majority of the long-term mentally ill, who do not require such highly structured, twenty-four-hour care.

Where to treat—hospital versus community—should not be an ideological issue; it is a decision best based on the clinical needs of each person. Unfortunately, efforts to deinstitutionalize have, in practice, too often confused locus of care with quality of care. Where mentally ill persons are treated has been seen as more important than how they are treated. Care in the community has often been assumed by definition to be better than hospital care. In actuality, poor care can be found in both hospital and community settings.

Independence

For many long-term mentally ill persons, nothing is more difficult to attain and sustain than independence. The issue of supervised versus unsupervised housing provides an example. Professionals would like to see their patients living in their own apartments and managing on their own, perhaps with some outpatient support. But, as described in the 1992 American Psychiatric Association Task Force's report on the homeless mentally ill, the experience of deinstitutionalization has shown that most long-term, severely mentally ill persons living in unsupervised mainstream housing in the community find the ordinary stresses of managing on their own more than they can handle. After a while they tend to not take their medications and to neglect their nutrition. Their lives unravel; eventually they find their way back to the hospital or to the streets.

Mentally ill persons value independence highly, but they often underestimate their dependency needs and their needs for structure—for instance to have a living situation where their medication is dispensed to them and their meals are provided. Professionals need to be realistic about their patients' potential for independence, even if the patients are not.

Freedom

What about the issue of freedom? Persons with long-term, severe mental illness enjoy much more liberty than when they were institutionalized; in most cases, as was discussed earlier, this is appropriate. But that freedom may well be damaging to some patients if they are given more than they can handle. Many of those on the streets and in the jails suffer from the lack of structure and organization in their lives; they need, because of their illnesses, to have these elements imposed upon them.

However, involuntary treatment presents an extremely difficult ethical dilemma. Beliefs about civil liberties come into conflict with concerns for the welfare of persons with long-term, severe mental illness. A basis for facing this dilemma is provided by the belief that the mentally ill have a fundamental right to treatment, even if at times the treatment must be involuntary when, because of severe mental illness, they present a serious threat to their own welfare or that of others and are not able to make a rational decision about accepting treatment. Reaching out to patients and working with them to accept help on a voluntary basis is certainly a mandatory first step. But if this fails and the patient is at serious risk, professionals with direct responsibility for patients usually see that ethically they cannot simply stop there.

In such cases, humane commitment laws facilitate a prompt return to acute inpatient treatment when such treatment is needed. Ongoing measures, such as conservatorship or guardianship, court-mandated outpatient treatment, and appointing a payee for the person's disability check are components of a treatment philosophy and practice that recognizes that external controls such as these are a positive therapeutic approach for mentally ill persons who lack the internal controls to deal with their impulses and to cope with life's demands. Such external controls may help interrupt a self-destructive, chaotic life on the streets and in and out of jails and hospitals.

Conclusion

Further deinstitutionalization must be preceded by careful planning and the establishment of community services. In fact, community services set up in the United States have in most cases been swamped by the number of patients coming out of the hospitals or who are already in the community and in need of care. Clearly, deinstitutionalization should be implemented only to the extent that each long-term, severely mentally ill person in the community can be properly and adequately housed and treated. This should also be done for those mentally ill persons already in the community. Those who implement a policy of deinstitutionalization must take into account not only those still in hospitals but those mentally ill persons who are reaching an age where their mental illness is becoming manifest and who will never be long-term hospitalized mental patients.

For this latter group, it is essential that there be a system of case management with staff who understand their problems and their needs, as well as a range of supervised housing in the community that is sufficiently structured to accommodate those who require it. Although adequate case management, appropriate housing, and treatment should greatly decrease the need for involuntary treatment, there should still be a willingness to use it when it becomes necessary. It also needs to be recognized that there is a significant subpopulation of persons with long-term, severe mental illness who should not be deinstitutionalized.

Having dismantled such a large proportion of the institutions for the mentally ill, society surprisingly continues to face the grave ethical and clinical question of whether there is still an obligation to provide care and treatment in the community for the mentally ill persons who used to inhabit these institutions. It is a matter of priorities among the various social needs of our society. Mental-health professionals, at least those in public service, are coming around to giving this population the highest priority. With regard to legislators and the general public, there is much more ambivalence, and persons with long-term, severe mental illness often fare poorly in the struggle over setting priorities and allocating funds.

INTERNATIONAL HEALTH

• • •

The term *international health* has a variety of meanings that depend on the context in which it is used. In a geopolitical sense the term is used in regard to the numerous governmental and nongovernmental organizations (NGOs) throughout the world that are concerned with human health and disease. Those organizations broadly deal with health issues that involve both economically advanced and less developed nations, although the focus is frequently on impoverished populations in both settings. Examples include the World Health Organization (WHO); the United Nations (UN) and its various agencies, such as UNDP (United Nations

Development Programme), UNICEF (United Nations International Children's Emergency Fund), and UNHCR (United Nations High Commission on Refugees); the World Bank; and NGOs supported by philanthropy, such as the Wellcome Trust, the Rockefeller Foundation, and Médicin Sans Frontières. Those organizations work with national and regional health authorities to address operational and research issues. The creation and maintenance of those groups have resulted from moral, social, and financial obligations and altruism (Basch; Merson et al.).

International health also relates to biomedical research and health policy issues that cross national boundaries and increasingly involve the participation of people who live in developing countries. Bioethical issues arising from the conduct of research on people in economically depressed regions have received much attention over the last several years. This entry deals with ethical issues that have been sources of controversy and debate in the context of international health.

History of Bioethical Principles and International Health

Bioethical guidelines for the conduct of research involving humans originally were put forth formally in the Nuremberg Code, a document that was generated after World War II, when atrocities conducted by physicians under the Nazi government became widely known. In 1964 the World Medical Association Declaration of Helsinki elaborated on those principles. The Declaration of Helsinki was concerned primarily with medical experimentation involving persons in economically advanced developed countries and made a distinction between *therapeutic* and *nontherapeutic* research. Bioethical issues concerned specifically with research that involved vulnerable populations and people in developing countries were addressed by the Council for the International Organization of Medical Sciences (CIOMS), which was last revised in 1993. Controversies about the interpretation of those documents have been commented on by several authorities in the field of bioethics (Levine; Singer and Benatar; Zion et al.).

When it became public knowledge that treatment for neurosyphilis was withheld deliberately from African-American men in Tuskegee, Alabama, to examine the natural course of the disease, a commission was organized to outline the principles of conducting research involving human subjects. This resulted in the publication of the Belmont Report, which built on the Declaration of Helsinki. The Belmont Report emphasized the notion that individual autonomy, beneficence, and justice were central to the ethical conduct of research involving humans (National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research). Committees in the United States (National Bioethics Advisory Commission) and the United Kingdom (Nuffield Council for Bioethics) later addressed bioethical aspects of research in the international setting. Those principles are being refined by organizations and people from developing countries where the research is being conducted (Bhotta).

Major Issues in Biomedical Research Ethics in Developing Countries

Research involving human subjects implies a wide range of responsibilities on the part of the participants and their communities, the investigator, and funding agencies. In the context of international health those issues generally have been viewed from the perspective of the cultural and legal norms of developed countries, which historically have been interpreted by institutional review boards (IRBs) (Shuklenk and Ashcroft).

Issues issues of recent debate and controversy in international health are illustrated by a clinical trial that tested the efficacy of the antiretroviral drug zidovudine in limiting maternal-infant transmission of human immunodeficiency virus (HIV). A study conducted in East Africa in the mid-1990s involved randomization of HIV-infected pregnant women to either short-duration therapy with zidovudine or inert placebo. The lack of any treatment with an antiretroviral drug was the normal standard of care in Africa at that time. When it became widely known that earlier research conducted in developed countries (AIDS clinical trial group protocol 076) showed that a longer course of zidovudine therapy reduced the risk of transmission of HIV from mothers to their offspring from approximately 25 percent to 8 percent (Connor et al.), several highly cited publications in the lay and professional press suggested that the African study was unethical because it denied therapy of known efficacy to participants who were randomized to the placebo group (Lurie and Wolf, 1997, 1998; Angell et al).

Moreover, on the basis of the concept that the *best available therapy* should be made available to HIV-infected women, it was suggested that the duration of a course of zidovudine in developing countries be as long as the course given in developed countries (Angell et al.). The cost of the longer course of the antiretroviral drug at that time was $800, an amount that far exceeded the annual per capita financial allocation for healthcare in African countries where the HIV pandemic was present.

This controversy highlights several bioethical concepts that are germane to research in international health, including (1) local standards of care and achievement of equipoise,

(2) informed consent, (3) incentives and benefits of biomedical research and clinical trials to the individual and the community, and (4) disparities in global health between developed and developing countries.

LOCAL STANDARDS OF CARE AND EQUIPOISE. It is a central tenet of clinical research trials involving humans that hypotheses generated to evaluate new therapies be compared with the established standard; that is, the design of a trial must achieve equipoise. The controversy cited above is paradigmatic of the differing perceptions of this issue as it applies to a disease that affects resident populations of both the developed world and the developing world. The standard of care for HIV-infected pregnant women in Uganda at the time the study was conducted—no treatment with an antiretroviral drug—was strikingly different from that for residents of the United States, who had reasonable access to long-duration zidovudine despite its cost.

Acknowledgment of differences based on economic and cultural differences is important in the design and implementation of international research studies so that real or perceived issues that imply ethical imperialism can be avoided (Mbidde). This constitutes a broad rather than a narrow interpretation of the concept that the best therapy be made available to participants in research studies and their local community. A stricter interpretation inadvertently may led to a situation that, ironically, some may consider unethical because clinical research not performed in developing countries cannot possibly benefit the local population; that is, the efficacy of short-term zidovudine would not be known unless the African study were performed. Tensions arising from the fact that financial support for research studies conducted in developing countries comes mainly from governmental organizations and NGOs based in developing countries undoubtedly will continue to raise these issues. It is thus a positive development that training in the bioethical aspects of international research is receiving greater emphasis in both developed and developing countries, for example, through programs supported by the Fogarty International Center of the National Institutes of Health in the United States.

Bioethical aspects of international health research have been focused on disease and health issues that affect the inhabitants of both developed and developing countries, such as HIV infection. With increasing attention to research on health issues that primarily or exclusively affect residents of developing countries, such as the global health initiatives of the Gates Foundation, it is important that investigators and IRBs with different backgrounds come together to develop study designs that are acceptable in a broad cultural context.

It is critical that a study have potential benefit to the local population and not entail exclusively the care or prevention of a disease in persons in developed countries. For example, the development of a vaccine against blood-stage infection with the parasite *Plasmodium falciparum* has advanced to clinical trials in Africa and other areas in the tropics. The need for such a vaccine is great because falciparum malaria is estimated to kill approximately one million African infants per year. Residents of developed countries, where funding for the development and testing of vaccines comes from, are at minimal risk of malaria unless they visit endemic areas and do not take appropriate chemoprophylaxis. At the extreme, some diseases, such as lymphatic filariasis, do not exist in economically advanced countries, yet global initiatives for research and treatment of those health problems will benefit impoverished residents of developing countries exclusively.

On the one hand, investigators engaged in these research activities are largely from developed countries and stand to benefit from the conduct of clinical trials through increased scientific stature and competitiveness for additional funding and fame. On the other hand, agreement to participate in clinical trials by local populations may be motivated by the perceived short-term health benefit for oneself and one's family, community, or nation. It is therefore important that the topic of the research study and the details of its design address the health needs that are important in the local context. Moreover, participants in such studies need to understand how and in what time frame the research ultimately will benefit them and their community (Participants in the 2001 Conference on Ethical Aspects of Research in Developing Countries).

INFORMED CONSENT. European and North American concepts of informed consent generally are aimed at preserving the integrity and autonomy of the individuals who are recruited to participate in a research study. Excessive financial or other types of incentives are considered coercive. In the case of the United States the litigious nature of the interaction between the research subject and the investigator is also a significant factor in the process of obtaining and documenting informed consent.

Informed consent in many developing countries is an equally complex process with important variables that distinguish it from the process in developed countries. Community participation and educational sessions that include an ongoing dialogue with the researchers before, during, and after the completion of clinical research studies are prominent features, especially when the disease or health issue being studied has great significance for public health. Because many studies in international health involve investigators

who are not residents of the area where the participants live, it is prudent and appropriate that scientists, public health officials, and community leaders be involved in developing methods of obtaining informed consent that are culturally appropriate. For example, although documentation of consent by signing a piece of paper that describes the risks and benefits of participation generally is done in developed countries, the residents of many rural areas of sub-Saharan Africa and developing countries in Asia and Latin America may not have achieved a literate status that enables them to be competent to appraise such a document critically. An extreme example would be to ask an illiterate individual to mark a piece of paper that contains information that that person cannot read. In this scenario oral informed consent obtained from local persons trained for this purpose is appropriate. Attention to this process is especially important for vulnerable populations in developing countries who may feel pressured to cooperate because of gender or economic biases that are prevalent in developed as well as developing countries (London 2001, 2002).

INCENTIVES AND HEALTH BENEFITS. Financial incentives to participate in clinical trials have been the subject of debate. Some have argued that financial incentives are coercive, especially in populations that are considered vulnerable because of extreme poverty. Reasonable financial inducements that account for time spent away from normal daily activities, for example, farming in populations in which subsistence agriculture is common, may be appropriate. In the international health setting, in which village and neighborhood life is common, inducements in the form of community improvements may be considered not coercive at the individual level and as representing reasonable "payment" for participation by community members. For example, financial support for a local health center may benefit populations that participate in malaria vaccine trials. Thus, although the benefit of a malaria vaccine may not materialize until years after the completion of a specific clinical trial, education of mothers in recognizing the symptoms of malaria in infants and improved access to antimalarial drugs will improve the local standard of care.

EQUITY AND GLOBAL DISPARITIES IN INTERNATIONAL HEALTH. Consideration of bioethical principles in international health must be seen in the context of the moral dilemma that more than 87 percent of the annual global health budget is devoted to 16 percent of the world's population in the most affluent developed countries (Iglehart). As the amount of money and scientific talent committed to the examination of health issues associated with the changing demography of developed countries, such as Alzheimer's disease and other dementias associated with old age, is increasing, infectious diseases that are rampant in developing countries continue to perpetuate the cycle of poverty and high childhood mortality and morbidity. This inequity may increase as the servicing of debt limits the economic advancement of developing countries and the internationalization of industrial and agriculture markets influences research priorities (Benatar). In the long term political advocacy on the part of those who conduct international biomedical research is needed to change this power disparity and increase research capacity training in developing countries (Nchinda).

ISLAM, BIOETHICS IN

• • •

Islam, the last of the Abrahamic religions (literally meaning "submission [to God's will]"), was proclaimed by Muhammad (born ca. 570 C.E.), the prophet of Islam and the founder of Islamic public order in the seventh century C.E. in Arabia. This article will focus on the historical development of Islam, its fundamental teachings, Islamic legal thought, the Islamic theological and ethical tradition, Islamic mysticism, and Islam and modernity. Throughout the article an attempt will be made to relate religious-moral belief to practice, thereby indicating implications of the tradition in molding attitudes toward maintenance and preservation of life, including ways of dealing with suffering, pain, illness, death, and connected issues.

Historical Development

Seventh-century Arabia was socially and politically ripe for the emergence of new leadership. When Muhammad was growing up in Mecca, a city that had become an important center of a flourishing trade between Byzantium and nations on the Indian Ocean, he was aware of the social inequities and injustices that existed in the tribal society dominated by a political oligarchy made up of a few powerful chiefs. Monotheistic traditions like Judaism and Christianity were known to the Arabs; but they had persisted in worshiping their pagan deities, who dwelt in sanctuaries in and around Mecca. The most important shrine in Mecca was the Kaaba, a rectangular building, to which tribes made annual pilgrimage, using the occasion to trade with people who came from all over Arabia.

Religious practices and attitudes before Islam, then, were determined by the tribal aristocracy who also upheld tribal values: "bravery in battle, patience in misfortune, persistence in revenge, protection of the weak, defiance of the strong," generosity, and hospitality as part of their moral code (Watt, p. 20). The growth of Mecca as a commercial center where individuals acted more freely in their own private interest than in the interest of the tribe, had weakened this tribal ethic to the extent that weaker members of a tribe and those who had been marginalized were left without security. Islam emerged in the midst of a serious socioeconomic imbalance between the rich and the poor, between extreme forms of individualism and tribal solidarity.

Muhammad was born into the Hashimite clan of the powerful Quraysh tribe in Mecca. His father died before he was born, and his mother died when he was six years old. In accordance with Arab tribal norms, he was brought up first by his grandfather, then, following the grandfather's death, by his uncle, with whom he traveled on trade missions to Syria. As a young man he was employed by a wealthy Meccan woman, Khadija, as her trade agent. He was twenty-five when he accepted a marriage offer from Khadija, who was fifteen years his senior. When Muhammad received his prophetic call at the age of forty, Khadija was the first person to become *muslim* ("believer in Islam").

This was the beginning of Islam as a struggle to establish a monotheistic faith and create an ethical public order embodying divine justice and mercy. Meccan leadership resisted Muhammad and persecuted him and his followers, who were drawn mainly from among the poor and disenfranchised. Under unbearable conditions, Muhammad decided to emigrate to Medina, an oasis town in the north, where two warring Arab tribes had invited him to arbitrate their affairs. This emigration in 622 C.E. marks the beginning of the Muslim calendar and the genesis of the first Islamic

polity: Muhammad as a statesman instituted a series of reforms to create his community, umma, on the basis of religious affiliation. It also established a distinctive feature of Islamic faith, which does not admit the separation between the religious and temporal spheres of human activity, and has insisted on the ideal unity of civil and moral authority under the divinely ordained legal system, the *shariʿa.*

Muhammad died in 632 C.E., having brought the whole of Arabia under the Medina government. However, he had left no explicit instructions regarding succession to his religious-political authority. The early Muslim leaders who succeeded him as caliphs exercised Muhammad's political authority, making political and military decisions that led to the expansion of Muslim domains beyond Arabia. The community leaders were convinced that the Islamic domain, and not necessarily Islamic faith, was to prevail over all other nations. This conviction, in addition to the political need to consolidate the Muslim polity threatened by internal tribal strife, became the driving force behind the early territorial expansion. Within a century Muslim armies had conquered the region from the Nile in North Africa to the Oxus in Central Asia and as far as India. This vast empire required an Islamic legal system for the administration of the highly developed political systems of the conquered Persian and Byzantine regions. Muslim jurists formulated a comprehensive legal code, using the ethical and legal principles set forth in the Qur'an, the collected revelations of Muhammad, and the precedents set by the Prophet and the early community, in addition to the customary law in the conquered regions.

Differences of opinion on certain critical issues emerged as soon as Muhammad died. The question of succession to Muhammad was one of the major issues that divided the community into the Sunni and the Shia. Those supporting the candidacy of Abu Bakr (d. 634), an elderly associate of the Prophet, as caliph (political successor) formed the majority of the community, who gradually came to be known as the Sunnis; those who acclaimed ʿAli (d. ca. 660), Muhammad's cousin and son-in-law, as the imam (religious and political leader) designated by the Prophet, formed the minority group, known as the Shia ("partisans").

The dispute had profound implications beyond the political. The ideal nature of prophetic prestige in the community, established both in the Qur'an through persistent admonition to obey the prophet and through the prophet's personal exercise of discretionary power in shaping the public order, meant acknowledgment of an authority whose decisions in all spheres affecting Muslim life would be binding on posterity.

The early years of military victories over the Persians and the Byzantines were followed by the civil wars that broke out in 656 C.E. under Muhammad's third successor, ʿUthman. The tension occasioned by the existence of political and social injustices in the Muslim polity gave rise to two distinct, and in some ways contradictory, attitudes among Muslims: quietist and activist. The supporters of a quietist posture supported authoritarian politics, which feigned unquestioning and immediate obedience to almost any *de facto* Muslim authority who publicly promised to uphold Islamic norms. The exponents of an activist posture supported radical politics and taught that under certain circumstances, it was imperative to remove an unjust authority from power. Gradually the quietist and authoritarian stance became associated with the majority of the Sunnite Muslims. The activist and radical stance came to be associated with Shiite Islam.

By the end of the third Islamic century (ninth–tenth C.E.), these two distinct responses to the question of political-religious authority were expounded by the Sunni and Shia schools of thought. Despite the disintegration of the caliphal authority in the thirteenth century C.E., the Muslim community has continued to live in the shadow of the idealized history of early Islam, when the religious and secular authority was united under the divinely guided caliph.

Fundamental Teachings

The two authoritative sources of Islamic teachings are the Qur'an, regarded by Muslims as the book of God, and the *sunna,* the exemplary conduct of the Prophet. The Qur'an consists of the revelations Muhammad received intermittently from the time of his call as prophet in 610 C.E. until his death in 632. Muslims believe that the Qur'an was directly communicated to the Prophet by God through the archangel Gabriel; accordingly, it is regarded as inerrant and immutably preserved. It has served as the source for ethical and theological doctrines and principles for the public organization. The *sunna* (meaning "trodden path") has functioned as the elaboration of the Qur'anic revelation, providing details about each and every precept and deed purportedly traced back to the Prophet's own precedent. The narratives that carried such information were designated as *hadith.* In the ninth century, Muslim scholars developed an elaborate system for the theological and legal classification of these *hadith* to deduce certain beliefs and practices.

The *hadith* literature describes the Muslim creed and practice as "the Five Pillars of Islam." The First Pillar is the *shahada,* the profession of faith: "There is no deity but God, and Muhammad is the messenger of God." Belief in God constitutes the integrity of human existence, individually and as a member of society. The Qur'an speaks about God as

the being whose presence is felt in everything that exists; everything that happens is an indicator of the divine. God is the "knower of the Unseen and the Visible; … the All-Merciful, the All-compassionate, … the Sovereign Lord, the All-holy, the Giver of peace, the Keeper of faith, the All-preserver, the All-mighty, the All-powerful, the Most High" (Qur'an, 59:23). Faith in God results in being safe, well integrated, sound, and at peace.

Life is the gift of God, and the body is the divine trust given to humankind to enable it to serve God as completely and fully as the wonderful creation of God has made that serving possible. The humble origin of humans is established by the Qur'anic reference to their creation from "dry clay of black mud formed into shape" (15:26). Through the well-proportioned creation of the human body and the perpetual guidance provided to perfect it both spiritually and morally, human beings have been given the trusteeship of their body. On the Day of Resurrection, all parts of the human body will have to account for the actions of the person whose bodily organs they formed. God has set limits on what human beings may do with their own bodies. Suicide, homicide, and torturing one's body in any form are regarded as transgressions.

The Qur'anic affirmation of bodily resurrection has determined many religious-moral decisions regarding cadavers. Dead bodies should be buried reverently, as soon as possible. Islamic law prohibits mutilation of the cadaver and, thus, cremation. Under certain circumstances, in order to determine the cause of death, autopsy is permitted. Post-mortem dissection is permitted, for instance, to retrieve a valuable object belonging to another person that might have been swallowed by a deceased person. There was doubt about the use of human cadavers for medical research until fairly recently.

The rulings are now well established in regard to the cadavers of non-Muslims, which do not require any monetary compensation for their mutilation (as required by the *shari'a* for the cadaver of a Muslim). However, if the research for a cure of a disease is dependent on the dissection of a Muslim cadaver, then most Sunni and Shi`ite jurists rule it permissible and, as a precautionary measure, require the payment of compensation to the family of the deceased (*Fiqh al-tabib* [Islamic Laws for Physicians], pp. 159–180). Some recent rulings from Shi`ite jurists make no distinction between a Muslim and a non-Muslim cadaver, thereby permitting research and use of organs for transplantation (*Fiqh al-tabib* [Islamic Laws for Physicians]).

The Qur'an affirms reverence for human life in reference to a similar commandment given to other monotheists: "We decreed for the Children of Israel that whosoever killeth a human being for other than manslaughter or corruption in the earth, it shall be as if he had killed all humankind, and whoso saveth the life of one, it shall be as if he saved the life of all humankind" (5:32). This passage has provided modern Muslim jurists with religious documentation to legitimize medical advances in saving human lives. It has also served as an incentive to protect humanity against peril by choosing to save oneself and others from perdition and to serve humanity as service to God.

The corollary of the belief in God's guidance is human accountability to further divine purposes on earth. The purpose of creation is to allow human beings, created with cognition and volition, freely to accept the responsibility of perfecting their existence by working with the laws of nature grasped by the divinely endowed innate disposition (*fitra*) and by understanding principles of causality that regulate their well-being. The Qur'an emphasizes God's benevolence, all-forgivingness, and mercy. But it also accentuates God's justice, and stresses that humanity should develop moral and spiritual awareness (*taqwa*) in fulfilling everyday requirements of life.

Human existence is not free of tension and inner stresses caused by rejection of truth (*kufr*) and impairment of moral consciousness. To help humanity, God sends prophets "to remind" humanity of its covenant with God (Qur'an, 7:172). There have been 124,000 prophets from the beginning of history, of whom five (Noah, Abraham, Moses, Jesus, and Muhammad) are regarded as *messengers* sent to organize their people on the basis of the guidance revealed by God.

The Second Pillar is daily worship (*salat*), required five times a day: at dawn, midday, afternoon, evening, and night. These very short prayers entail bowing and prostrations. A Muslim may worship anywhere, preferably in a congregation, facing Mecca. Muslims are required to worship as a community on Fridays at midday and on two major religious holidays, celebrating the end of Ramadan and the completion of the pilgrimage in Mecca. The congregational prayer gives expression to the believer's religious commitment within the community. Women are exempt from the obligation of congregational participation, and the tradition recommends that they worship in the privacy of their homes. However, they have always worshiped at designated areas in the mosque, apart from men. The Qur'an prescribes physical purity for the worshiper through the performance of ablutions, and a full washing after sexual intercourse or a long illness, prior to undertaking worship. Women are required to perform a full washing after the menstrual cycle and childbirth, because blood is regarded as ritually unclean. Islamic law prescribes regular cleansing and physical hygiene as expressions of one's faith.

Prayer in Islam is regarded as therapeutic. Besides seeking medical treatment, Muslims are encouraged to seek healing, especially of psychological illnesses, by praying to God. Many illnesses, according to the teachings of the Prophet, are caused by psychological conditions like anxiety, sorrow, fear, loneliness, and so on. Hence, prayer restores the serenity and tranquillity of the soul.

The Third Pillar is the mandatory "alms levy" (*zakat*). The obligation to share what one possesses with those less fortunate is stressed throughout the Qur'an. The Muslim definition of the virtuous life includes charitable support of widows, wayfarers, orphans, and the needy. Islamic law includes technical regulations about how much *zakat* is due and upon what property it is to be levied. These legal rulings, which originated before the disintegration of the Islamic public order, do not necessarily prevail in contemporary Muslim nations. Although *zakat* has for the most part been left to the conscience of Muslims, the obligation to be charitable and contribute to the general welfare of the community continues to be emphasized. In a number of poor Muslim countries this benevolence, provided by wealthy individuals, has underwritten badly needed healthcare for those who cannot afford the rising cost of medical treatment. It has also led to the creation of private charitable foundations that compete with the cumbersome and poorly administered government welfare institutions.

The Fourth Pillar is the fast during the month of Ramadan. Since the Muslim calendar, which has been in use since the seventh century, is lunar, the month of fasting moves throughout the year over a period of time, because the lunar year is shorter than the solar. Ramadan is regarded as the holy month during which the Qur'an was revealed to Muhammad. During the fast, which lasts from dawn to dusk, Muslims are required to refrain not only from eating, smoking, and drinking but also from sexual intercourse and acts leading to sensual behavior. The fasting is meant to alter the pattern of life for a month, and Muslims are required to make necessary adjustments in their normal schedules of work and study. The end of the month is marked by a festival, `Id al-fitr, after which life returns to normal.

Instituted to cultivate individual spiritual and moral self-control, Ramadan also provides a community experience in which families and friends share both fasting and evening meals in the spirit of thanksgiving. Like prayer, fasting possesses therapeutic value. Prophetic medical tradition prescribes fasting for various kinds of ailments, including psychological problems caused by fear and anxiety. It was regarded as a remedy for excessive sexual drive.

The Fifth Pillar is the pilgrimage, the *hajj,* which all Muslims are required to undertake once in their lives, provided they have the financial means. The rituals of the pilgrimage at Mecca are a collective commemoration of the sacrifice story of Abraham and of lessons to be derived from it. Its spiritual objective is to inculcate a form of asceticism accompanied by renunciation of worldly desires (sexual intercourse, use of perfumes, and so on) and concern with the hereafter. The experience brings together Muslims of diverse cultures and nationalities to achieve a purity of existence and a communion with God that will exalt the pilgrim for the rest of his or her life.

Islamic Legal Thought

Islamic jurisprudence (*fiqh*) was developed to determine normative Islamic conduct as detailed in the *shari^{c}a,* the sacred law. The *shari^{c}a,* the divinely ordained blueprint for human conduct, is inherently and essentially religious. The juridical inquiry that led to the *shari^{c}a* code was comprehensive because it necessarily dealt with every case of conscience covering God-human relations, as well as the ethical content of interpersonal relations in every possible sphere of human activity. Most of the legal activity, however, went into settling more formal interpersonal activities that affected the morals of the community. These activities dealt with the obligation of doing good to Muslims and guarding the interests of the community.

Islamic legal theory recognized four sources for judicial decisions: the Qur'an, the *sunna,* consensus (*ijma^{c}*) of the early community of the Muslims, and analogy (*qiyas*), a method of reasoning from data furnished by the Qur'an and the *sunna* in an attempt to estimate the unknown from the known ruling. Al-Shafi`i (d. 820), a rigorous legal thinker, systematically and comprehensively linked the four sources in order to derive the *shari^{c}a* to cover all possible contingencies. The legal precedents and principles provided by the Qur'an and *sunna* were used to develop an elaborate system of rules of jurisprudence. Human conduct was to be determined in terms of how much legal weight was borne by a particular rule that rendered a given practice obligatory or merely recommended.

For instance, if it is deemed that by risking one's life, one may be able to save another person from impending death, then the law permits not only donation but also sale of a needed body part or an organ after a careful risk-benefit analysis. Vital organs like eyes are excepted in this ruling. Likewise, it had to be decided whether an obligatory act, because of its social relevance and the degree of applicability of a given rule or precedent, was to be enforced by penalties in the courts or left to God's judgment in the hereafter.

In family law, the rights of women, children, and other dependents were protected against the male head of the

family, who, on the average, was stronger than a woman and more independent, being free of pregnancy and having to care for children. Islamic marital rules encouraged individual responsibility by strengthening the nuclear family. *Sharīʿa* protected the prerogative of the male because he was required to support the household; the woman was protected primarily by her family. Muslim jurists gave the husband one-sided divorce privileges because for a woman to divorce a man would mean to unsettle her husband's economic investment. Under these rules a husband could divorce a wife almost at will; a wife who wished to leave her husband had to show good reason.

The main legal check upon the man in divorce was essentially financial and a matter of contract between equal parties that included a provision about the bridal gift. Part of the gift, which might be substantial, was paid at the time of marriage; if a husband divorced his wife without special reason, he had to pay her the rest. The equality of women in the *sharīʿa* carried with it an important financial independence. The Muslim woman could own property that could not be touched by any male relative, including her husband, who was required to support her from his own funds. Moreover, she had a personal status that might allow her to go into business on her own. However, this potential female independence was curbed primarily by cultural means, keeping marriages within the extended family, so that property would not leave the family through women marrying out.

Muslim jurists, although tending to give the male an extensive prerogative, presupposed a considerable social role for women. The Qur'anic injunction to propriety was stretched by means of the *sunna* to impose seclusion. The veil was presented simply in terms of personal modesty; the female apartments, in terms of family privacy. It was not intended to become a form of social distinction, as it did with upper-class women living in rigorous segregation. Among the latter it became a mark of a woman of a quality that she was secluded from all men but those in her own family.

Segregation of the sexes as required by the *sharīʿa* has led to untold problems in the teaching and practice of medicine today. The problems cover such areas as closely examining and touching the reproductive organs (male-female, female-male, male-male, and female-female); looking at photographs of naked persons for studying physiology and anatomy; taking the pulse and other vital signs of patients of opposite sex. While the classical decisions were prohibitive in all these cases, the majority of the modern Muslim jurists have casuistically accommodated the need to carry out necessary medical training, research, and treatment.

In the patriarchal family structure, and not necessarily in the *sharīʿa,* women were assigned a subordinate role in the household and community. Through certain cultural practices women's reproductive capacity was controlled. In some parts of the Muslim world women are subjected to traditional practices that are often harmful to their well-being and that of their children. One of the controversial and persistent practices is female circumcision (*khafd* or *khifad*), without which it is believed that girls cannot attain the status of womanhood. Islamic views on female circumcision are ambiguous. While Islam does not condone the practice, neither does it forbid it. The operation was performed long before the rise of Islam. It is not a practice in many Muslim countries, including Saudi Arabia, Tunisia, Iran, and Turkey. There is nothing in the Qur'an that justifies female circumcision, especially its most severe form, infibulation. The Prophet opposed the custom as found among pre-Islamic Arabs, since he considered it harmful to women's sexual well-being. Yet the official juridical position among the majority of Sunni jurists is that female circumcision is sanctioned by the *sunna.* However, the *sharīʿa* does not regard it as obligatory. It is merely a recommended act.

As Islamic jurisprudence became highly technical, disputes about method and judicial opinions crystallized into legal schools designated by the names of prominent jurists. The legal school that followed the Iraqi tradition was called Hanafi, after Abu Hanifa (d. 767), the great imam (teacher) in Iraq. Those who adhered to the rulings of Malik ibn Anas (d. 795), in Arabia and elsewhere, were known as Malikis. Al-Shafi`i founded a legal school in Egypt whose influence spread widely to other regions of the Muslim world. Another school was associated with Ahmad ibn Hanbal (d. 855), who compiled a work on *hadith* reports that became the source for juridical decisions of those who followed him. Shiites developed their own legal school, whose leading authority was the imam Ja`far al-Sadiq (d. 765).

Normally, Muslims accepted one of the legal schools prevalent in their region. Most Sunnites follow Hanafi or Shafi`i; the Shiites follow the Ja`fari school. In the absence of an organized *church* and ordained *clergy* in Islam, determination of valid religious praxis was left to the qualified scholar of religious law. Hence, there emerged a living tradition, with different interpretations of the Qur'anic laws and prophetic traditions, giving rise to different schools of the *sharīʿa.*

The scope of *sharīʿa,* understood as the norm of the Muslim community as a community, was defined by two essential areas of human life: acts of worship, both public and private, connected with the pillars of faith; and acts of public order that ensure individual justice. The *sharīʿa* reflected Muslim endeavors to ensure that Islam pervaded

the whole of life. However, many areas of human existence, including the ethical problems connected with the medical treatment of ailments, received little systematic attention in the classical formulations of the legal thought.

Islamic Theological and Ethical Tradition

In the first half of the eighth century, the debates about qualified leadership, the existence of injustices in the community, and the appropriate response to redress the situation, formed the rudiments of the earliest systematic theology of the group called Muʿtazilites. Before them, some Muslim thinkers had developed theological arguments, including a doctrine of God and human responsibility, in defense of the Islamic revelation and the prophethood of Muhammad when these were challenged by other monotheists. The Muʿtazilites undertook to show that there was nothing repugnant to reason in the Islamic revelation. Their theological system was worked out under five headings: (1) belief in God's unity, which rejected anything that smacked of anthropomorphism; (2) the justice of God, which denied any ascriptions of injustice to God's judgment of human beings, with the consequence that humans alone were responsible for all their acts, and thus punishable for their evil ones; (3) the impending judgment, which underscored the importance of daily righteousness and rejected laxity in matters of faith; (4) the middle position of the Muslim sinner, who, because of disobeying God's commandments was neither condemned to Hell nor rewarded with Paradise but was regarded as reformable; and (5) the duty to command the good and forbid the evil in order to ensure an ethical social order.

In defining God's creation and governance of the world, these early Muslim theologians sought to demonstrate the primacy of revelation. At the same time, their theology reflected Hellenic influences. From the ninth century on, translations of the full Greek philosophic and scientific heritage became available in Arabic. The result was the development of a technical vocabulary and a pattern of syntax that enriched theological terminology.

The Ashʿarites, reacting to Muʿtazilite rationalism, limited speculative theology to a defense of the doctrines given in the *hadith* reports, which were regarded as more reliable than abstract reason in deducing individual doctrines. The Ashʿarites emphasized the absolute will and power of God, and denied nature and humankind any decisive role. What humans perceive as causation, they believed, is actually God's habitual behavior. In their response to the Muʿtazilite view on the objective nature of good and evil, and in their effort to maintain the effectiveness of a God, at once omnipotent and omnibenevolent, who could and did intervene in human affairs, they maintained that good and evil are what God decrees them to be. Accordingly, they cannot be known from nature but must be discovered in the sources of revelation, like the Qur'an and the Prophet's example. There are no inherently unchanging essences and natural laws that self-subsistent reason can discern. God transcends the order of nature. Hence, the notion of free will is incompatible with the divine transcendence, which determines all actions directly.

Ashʿarite theological views remained dominant well into modern times, and had a profound effect upon scientific (and particularly medical) theory and practice among the Sunnites. The attitude of resignation, a by-product of belief in predestination, is summed up in the Sunni creedal confession: "What reaches you could not possibly have missed you; and what misses you could not possibly have reached you" (*Fiqh akbar,* art. 3, in Wensinck, p. 103). This belief in overpowering destiny was bound to have negative implications for some Sunni Muslims encountering adversities caused by illness and other forms of suffering. The Shiite theological and ethical doctrines were based on the Mu`tazilite thesis about the justice of God and the objective nature of moral values.

Positive sciences, especially medicine and astronomy, emerged from the rationalism of Muslim theologians influenced by translations of the works on these subjects from Greek into Arabic. Nature studies in Islamic civilization were pursued by intellectuals who contributed to the Muʿtazilite and Shiite rational theology. Human nature was studied in order to deduce rational principles that could help direct human life to create an ideal society. Ethics and politics were regarded as rational knowledge necessary to harmonize human existence in the universe.

At the practical level, medicine involved the training necessary to apply techniques that demonstrated tact and insight in the treatment of patients. Medical practice was based on a tradition of clinical observation, which became the source for encyclopedic works like the *Canon* (*al-Qanun*) of Avicenna (d. 1037). Since dissection of human cadavers was impossible because of the prohibition in Islamic law against mutilation of the dead and the requirement of immediate burial, physicians treated their patients partly on the basis of their knowledge of anatomy and partly by relying on their understanding of the rationality and harmony of the cosmos. Diagnosis and prognosis were also based on their insights about psychological and environmental factors. Despite the disapproval of some orthodox Muslims, who rejected Greek medicine as not provided for in the Prophetic medical tradition, many of these Greek-influenced philosopher-physicians came to be known as the *hakim* (wise). Prophetic medicine (*al-tibb al-nabawi*) was believed

to have arisen to counter the authority of Greek-based medical tradition by positing the notion that certainty in knowledge, including medicine, depended upon revealed sources. However, although seemingly based on the Qur'an and statements attributed to the Prophet, Prophetic medicine actually was the remnant of the medicine customarily practiced among the Arabs in the pre-Islamic age.

Islamic Mysticism

In the early days of the Islamic empire under the Umayyads (eighth century), the mysticism that began as an ascetic reaction to growing worldliness in the Muslim community became institutionalized. Sufism, as Islamic mysticism came to be known, aimed to interiorize the formally undertaken ritual acts, and emphasized rigorous self-assessment and self-discipline for the achievement of spiritual and moral perfection. In its early form Sufism was mainly a form of ascetic piety that involved ridding oneself of any dependence on satisfying one's desires, in order to devote oneself entirely to God. Mystical practices developed by the Sufi masters comprised a moral process to gain the relative personal clarity that comes at moments of retreat and reflection. A further dimension of this reflection was to cultivate an ability to face reality about oneself and to love any being capable of needing love. The mystic experienced more intense levels of awareness, which could take ecstatic forms, including ecstatic love of God.

This aspect of Sufism brought the mystics into direct conflict with orthodox Muslims. Sufi teaching that a symbolic and spiritual fulfillment of religious duties was as good as the actual rites was seen by orthodox Muslims as a kind of antinomian behavior within the community that considered literal adherence to the requirements of law as the valid form of religiosity. In general, Sufis increasingly tended to minimize religious differences among various faiths and cultivated humanism based on universalistic spiritual and moral qualities.

By the eleventh century the Sufi masters had developed a new form of religious orientation that brought about the acceptance of Sufism in many parts of the Islamic world. Near the end of the twelfth century, several formal Sufi brotherhoods or orders (*tariqa*), in which women also participated, were organized. Each order taught a pattern of invocation and meditation that used devotional practices to organize a group of novices under a master. Special controls of breath and bodily posture accompanied invocative words or syllables to make possible more intense concentration. The orthodox, who had been suspicious of early elitist Sufism, were now persuaded to accept the Sufism of the masses and to try to discipline it. The ultimate approval of Sufism as a genuine form of Islamic piety was facilitated by Abu Hamid al-Ghazali (d. 1111), who taught Islamic law and theology in Baghdad. His writings in connection with his personal spiritual crisis at the height of his professional success demonstrated that Sufism could be a powerful discipline for curing doubt and experiencing truth.

A number of Sufi masters served as analysts for younger Sufis, helping them to understand their psychic states and making sense of their place in the universe. In the premodern Islamic world, where medical treatment was not generally available to an average person, some prominent Sufis practiced traditional medicine based on the theory of the four humors that kept the body functioning. Herb remedies were used to treat ailments caused by imbalance in the four qualities of the body (hot and cold, moist and dry), which led to an imbalance of the humors. Other Sufis treated physical and psychic disorders through the writing of talismans and amulets. Talismans, some using sections of the Qur'an, and exorcism are used in treating mental disorders even today in rural areas of the Islamic world.

Islam and Modernity

The modern age brought Islam and Muslims face to face with intellectual as well as political challenges both from within and from without. From within, Muslims faced the deterioration of Islamic religious life caused by centuries of stagnation and petrification of doctrines and beliefs. From without, the hegemony of the West since the mid-nineteenth century resulted in alien domination of Muslim societies. Since that time, Muslims have endeavored to strike a balance between the divine promise of earthly success to Muslims and their tenuous contemporary situation by introducing internal reforms to prevent further degeneration of Islamic life, and by resisting any form of domination of Muslim societies by the Western powers.

Islamic fundamentalism in modern times stems from the acute awareness among Muslims of a conflict between the religion that promises worldly as well as eternal prosperity to its followers, on the one hand, and the historical development of the Muslim world, which points to the breach of a divine promise, on the other. Muslim leaders call for a return to the original teachings of Islam in the Qur'an and the Prophet's exemplary life. To regain the power and prestige of early Islam, they propose fashioning the modern nation-state on ideals derived from the practices of the original Muslim community. Muslim brotherhoods throughout the Islamic world have joined forces to implement strictly religious reform in a modern society, requiring adherence to the restrictive traditional social-cultural norms.

Resistance to modern secular ideologies and their implications has posed a greater challenge to the Muslim leadership. It has meant providing an Islamic alternative to intentionally imported or externally imposed sociopolitical systems. Such an alternative entails creative interpretation of religious ideas and symbols. Thus far, the traditional Muslim leadership has not succeeded in providing such an alternative as the only viable solution to the multifarious problems faced by the Muslim societies.

A case in point is provided by enormous problems that have arisen with the technological advancement in medicine. Muslim jurists are faced with a crisis because, by its own standards, Islamic jurisprudence has ceased to progress toward some further stage of development. The methods of inquiry and the forms of argument have disclosed inadequacies to furnish solutions to concrete problems faced by the community. Hence, important questions connected with the role of female physicians and patients in a male-dominated profession; conflict between rigorous religious observance and medical education; state policy toward family planning; and social and cultural factors that affect women's health adversely are among numerous pressing issues that remain to be authoritatively resolved.

The judicial decisions issued so far in various Muslim countries, where conferences on bioethics have been held in the last three decades, are mostly in the form of supposition or opinion, and lack the intellectual rigor to become part of state-sponsored health policy.

The greatest challenge to Muslim leadership, both religious and political, remains that of correcting the social and political injustices endured by the common people, who encounter a modern, materialist world over which they have minimal control.

Muslims living as a minority outside the geographical sphere of Islam face the challenge of integration and assimilation in the non-Muslim social universe. Muslim communities belonging to various ethnocultural groups in the West, including North America, are engaged in working out socially interactive strategies that will enable them to establish their identity as Western Muslims. African-American Muslims in North America have reminded the immigrant Muslims of the difficult process of integrating ethnic-cultural and religious identities in modern secular society. African-American Muslims, having been part of American society for a long time, have emerged with a rare ability to combine the most relevant and applicable facets of the modern American social universe and their adopted religion, Islam.

J

JAINISM, BIOETHICS IN

• • •

The Jaina religious tradition originated in India. Its adherents currently number approximately seven million, most of them living in India. According to tradition, the founders of the faith were not emissaries or embodiments of a supreme being, but were human beings who through their own efforts reached an elevated spiritual state called Kevala, characterized as blissful, omniscient solitude free from all karmic suffering and hence liberated from rebirth. According to Jaina lore, twenty-four persons known as Tīrthaṇkaras crossed over the river of rebirth and conquered the influences of negative karma. They then established and promulgated the Jaina religion. Their stories extend back into the prehistory of India. Historical records exist for the two most recent Tīrthaṇkaras: Parśvanatha, who lived around 850 B.C.E., and Vardhamāna Mahāvīra, the Jina or Conqueror, whose approximate dates are 599–527 B.C.E. The term *Jaina* means "follower or disciple of the Jina."

The belief structure and lifestyle of the Jainas are closely linked. In Jainism, there is no creator God. Rather, the Jaina religion is rooted in a unique respect for all life forms that serves as the basis for a sophisticated system of ethics based on the observance of nonviolence (*ahiṃsā*).

According to the Jainas, there are two categories of reality: one possesses life (*jīva*); the other is lifeless (*ajīva*). However, unlike Western definitions of life, which require "metabolism, growth, response to stimulation, and reproduction," the Jainas regard even seemingly inanimate objects as possessing life. The universe is said to be suffused with countless life forces grouped in five categories: earth, water, fire, and air bodies; microorganisms (*nigoda*); plants; animals; and humans. These *jīva* take the shape of their particular life form, whether it be large as a whale or small as a pebble. Each of these life forces is involved in a process of transmigration, moving after death into a new form.

According to Jaina tradition, sticky particles of nonliving matter called karmas adhere to *jīvas* when acts of desire, passion, or violence are committed. Though not visible to the naked eye, six subtle color distinguish this karma. Black, blue, and gray are associated with sinful or brutish karma, and yellow with less serious offenses. Pink and white indicate that one's karmic burden is being lessened. Through unethical passionate or violent behavior, one increases the inhibiting influence of darker, heavier karma. Through adherence to the Jaina code of ethics, one can expel the negative karma and cultivate the purer forms. Eventually, the goal of Jainism entails breaking free from all karmic influence. In this state, referred to as Kevala, one gains omniscience and freedom from rebirth, dwelling eternally in energy, consciousness, and bliss.

Jaina ethics consists of taking vows (*vrata*) designed to eliminate karma. Both lay Jainas and members of monastic orders are expected to observe these vows, though the rules for nuns and monks are much more stringent. Earliest Jaina tradition lists four vows: nonviolence (*ahiṃsā*), truthfulness (*satya*), not stealing (*asteya*), and nonpossession (*aparigraha*). Vardhamāna Mahavīra is credited with adding a fifth vow, chastity (*brahmacarya*). Scriptures such as the *Acārāṅga Sūtra* serve as authoritative sources for religious life.

From ancient times to the present, Jaina monks and nuns have served as preceptors and living symbols of this tradition. Though there are many "lineages" within the Jaina tradition, all modern Jainas can be classified as belonging to

either the Śvetāmbara (White Clad) or the Digambara (Sky Clad) group. In the former group, all monks and nuns wear white robes. In the latter group, the highest order of monks renounces all possessions, including clothing. Both sects allow women to take advanced religious vows, though only the Śvetāmbara allow women to take final vows.

Jaina monks and nuns wander throughout India, teaching the lay community about the lives of earlier saints, advocating the practice of nonviolence, and discussing such topics as the all-pervasiveness of life forms and the karmic effects of behavior. Depending upon the rules of their particular subsect, they may cover their mouths with cloth to avoid injuring insects and microorganisms, or gently sweep the path in front of them to remove insects. In 1949, Acārya Tulsi, head of the Terāpanthi Śvetāmbara monastic order, began teaching a twelvefold system of vows, including modern adaptations such as "not to resort to unethical practices in elections" and "to avoid contributing to pollution."

Although these vows are most intently observed by members of monastic communities, the Jaina lay community has developed a culture anchored in the practice of nonviolence. Lay Jainas generally enter professions in which they can avoid violent action that would increase the depth and darkness of one's karma. Many Jainas engage in trade and commerce, provided that animal products and weaponry are not involved. All Jainas, both laypersons and members of religious orders, are lacto vegetarians.

Although the Jaina system was originally conceived as outlining a path of personal liberation and spiritual enlightenment, many of the practices inspired by a desire to avoid the accumulation of karma have found new relevance in the modern ethical context, especially vegetarianism, animal protection, attitudes toward death, and the Jaina ideal of tolerance.

Jainas regard vegetarianism as a way to ensure that one does not accumulate the negative karmas associated with animal slaughter. In modern medical terms, it also purifies one's body, minimizing the violence done to the body that is often associated with the consumption of meat. Jaina eating habits, rooted in the ancient doctrine of nonviolence, are compatible with modern, scientific concerns about enhancing personal health through a low-fat, low-cholesterol diet.

Respect for animals has long been a mainstay of Jaina tradition. Throughout Indian history Jainas have lobbied for animal protection, building shelters and providing food for lost or wounded animals, and successfully campaigning to ban animal sacrifice in most parts of India. The Mogul emperor Akbar (1556–1605), influenced by Jaina monks, proclaimed days of restraint from hunting and renounced the consumption of several types of meat. Jaina laypersons periodically visit slaughterhouses and purchase animals for release and protection. In India, pharmaceutical companies owned by Jainas, though required to test medicines on animals, rehabilitate their test animals and then release them.

Jaina tradition regards the death of an older person to be both natural and an opportunity for spiritual advancement. For many centuries, Jainas of advanced age or infirmity have engaged in a practice known as *sallekhanā,* referred to by modern Therāpanthi Śvetāmbara Jainas as *santhārā.* Rather than prolonging death when the process of decline becomes irreversible, some Jainas obtain permission from their religious preceptor to engage in a fast unto death. This final ritual is deemed in Samantabhadra's *Ratnakarandaśrāvakācāra,* a Jaina text of the second century, as acceptable only in "calamity, severe famine, old age, or illness from which there is no escape." One first renounces food, then milk, then water, and is encouraged to "depart from the body repeating the *nammokkāra mantra* [prayer] until the last." The Jainas assert that such a fast is neither suicide, which is done out of despair or hopelessness, nor euthanasia, which requires the assistance of a second party and a violent act. This practice, associated with a quest for spiritual freedom, embodies the Jaina ideal of encountering and embracing death without fear.

In a more philosophical vein, the Jainas have developed an ethic of debate, according to which each position or opinion is given provisional status. Any statement or perspective is said to be perhaps true or partially true, including the religious views held by non-Jainas. This ethic both reflects and fosters an attitude of tolerance for which the Jainas have become well known. Mahatma Gandhi, Albert Schweitzer, and Leo Tolstoy were all influenced by Jaina principles.

Technology and modernity present new challenges to the Jaina tradition in that they have spawned new forms of violence not discussed in the original Jaina texts. At Jaina Viśva Bhārati, a university dedicated to the teaching of Jainism located in western India, a curriculum has been developed to help apply Jaina principles to contemporary life, to minimize conflict among groups of people, and to encourage sensitivity to ecological issues.

The Jaina worldview sees the world as a biocosmology, a reality suffused with life. From the perspective of bioethics, this religion is unique in its advocacy of vegetarianism, animal protection, tolerance of multiple perspectives, and philosophical approach to the inevitability of death.

JEHOVAH'S WITNESS REFUSAL OF BLOOD PRODUCTS

• • •

Jehovah's Witnesses are members of a biblically based, semi-Christian religious denomination that forbids its adherents from accepting transfusions of blood and blood products. This religious tenet is based on a literal interpretation of specific passages in the Bible. As a result of this doctrine, most baptized Jehovah's Witness *believers* refuse blood transfusions in their pursuit of medical treatment and healthcare. Some nonblood, transfusion-like replacement techniques and agents derived from minor blood fractions are left to individual believers to accept or reject. Jehovah's Witnesses do not subscribe to "faith healing," and thus seek the assistance of modern medicine as needed, excluding blood transfusions. This belief creates ethical questions and dilemmas related to patient autonomy, informed consent, advance directives, decisional capacity, surrogate decision making, professional integrity and promotion of patients' best interests, medical treatment for children, maternal–fetal conflicts, and the use of healthcare resources.

Historical Development and Organizational Structure

Jehovah's Witnesses trace their historical roots to Charles Taze Russell (1852–1916) and the nineteenth-century North American Adventist movement (a group of Christians who predicted an imminent "second coming" of Jesus Christ). In 1881, as a result of his teaching and writings, Russell founded the Zion's Watch Tower Tract Society. Russell had calculated and predicted that Jesus Christ would return in 1914, when God's direct rule would be established on earth and humanity would be restored to perfection. At the time of Russell's death, he had not appointed a successor.

Russell's religious movement floundered and fractionated until 1931, when Joseph Franklin Rutherford (1869–1942), a lawyer from Missouri, took over leadership. At a meeting of the renamed Watchtower Bible and Tract Society in Columbus, Ohio, in 1931, the name *Jehovah's Witnesses* was adopted and Rutherford became the group's president. Rutherford believed that because the Hebrew name for God was Jehovah, God's people should be known by the same name. In addition to authoring twenty books and numerous pamphlets that greatly influence the denomination's evolving belief system, Russell focused the lives of Jehovah's Witnesses on local congregations and places of assembly known as *Kingdom Halls,* which were established throughout the United States. A principle tenet of Jehovah's Witnesses is to inform the world about Jehovah's reign and kingdom via missionary activity, including door-to-door evangelization.

Nathan H. Knorr (1905–1977) succeeded Rutherford as the society's president in 1942. During Norr's term, the belief about the divine mandate to refuse blood transfusions was first introduced and promulgated in one of the Society's official publications, *The Watchtower* (July 1, 1945). By 2002, there were 6 million Jehovah's Witnesses participating in over 90,000 congregations in 230 countries.

Similar to other religious groups, Jehovah's Witnesses have developed a theologically justified organizational structure with accompanying degrees of hierarchical authority. God's will and direction are revealed primarily through the Bible, and secondarily through the leadership at the international headquarters of the Watchtower Bible and Tract Society, based in Brooklyn, New York. The teaching and organizational authority of the Society is composed of a president and a governing body of seventeen members who head up various committees.

Educational and instructional resources, including printed materials such as official publications (e.g., *The Watchtower,* and *Awake!*) are primarily written, produced, and published at the Brooklyn headquarters. Distribution of materials takes place through branch offices, districts, and circuits, the last consisting of approximately twenty congregations. Districts and circuits have overseers appointed by the society's governing body. Local Kingdom Halls, where individual congregations are centered, are presided over by elders responsible for worship, training, and evangelization.

Biblical Beliefs about Blood

As noted above, the Jehovah's Witness belief system is biblically based. The exegetical method used to interpret biblical texts is a literal, or fundamentalist, method (what the words literally state or do not state), rather than a historical-critical method (taking into consideration the human author's intention and the cultural and historical milieux of the text). Jehovah's Witnesses view the sixty-six books of the Bible as inspired by God and historically accurate. As a result of this literal exegesis of the scriptures, Jehovah's Witnesses find biblical support for pacifism; the practice of adult baptism by immersion; the practices of not saluting national flags and not celebrating birthdays or Christmas (because such celebrations are not mentioned or mandated in the Bible); a belief that the reign of God will be established on the earth, where people will live forever; and the belief that the number of the "spiritual sons of God" who will rule with Jesus Christ in heaven is limited to 144,000. The literal interpretation of the "Christian Greek Scriptures" (their official name for the New Testament) has led Jehovah's Witnesses to conclude that Jesus Christ is God's son, but is inferior to God and was the first of God's creations. This last set of beliefs about Jesus Christ technically places Jehovah's Witnesses outside of mainstream Christian denominations, which profess God as a trinity of "equal persons," including Jesus Christ as God incarnate.

A literal interpretation of the Bible helps to explain why, in 1945, the governing body of the Watchtower Bible and Tract Society determined that accepting blood or blood products for medical purposes violated the biblical word of God. Pertaining to blood, there are at least three scriptural passages that have great significance for Jehovah's Witness belief and practice. These passages are:

> Every moving animal that is alive may serve as food for you. As in the case of green vegetation, I do give it all to you. Only flesh with its soul—its blood—you must not eat (Gen. 9:3–4).
>
> As for any man of the house of Israel or some alien resident who is residing as an alien in their midst who eats any sort of blood, I shall certainly set my face against the soul that is eating the blood, and I shall indeed cut him off from among his people (Lev. 17:10).
>
> The holy spirit and we ourselves have favored adding no further burden to you, except these necessary things, to keep abstaining from things sacrificed to idols and from blood and from things strangled and from fornication (Acts 15:28).

Viewed as inspired by God and to be interpreted literally, these three scriptural texts forbid the eating or ingestion of blood. An important step in the reasoning and interpretive process for Jehovah's Witnesses is that the relatively recent medical practice of intravenous blood transfusion is seen as a way of nourishing or feeding the human body. With this understanding and perception of blood transfusions, a literal interpretation and application of the cited biblical texts becomes clear: Through God's inspired and literal word contained in the Bible, he has expressly forbidden the eating of blood, and, when applied to modern medical practice, this means that God has forbidden the nourishing of the human body with blood transfusions. This divine prohibition applies in all circumstances, including emergency and life-threatening situations. Jehovah's Witnesses who knowingly and willfully accept transfusions of blood or blood products violate God's commandment and disassociate themselves from the congregation of believers.

What Is Forbidden and Permitted

Because of medicine's increasing abilities and techniques to collect, store, dissect, develop, infuse, and salvage blood and blood-based products, numerous and specific questions about what is forbidden and permitted have arisen among Jehovah's Witnesses, as well as among healthcare professionals who treat them. For example, can a Jehovah's Witness accept the use of an intraoperative cell-saver technique or the administration of albumin, erythropoietin, bone marrow, stem cells, or clotting factors for hemophilia?

Jehovah's Witnesses are officially and specifically prohibited from receiving whole blood, packed red blood cells, white blood cells, plasma, and platelets. This explicit prohibition remains the same regardless of the source of the blood, that is, whether the donation is autologous (derived from the same individual) or donated by someone else. Once blood has left the body and the body's circulatory system, it cannot be transfused into a Jehovah's Witness patient. Some techniques and blood-based agents, however, are left to the discretion and conscience of the individual believer. One example is an intraoperative cell-saver procedure that involves salvaging blood from a surgical field (e.g., a body

cavity), cleansing the blood, and then returning the blood to the patient. If during this process a continuous, closed circulation of the blood is maintained as it moves from the body of the patient through the tubing of the salvaging machine and then back into the body, this external circulatory process can be viewed as an extension of the body's own circulation system, consequently the procedure can be acceptable. Also left to the individual believer's conscience and decision are the use of agents derived from minor fractions of blood components, such as immune globulins, albumin, clotting factors for hemophilia, as well as bone marrow and stem cells.

Medical Management of Jehovah's Witnesses

With the exception of transfusions of blood and blood products, Jehovah's Witnesses do not have religious objections to any other medical treatment or procedure that promotes the patient's health. In fact, seeking medical treatment for disease and the promotion of health are seen as concrete ways for believers to respond appropriately to God's gift of life. Thus, as long as blood transfusions are not involved, and when medical necessity arises, Jehovah's Witnesses will seek solid organ transplantation, surgery (including coronary artery bypass grafting, dialysis, and various life-sustaining measures such as intubation and ventilatory support), and medically supplied nutrition and hydration.

When blood loss is a likely risk with an accompanying decrease of hematocrit, hemoglobin, and blood pressure (such as during many surgeries), Jehovah's Witnesses hope for and encourage the medical team to engage in a variety alternative medical and surgical methods that obviate the need for blood transfusions. These methods include limiting phlebotomies or using pediatric needles for blood draws; inducing hormonal suppression of menstruation; stimulating red-blood-cell production through administration of recombinant (synthetic) erythropoietin; utilizing proven and published techniques to reduce surgical blood loss (e.g., cooling a patient to lessen oxygen needs; electrocautery; using laparoscopic and minimally invasive instruments; administration of desmopressin, aprotinin, antifibrinolytics); or preventing shock (from inadequate blood flow to the body's peripheral tissues) by use of nonblood volume expanders such as saline solution, lactated Ringer's solution, and dextran.

To promote respect for their beliefs and help educate healthcare professionals, many Jehovah's Witness congregations and circuits have formed Hospital Liaison Committees to educate healthcare professionals and hospital administrators about the nuances of what is forbidden and permitted, according to Jehovah's Witness beliefs. Committee members have available current literature and bibliographies, usually from prestigious peer-reviewed clinical journals, that reference bloodless management and blood-substitute treatment techniques that have had successful outcomes.

Most of this medical reference material is also available from the Brooklyn headquarters. Hospital Liaison Committees also strives to identify physicians, especially surgeons and anesthesiologists, who are willing to treat Jehovah's Witness patients while respecting their beliefs about blood. Of special significance for Jehovah's Witnesses are hospitals and surgery centers that are willing to develop and advertise bloodless surgery programs (deCastro). Hospital Liaison Committees promote a five-step protocol addressed to healthcare professionals treating Jehovah's Witnesses:

1. Review nonblood medical alternatives and treat the patient without using homologous blood.
2. Consult with other doctors experienced in nonblood alternative management at the same facility.
3. Contact the local Hospital Liaison Committee for locating experienced and cooperative doctors at other facilities to consult on alternative care.
4. Transfer the patient, if necessary, to a cooperative doctor or facility before the patient's condition deteriorates.
5. In a rare situation, if the above steps have been exhausted and governmental or court intervention is deemed necessary, the patient, the parents, or the guardian should be notified as soon as possible of such intended action.

Ethical Evaluation and Analysis

In general, informed adult patients with decisional capacity have an ethically supported right to refuse medically recommended treatment, including treatment that is life-sustaining and death-preventing. This is true regardless of the patient's motive or rationale and whether the refusal is religiously based or not. The American Hospital Association's "Patient's Bill of Rights" echoes this ethical and legal consensus when it states: "The patient has a right to make decisions about the plan of care prior to and during the course of treatment and to refuse a recommended treatment or plan of care to the extent permitted by law and hospital policy" (Right # 3). Some ethical and legal limitations on this right have been argued when the adult refusing treatment has dependent minor children; that is, when there are *innocent third parties* who will be affected by the adult's refusal.

Thus, adult Jehovah's Witnesses with decisional capacity have the right to refuse blood transfusions, even in life-threatening situations. Although the recommended treatment of a blood transfusion can be presumed in most situations to be in the patient's best interests, a patient's right to self-determination (i.e., autonomy) and the corresponding norm of informed consent, ethically and legally "trump" a physician's or medical team's recommendations and perception of the patient's best interests.

This right to refuse can be extended to include patients who once had, but no longer have, decisional capacity, if such patients have indicated their wishes through an advance directive. In anticipation of such situations, many Jehovah's Witnesses sign and carry a specially prepared, wallet-size *medical directive/release* card indicating their wishes not to receive blood transfusions "even though physicians deem such vital to my health or life." In general, such an advance directive should be honored unless there is clear evidence that the patient revoked the advance directive or completed it when coerced or inadequately informed.

An adequate informed-consent process has great ethical significance for Jehovah's Witnesses' refusals of blood products. In the usual fashion for informed consent, the nature, purpose, risks, benefits, and alternatives associated with consenting to or refusing blood products should be explained to Jehovah's Witnesses. This proactive process is even more important prior to medical and surgical interventions that risk significant blood loss. Many hospitals and surgery centers have informed-consent forms that specifically address the use of blood transfusions. However, a form signed by a patient is less important than the conversation and education between physician and patient, which can be triggered by the presentation of a form to be signed.

Unless there has been an acute event or an emergency situation, there is usually time for physicians to present sensitively and clearly the likely outcomes should blood be needed and not provided, and for patients to be queried about their willingness, for each projected outcome, to consent to blood, blood products, agents partially derived from blood, and nonblood alternatives. Also, during such discussions, physicians should communicate their willingness (or unwillingness) to honor Jehovah's Witnesses' refusals of blood transfusions. Because physicians' professional integrity should be protected and respected as much as possible, the transfer of a Jehovah's Witness patient to another qualified physician, who is willing to limit treatment according to the patient's religious beliefs, might become necessary and is ethically supportable as long as continuity of the patient's care is preserved.

When Jehovah's Witness patients have lost decisional capacity and healthcare decisions must be made, the healthcare team may need to involve surrogate decision makers (often family members or someone specifically designated by the patient through a medical-power-of-attorney document). The surrogate should provide a substituted judgement on behalf of the patient; that is, consent to or refuse a specific treatment in accord with the patient's wishes, values, and beliefs. Providing a substituted judgement may be especially difficult for a surrogate who does not share the patient's beliefs and if the outcome could be death or serious debilitation (e.g., a stroke) if blood is not transfused.

When the interests of *innocent third parties* will be affected by a refusal of treatment, additional cautions and considerations are in order. Such situations occur when a pregnant woman refuses life-sustaining treatment, or when a parent's refusal of treatment will likely result in death or serious and permanent disability and any dependent children will subsequently be abandoned or lose parental support and nurturing. An analysis of the latter situation should include whether support is available from other family members or the community. In such instances, some courts have intervened in the decision process in favor of preserving life (*Raleigh-Fitkin Hospital v. Anderson; Werth v. Taylor*), while other courts have supported the patient's refusal (*Fosmire v. Nicoleau; Norwood Hospital v. Munoz; Stamford Hospital v. Vega*). Because neither a consistent ethical nor legal consensus exists for such *third party* circumstances, in actual cases of this kind professionals should seek the guidance and support of institutional ethics committees, hospital legal counsel, or the courts.

When the Patient Is a Child

Jehovah's Witnesses who are parents generally refuse to give permission for blood transfusions for their children when transfusions are needed. Members of healthcare teams usually experience such refusals as much more troublesome and problematic than when adult patients refuse recommended treatments for themselves. With treatment decisions involving children, it is usually not a situation of patient autonomy clashing with medical perception of best interests, but rather parental perception of best interests (based on parental religious beliefs) clashing with medical perception of best interests.

At least for younger children who have not achieved a level of cognitive and emotional development to make their own decisions, most ethicists and legal commentators echo the sentiments of the 1944 U. S. Supreme Court conclusion that, "Parents may be free to make martyrs of themselves.

But it does not follow [that] they are free, in identical circumstances, to make martyrs of their children before they have reached the age of full and legal discretion when they can make that choice for themselves" (*Prince v. Massachusetts*). Especially in life-threatening situations, there is ethical support (based primarily on a best interest standard) for providing needed blood transfusions for patients who have never had decisional capacity.

The American Academy of Pediatrics (AAP) supports such a stance: "The AAP … advocates that children, regardless of parental religious beliefs, deserve effective medical treatment when such treatment is likely to prevent substantial harm or suffering or death" (AAP, 1997). This position can be extended to include patients with severe mental retardation, regardless of chronological age. However, outside of life-threatening situations, and when nonblood alternatives have a reasonable likelihood of being effective, physicians should give serious consideration to honoring the parent's religious tenets that the child not be given transfusions. If a decision is made to seek a court order to permit blood transfusions, the parents should be informed about this decision before it is carried out.

More ethically complex are cases of adolescent Jehovah's Witness patients who have not reached the legal age of majority or adulthood (usually age 18), or who have not been declared emancipated minors by a court, and who refuse blood transfusions. Some of these adolescents may have the requisite cognitive skills to give an informed consent or refusal (Leikin; Weir; Weithorn). From an ethical perspective, healthcare professionals should use the same criteria for assessing decisional capacity (Grisso) and the same process of informed consent and information disclosure as is used for legal adults. Some courts in North America have affirmed this judgement, specifically if adolescent patients can demonstrate sufficient cognitive skills to consent to or refuse medical treatment (Robb).

Use of Resources

From one perspective, Jehovah's Witnesses could be accused of increasing medical expenses and the use of scarce medical resources because of their idiosyncratic beliefs. Although there have not been comprehensive studies comparing and calculating costs for medically managing Jehovah's Witness patients versus non–Jehovah's Witness patients with similar diseases, many physicians and hospitals caring for Jehovah's Witness patients could likely provide individual case reports demonstrating a greater use of resources for some specific patients. A few published reports have claimed an increase in expenses because the usual *standard of care* could not be followed due to patient wishes (Busuttil). As healthcare teams work for good medical outcomes while honoring patients' refusals of blood transfusions in some individual cases, there can be increases in hospital lengths-of-stay, occupancies of intensive-care beds, time in operating rooms, and costs for medications.

But from another perspective, Jehovah's Witnesses could argue that respect for their religious beliefs has occasioned discoveries and developments that conserve a scarce resource—blood products—while benefiting all patients. Jehovah's Witnesses can make the claim that their refusals of blood have accelerated research and the adoption of innovative practices that reduce, eliminate or substitute for the use of blood transfusions. Further, because transfusions of blood and blood products always involve some risk to recipients, any reduction of transfusion therapy by using safe and effective nonblood alternatives and techniques decreases potential medical risks for all patients.

Treating some Jehovah's Witnesses within the context of their beliefs about blood may indeed increase costs and the use of resources in comparison to the general population. But without sufficient comparative studies, such claims remain hypothetical. Even if it can be shown that Jehovah's Witness beliefs increase healthcare costs, would that be sufficient justification for either not honoring refusals of blood therapy or expecting Jehovah's Witnesses to contribute more financially for their healthcare (e.g., in the form of higher insurance premiums)? Such a conclusion seems to fail, based on fairness, until such time as all or most individual behaviors and decisions that increase demands on healthcare resources (e.g., smoking, routinely eating foods high in fat, not wearing seat belts) result in those individuals being either denied treatment or paying more for their healthcare as well.

Conclusion

In general, there is strong ethical and legal support for honoring Jehovah's Witnesses' informed refusals of blood transfusions. Some exceptions to this general principle do exist, however. Because persons can have varying degrees of commitment to religious beliefs, and because the Jehovah's Witness leadership leaves some issues for individual judgement and decision, physicians and healthcare professionals should explore the limits and desires for specific treatments with each Jehovah's Witness. For this patient population, as much as possible, safe and effective nonblood alternatives should be used to promote restoration of health and preserve life. Healthcare professionals and others do not need to agree with Jehovah's Witnesses' beliefs and biblical exegesis in

order to show them respect, honor their religiously based refusals of transfusion therapy, and provide them with high-quality care.

JUDAISM, BIOETHICS IN

• • •

As a specific discipline, bioethics is as new to Judaism as it is to human culture in general. To be sure, every cultural tradition throughout history has developed various ethical norms or rules to govern the different areas of human action. But it is only with the great innovations in biomedical science and technology during the second half of the twentieth century that there has been a need for a distinct schematization of traditional rules, and even the formulation of new ones, for this increasingly complex area of human action.

Judaism is no exception to this general cultural phenomenon. Indeed, Jewish ethicists have been particularly eager to make a Jewish contribution to bioethics, not least of all because of the great interest Jews have always taken in medical practice throughout history, and because many Jewish scholars maintain that there is no area of human action, however unprecedented, to which the rules formulated in the Jewish tradition do not somehow apply. Furthermore, the increasingly cross-cultural context of bioethics gives Jewish ethicists a much larger audience of interested parties than they have had heretofore.

Origins and Development of Jewish Bioethics

Historically, Judaism has seen the normative authority of Jewish life, both communal and individual, as stemming from a twofold teaching (Torah): Scripture and Tradition, or the Written Torah and the Oral Torah. The Written Torah consists of the divinely mandated precepts of the first five books of the Hebrew Bible. The Oral Torah consists largely of the legislation of the rabbis of the Talmudic period (first century B.C.E. to the sixth century C.E.) along with a few ancient traditions (*halakhot*) accepted as having been revealed to Moses at Mount Sinai. Regarding many ethical (as opposed to ritual) norms, moreover, especially those dealing with basic human questions of life and death, Judaism has seen the Torah's commandments as binding on all humankind, at least in theory. This area of the law has been designated as *Noahide Law,* the descendants of Noah being the name for humankind. Since it has long been accepted that there cannot be a double standard differentiating between Jews and non-Jews in questions of life and death (*Sanhedrin* 59a; *Tosafot* s. v. "leika"), and since virtually all medical treatment and so much contemporary Jewish discussion of bioethical issues is conducted in the context of a pluralistic society, this universal aspect of Jewish law has become the most prevalent standard for the formulation of most Jewish views on the subject.

Scriptural law is subject to human interpretation, but it cannot be amended or repealed (Num. 15:23; Deut. 4:2; *Kiddushin* 29a; cf. *Sotah* 9.9) because it is taken to be the direct word of God. Because rabbinic law is considered human-made law only, although legislated by authority sanctioned by Scripture (*Shabbat* 23a), it has been much easier to change and adapt than scriptural law. Rabbinic legislation, at least in theory, admits of amendment and repeal (*Eduyot* 1.5), but since the demise of the *Sanhedrin* as the central Jewish legislative authority, reinterpretation of already existing norms has been the method of changing rabbinic law. Since the actual practical rules of any area of Jewish law—certainly those pertaining to bioethics—are much more rabbinic than scriptural, the authorized range for the exercise of human reason is the widest.

Within the immediate confines of the traditional Jewish community, the method of judgment employed in Jewish bioethics is not different from the method employed in any other area of Jewish law. The basic scriptural norm is located, its rabbinic elaborations are traced through the Talmud and related literature, its authoritative structure is determined, relevant precedents (if there are any) are culled from the vast literature of legal responsa by individual rabbinical authorities, and finally the person accepted by a community of Jews as their legal authority frequently seeks the counsel of learned colleagues. This process involves the ordering and application of rules to apply adequately to a case at hand, and occasionally the recognition of more basic principles behind the rules as well as procedures that direct their application. More and more frequently, in the cases posed by the new medical technology we see a greater role for principles. It is often much more difficult to find appropriate rules for the novel situations at hand, and principles must more directly guide the formulation of rather tenuous analogies from existing rules. Also, in the context of cross-cultural discussion of bioethical issues, the general guidance suggested by principles is sought much more than the governance of the rules of a singular tradition.

Theological and Moral Principles in Jewish Bioethics

A number of theological-moral principles operate in Jewish discussions of bioethics. The most prominent of these principles are God as creator, God as covenanter, the sanctity of human life, human benevolence, the authority of medical expertise, and the personal prerogatives of the patient.

GOD AS CREATOR. All the great Jewish theologians throughout history have emphasized that the first principle of Judaism is that God is the creator and Lord of the entire universe, who maintains its perpetual order (*maʿaseh beresheet*), its "nature." Accordingly, God is considered to be the only possessor of absolute property rights. All creatures are the subjects of varying privileges granted by their divine creator. In accordance with its exalted status as the image of God, the human creature is given duties (*mitsvot;* Gen. 2:16) as well as the highest privileges (Gen. 1:26). However, whatever powers humans have are legitimate only when they are seen as from God for the sake of God, and not as the possessions of the individual or the community in any way. "Indeed, all lives are Mine" (Ezek. 18:4).

This principle is at the very heart of the differences between Jewish law and the secular norms based on the primacy of human autonomy or utility. This is especially apparent in the current intense debates concerning the beginning of human life in relation to abortion, and concerning the end of human life in relation to euthanasia. Arguments insisting upon a *right* to abortion or a *right* to euthanasia, be that *right* the individual's or the community's, essentially deny divine creatorship and lordship as the fundamental norm, which is contrary to what Judaism teaches. Therefore, one can see that the most intense debates in bioethics are quite often more about theological principles than ethical precepts as such.

GOD AS COVENANTER. God is not only the creator of the universe and its perpetual Lord but is also in intimate historical relationship with the people of Israel. This relationship is called the "covenant" (*berit*). According to Moses Maimonides (1135–1204) and other Jewish theologians, Christians and Muslims, who also see themselves as related to this covenantal God, share in some of this covenantal intimacy (*Mishneh Torah: Melakhim,* chap. 11, uncensored ed.). This theological principle impinges upon the main issues of bioethics because it largely determines the status of human personhood as the "image of God" (*tselem Elohim*), a term that seems to designate the essential human capacity for a direct personal relationship with God. Accordingly, human persons are not seen as being primarily defined by innate capacities such as intelligence or freedom of choice, because these qualities vary too much from person to person and are not possessed by everyone born into the human race. Thus, according to the first-century sage Ben Azzai, the most all-encompassing principle of the entire Torah is expressed in the verse "This is the book of the human generations" (Gen. 5:1; quoted in *Palestinian Talmud: Nedarim* 9.3/41c). This means that full personhood is gained solely by one's birth to human parents, and not by less comprehensive criteria based on such capacities as rationality or freedom of choice.

The principle of God as covenanter is also at the heart of the issue of care for the sick. If the sick have the privilege of making special claims upon those able to care for them, claims that translate into the duties of caretakers, then these privileges and duties are rooted in God's care for his creation, care that is epitomized by God's covenantal involvement with Israel. This is clearly seen in the role of prayer in the treatment of illness, both the special privilege of the prayers of the sick themselves (*Shabbat* 12b) and the duty of those who care for them to pray for them as well (*Nedarim* 40a). In fact, the Talmud interprets the scriptural command that the sufferer from the disease tsaraʿat (mistranslated as *leprosy*—but actually a skin disease with symptoms close to those of eczema or psoriasis) publicly declare himself "unclean! unclean!" (Lev. 13:45)—to be a cry to those hearing these words of anguish to pray for the sufferer (*Moʿed Qatan* 5a). In another Talmudic text this requirement is extended to include prayer for the plight of anyone suffering from any other illness of calamity (*Sotah* 32b). Those with whom God has covenanted must show genuine sympathy to one another. The extension of this sympathy is, finally, seen as reaching even to nonmembers of the covenant in the interest of peace and general goodwill (*Gittin* 61a).

THE SANCTITY OF HUMAN LIFE. The term *sanctity of human life* does not appear in the classical Jewish sources but is an accurate expression of the principle that "one human life is not pushed aside for another" (*Ohalot* 7.6; see also *Tosefta: Terumot* 7.20), that is, that one human life has no more inherent value than another, that the blood of one person "is not redder than someone else's" (*Pesahim* 25b; cf. *Sefer Hasidim,* ed. Parma, no. 252; Luria, *Yam shel Shlomoh: Baba Kama,* 8.59). The underlying assumption of the basic sanctity of each individual human life is expressed by the Mishnah: "Whoever saves even one human life, it is as if he saved an entire world" (*Sanhedrin* 4.5; *Palestinian Talmud: Sanhedrin* 4.5/22a).

However, this does not mean that the value of any human life is infinite. In certain cases Judaism demands martyrdom, especially when continued life requires that the God of Israel be denied (*Sanhedrin* 74a). Moreover, at times, priorities are assigned when only one life in a particular situation can be saved as opposed to all lives in that same situation being lost (*Horayot* 3.7–8; *Tosefta: Terumot* 7.20; *Baba Metsia* 62a; *Sanhedrin* 72b). It is in the realm of ritual practice that the sanctity of human life and the duty to rescue are paramount (*Yoma* 85b). Any doubt is to be resolved in favor of human life; thus the practice of any ritual act that endangers human life is proscribed (*Shabbat* 129a). The classic example of this is the rule that rescue efforts are to be conducted on the Sabbath or on the Day of Atonement, irrespective of whatever labors are involved, as long as there is any chance that human life might be saved (*Yoma* 85a). But once the death of the person endangered is ascertained, all ritual restraints are in effect once more (*Tosefta Shabbat* 17.19; *Shabbat* 30b, 151b).

The principle of the sanctity of human life can be seen most clearly operating in cases of nonviability, that is, when there is no reasonable expectation of survival. Thus a child born so defective as to be considered nonviable is still to be nursed by its mother (*Yevamot* 80b, *Rashi* and *Bach* thereto; also, *Tosefta*: *Ketubot* 5.5; *Tosefta*: *Niddah* 2.5), that is, not abandoned to die, as was the case in many ancient cultures. And a human life in the very last stages of its existence, in its death throes, is not to be extinguished on the assumption that death is inevitable (*Shabbat* 151b).

There is debate among later authorities as to what measures may or may not be taken to extend the death throes called goses (Isserles's note on *Shulhan Arukh: Yoreh Deʿah* 339.1; cf. *Bach* on Tur: *Yoreh Deʿah* 339). This debate anticipates current ones as to whether one can distinguish between active and passive euthanasia. Those authorities who argued that not extending the death agony automatically shortens the life of the patient would seem to support the view that no cogent distinction can be made in euthanasia: either one must permit it per se (as Judaism clearly does not) or one must prohibit it per se (as Judaism seemingly

does). This is based on a rejection in the Talmud of any *double effect* rationale (*Shabbat* 75a).

However, the treatment of pain is something that may be done as an end in itself as long as it is not simultaneous with the actual death of the patient (*Avodah Zarah* 18a). Moreover, one is allowed to pray for the death of the patient in cases where agony is extreme and there is no real hope for recovery (*Ran* on *Nedarim* 40a re *Ketubot* 104a). Yet this is always an appeal for divine action and not an endorsement of humans acting in place of God. Even in cases of extreme suffering, the taking of human life is never to be the purpose of any intervention (*Avodah Zarah* 18a). Whereas a cure cannot always be effected, care is always mandated until the very end of human life. That is why, for example, a dying person is not to be left alone even when there is very little time left (*Shulhan Arukh: Yoreh De'ah* 339.4).

HUMAN BENEVOLENCE. The duty to care for the sick, and to heal them whenever possible (*biqur holim,* literally, "visitation of the sick"), is derived from two different sets of biblical and rabbinic sources. The difference in the selection of the sources indicates two distinct approaches to the issue of medical treatment in general.

Maimonides, who was the prototypical rabbi-physician for later generations, categorized the specific duty to care for the sick as a rabbinically mandated act stemming from the general duty of benevolence commanded in Scripture: "You shall love your neighbor as yourself" (Lev. 19:18), which, undoubtedly basing himself on earlier rabbinic sources (*Shabbat* 31a; *Targum Jonathan* on Lev. 19:18), he paraphrased as "Everything you want others to do for you, you do" (Mishneh Torah: Evel 14.1). As for the duty actually to save a human life, Maimonides based this directly on the scripturally mandated act: "Do not stand idly by your neighbor's blood" (Lev. 19:16), that is, whoever can save a life and does not do so has violated a negative commandment (*Mishneh Torah: Rotseah* 1.13).

Finally, he located the specific duty to heal the sick by those competent to do so in the scriptural command concerning the duty to return lost property to its owner (Deut. 22:2). He reasoned, as the Talmud had earlier (*Sanhedrin* 73a), that if one is to return someone else's lost property, then certainly one is to return someone else's *lost body* to him or her—namely, the bodily function lost through illness or injury (*Mishnah Commentary: Nedarim* 4.4). All of this is quite consistent with Maimonides's high regard for the regularity of the natural order and the role of medicine as part of the general human attitude of respect for that order and cooperation with its inherent teleology (*Guide of the Perplexed,* 2.40). Any special role for medicine, by separating it from the commandment of general benevolence, might very well lead to its being considered a magical function. This would contradict the essentially scientific role of medicine insisted on by Maimonides (*Mishnah Commentary: Pesahim* 4.10).

Many commentators wondered why Maimonides never quoted the most direct Talmudic source for the duty to heal the sick: "It was taught in the School of Rabbi Ishmael that from the words of Scripture 'he shall surely provide for his healing' (Exod. 21:19) we derive permission for a physician to heal" (*Baba Kama* 85a). Perhaps he did not think that the verse itself supported this inference, since the text refers directly to the duty of an assailant to pay the medical bills of his or her victim, not the duty of the physician to heal. Also, the use of the word "permission" (*reshut*) might have seemed to him too weak to ground a duty, since it seems only to allow an option.

Nevertheless, Moses Nahmanides (1194–1270) does use this Talmudic text, reflecting his entirely different approach to the practice of medicine. He sees this use of the word "permission" as being an answer to those who might say that medicine is an unwarranted interference with divine healing. Just as a judge is not interfering with God's dispensing justice, he argued, so is a physician not interfering with God's dispensing healing. Both judge and physician have the exalted role of participating directly in acts that are seen as essentially divine (*Torat Ha'Adam,* ed. Chavel, 41–43). Both roles are forms of *imitatio dei*. This follows from Nahmanides's emphasis that medicine is needed by those in less than a full state of grace, who are within the confines of nature alone, and that the truly righteous will not need any such human intervention, being assured of direct divine attention (*Torah Commentary:* Lev. 26:11).

Nahmanides's connection of medical treatment with what the rabbis called "following after God's attributes" (*middotav*) has a precedent in the rabbinic location of the duty to attend to the sick in God's visitation of Abraham immediately after his circumcision (*Sotah* 14a re Gen. 18:1; also *Baba Metsia* 30b re Exod. 18:20; 86b). Indeed, attending to the needs of the sick has been seen in Jewish tradition as being more than general benevolence; it is an act having even mystical connotations. This appears in the many biblical texts that see illness and healing as specifically supernatural interventions (e.g., Gen. 18:14, 25:21–22; Exod. 15:26; Lev. 26:16; Num. 5:21; Deut. 28:20–22, 32:39; 2 Kings 5:7–8, 20:1–5; Jer. 17:14; Ps. 103:1–3; 2 Chron. 16:12). The rabbis, too, saw any affliction as being God's special visitation that calls for a special human response (*Berakhot* 5a re Isa. 53:10; cf. *Shabbat* 55a–b).

PROTECTION OF THE HUMAN CONDITION. The human condition is always to be the subject of care, and its

infirmities are to be cured if possible. The question of the relation between care and cure is especially acute today, when the new means to extend life provided by advances in medical technology are seen by many as simultaneously compromising care by extending the agony of the terminally ill. Contemporary Jewish bioethicists certainly struggle with this problem as much as any other group. One can find no sufficient body of rules on this subject in the tradition, because the death agony in the past was seen as being quite brief (*Mordecai: Moʿed Qatan* no. 864). There do not seem to be any rules at hand for dealing with persons in irreversible comas lasting weeks, months, or even years.

Some precedent for this dilemma, however, can be found in an eighteenth-century responsum by Rabbi Jacob Reischer. He asked whether one may risk one's life by undergoing surgery that has a chance to prolong it, but also a chance to terminate it sooner than would be the case if nothing were done and nature were left to run its course. Reischer permitted such surgery if there was reasonable consensus of medical opinion that there was a good chance for success (*Shevut Yaʿagov: Yoreh Deʿah* no. 75). But without this consensus, it seems that the patient might have the right to refuse what is in effect an unwarranted invasion of his or her body.

The most immediate phenomenon that medicine treats is pain. Whereas the patient knows he or she is alive by inference from consciousness, one is immediately conscious of the presence of pain. Pain is a primary datum for all sentient beings (Maimonides, *Guide of the Perplexed,* 3.48). Jewish tradition mandates the treatment of unbearable pain in much the same way it mandates the treatment of mortal danger to human life. This can be seen by looking at the laws pertaining to the Sabbath, which is the most important religious observance in Judaism (*Palestinian Talmud: Nedarim* 3.9/38b). Just as the Sabbath is to be violated in case of a threat to human life (*sakkanat nefesh*), so may medical procedures normally prohibited on the Sabbath be performed when they can alleviate bodily pain. Such procedures as lancing a painful boil (*Shabbat* 107a; *Tosafot* s.v. "u-memai") and a woman removing by hand milk from her engorged breasts (*Shabbat* 135a; *Tosafot* s.v. "mipnei") are mentioned in the Talmud.

The great public-health problem of AIDS entails another challenge to Jewish tradition and its ability to rule in the interest of protecting the human condition of all sufferers from any disease whatsoever. That challenge arises when it must be determined what is to be done with those who have contracted AIDS through acts that the normative tradition regards as sinful. Most AIDS sufferers have contracted the disease through male homosexual acts and intravenous drug use. These acts are proscribed by Scripture and Jewish tradition (Lev. 18:22; Maimonides, *Mishneh Torah: Ishut,* 1.4; *Deʿot* 4.1). Furthermore, one Talmudic text minimally prescribes neglect for those who are seen to be "habitual sinners" (*Avodah Zarah* 26b). Nevertheless, the important twentieth-century authority Rabbi Abraham Isaiah Karelitz contended that this harsh law no longer applies because its intention is to dissuade sinners, and in this day and age such harshness would be counterproductive (*Hazon Ish: Yoreh Deʿah* sec. 2). His opinion has rarely been contested, for it is not unprecedented (*Teshuvot Ha-Rosh* 17.1). This legal opinion is important because it removes the one main impediment in the tradition for treating AIDS patients with the same concern as those suffering from any illness not contracted through acts the tradition considers illicit.

MEDICAL EXPERTISE. Jewish tradition has long recognized that a trained medical profession is a requirement of a humanly sufficient society. This can be seen in the Talmud's ruling (*Sanhedrin* 17b; cf. *Baba Batra* 21a; *Bach* on *Tur: Hoshen Mishpat* 156) that no educated Jew should live in a locality where there is no physician (*rofe*). Because of this, members of the medical profession have special duties and special privileges connected with these duties.

The first duty of medical professionals is to attend to whoever requires their attention. The centrality of this duty is seen in the interpretation by *Rashi*, the great eleventh-century commentator on the Bible and the Talmud, of the rather bizarre statement in the *Mishnah* that "the best of the physicians are destined for hell" (*Kiddushin* 4.14). Rashi takes this to be an indictment of persons who are physicians rather than of the institution of medicine as such (Nahmanides, *Torat Ha'Adam,* ed. Chavel, 43). He emphasizes the frequent carelessness and arrogance of physicians, and that they often refuse to treat the poor. This final indictment presupposes that lack of funds should not be an impediment to a person's right to medical treatment (*Tur: Yoreh Deʿah* 336; see also *Ketubot* 67b re Deut. 15:8).

Medical practitioners are considered to be "experts" (*beqi'im*), and thus have a professional status (*Yoma* 8.5). Hence they are to be publicly licensed (*Avodah Zarah* 26b–27a). Publicly licensed medical professionals are exempt from paying damages to their patients unless it can be proven that they were grossly negligent or actually malicious in performing their medical duties (*Tosefta*: *Baba Kama* 9.11, 6.17; *Gittin* 3.8). Based on the analogy between physicians and judges, Nahmanides (*Torat Ha'Adam,* ed. Chavel, 41) sees the basis of this unusual dispensation from civil and even criminal liability in the Talmud's acceptance of the inherent subjectivity of judgment in even the most precise human activities: "The judge only has what his eyes

see" (*Sanhedrin* 6b). However, this dispensation applies only to licensed personnel and does not extend to unlicensed personnel, even if they are otherwise "expert" (*Sanhedrin* 44).

Because medical professionals are engaged in an activity commanded by the Torah (*mitsvah*), they are not to be paid directly for their services because no one is to receive direct monetary benefit for the performance of a commandment (*Sanhedrin* 44 re *Bekhorot* 29a; see also *Rosh Hashanah* 28a). In this respect they are like Torah scholars, who are to study and teach the Torah for its own sake and not for the sake of any monetary benefit (*Avot* 4.5; *Nedarim* 37a). Nevertheless, based on this analogy, one cannot be expected regularly to deplete his or her own income when benefiting someone else. If this were the case, only those of independent wealth could possibly function either as scholars or as physicians, or in any other necessary communal function. For this reason, then, both scholars and medical personnel, being deemed necessary for a well-functioning Jewish community, are to be paid, not for what they actually do but for what they do not do—in other words, what they would be paid if they were making a living doing something else. This legal fiction is called "payment for idleness" (*sekhar betalah*).

Medical personnel are exposed to the danger of contagion in treating persons suffering from diseases. The question arises of how much danger they are required to expose themselves to in the course of their work, and how much danger is considered to be above and beyond the call of duty. This question has become especially acute today with the proliferation of a number of highly contagious diseases, such as hepatitis B.

In cases of clear and direct danger to one's own life, Jewish tradition mandates the priority of one's own life (*Baba Metsia* 62a re Lev. 25:36) irrespective of whether one is a layperson or a professional. Acts above and beyond the call of duty are considered forms of supererogatory piety. Such acts cannot be seen as being derived from a universal rule applicable to everyone and anyone, however meritorious they might be to the person performing them (*Palestinian Talmud: Terumot* 8.4/46b). However, the real moral problem arises in cases where there is possible danger (*safeq sakkanah*) to those involved in treating the sick. There is a passage in the Talmud that states, "When there is a plague in the city, gather up your legs" (*Baba Kama* 60b re Isa. 26:20; Deut. 32:25), which implies that one should save oneself in the face of possible danger.

Nevertheless, the sixteenth-century commentator Rabbi Solomon Luria argued that in the absence of clear and direct danger to oneself, one ought to remain in the city if one is able to save other lives there. He also indicates that those who had already suffered from "the plague" (he probably meant smallpox) were in no danger of further recurrence and so should remain in the city to help others in distress (*Yam shel Shlomoh: Baba Kama* 6.26). Earlier, Rabbi Joseph Karo (1488–1575) had ruled that one was to expose oneself to possible danger if this enabled one to save other human lives (*Kesef Mishneh* on Maimonides, *Mishneh Torah: Rotseah* 1.14; *Bet Yosef* on *Tur: Hoshen Mishpat* 426; cf. Rabbi David ibn Zimra, *Teshuvot Ha-Radbaz* 3, no. 627). Of course, the difference between certain possible danger can be decided only on an ad hoc basis. Nevertheless, the distinction must always be kept in mind, that is, one can rule neither that healthcare personnel must treat every patient nor that they may absolve themselves from treating any patient whom they consider at all dangerous to their well-being.

Medical professionals are to keep abreast of scientific developments that affect their ability to treat patients. Along these lines, the tenth-century authority Sherira Gaon argued that the medical opinions of the rabbis of the Talmud, unlike their legal opinions, had no inherent value and should be accepted or rejected solely on the basis of whether they are actually effective (Jakobovits). Maimonides made the same point two centuries later (*Mishnah Commentary: Yoma* 8.4). In cases where human viability is to be determined, Maimonides ruled that current medical opinion is the criterion to rely on (*Mishneh Torah: Rotseah* 2.8; cf. *Shehitah* 10.13). As in all scientific questions, it is irrelevant whether those offering the accepted opinion are Jews (*Pesahim* 94b; Maimonides, *Shemonah Peraqim,* intro.).

However, other authorities were more conservative in their treatment of the medical counsels of the rabbis of the Talmud. Some of them held that the cures prescribed by the Talmud are ineffective in later times because human nature has changed significantly (*Moʿed Qatan* 11a; *Tosafot* s.v. "kavra"; Isserles's note on *Shulhan Arukh: Even Haʿ Ezer* 156.4). This view denies that earlier sages were deficient in any knowledge whatsoever, a point in keeping with the general rabbinic tendency to consider past sages always to have been wiser than present sages (*Shabbat* 112b). Thus, present sages are taken to be incapable of making some of the fine scientific distinctions that were made by past sages in medical issues pertaining to the law (Isserles's note on *Shulhan Arukh: Orah Hayyim* 330.5).

Nevertheless, whether one accepts changed medical practice on the more radical grounds suggested by Sherira Gaon and Maimonides, or on the more conservative grounds suggested by the tosafists (medieval Franco-German glossators on the Talmud) the Isserles, the fact is that no Jewish authority sees the medical remedies from the Talmud or any other classical source as being valid in the present. This has enabled the most religiously traditional Jewish medical

professionals to take advantage of all the current and future advances in medical technology.

PERSONAL PREROGATIVES OF THE PATIENT. Current bioethics has stressed the personal prerogatives of those who are ill so that they can take a more active and responsible role in their own treatment and not simply be the passive *patients* of medical professionals. Most advocates of patient activism in medical treatment have looked to the modern principle of autonomy for grounding—namely, that human individuals are essentially their own masters. Clearly, the theocentric Jewish tradition does not underwrite autonomy in this strong sense of the term. However, it does supply the basis for allowing patients to take an active role for other reasons.

Pain, for example, is to be treated immediately, and the patient is considered the final authority in determining just how much pain he or she can stand, even if that personal determination contradicts expert opinion. It is assumed that the person is the best judge of his or her own condition at this most elementary level of experience (*Yoma* 83a re Prov. 14:10; see also *Baba Kama* 8.1). This judgment by the suffering person can exempt that person from the same ritual obligations (such as fasting) as an expert's judgment concerning a life-threatening condition can. Unbearable pain is considered worse than death, and to escape it, anything short of direct killing is exonerated (*Ketubot* 33a; *Shir Ha-Shirim Rabbah* 2.18; Rabbi Tsvi Hirsch Chajes, *Tiferet Yisrael,* beg.).

A second personal prerogative of the patient is the right to be told the exact nature of his or her illness and the opinion of the experts about whether death is imminent. Thus the Talmud rules that when it is determined that one's death is imminent, one is to be told so that there may still be time for the patient to offer the deathbed confession known as *vidui* (*Shabbat* 32a). This is considered extremely important because whether one dies in a state of repentance could very well affect whether one merits the life of the world to come (*Sanhedrin* 6.2). If the life in this world is considered a preparation for the unending life of the world to come (*Avot* 4.16), and if no one but the person himself or herself can make the proper preparation, then it follows that one may not be kept in ignorance about the gravity of one's condition. Only persons considered too emotionally unstable to be able to make proper use of this information are to be spared (Nahmanides, *Torat Ha'Adam,* ed. Chavel, 46).

The Stages of Human Life

Judaism is concerned with the human condition from conception to death. Especially at the edges of life, where there is much public dispute, Jewish teachings have been very much in the forefront of current debate.

ABORTION. The abortion debate has usually centered on the question of when human personhood begins. Those on the *pro-life* side of the issue argue that human personhood begins at conception, and abortion is therefore murder. Those on the *pro-choice* side of the issue argue that human personhood begins at birth, and abortion is therefore not murder and ought to be the option of the individual pregnant woman.

In Jewish tradition there seem to be two differing views as to when human personhood begins. One view (*Sanhedrin* 57b re Gen. 9:6; see also *Sanhedrin* 91b re Job 10:12) is that it begins at conception; another view (*Ohalot* 7.6; *Sanhedrin* 72b; *Rashi* s.v. "yatsa rosho") is that it begins at birth. Nevertheless, these views are more statements of principle than actual rules. Rules are not directly derived from principles in Jewish law (*Baba Batra* 130b). Instead, principles are formulated to explain rules, coordinate them with other rules, and guide their application. Therefore, one should not automatically deduce from principles defining human personhood just what the rule concerning abortion is to be.

The rule proscribes abortion unless there is a threat to the life or health of the mother. Those who hold that personhood begins at conception thus see abortion as being akin to murder (although, on technical legal grounds, not literally murder that is liable for capital punishment; see *Niddah* 5.3; *Niddah* 44b re Lev. 24:17). They would tend to be more conservative in judging what constitutes a threat to the life or health of the mother. Yet even they would judge some abortions (however few) to be mandated. Those who hold that personhood begins at birth, and who are thus likely to be more liberal in judging just what constitutes a threat to the mother's life or health, still hold that abortion is usually proscribed because even fetal life has enough rights of its own (*Yoma* 82a; *Rashi* s.v. "ubar"). It may not be destroyed unless it is a threat (*rodef*) to the mother's life or health. Even assuming that the fetus is still considered part of the mother's body in utero (*Sanhedrin* 80b) does not lead to permission for elective abortion because self-mutilation is proscribed (*Baba Kama* 91b).

Hence traditionalist authorities, however they might view the actual beginnings of human personhood in principle, all regard abortion as generally proscribed, and permitted only under specific conditions. Their practical debates all center on the interpretation of the exceptions to the general proscription of abortion. In that sense, the more conservative authorities are no more absolutely *pro-life* than the more liberal authorities are absolutely *pro-choice.* In fact, abortion is not an option at all. Either it is proscribed in most cases, or it is prescribed in some exceptional cases. Nonetheless, less traditionalist Jewish feminists have argued that the whole issue of abortion must be reconsidered inasmuch as it most

directly affects women, and women's voices have been absent from the legal debates about it in the Jewish community heretofore (see Davis).

DEFINITION OF DEATH. The question of precisely when human life ends is an issue of much current debate among contemporary Jewish bioethicists. Some of the more conservatively inclined have insisted that the traditional criteria for determining death be literally interpreted: the cessation of spontaneous reflexes, heartbeat, and breath (*Yoma* 85a; Teshuvot Hatam Sofer: *Yoreh De'ah* no. 338). Yet other Jewish bioethicists, more liberally inclined, or more influenced by current scientific trends, have argued that *brain death* can constitute a ground for taking a patient off a respirator, inasmuch as breathing in this case is not being done by the patient, but by a machine (Task Force on Death and Dying). In fact, not doing this might constitute a violation of Jewish law, the prohibition against leaving the dead unburied (*Sanhedrin* 46b re Deut. 21:23). However, the motive behind this innovation, whether stated or not, is that the interpreters of Jewish law must accept growing medical consensus on any major issue if their rulings are to be taken seriously in the general society, where even the most pious Jews receive their medical treatment.

JUSTICE

• • •

At some time or another, virtually all of us become involved in disputes about justice. Sometimes our involvement in such disputes is rooted in the fact that we believe ourselves to be victims of some form of injustice; sometimes our involvement is rooted in the fact that others believe us to be the perpetrators or at least the beneficiaries of some form of injustice affecting them. Sometimes the injustice at issue seems to require for its elimination a drastic reform, or even a revolutionary change in the political system. Sometimes it seems to require only some electoral pressure or administrative decision, as may be required in ending a war. Whatever the origin and whatever the practical effect, such disputes about justice are difficult to avoid, especially when one is dealing with issues, like the distribution of income or healthcare resources, that have widespread social effects.

Reasonable resolutions of such disputes require a critical evaluation of the alternative conceptions of justice available to us. In philosophical debate at the end of the twentieth century, five major conceptions of justice are defended:

(1) a libertarian conception, which takes liberty to be the ultimate political ideal;
(2) a socialist conception, which takes equality to be the ultimate political ideal;
(3) a welfare liberal conception, which takes contractual fairness or maximal utility to be the ultimate political ideal;
(4) a communitarian conception, which takes the common good to be the ultimate political ideal; and
(5) a feminist conception, which takes a gender-free society to be the ultimate political ideal.

All these conceptions of justice have certain features in common. Each regards its requirements as belonging to the domain of obligation rather than to the domain of charity; they simply disagree about where to draw the line between these two domains. Each is also concerned with giving people what they deserve or should rightfully possess; they simply disagree about what it is that people deserve or rightfully possess. These common features constitute a generally accepted core definition of justice. What we need to do, however, is examine the aspects of each of these conceptions of justice over which there is serious disagreement in order to determine which conception, if any, is most defensible.

Libertarian Justice

Libertarians frequently cite the work of Friedrich A. Hayek, particularly *The Constitution of Liberty* (1960), as an intellectual source of their view. Hayek argues that the libertarian ideal of liberty requires "equality before the law" and "reward according to market value," but not "substantial equality" or "reward according to merit." Hayek further argues that the inequalities due to upbringing, inheritance, and education that are permitted by an ideal of liberty actually tend to benefit society as a whole.

In basic accord with Hayek, contemporary libertarians define "liberty" as "the state of being unconstrained by other persons from doing what one wants." Libertarians go on to characterize their moral and political ideal as requiring that each person have the greatest amount of liberty commensurate with the same liberty for all. From this ideal, libertarians claim that a number of more specific requirements—in particular a right to life; a right to freedom of speech, press, and assembly; and a right to property—can be derived.

The libertarians' right to life is not a right to receive from others the goods and resources necessary for preserving one's life; it is simply a right not to be killed. So understood, the right to life is not a right to receive welfare. In fact, there are no welfare rights in the libertarian view. Accordingly, the libertarian's understanding of the right to property is not a right to receive from others the goods and resources necessary for one's welfare but, rather, a right to acquire goods and resources either by initial acquisition or by voluntary agreement.

By defending rights such as these, libertarians can support only a limited role for government. That role is simply to prevent and punish initial acts of coercion—the only wrongful acts for libertarians.

Libertarians do not deny that it is a good thing for people to have sufficient goods and resources to meet their basic nutritional needs and basic healthcare needs, but they do deny that government has a duty to provide for such

needs. Some good things, such as the provision of welfare and healthcare to the needy, are requirements of charity rather than justice, libertarians claim. Accordingly, failure to make such provisions is neither blameworthy nor punishable.

A basic difficulty with the libertarian's conception of justice is the claim that rights to life and property, as the libertarian understands these rights, derive from an ideal of liberty. Why should we think that an ideal of liberty requires a right to life and a right to property that excludes a right to welfare? Surely it would seem that a right to property, as the libertarian understands it, might well justify a rich person's depriving a poor person of the liberty to acquire the goods and resources necessary for meeting basic nutritional needs. How, then, could we appeal to an ideal of liberty to justify such a deprivation of liberty? Surely we could not claim that such a deprivation is justified for the sake of preserving a rich person's freedom to use the goods and resources he or she possesses to meet luxury needs. By any neutral assessment, it would seem that the liberty of the deserving poor not to be interfered with when taking from the surplus possessions of the rich what they require to meet their basic needs would have priority over the liberty of the rich not to be interfered with when using their surplus possessions to meet their luxury needs. But if this is the case, a right to welfare—and possibly a right to equal opportunity as well—would be grounded in the libertarian's own ideal of liberty.

Socialist Justice

In contrast with libertarians, socialists take equality to be the ultimate political ideal. In the *Communist Manifesto* (1848), Karl Marx and Friedrich Engels maintained that the abolition of bourgeois property and bourgeois family structure is a necessary first requirement for building a society that accords with the political ideal of equality. In the *Critique of the Gotha Programme* (1891), Marx provided a much more positive account of what is required to build a society based on the political ideal of equality. In such a society, Marx claimed, the distribution of social goods must conform, at least initially, to the principle "from each according to his ability to each according to his contribution." But when the highest stage of communist society has been reached, Marx added, distribution will conform to the principle "from each according to his ability to each according to his need."

At first hearing, this conception might sound ridiculous to someone brought up in a capitalist society. The obvious objection is, how can you get people to contribute according to their ability if income is distributed on the basis of their needs and not on the basis of their contributions?

The answer, according to a socialist conception of justice, is to make the work that must be done in a society as enjoyable, in itself, as possible. As a result, people will want to do the work they are capable of doing because they find it intrinsically rewarding. For a start, socialists might try to get people to accept currently existing intrinsically rewarding jobs at lower salaries—top executives, for example, to work for $300,000 rather than $900,000 a year. Yet ultimately, socialists hope to make all jobs as rewarding as possible, so that after people are no longer working primarily for external rewards while making their best contributions to society, distribution can proceed on the basis of need.

Socialists propose to implement their ideal of equality by giving workers democratic control over the workplace. They believe that if workers have more to say about how they do their work, they will find their work intrinsically more rewarding. As a consequence, they will be more motivated to work, because their work itself will be meeting their needs. Socialists believe that extending democracy to the workplace will necessarily lead to socialization of the means of production and the end of private property. Socialists, of course, do not deny that civil disobedience or even revolutionary action may be needed to overcome opposition to extending democracy to the workplace.

However, even with democratic control of the workplace, some jobs, such as collecting garbage or changing bedpans, probably cannot be made intrinsically rewarding. Socialists propose to divide such jobs up in some equitable manner. Some people might, for example, collect garbage one day per week and then work at a more rewarding job for the rest of the week. Others would change bedpans or do some other menial work for one day per week and then work at a more rewarding job the other days of the week. Socialists believe that by making jobs intrinsically as rewarding as possible, in part through democratic control of the workplace and an equitable assignment of unrewarding tasks, people will contribute according to their ability even when distribution proceeds according to need.

Another difficulty raised concerning the socialist conception of justice is in the proclaimed necessity of abolishing private property and socializing the means of production. It seems perfectly possible to give workers more control over their workplace while the means of production remain privately owned. Of course, private ownership would have a somewhat different character in a society with democratic control of the workplace, but it need not cease to be private ownership. After all, private ownership would also have a somewhat different character in a society where private holdings, and hence bargaining power, were distributed more equally than they are in most capitalist societies, yet it would not cease to be private ownership. Accordingly, we could imagine a society where the means of production are

privately owned but where—because ownership is so widely dispersed throughout the society and because of the degree of democratic control of the workplace—many of the criticisms socialists make of existing capitalist societies would no longer apply.

Welfare Liberal Justice: The Contractarian Perspective

Finding merit in both the libertarian's ideal of liberty and the socialist's ideal of equality, welfare liberals attempt to combine both liberty and equality into one political ideal that can be characterized as contractual fairness or maximal utility.

A classic example of the contractual approach to welfare liberal justice is found in the political works of Immanuel Kant, who claimed that a civil state ought to be founded on an original contract satisfying the requirements of freedom (the freedom to seek happiness in whatever way one sees fit as long as one does not infringe upon the freedom of others to pursue a similar end), equality (the equal right of each person to restrict others from using his or her freedom in ways that deny equal freedom to all), and independence (which is necessarily presupposed for each person by the free agreement of the original contract).

According to Kant, the original contract, which ought to be the foundation of every civil state, does not have to "actually exist as a fact." It suffices that the laws of a civil state are such that people would agree to them under conditions in which the requirements of freedom, equality, and independence obtain. Laws that accord with this original contract would then, Kant claimed, give all members of society the right to reach any degree of rank that they could earn through their labor, industry, and good fortune. Thus, the equality demanded by the original contract would not, in Kant's view, exclude a considerable amount of economic liberty.

The Kantian ideal of a hypothetical contract as the moral foundation for a welfare liberal conception of justice has been further developed by John Rawls in *A Theory of Justice* (1971). Rawls, like Kant, argues that principles of justice are those that free and rational persons who are concerned to advance their own interests would accept in an initial position of equality. Yet Rawls goes beyond Kant by interpreting the conditions of his "original position" to explicitly require a "veil of ignorance." This veil of ignorance, Rawls claims, has the effect of depriving persons in the original position of the knowledge they would need to advance their own interests in ways that are morally arbitrary.

According to Rawls, the principles of justice that would be derived in the original position are the following: (1) Special conception of justice, involving (a) A principle of equal political liberty; (b) A principle of equal opportunity; and (c) A principle requiring that the distribution of economic goods work to the greatest advantage of the least advantaged. (2) General conception of justice: a principle requiring that the distribution of all social goods work to the greatest advantage of the least advantaged.

The general conception of justice differs from the special conception of justice by allowing trade-offs between political liberty and other social goods. According to Rawls, persons in the original position would want the special conception of justice to be applied in place of the general conception of justice whenever social conditions allow all representative persons to benefit from the exercise of their political liberties.

Rawls holds that these principles of justice would be chosen in the original position because persons so situated would find it reasonable to follow the conservative dictates of the "maximin strategy" and maximize the minimum, thereby securing for themselves the highest minimum payoff.

Rawls's defense of a welfare liberal conception of justice has been challenged in a variety of ways. Some critics have endorsed Rawls's contractual approach while disagreeing with him over what principles of justice would be derived from it. These critics usually attempt to undermine the use of a maximum strategy in the original position. Other critics, however, have found fault with the contractual approach itself. Libertarians, for example, have challenged the moral adequacy of the very ideal of contractual fairness because they claim that it conflicts with their ideal of liberty.

This second challenge to the ideal of contractual fairness is potentially the more damaging because, if valid, it would force its supporters to embrace some other political ideal. This challenge, however, would fail if it were shown that the libertarian's own ideal of liberty, when correctly interpreted, leads to much the same practical requirements as are usually associated with the welfare liberal ideal of contractual fairness.

Welfare Liberal Justice: The Utilitarian Perspective

One way to avoid the challenges that have been directed at a contractarian defense of welfare liberal justice is to find some alternative way of defending it. Historically, utilitarianism has been thought to provide such an alternative defense. It has been claimed that the requirements of a welfare liberal

conception of justice can be derived from considerations of utility in such a way that following these requirements will result in the maximization of total happiness or satisfaction in society. The best-known classical defense of this utilitarian approach is certainly that presented by John Stuart Mill in *Utilitarianism* (1861).

In Chapter 5 of this work, Mill surveyed various types of actions and situations that are ordinarily described as just or unjust and concluded that justice simply denotes a certain class of fundamental rules, the adherence to which is essential for maximizing social utility. Thus Mill rejected the idea that justice and social utility are ultimately distinct ideals, maintaining instead that justice is in fact derivable from the ideal of social utility.

Nevertheless, a serious problem remains for the utilitarian defense of welfare liberal justice. There would appear to be ways of maximizing overall social utility that do injustice to particular individuals. Think of the Roman practice of throwing Christians to the lions for the enjoyment of all those in the Colosseum. Did this unjust practice not maximize overall social utility?

John Rawls (1971) makes the same point somewhat differently. He criticizes utilitarianism for regarding society as a whole as if it were just one person, and thereby treating the desires and satisfactions of separate persons as if they were the desires and satisfactions of just one person. In this way, Rawls claims, utilitarianism fails to preserve the distinction between persons. But is Rawls right? It may well be that a proper assessment of the relative merits of the contractual and utilitarian approaches to welfare liberal justice will turn on this very issue.

Communitarian Justice

Another prominent political ideal defended by contemporary philosophers is the communitarian ideal of the common good. Many contemporary defenders of a communitarian conception of justice regard their conception as rooted in Aristotelian moral theory. In the *Nicomachean Ethics* (332 B.C.E.), Aristotle distinguished between different varieties of justice. He first distinguished between justice as the whole of virtue and justice as a particular part of virtue. In the former sense, justice is understood as what is lawful, and the just person is equivalent to the moral person. In the latter sense, justice is understood as what is fair or equal, and the just person is the one who takes only a proper share. Aristotle focused his discussion on justice in the latter sense, which further divides into distributive justice, corrective justice, and justice in exchange. Each of these varieties of justice can be understood to be concerned with achieving equality. For distributive justice, it is equality between equals; for corrective justice, it is equality between punishment and the crime; and for justice in exchange, it is equality between whatever goods are exchanged. Aristotle also claimed that justice has both its natural and conventional aspects: this twofold character of justice seems to be behind his discussion of equity, in which equity, a natural standard, is described as a corrective to legal justice, a conventional standard.

Few of the distinctions Aristotle made seem tied to the acceptance of any particular conception of justice. One could, for example, accept the view that justice requires formal equality, but then specify the equality that is required in different ways. Even the ideal of justice as giving people what they deserve, which has its roots in Aristotle's account of distributive justice, is also subject to various interpretations. An analysis of the concept of desert would show that there is no conceptual difficulty with claiming, for example, that everyone deserves to have his or her needs satisfied or that everyone deserves an equal share of the goods distributed by society. Consequently, Aristotle's account is helpful primarily for clarifying the distinctions belonging to the concept of justice that can be made without committing oneself to any particular conception of justice.

Yet rather than draw out the particular requirements of their own conception of justice, contemporary communitarians have frequently chosen to defend their conception by attacking other conceptions of justice; by and large, they have focused their attacks on the welfare liberal conception of justice. Alasdair MacIntyre, for example, argues in "The Privatization of the Good" (1990a) that virtually all forms of liberalism attempt to separate rules defining right action from conceptions of the human good. MacIntyre contends that these forms of liberalism not only fail but must fail because the rules defining right action cannot be adequately grounded apart from a conception of the good. For this reason, MacIntyre claims, only a version of a communitarian theory of justice that grounds rules supporting right action in a complete conception of the good can ever hope to be adequate.

But why cannot we view most forms of liberalism as attempting to ground moral rules on part of a conception of the good—specifically, that part of a conception of the good that is more easily recognized, and needs to be publicly recognized, as good? For Rawls, this partial conception of the good is a conception of contractual fairness, according to which no one deserves his or her native abilities or initial starting place in society. If this way of interpreting liberalism is correct, in order to evaluate welfare liberal and communitarian conceptions of justice properly, we would need to do a comparative analysis of their conceptions of the good and

their practical requirements. Moreover, there is reason to think that once the practical requirements of both liberal and communitarian conceptions of justice are compared, they will be found to be quite similar.

Feminist Justice

Defenders of a feminist conception of justice present a distinctive challenging critique to defenders of other conceptions of justice. In *The Subjection of Women* (1869), John Stuart Mill, one of the earliest male defenders of women's liberation, argued that the subjection of women was never justified but was imposed on women because they were physically weaker than men; later this subjection was confirmed by law. Mill argued that society must remove the legal restrictions that deny women the same opportunities enjoyed by men. However, Mill did not consider whether, because of past discrimination against women, it may be necessary to do more than simply removing legal restrictions: he did not consider whether positive assistance may also be required.

Usually it is not enough simply to remove unequal restrictions to make a competition fair among those who have been participating. Positive assistance to those who have been disadvantaged in the past may also be required, as would be the case in a race where some were unfairly impeded by having to carry ten-pound weights for part of the race. To render the outcome of such a race fair, we might want to transfer the ten-pound weights to the other runners in the race for an equal period of time. Similarly, positive assistance, such as affirmative-action programs, may be necessary if women who have been disadvantaged in the past are going to be able to compete fairly with men.

In *Justice, Gender and the Family* (1989), Susan Okin argues for the feminist ideal of a gender-free society, that is, one in which basic rights and duties are not assigned on the basis of a person's sex. Being male or female is not the grounds for determining what basic rights and duties a person has in a gender-free society. Since a conception of justice is usually thought to provide the ultimate grounds for the assignment of rights and duties, we can refer to this ideal of a gender-free society as *feminist justice.*

Okin goes on to consider whether Rawls's welfare liberal conception of justice can support the ideal of a gender-free society. Noting Rawls's failure to apply his original position-type thinking to family structures, Okin is skeptical about the possibility of using a welfare liberal ideal to support feminist justice. She contends that in a gender-structured society like that of the United States, male philosophers cannot achieve the sympathetic imagination required to see things from the standpoint of women. In a gender-structured society, Okin claims, male philosophers cannot do the original position-type thinking required by the welfare liberal ideal because they lack the ability to put themselves in the position of women. According to Okin, original position-type thinking can really be achieved only in a gender-free society.

Yet, at the same time that Okin despairs of doing original position-type thinking in a gender-structured society, she purportedly does a considerable amount of just that type of thinking. For example, she claims that Rawls's principles of justice "would seem to require a radical rethinking not only of the division of labor within families but also of all the nonfamily institutions that assume it" (Okin, p. 104). She also claims that "the abolition of gender seems essential for the fulfillment of Rawls's criterion of political justice" (Okin, p. 104). So Okin's own work would seem to indicate that we can do such thinking, and that her reasons for thinking we cannot are not persuasive. To do original position-type thinking, it is not necessary that everyone be able to put themselves imaginatively in the position of everyone else. All that is necessary is that some people be able to do so. Some people may not be able to do original position-type thinking because they have been deprived of a proper moral education. Others may be able to do original position-type thinking only after they have been forced to mend their ways and live morally for a time.

Of course, even among men and women in a gender-structured society who are in a broad sense capable of a sense of justice, some may not be able to do such original position-type thinking with respect to the proper relationships between men and women; these men and women may be able to do so only after the laws and social practices in our society have significantly shifted toward a more gender-free society. But this inability of some to do original position-type thinking does not render it impossible for others, who have effectively used the opportunities for moral development available to them, to achieve the sympathetic imagination necessary for original position-type thinking with respect to the proper relationships between men and women.

Drawing Conclusions

What conclusion should we draw from this discussion of libertarian, socialist, welfare liberal, communitarian, and feminist conceptions of justice? Should we draw the conclusion defended by Alasdair MacIntyre in *After Virtue* (1981) that such conceptions of justice are incommensurable and, hence, there is no rational way of deciding between them? Many philosophers have challenged this view, and even

MacIntyre, in *Three Rival Versions of Moral Enquiry* (1990b), has significantly qualified it, now claiming that it is possible to argue across conceptions of justice.

Another conclusion that we might draw from this discussion of conceptions of justice is that if the ideal of liberty of libertarian justice can be shown to require the same rights to welfare and equal opportunity that are required by the welfare liberal conception of justice, and if the communication critique of welfare liberalism can be rebutted, it may be possible to reconcile, at a practical level, the differences between welfare liberal justice, socialist justice, and feminist justice. If this can be done, all that would be necessary to reasonably resolve disputes about justice would be to clarify what the shared practical requirements of these conceptions of justice are and simply to act on them.

The Provision of Just Healthcare

Assuming that it is possible to show that libertarian, welfare liberal, socialist, communitarian, and feminist conceptions of justice have the same practical requirements as a right to welfare and a right to equal opportunity, then in order to determine the morally appropriate level of healthcare, it would be necessary to determine what provision of healthcare would be required by these rights. Since a right to welfare and a right to equal opportunity are usually associated with a welfare liberal conception of justice, it would seem reasonable to use Rawls's original position decision procedure—a procedure favored by welfare liberals—to determine what level of healthcare would be required by a right to welfare and a right to equal opportunity.

In *Just Health Care* (1985) and *Am I My Parents' Keeper?* (1988), Norman Daniels develops just such an account of healthcare. Daniels imagines people behind a veil of ignorance trying to determine how they should allocate healthcare services over their lifetimes. Behind this veil of ignorance, people are to imagine themselves ignorant of their actual age so that they could be young or old. Daniels claims that people using this Rawlsian decision procedure would reserve certain life-extending technologies for their younger years and thus maximize their chances of living a normal life span, even if that meant reducing the medical resources that would be available in their old age.

The consequences of using a Rawlsian decision procedure to determine the morally appropriate level of healthcare required by a right to welfare and a right to equal opportunity are (1) a focus on death-preventing level of healthcare for the young, (2) a focus on a life-enhancing healthcare for both young and old, and (3) a willingness to cut back on death-preventing healthcare for the old to some extent when it conflicts with (1) and possibly when it conflicts with (2) as well.

Yet these consequences remain indeterminate until we can specify the amount of resources that are to be devoted to healthcare rather than to meeting the various other needs and wants that people have. It will not do simply to have each person choose the level of healthcare that he or she prefers, because we cannot assume that everyone will have sufficient income to purchase whatever level of healthcare he or she wants or needs. Rather, there seem to be two options.

One option is to specify an optimal and affordable level of healthcare and then guarantee this level of healthcare to all legitimate claimants. The other option is to specify a decent minimal level of healthcare and guarantee that level of healthcare to all legitimate claimants, but then allow higher levels of healthcare to be purchased by whoever has the income and desire to do so. Of course, both these options will leave some people dissatisfied. The equal-healthcare option will leave dissatisfied people who would have preferred and could have afforded a higher level of healthcare that would have been available under the multi-tiered healthcare option. The multi-tiered healthcare option will leave dissatisfied people who would receive only the decent minimum level of healthcare under that option but who want or need more healthcare than they will be receiving. Is there any just resolution of this conflict?

Assuming again that we are trying to determine the morally appropriate level of healthcare required by a right to welfare and a right to equal opportunity, it is surely the case that nothing less than a guaranteed decent minimum level of healthcare to all legitimate claimants would be morally acceptable. But is a multi-tiered option for healthcare morally permissible, or is the option of an equal level of healthcare morally required?

To answer this question, we must take into account all the morally legitimate claimants to our available resources. They include not only the members of the particular society to which we happen to belong but also distant peoples and future generations as well. Once we recognize how numerous are the morally legitimate claimants on the available resources, it becomes clear that all that we can hope to do is provide a decent minimal level of healthcare to all claimants. Given the morally legitimate claims that distant peoples and future generations make on our available resources, it is unlikely that we will have sufficient resources to allow people to purchase higher levels of healthcare (the multi-tiered option). Morally, we would seem to have no other choice than to favor the same level of healthcare for everybody (the equal-healthcare option).

In preferring the equal-healthcare option, we appealed not to the ideal of equality itself but, rather, to the goal of providing all legitimate claimants with a decent minimum level of healthcare. Given that available resources are limited, to meet the goal of providing a decent minimum of healthcare to all legitimate claimants, equality of healthcare for all legitimate claimants is required. In this context, no one can have more than equality if everyone is to have enough. This choice would clearly be favored by people behind a Rawlsian veil of ignorance, assuming that the hypothetical choosers are understood to represent all morally legitimate claimants.

Nor could one reasonably object to the ideal of including distant peoples and future generations within the class of morally legitimate claimants, because each of the five conceptions assumes that each human being has the same basic rights. So if these basic rights that each human being has include a right to welfare and a right to equal opportunity, the requirements to provide each human being with a decent minimum of healthcare would clearly follow.

Nevertheless, there remains the question of how to specify this minimum level of healthcare that all legitimate claimants are to receive. The problem here is how to specify how much of the available resources should go to providing everyone with a decent minimum of healthcare rather than providing for the satisfaction of people's other needs and wants. Yet here, too, the question seems resolvable with the aid of a Rawlsian hypothetical choice procedure. We simply need to introduce behind the veil of ignorance the knowledge of the relevant technology for meeting people's basic needs and the knowledge of available resources to decide how much of the resources should be devoted to providing a decent minimum level of healthcare and how much should be devoted to meeting the other needs and wants that people have.

In this way, we should be able to determine what specific requirements of just healthcare are grounded in a right to welfare and a right to equal opportunity. Moreover, these specific requirements of just healthcare would be further supported if it can be shown that the rights from which these healthcare requirements are derived are themselves the shared practical requirements of libertarian, welfare liberal, socialist, communitarian, and feminist conceptions of justice.

JUST WAGES AND SALARIES

• • •

The ethics of just compensation are informed by the continual effort to balance three powerful principles; several other considerations contest and limit the reach of these ethical principles.

Overview of Ethical Dimension of Just Compensation

The first ethical principle is that every working person possesses an inherent dignity and deserves respect. All workers, no matter how high or low their skills or compensation, are important and valued members of the institution. In fact, ethically, each person, no matter what job they perform, is entitled to the same amount of respect as any other worker.

The second ethical principle is that each working person has the right to be able to support themselves and their families by the fruits of their work. Few argue with the proposal that people who work full-time should earn enough to support themselves and their families. That means people who work full-time should earn at least a living wage. How much constitutes a living wage is open to discussion, but most people of goodwill agree that part of being a good employer involves paying workers a living wage. While an employer has many obligations and paying fair wages is not their only duty, it is certainly one of the most important.

The third ethical principle is that economic considerations and the health of the employer are also important. Without an economically healthy employer, opportunities for jobs paying living wages are limited. Wages are an important part of the overall budget of all healthcare providers and must be set with the economic health of the institution in mind. If an employer is in a precarious financial situation, then the obligation to pay a living wage must be adjusted accordingly. Ethically, however, the employer is obligated to pay living wages to workers before spending money on other, less important matters. For example, corporations have a duty to produce returns for shareholders. But the corporate duty of employers to shareholders is not as compelling ethically as the duty to pay living wages to employees. Healthcare institutions often present themselves as, and are expected by the public to be, community resources. As community resources, healthcare employers are viewed differently than, for example, the local food and beverage industry or other retail businesses. This creates different and legitimately higher justice expectations for the healthcare employer. Unlike other corporations, healthcare institutions are expected to operate with a commitment to the common good and not just for private gain.

Several countervailing arguments are used to attempt to limit these ethical considerations in determining just compensation. The first and most pervasive argument is that economic market forces alone set ranges of compensation. To many, these market forces are apart from and unaffected by ethical principles. From this perspective, the ethical duty of employers to pay each and every worker at least a living wage is a discussion that philosophers may engage in, but is not realistic enough to engage business decision-makers.

A second argument, which arises out of the first, is that the labor of some people is inherently worth more than the labor of others. In this perspective, considerations of productivity, educational achievement, difficulty of replacement, and competition from other institutions are the real standards for determining compensation. Considerations of human dignity and the right to a living wage are at best peripheral. The determination of what is just compensation is analyzed, evaluated, and decided in the continual contest between these considerations.

Just Compensation

Justice demands that all compensation decisions start with the recognition that each worker has a fundamental human dignity and worth that is equal to every other worker. People work to support themselves and their family members. Thus, at a minimum, each worker must earn enough to

support themselves and their family as a result of their labor. Justice does not demand, however, that all persons earn the same amount.

Compensation decisions involving individuals engaged in the same type of occupation are often based on considerations of ability to perform the task assigned, demonstrated and consistent effort, overall quality of work performed, and special skills, ability, or training that allow the person to perform tasks that coworkers do not or cannot. Compensation decisions involving allocation of funds between different categories of workers are often based on principles of productivity, scarcity, comparative effort, and market forces.

Justice demands that the basic needs of all workers be respected as a first principle, and that the decisions about how to apportion the surplus be made in a manner which is fair in both process and result. Fair process for determining compensation in a healthcare institution means that the needs of all workers, the needs of the recipients of healthcare, and the economic needs of the institution are given fair opportunity to be heard and balanced in decision making. To be fair, the process of determining just compensation must be transparent, inclusive, responsible, and participatory. The ability of workers to bargain collectively if they choose to do so must be protected and respected. Fair results in determining compensation are difficult to define, because there are so many competing needs. At a minimum, fair results require decisions that are rational, explainable, and non-discriminatory. Even when fair results are achieved, rapidly changing circumstances can undermine the appropriateness of prior decisions.

Lowest-Paid Workers

A critically important part of the ethical evaluation of any institution is how it compensates its lowest-paid workers. This is the point where the contest between living wages and market forces is played out.

Living wages are the ethical goal of all responsible employers, but as noted above, there are considerations opposed to living wages for the lowest-paid worker. The need to keep overall lower-skilled labor costs down is a constant concern of management. Part of the determination of what is fair compensation is the answer to the question of "what is everyone else, at least those in the surrounding community, paying for similar work?" Employers who pay less than prevailing wages will find it hard to attract and retain a full complement of good workers. Employers who pay a living wage when others pay less will be faced with internal and institutional criticism that there is an overpayment of wages that may harm the financial health of the institution. And, in some lower-wage communities, healthcare institutions need not pay a living wage to attract and retain entry level or lower-skilled employees.

What is a living wage? While there are many definitions of what constitutes a living wage, all involve the worker earning enough to be able to be self-sufficient and to have enough income to support their family. While the precise amount needed to be self-supporting varies by locale, it is always significantly higher than the federal minimum wage. Some living wage laws have calculated the amount of living wages as the amount necessary for a full-time worker to lift a family of four over the federal poverty guidelines, roughly twice the federal minimum wage. The living wage is sometimes even called the family wage.

Highest-Paid Workers

While ethics indicates that all persons are entitled to be treated with human dignity and respect, there is also general agreement that just compensation does not mean that all people must earn the same amount. Once the basic needs of all workers have been met, justice recognizes that more educated and skilled workers have first claim to higher compensation out of the surplus that remains. This recognizes that higher pay is a partial motivation for people to continue education and to defer other work opportunities while learning higher skills.

Higher compensation is particularly called for in healthcare, where many of the higher-skilled workers have developed their expertise by accumulating substantial educational debt and where the risks associated with their practice require significantly higher insurance costs. People who invest more in their education, who continually improve their skills, who sacrifice more, who are more difficult to attract to provide needed work, and who risk more to provide needed services to others, are ethically deserving of extra compensation.

Compensation for higher-skilled workers should be calculated after consideration of many factors: the overall economic health of the institution, the provision of quality care to those who seek healthcare, and the needs of the lower-paid workers to receive living wages.

There is an ethical caution in the actual calculation of compensation for higher-paid workers: the duty to provide fair and adequate compensation for low-wage workers is ethically more important than the goal of providing competitive compensation for the highest-paid workers. Where there is a conflict within an institution between providing more attractive compensation for higher-wage workers versus paying a living wage to lower-wage workers, the needs of

the lower-wage workers ethically trumps the wants of the higher-salaried workers.

Pay Equity Considerations

Equity issues in determining just compensation are aimed at eliminating the effects of gender-, race-, age-, and disability-based wage discrimination. While these types of wage discrimination are now illegal, the effects of discrimination remain. For example, a quick look at most institutions will show that occupations dominated by women and people of color usually pay less than others within the same institution. Gains have been made toward removing the barriers of intentional discrimination. Most people of goodwill agree that intentional acts of discrimination are wrong and should be immediately corrected. But discrimination is not confined to overt acts of prejudice on the part of individuals. Discrimination continues in many institutions as the structural effects of past practices continue to have a negative impact. Differences in education, experience, and time in the workforce form a part of the legitimate criteria for determining compensation. However, concerns for pay equity require the institution to continually question and readjust the institutional respect for the value of work performed by lower-paid workers. Action should be taken to upgrade lower-paying jobs and to correct unjust wage discrimination based on gender, race, age, and disability.

Another equity issue is the large income gap between the highest-paid workers and the lowest-paid workers found in many institutions. Economic inequality within an institution often reflects an uneven participation in the decision-making process within the institution. Further, income disparity within institutions usually becomes a heightened source of concern in times of economic trouble and transition. While some accept this disparity as inevitable, it is not. Like all economic decisions, wage and salary scales are set by people in an ethical, legal, economic, and community context.

Role of Government

The government has an obligation to provide the legal and economic framework necessary for employers and workers to engage in fair and just compensation relationships. Government has a duty to help citizens secure basic justice and to protect the civil and human rights of those without the power to secure those rights for themselves.

The government exists to protect the common good. Just compensation of all members of the community is certainly in the common good. Government must protect the rights of the employer and all workers to fair and just determinations of compensation. Where there are unequal power relationships between workers and employers, the government should participate in leveling the playing field. Government has a role in securing fair labor practices that lead to just compensation.

If the government assists the common good, it acts justly; when individuals or institutions prompt the government to assist the common good, they act justly. When the actions of government are contrary to the common good, they are unethical and unjust; when private individuals or institutions attempt to prevent government from regulating for the common good, their actions are unjust. The government has an important role to promote fairness and equity in the continual process of securing just compensation, particularly for lower-paid workers and those who have been the victims of pay inequity.

LABOR UNIONS IN HEALTHCARE

• • •

The relationship between unions, employers, and employees in healthcare raises a wide range of ethical issues at the levels of policy, strategy, and practice. From initial attempts at employee organization, through union elections, contractual negotiations, and interactions over the life of the contract, to strikes, lockouts and union decertification activities, all have an ethical dimension. But the ethical stance taken at the level of policy, strategy and practice depends upon the way three fundamental questions are answered: Do employees have a right to *self-organization;* and, if so, what does that right mean? Do healthcare employees have a right to strike? Do healthcare employees through their self-organization have broader social responsibilities?

The term *self-organization* refers to the shared means employees establish to have a voice in the terms and conditions of their employment. It includes joining a union, forming a union, and developing other types of concerted effort.

In addressing the ethical dimensions of self-organization in healthcare, two points need to be made. First, self-organization in healthcare and other human service organizations is different from self-organization in other forms of employment not because it is completely distinct but because it adds the further component of responsibility to the public served. Second, in considering employee self-organization as a right from an ethical perspective, it is important also to look at that right from a legal perspective. Within the United States, labor law is based on a specific ethical understanding of that right; and often little distinction is made between ethics and law, with the legal being accepted as the ethical.

Self-Organization as a Right

HISTORICAL BACKGROUND. At the beginning of the twenty-first century, the right of employees to organize is widely accepted. Even libertarians acknowledge the right of individuals to choose what groups they wish to join. But getting that right accepted was difficult and costly in human suffering. The experience in the United States is instructive. While the U.S. Constitution guarantees "the right of the people peaceably to assemble," the courts found early attempts by employees to establish permanent organizations to achieve improvements in wages and working conditions through concerted action to be criminal conspiracies in constraint of trade. Later judges granted injunctions against strikes and picketing. Following World War I, unions were branded as *un-American* and *Bolshevic.* Employers used intimidation and violence to break up unionizing efforts and strikes.

In 1935 President Roosevelt signed the National Labor Relations Act (Wagner Act) which recognized employees's right to organize. According to Section 7 of the Act, "Employees shall have the right to self-organization, to form, join or assist labor organizations, to bargain collectively through representatives of their own choosing, and to engage in concerted activities for the purpose of collective bargaining or other mutual aid or protection." Two years later, in *National Labor Relations Board v. Jones & Laughlin Steel Corp.,* the U.S. Supreme Court termed this right a *fundamental right,* stating that labor unions grew "out of the necessities of the situation; that a single employee was

helpless in dealing with an employer; … that union was essential to give laborers opportunity to deal on an equality with their employer" (p. 33).

In 1947 in the face of problems in labor-management relations following World War II, Congress passed the Taft-Hartley Act which restricted union powers, adding to the employee rights set out in the Wagner Act the right to *refrain from* self-organization and concerted activities. While the Taft-Hartley Act exempted not-for-profit hospitals, denying those employees the right to organize, this exemption was lifted in 1974. Employees of public hospitals cannot organize under the National Labor Relations Act. In 1987 the National Labor Relations Board (NLRB) established the number of separate bargaining units within a healthcare institution as eight (Lichtenstein).

CIVIL RIGHT. Terming self-organization a right within the United States generally means interpreting it in light of the rights set out in the U.S. Bill of Rights. Those rights, known as civil rights, which include freedom of speech and freedom of assembly, focus on the individual and emphasize freedom. They allow the individual freely to pursue self-interest, protecting the individual against external coercions. While legally the rights contained in the Bill of Rights pertain only to the relation of the individual to the government, an ethic embodying this perspective views the protections of individual freedom broadly.

From the perspective of self-organization as a civil right, the right of the individual to choose freely is a primary focus. This focus has played an important role in addressing the racism and sexism which have marked the history of unions in the United States, upholding the right of each and all to join unions regardless of gender or race. But emphasizing individual choice also has implications for the effectiveness and even the future of unions. The right to choose includes the right to forego. As a result, interpreting the right to self-organization from a civil rights perspective often leads to the conclusion that individuals not only should have a say on whether a unit within a healthcare facility is unionized but also should have a right to refuse to join a union. This has led to so-called *right to work* legislation which supports such a refusal. But, bargaining collectively and engaging in concerted action require a cohesiveness that can be undercut by individual free choice. Allowing an individual to exercise a right of refusal with regard to union membership also opens the possibility that the individual will enjoy the benefits from union activity while bearing none of the costs.

Equally important from a civil rights perspective is the right of freedom of speech. As this right relates to and impacts employees's right to self-organization, there are ethical concerns about what limits, if any, should be placed on the right to free speech of the various parties with an interest in the self-organization process. In the years immediately following the Wagner Act, the NLRB took the position that employers should remain neutral while employees were determining their form of self-organization. By 1941, however, employers's free-speech right to voice their opinion and take sides on employees's self-organization was recognized. In exercising that right, employers, according to the National Labor Relations Act, were not allowed to "interfere with, restrain, or coerce employees in the exercise of their right" to self-organization. That raises questions about what counts as interference, restraint, and coercion. The greater the emphasis on freedom of speech, the greater the latitude employers have to express through word and deed their negative reaction to unionization. Allowing employers to voice their opinion about unionization recognizes their right to free speech; but it can also have the effect of shifting the focus of the exercise of the right to self-organization from the efforts of employees to the interaction between union and employer. The self-organization process can move from one of deliberation among employees to one of antagonism between employer and union.

As the right to free speech of employees, employers and unions comes more to the fore, the danger is that the differentials of power existing between employers and individual employees will be lost to sight, and employers and employees will be treated simply as individuals with different and competing interests, each struggling to achieve their own ends. The right to self-organization then becomes primarily a matter of self-determination. Employees can choose to exercise or not exercise this right; and, even after exercising it, they can retreat from their decision through decertification of the union.

Employees's ability to deal with an employer from a position of equality is especially important in healthcare. In addition to their proper concern about wages and working conditions, healthcare employees have a responsibility as advocates for their patients. Without the power from collective bargaining and concerted action made possible by self-organization, healthcare employees's ability to carry out that responsibility can be severely restricted (White).

SOCIAL RIGHT. Employee self-organization, however, can also be viewed as a social right. Unlike civil rights, which protect the individual against external intrusions and coercions, particularly by the government, social rights set out the basic elements each individual requires to participate within society. Participation here means more than just not being hindered from voting, assembling or speaking one's

mind. Its focus are the basic resources needed to take one's place within society and interact substantively with one's fellow citizens to achieve personal and communal good. Social rights include the right to food, housing, education, and healthcare.

Self-organization can be understood as a social right. Then, the right to self-organization, just like the right to food, education, housing, and healthcare, is not treated as a right in conflict with civil rights. It is a basic need that must be met to achieve and ensure social participation for individuals, to establish the foundation needed for exercising civil rights. For example, from this perspective, to say that a person who is homeless or without an education has the right of freedom of expression is formalistic and empty.

Understood as a social right, employees's right to self-organization is not in competition with an employer's right to self-expression. Employees need to exercise their right to self-organization in order to make use of their right of freedom of expression with regard to their working conditions and, in the case of healthcare, with regard to their responsibility for patient care. Thus, in 1999, the American Medical Association (AMA) announced its intention to develop an affiliated national labor organization to represent employed physicians to help them advocate more effectively on behalf of their patients.

Clearly employers have an interest in the results of employees's self-organization; but employees also have an interest in their employer's self-organization. Employees of course are free to make comments about an employer's self-organization. But, because of the power differentials between employers and employees, those comments have neither the power nor the possibility of interference and hindrance that an employer's words have during employees's self-organization.

Viewing employees's right of self-organization from the perspective of social rather than civil rights also has implications for employees's exercise of individual freedom. An approach emphasizing civil rights focuses on the individual as the fundamental element within society and the exercise of freedom as a primary defining factor for the individual. An approach emphasizing social rights looks to the community as the basic building block of society and emphasizes participation as a primary defining activity of the individual. From the latter perspective, freedom is mainly concerned with the way an individual participates, not whether one participates. Applying that to employees's right to self-organization understood as a social right, employees's exercise of freedom goes toward determining the form of their self-organization, not whether there will be some form of self-organization. Loss of a union election does not remove the discussion of employee self-organization from the table; it simply moves the discussion to other possible forms that self-organization might take. Underlying this is an understanding that, given the differentials of power between employees and employer and given the right and responsibility of healthcare employees to advocate for their patients, healthcare employees can exercise freedom only through self-organization (Hirschl).

Ultimately, these two categories, the right to employee self-organization as a civil right and as a social right, are points on either end of a continuum. Where one comes down on the continuum affects the policies, strategies and actions of the parties involved. For example, as already noted, the stronger the emphasis on self-organization as a civil right, the greater the stress on employer freedom of self-expression and on employee individualism; the stronger the emphasis on self-organization as a social right, the greater the stress on seeing employees's self-organization activity as fundamental for, and thus a prelude to, their exercise of freedom of speech. Regardless of where one is on the continuum, it is important not to lose sight of the fact that the employees are the center focus. When union organizing efforts are underway, events can easily escalate to what can best be described as a war where the focus shifts from the employees's attempts at self-organization to antagonism between the employer and the union. It is also important not to forget the differentials of power that exist between employees and employer.

Right to Strike

A second issue, closely related to the right to self-organization, is whether healthcare employees can strike. Those replying in the negative often base their response on the adverse effect such an action would have on the community at large, taking away a basic resource, and/or on the patients at the healthcare facility, depriving them of needed immediate care. Those replying in the positive often add a qualifier, indicating that in any strike action healthcare employees have a responsibility to ensure that immediate, emergent care is available.

Differences between human service organizations such as healthcare facilities and other organizations involving employees, while they exist, should not be exaggerated, because doing so often leads to the conclusion that healthcare employees should be denied the right to strike. In healthcare, as in other organizations, employee interests differ from, and at times clash with, employer interests in all areas, including

patient or resident care. In healthcare, as in other organizations, a power differential exists between employees and employer that always has the potential of hindering employees from pressing their case for proper benefits and working conditions and (in healthcare) proper patient care. The power to strike is essential in light of that power differential.

While a strike can have a negative effect on patient care and the availability of medical care to the community, this result can be the consequence of employer as well as employee action. If, for example, the managers of a healthcare facility have developed policies that result in less than proper benefits, working conditions, or patient care and refuse to bargain fairly with employees, their responsibility for a strike cannot be overlooked. Actions must be evaluated in light of the totality of the circumstances. In addition, during a strike, managers share with employees responsibility for ensuring that basic healthcare resources continue to be available.

Employees's right to strike should not be undercut by the hiring of permanent replacement workers. Such action takes away from managers any incentive to address the concerns employees have about benefits, working conditions and patient care (Gibson; Lauer; Muyskens, 1982a, 1982b; Priest; Weber).

Social Responsibility of Unions

Third, the right to self-organization carries with it social responsibilities. This is especially true when the right to self-organization is seen as a social right. But even civil rights, which, although not created by society, require social promotion and protection, must be exercised in a socially responsible manner and at times give way to the good of the whole. The social responsibilities attendant to healthcare employees's exercise of their right of self-organization require that they take into account the effects their actions (seeking greater benefits, demanding better working conditions, striking) have on the care of patients and the ability of the community to access healthcare. At the same time, employee action in this regard should not be termed *self-interest* and placed in opposition to the common good of the community. Adequate salary and benefits, proper working conditions, and a voice in one's work are all as much social rights as is access to healthcare. At issue is appropriately allotting the resources of society so that each and all can meet their needs and participate in society. Moreover, the responsibility for working to provide access to healthcare to the community rests with management as well as employees.

Finally, healthcare employees have a duty to use the power they achieve through self-organization to actively advocate for better and broader access to healthcare. The dedication of healthcare employees to care for the injured and diseased should not stop with their ministrations to those seeking help at their facility. Through the power self-organization gives healthcare employees, they should be a voice for those lacking adequate healthcare and work to address the stark inequities in the United States where the only access to healthcare for too many is through emergency departments or through healthcare providers willing to offer *charity care* as well as to address the stark inequities worldwide with so many people lacking access (Muyskens, 1986).

LAW AND BIOETHICS

• • •

Bioethics began as, and remains, an interdisciplinary field. If developments in biology and medicine have fueled the bioethics train and philosophy has laid down the tracks on which it has run, then law has been the engineer at the controls of the locomotive and statutes and court decisions have thrown the switches that guided the train through the rail yards. Law's influence on bioethics has been so pronounced as to be unmistakable, yet so pervasive as sometimes to be unnoticed.

It might be argued that law's role was pronounced for purely historical reasons: Bioethics began as an American phenomenon and hence was shaped by certain aspects of American culture. Lacking an established church or a single heritage of values, though committed to the rule of law and to the equality of all persons, Americans have a habit of turning to courts to resolve moral conflicts. Moreover, other features of the terrain also indicated a major role for the law. Bioethics frequently presents central civic issues, among them these: When does a human entity first become (or cease being) a legal person? What conduct of healthcare professionals treating incurably ill patients would constitute murder? May parents be paid for transferring to other persons the rights of custody and control over their children? Does the prospect of gaining knowledge of potential benefit to the community ever justify using people without their consent or even their knowledge?

Dependence on the legal system to settle many ethical and social issues generated by medicine and the life sciences does more than merely provide a means for resolving disputes. Reliance on the legal system denotes that an issue should be understood as having two opposing sides that will do battle for their respective rights to act in a particular fashion or to restrain the other side from acting in a contrary fashion. Moreover, as a means of discovering and articulating principles, the law favors certain implicit and explicit values.

The relationship of law and bioethics has not, however, been unidirectional: Bioethics has also affected the law. While much of law is concerned with commerce and institutions, both public and private, bioethics is essentially about people and about the fundamental choices that determine and even define their lives. If the law has brought to bioethical cases an attention to rights and procedure, bioethics has enriched legal analysis with life-and-death dramas. It would strain the point to say that medicine saved the law, as Stephen Toulmin observed medicine did for philosophy. But the ethical dilemmas arising from medicine and its associated scientific disciplines have helped to humanize the law, providing a setting in which the central struggles of our times—of individual rights and the collective good, of liberty as against equity and equality, of justice and fairness, of personal wishes versus expert judgment or the will of the majority—are played out with unparalleled urgency and vitality. When the question is whether a life is worth living, for example, the answer is consequential. And when legal institutions falter in answering such questions, then lawyers and others are reminded that perfect legal solutions may not exist for all bioethical dilemmas. Bioethics raises fundamental challenges for theorists as well as practitioners of the law about the harm that society may impose upon a minority in order to uphold values believed to be of fundamental importance to the majority, or the limits of the law as a guide to human conduct. Yet the focus of this essay is not the theoretical connection between morality and law, but rather the law as a practical force in shaping and defining bioethics.

What Is the Law?

SOURCES OF LAW. The term *law* carries a number of meanings. In ordinary speech, it usually refers to specific criminal or regulatory provisions ("It's against the law to …"). This usage also reflects the common equation of law with statutes, denoting not just criminal statutes but also those governing civil or procedural matters, such as the ownership of property or how one is called for jury duty. A fuller understanding of the law would emphasize other important sources. Of particular prominence today are the detailed and voluminous regulations issued by governmental departments and administrative agencies to implement the powers and carry out the duties conferred on them by statutes. Although statutes are sometimes quite detailed, many areas of human activity (especially of an industrial or commercial nature) are so complex that the legislature must almost of necessity confine itself to framing the basic legal structure, while delegating the task of supplying all the details to those with greater time and expertise at the administrative level, subject to various degrees of public, executive, legislative, and judicial oversight.

Especially in countries, including the United States, whose legal systems are derived from the English model, judicial decisions are a source of law at least as important as

statutes. In some decisions, judges interpret statutes and hence give meaning and shape to them; while in others, judges decide issues not directly addressed by statutes and effectively make new law. At one time, when statutory rules covered only a small portion of human affairs, most of English law consisted of judicial resolution of individual disputes, collectively known as "the common law." To this day, many areas of law have a strong common-law flavor, which is constantly reinforced and renewed by judges' decisions about novel issues. Even in countries with civil-law systems based on Roman law or the Napoleonic Code, judges participate in the crafting of the law by their interpretation of code provisions.

Finally, in legal systems that follow the model of the United States, in which all activities of the government—including making and interpreting the law—are subject to limits specified in a constitution, no statement of the law would be complete without reference to the text of that supreme law, as well as the authoritative interpretations of its provisions by the courts.

Even these sources—statutes, regulations, judicial decisions, and the constitutions—do not exhaust the meaning of *the law,* which also connotes the legal system, the institutions, and the processes through which the law is applied. In this sense, the law encompasses the processes and rules of courts and administrative bodies (for example, on admission of evidence), as well as the more informal standards or practices that are reflected in the action of those law-applying people and institutions (such as public prosecutors or bureaucrats) who have wide discretion in administering statutes and regulations. Within their sphere of authority, the law is what they say it is. Indeed, to the extent they are not expressly forbidden, the customs and practices of people in any field may properly be described as part of the law, though those customs and practices may formally be denominated *law* only when explicitly incorporated into a judicial opinion, statute, or regulation.

Seen in this way, the law is a basic framework for society; it is a system not only for promulgating official policies and procedures and for administrating prosecutorial, judicial, and regulatory affairs but also for providing explicit or implicit sanction for the private arrangements through which activities and relationships are ordered. Of course, many people would not identify the law as the source for the way they conduct their affairs. Instead, they would point to the influence of family and community customs or values, as well as to explicit moral or religious teachings. But as members of society, they must still operate within the law; this means that if their private arrangements run afoul of the expectations of society as embodied in the law, these arrangements may be limited or nullified. For example, in a number of U.S. jurisdictions, legislatures or judges have declared contracts for women to bear children for couples (so-called surrogate motherhood) to be null and void, as against public policy, even though a purported contract is freely and knowingly agreed to by all parties.

The existence of such private ordering as an important but often overlooked source of lawmaking also serves as a reminder that even in a society, such as the United States, with a high proportion of lawyers, lawmaking is not restricted to lawyers. From the local to the national level, many members of the legislative and executive branches of government are not lawyers; indeed, the federal constitution does not even require that judges be legally trained. Law is one of the three traditional learned professions (along with medicine and the clergy). Its members are licensed by the state and admitted "as officers of the court" to practice "at the bar of justice." Accordingly, like physicians, they are governed by ethical standards articulated by their profession through its associations as well as through the decisions of judges passing on cases of alleged transgression of professional obligations.

Around the world, most legal education occurs in schools affiliated with universities. Characterizing legal education in the early twentieth century as akin to a trade school, Thorstein Veblen opined that "the law school belongs in the modern university no more than a school of fencing or dancing" (p. 211); but this complaint is no longer justified, if indeed it ever was. Today, schools provide much more than mere vocational training, and scholarship is not limited to exegesis of doctrine; it encompasses empirical, normative, and theoretical work. Nonetheless, the law is a practical field, not simply one of the liberal arts and sciences.

DIVISIONS OF THE LAW. Traditionally, for purposes of basic study and classification, law has been divided along such doctrinal lines as tort law, criminal law, contract law, constitutional law, equitable remedies, property law, wills and trusts, and civil and criminal procedure. Each of these areas is characterized by prototypical relationships among parties and a set of analytic and practical devices for structuring those relationships and determining the outcomes of disputes. In recent years, legal scholarship has taken on several additional layers.

One is an enrichment of the tools brought to the law's tasks by combining with another discipline: legal anthropology, law and economics, legal history, law and literature, law and philosophy, law and psychology or psychoanalysis, sociology of law, and law and religion, to mention prominent examples. Each of these combined subdisciplines has not only a methodology but also its own theories and assumptions. Furthermore, additional schools of thought

have arisen—such as legal realism, critical legal studies, feminism, and critical race studies—that provide perspectives on the law by combining the tools of several disciplines and a set of attitudes toward legal, social, economic, and personal relationships. Plainly, a person working in an interdisciplinary field may bring one of the analytic perspectives to bear—for instance, a feminist approach to legal history or a legal-realist perspective on law and economics.

A third way of dividing the domain of law is by focusing on its application to specialized types of personal, commercial, institutional, and sociopolitical activities. (The range of specialized areas of the law seems virtually limitless; attorneys now practice antitrust law, art law, bankruptcy law, civil-rights law, commercial law, education law, employment and labor law, entertainment law, family law, insurance law, intellectual-property law, juvenile and dependency law, media and broadcast law, mental-health law, probate law, public and private international law, regulated industries law, sports law, securities law, and even space law, to name a few.) Whether from an academic or a practice vantage point, specialized fields of law usually link traditional doctrinal categories with information and methods derived from the disciplinary and analytic approaches just described. For example, people working in family law will draw not only on legal doctrines from remedies, from property law, from wills and trusts, and from criminal and civil law and procedure, but also on psychological, sociological, or feminist analyses and perspectives; while those pursuing antitrust law will draw not only on various aspects of business law and criminal and civil law but also on law and economics studies and perhaps historical and sociological analysis as well.

HEALTH LAW. Traditionally, medicine and law intersected in civil or criminal cases in which proof of medical facts was at issue. From the medical side, those involved were usually pathologists, who became specialists in "forensic medicine," as the field was known to prosecutors and criminal-defense attorneys; on the legal side, torts specialists who handled a large proportion of malpractice cases (and some of whom held degrees in both law and medicine) described their expertise as encompassing "medical law." With the tremendous growth in healthcare and research beginning in the mid-1960s, healthcare law—or more simply health law—emerged as a new field that includes these areas and more. It is one of the fastest-growing, most diverse, and most exciting legal specialties.

Health law draws on practically the entire corpus of traditional doctrinal fields—civil, criminal, constitutional, property, and procedural—as well as many other specialized areas, such as labor, insurance, antitrust, and government regulation. Practitioners represent hospitals and other healthcare providers; academic research centers; physicians, nurses, and other healthcare professionals and nonprofessional employees; insurance carriers and employers that provide health insurance as an employee benefit; manufacturers and distributors of drugs and medical devices; patients and their families; and governmental departments and agencies that finance and regulate the individuals and institutions providing healthcare. Although cases involving ethical dilemmas are the ones that draw public attention, they are the exception for most health lawyers, who are more likely to spend their time drafting contracts for the purchase of goods and services; bargaining about insurance reimbursement; preparing staff bylaws, checking professional peer activities, or handling other issues that arise in accreditation, credentialing, or certification of practitioners or institutions; negotiating with government agents about licensing, taxation, and environmental controls; or litigating a case of professional malpractice (Macdonald et al.).

The Impact of Law on Bioethics

The relationship of law and bioethics is complex and multifaceted. One need not share the view of a leading legal commentator—"American law, not philosophy or medicine, is primarily responsible for the agenda, development, and current state of American bioethics" (Annas, 1993, p. 3)—to conclude that the law has strongly influenced the methodology of bioethics, the central focus of bioethics, and the values of bioethics. "And—to the considerable extent that bioethics is an American invention and export—the influence of American law has been felt even in societies in which legal institutions play a less pronounced role than they do in the United States" (Capron, p. 43). Law's role in shaping bioethics has at least five facets.

FAMOUS LEGAL CASES. Notable cases have played a major role not merely in the development of bioethics but also in making it, by the 1990s, a prominent part of private reflection and public discourse. Difficult ethical issues are nothing new to the health professions. Yet until recently, issues were examined largely behind closed doors by physicians and nurses and an occasional theologian. In democratic societies, legal proceedings are usually open (though sometimes parties are permitted to use fictitious names, to help preserve their privacy). Consequently, the media are able not merely to report about a difficult decision that must be taken but also to put a human face on it by recounting the drama as it unfolds in the hearing room.

And bioethics cases are often very dramatic. A familiar example: As Karen Quinlan's parents argued during

1975–1976 in the New Jersey courts for authority to order her ventilator turned off, her photograph appeared so often in the media that it was probably more familiar to most Americans than the faces of their local members of Congress. Likewise, bioethical breaches—particularly scandalous ones, such as the Nazi physicians' experiments on concentration camp prisoners and the Tuskeegee syphilis study—not only generate landmark judicial rulings but also provoke adoption of new statutory or administrative law.

METHODOLOGY. Related to the addressing of bioethical cases through the law is a second facet, the law's largely inductive methodology. This method is especially associated with the common law, the process through which judges render decisions specific to the facts of the individual cases before them that are grounded in, or justified by, the decisions in prior cases whose facts are sufficiently analogous. Not only do judges often apply the same methodology when interpreting statutes, but legislatures, in drafting statutes, usually operate concretely and incrementally, building on court decisions and existing legislation (or borrowing from other jurisdictions) rather than attempting to operationalize grand principles. The law's fact-based, inductive method provides a counterpoint to the "principlism" that characterizes much philosophically oriented analysis in bioethics. Of course, this approach is not unique to the law, but it reinforces other case-based traditions in ethics, such as casuistry and Jewish ethics.

PROCEDURAL EMPHASIS. Third, recognizing that midlevel ethical principles such as autonomy, beneficence, justice, and nonmaleficence cannot solve most bioethical dilemmas (which arise precisely when conflict occurs among these unranked principles), and that pluralistic societies do not necessarily hold enough moral views in common to agree upon the correct resolution of most controversies, many bioethicists have welcomed "a procedural ethic, based on respect of the freedom of the moral agents involved, even without establishing the correctness of any particular moral sense" (Engelhardt, p. 45). This emphasis on procedure is familiar to lawyers, though the suggestion that bioethics should concentrate on acceptable decision-making processes rather than substantive rules draws objections from some legal scholars who see in proceduralism the risk of a slide into "the arbitrary exercise of power" (Annas, 1988, p. xiii).

Even when they have mandated that procedures be followed, the courts have not insisted that bioethical disagreements outside court employ all the procedural niceties that attach to judicial proceedings. Indeed, judges, legislators, and administrators alike have not always been very clear about the mandate and membership, much less the process, of institutional committees to make judgments about medical treatment and research. For example, in its landmark *Quinlan* decision, the New Jersey Supreme Court held that the guardians of unconscious patients could order life-sustaining treatment forgone with the agreement of the treating physician, provided a multiprofessional committee at the hospital concurred; yet it said nothing about how that committee should gather, hear, or evaluate evidence or otherwise reach conclusions (*In re Quinlan,* 1976).

RIGHTS ORIENTATION. The issues in bioethics are some of the most sensitive and most divisive confronted by our society, not least because of the rapid development of the life sciences. In both the laboratory and the clinic, novel problems are constantly generated by new capabilities for organ transplantation and mechanical replacement, for genetic diagnosis and therapy, for assisting reproduction, for sustaining life, for modifying human behavior, and for myriad other means of altering nature; such problems also arise out of major changes in the way health services are organized and financed. These developments and changes challenge existing social and professional norms; where those challenges are substantial and intractable, the people involved not infrequently turn to courts, legislatures, or executive agencies to protect their rights. "The concept of rights … has its most natural use when a political society is divided, and appeals to cooperation or a common goal are pointless" (Dworkin, 1977, p. 184).

Concern over abuses of patients and research subjects has been a major theme in bioethics, reinforced repeatedly by instances in which healthcare professionals and institutions have acted—sometimes from good motives and occasionally not—to the detriment of people in their care. The law has offered bioethics not just a procedural response but also a long tradition of protecting people from harm by assertion of their rights; indeed, a rights orientation seems inherent in the law's perspective on the relationship of the healthcare system to patients and research subjects.

Certain risks to patients arise from the imbalance inherent in this relationship—the vulnerability and dependence that illness creates, physicians' superior knowledge and technical mastery, and the way the organization of healthcare enhances professionals' power and prestige. From ancient times, medical ethics proclaimed the duties of beneficence and fidelity to patients' interests in order to guard against harm to patients. Yet, as bioethicists have pointed out from the first, this traditional view of medical ethics is problematic because physicians not only promised to serve their patients' interests but often took it upon themselves to define those interests. Lawyers aided this assault on medical paternalism with concepts borrowed from civil-rights law,

such as political liberty and equality of treatment. From the 1960s onward, bioethicists adopting this stance "had much in common with the new roster of rights agitators" for consumers, racial and sexual minorities, and women (Rothman, p. 245).

The increase in the rights orientation coincided with the increasing effectiveness of medical interventions. Armed with wonder drugs, high-tech surgery, and new methods of resuscitation and intensive care, physicians saw their power to influence their patients' futures increase dramatically from the middle of the twentieth century; and that power became the subject of disputes concerning how it was to be distributed in the physician–patient relationship. Legal commentators suggested—and most bioethicists embraced—a reformulation of that relationship in terms of patients' rights (Annas and Healy). The dominance of the rights orientation dismays many healthcare professionals, who lament the adversarial tone they feel law has introduced into the practice of medicine. There may be a legitimate complaint here, but physicians have historically denied that they are making anything but medical decisions for patients. It has taken bioethicists to point out that once alternatives become available, the choice between them is usually based on value judgments, not medical judgments, and doctors have no special expertise that justifies their values taking precedence over patients' values. Rights are crucial to dealing with power inequality, even where one might prefer to conceive of relationships in terms of caring and connection. This tension remains a recurring theme in law and bioethics.

Although the incorporation of such central legal doctrines as informed consent into the core of bioethics can hardly be doubted, the transformative effects of law on medical practice are less clear. Commentators such as George Annas, who take a patients' rights approach, find many instances where those rights are still abused (1988); whereas scholars such as Jay Katz, who look at physicians' behavior, emphasize that powerful factors in physicians' training and psychology have prevented them from adopting a stance of open discussion and shared decision making. At the same time, other critics argue that the authority the law took from physicians is often transferred to lawyers and judges, not to patients; and that moreover, by replacing professional discretion with legal rules, the law has given physicians the unintended message that they need not exercise ethical judgment (Hyman). Even if physicians do not react in this fashion, the law's inclination to view relationships in terms of rights changes the way bioethical issues are analyzed and potentially displaces other forms of moral discourse traditionally associated with medicine. For example, by emphasizing what one has the right to do without helping to define what is the right thing to do, the law may have undermined the specifically moral aspects of bioethics (Schneider, 1994). "[N]othing but confusion of thought can result," as Justice Oliver Wendell Holmes observed, "from assuming that the rights of man in a moral sense are equally rights in the sense of the Constitution and the law" (p. 172).

SPECIFIC VALUES. Besides leading toward a rights orientation, the reliance upon the legal system imports specific values. These values are not unique to the legal system, though they tend to be associated with it, nor are they controversial, though they are not without consequence. That is, when one of these values is given preference in the resolution of a problem, other values, such as those that may be favored by medicine or by other philosophical systems, are likely to be overridden. The values usually associated with the law include justice, as opposed to progress or efficiency; equality, as opposed to inherent differences or measures of quality; due process, as opposed to scientific proof; and individual self-determination over one's life and body, as opposed to beneficence, psychological interdependence, or communal welfare. The law's values are generally those of liberal society: personal autonomy within a setting of ordered liberty in which individuals have wide but not unlimited freedom. Especially in pluralistic democracies, the law sets boundaries on the enforcement of majoritarian morality, thereby protecting many individual choices from interference.

Not all liberal societies treat the values involved in the same way. For example, although revolutions in France and the United States in the late eighteenth century drew on the same sources in articulating basic rights, the Declaration of the Rights of Man and the Citizen in France in 1789—unlike the Declaration of Independence in the United States in 1776—emphasized that individuals have duties as well as rights (Glendon). This difference between the American and European views of rights, which persists to this day, has important implications as bioethicists attempt to address such issues as self-risking behavior and limits on the allocation of scarce community resources to healthcare.

Law and Bioethics as a Field

As a field of study, law and bioethics can be viewed from several perspectives. First, from the vantage point of a nonlawyer doing bioethics—whether at a policy level or in individual clinical situations—one needs at least some understanding of the law and legal institutions. Moreover, institutional ethics committees usually include at least one lawyer, who can provide analytic abilities as well as expertise on statutory, regulatory, and case law.

Second, "law and bioethics" is a subject of increasing interest to students, scholars, and practitioners of law. In one view, law and bioethics can be seen as a subset of health law that deals with medical decision making, genetic and reproductive technology, human subjects research, and the like. In fact, health-law casebooks today typically include chapters or sections on bioethics. But this view does not fully capture the way in which bioethics is generally conceived. By the early 1960s, long before health law emerged as a separate field, courses dealing with bioethics were being taught at American law schools, although the first casebook with the title *Cases, Materials, and Problems in Bioethics and Law* was not published until 1981 (Shapiro and Spece). That volume, like other legal books dealing with bioethical issues, not only describes "the new biology" and recounts the dilemmas engendered by modern medicine and bioetechnology; it also discusses ethical theories and concepts, such as proportionality and personhood, that have crept from ethics into legal opinions. Nonetheless, law and bioethics is not just a subset of law and philosophy (or law and religion), since attention is usually focused on philosophical concepts not for their own sake but as they relate to understanding society's appropriate responses to technical developments that deeply affect people's lives and relationships. Most of the text of such books is drawn from reports of medical and scientific developments and from the rich array of relevant cases, statutes, and regulations, as well as commentaries about them (Capron and Michel).

In addition to academic attention, law and bioethics has been examined through commissions established by national and state governments through statutes and executive orders. These bodies have advanced bioethical analysis and promulgated legislative and administrative proposals (U.S. Congress).

Although people looking at the topic "law and bioethics" from the perspective of the latter field are likely to view it as a legitimate area of scholarship and practice, it is largely unrecognized among lawyers at large, who treat it neither as one of the distinctive "law and …" interdisciplinary fields nor as a distinct special application of law ("bioethics law") akin to employment law, sports law, and the like. The Association of American Law Schools does not categorize courses or teachers under such a heading, nor does the *Index to Legal Periodicals,* despite the existence in law journals of bioethics symposia as far back as the late 1960s (Capron and Michel). The literature of law and bioethics is not found only in law reviews or, for that matter, in scholarly journals of other disciplines such as philosophy. It also appears in medical and health-policy journals and in bioethics publications, such as the *Hastings Center Report,* the *Kennedy Institute of Ethics Journal,* and the *Journal of Law, Medicine, and Ethics.*

One important aspect of legal scholarship that can legitimately be said to be part of the "law and bioethics" literature is abortion. Recent treatments of this subject have been enriched by feminist legal analysis, which itself is greatly influenced by theorists such as Carol Gilligan and Nel Noddings, whose work concerns moral development and the different ways in which women and men may resolve moral dilemmas. This influence is perceptible not only in subjects dealing directly with women, such as abortion, maternal-fetal issues, and reproductive technology, but also in less obvious places such as analyses of ethics committees. Since feminist analysis emphasizes relationships and nurturance, it is not surprising to see that as the literature of law and bioethics moves beyond the rights orientation, feminist insights become important in developing a better legal understanding of the relationship between patients and health caregivers (Capron and Michel).

Conclusion

Scholars differ on the precise influence the law has had in shaping the content, methods, and focus of the interdisciplinary field of bioethics, but all would agree that the influence has been significant. Both those who applaud and those who bemoan the law's influence seem to agree that the law has done more than merely allow the enforcement of, or provide redress for breach of, existing moral rights possessed by participants in the healthcare system. Rather, the law has—through its orientation toward rights and through the values implicit in the processes it has fostered—established new rights and preferred certain values over others. On the positive side, this has helped promote the autonomy of patients and subjects, the openness of the processes by which decisions are reached, and equality of respect and concern for all participants. On the negative side, it has diminished the sense of community and of duties that attach to rights, while increasing many providers' sense of adversariness in their relationship to patients.

In a society in which ethical standards were sufficiently complete to address even novel technical problems, widely enough shared to be accepted without question by all or nearly all persons, and consistent and coherent enough never to lead to uncertain or contradictory results, bioethics might operate with little reference to the law. As Grant Gilmore observed, "A reasonably just society will reflect its values in a reasonably just law. The better the society, the less law there will be. In Heaven there will be no law and the lion will lie down with the lamb" (p. 1044). Until that time, the law will

continue to play a large role in bioethics—not only providing a relatively neutral means through which troubling issues can be addressed and contended points resolved in a manner that is socially sanctioned, but also shaping bioethics through its concerns for justice and fair procedures, equality, and personal self-determination.

LAW AND MORALITY

• • •

Bioethical problems are often discussed in legal as well as in moral contexts. Lawyers as well as ethicists are involved with

such questions as abortion, euthanasia, and experimentation upon human beings. This is not surprising; the law is seriously concerned with protecting such basic rights as life, bodily integrity, and privacy—the rights involved in these ethical questions.

The overlap between law and morality has been a source of the substantial debate about the relation between law and morality, a debate not confined to the bioethical context. It is best divided into two main issues, although the discussion of these issues often overlaps: (1) What, if any, bearing does the moral status of a rule have on its status as a law? (2) To what extent, if any, should the legal system be used to enforce moral perspectives?

Moral Status and Legal Status

Western legal thought has been dominated by a natural-law tradition. There are many variants of this tradition, and the differences among them will be discussed below; what they have in common is a belief in a body of laws governing all people at all times, and in a source for those laws other than the customs and institutions of a given society. Such beliefs are frequently accompanied by the additional beliefs that no society is authorized to create laws that conflict directly with natural laws, and that any such conflicting laws may therefore be invalid. In short, the natural-law tradition asserts the existence of a set of laws whose status as laws is based upon their moral status.

The beginning of this tradition lies in the ancient world. Aristotle (384–322 B.C.E.) drew a distinction between the part of justice that is natural and should have the same force everywhere, and the part that is legal and has its force only in those places where it has been adopted by the people who live there. That distinction was developed extensively by the Stoics, who emphasized two further points about natural justice: that it is based upon right reason and that it is in agreement with nature. Cicero (106–43 B.C.E.), whose legal writings are based upon the Stoic tradition, emphasized the claim that no legislation can alter the validity of natural laws, which remain binding on all people. Some of these ideas were incorporated into Roman law, and the later Roman lawyers probably identified *jus naturale* (the philosophical notion of natural law) with *jus gentium* (a system of laws that had developed in the Roman world and governed the relations among free men independently of their nationality). This identification strengthened the idea of natural law as universal law.

These classical ideas gave rise to a number of different natural-law traditions, the two most important of which are the religious tradition culminating in the writings of Saint Thomas Aquinas (1224–1274) and the secular tradition, exemplified by Hugo Grotius (1583–1645) and John Locke (1632–1704).

Saint Thomas Aquinas defined a law as an ordinance of reason for the common good, promulgated by the individual who has the care of the community. He then distinguished four types of laws: eternal laws, natural laws, human laws, and divine laws. The eternal laws are laws promulgated by God on the basis of divine reason. The natural laws are the eternal laws implanted by God in human beings, in that human beings are naturally inclined toward their proper acts and ends. In short, Saint Thomas postulated an eternal, unchanging set of laws implanted by God in human beings and knowable by reason. Human laws are valid only insofar as they do not conflict with divinely promulgated, unchanging laws. Valid human laws either are conclusions drawn from the basic natural laws or are determinations of details left undetermined by the natural laws.

The natural-law theories of Grotius and Locke also contain theological references, and Saint Thomas does emphasize the rational basis of natural law. Nevertheless, Grotius and Locke represent a different tradition of natural law, one that puts more emphasis on natural law as rationally derivable than on natural law as divinely ordained. In addition, their tradition, especially in the writings of Locke, puts great emphasis on the natural law's protection of natural rights, rights that all human beings have independently of the state and its laws. Locke explicitly drew the conclusion that a state loses its legitimacy insofar as its laws are in violation of natural rights, such as the right to life or liberty.

These natural-law traditions continue to influence discussions about the relation between the law and bioethics. Writers influenced by the theological version of the natural-law tradition continue to argue that any valid law must be in conformity with the divinely ordained natural law. Thus, many Roman Catholic writers (e.g., Grisez and Boyle) argue that there must be civil laws prohibiting abortion and euthanasia because those procedures are in conflict with the natural law. To those who would object that this is an illegitimate use of the law to enforce morality, these writers reply that it is the very nature of legitimate law to prohibit such activities. The most important recent reiteration of this view is found in the 1987 statement from the Congregation for the Doctrine of the Faith titled *Instruction on Respect for Human Life in its Origin and on the Dignity of Procreation.* Having argued that abortion from the moment of conception and various forms of assisted reproduction are immoral, the Congregation goes on to claim that there must be laws prohibiting both because "The task of the civil law is to ensure the common good of people through the recognition

of and the defence of fundamental rights and through the promotion of peace and of public morality" (p. 35).

Writers influenced by the ideas of natural-rights thinkers like Locke continue to argue that no purported law is legitimate if it allows the violation of the basic rights of human beings. This type of argumentation is particularly prevalent in countries such as the United States, where the courts possess the ability to declare laws unconstitutional when they infringe upon basic human rights. U.S. Supreme Court decisions from *Griswold v. Connecticut* (1965), in which the Supreme Court ruled that a Connecticut law prohibiting the use of contraceptives is unconstitutional, to *Roe v. Wade* (1973), in which the Supreme Court ruled that women have a constitutional right to abortions at least in the first two trimesters, have indicated that jurists are prepared to extend those rights to include ones not explicitly mentioned in the Constitution, suggesting to many—but by no means all—commentators that they are implicitly invoking some natural-law theory of rights.

The natural-law tradition has not been universally accepted. There has also been a long tradition of thinkers, dating back to antiquity, who have insisted that the only laws that exist are those adopted by a given society, and that there is no necessary connection between the legal status of a law and its moral status. Defenders of this position, the position of legal positivism, are not opposed to the moral criticism of individual laws and of whole legal institutions; positivists often advocate changes in the law on the basis of moral considerations. But the positivists insist that an immoral law, however much it should be changed, remains valid as a law until it is repealed by the society's appropriate social mechanisms.

Jeremy Bentham (1748–1832) and John Austin (1790–1859) were the two most influential proponents of this view, although earlier figures like Jean Bodin (1530–1596) and Thomas Hobbes (1588–1679) should also be mentioned. The basic thesis of positivism has often been conflated with another of Austin's theories, the imperative theory of law, which held that law is the command of the sovereign. Since this latter theory has not survived critical examination, it is crucial to distinguish it from the basic theme of positivism: that what the law is, is a separate question from what the law ought to be. H. L. A. Hart, the most influential contemporary positivist, placed particular emphasis on drawing this distinction.

Some legal positivists have taken their view to mean that laws must be obeyed no matter how immoral they are. But the most important positivists, Bentham and Austin, clearly argued that there are circumstances in which an immoral law should be violated despite its status as a law; this of course weakens the force of the claim that a law retains its status as a law despite its immorality.

In any case, legal positivists insist that questions about the relation between law and morality must be settled independently of questions about what the law is. The legal status of a rule is independent of its moral status. This leads us, therefore, to the second of our questions: When ought the law to be used to enforce certain moral positions?

Use of the Legal System to Enforce Morality

The law is clearly used on some occasions to enforce moral viewpoints. We believe that murder is wrong and that the coercive mechanism of the law should be used to prevent murders. However, even if we believe that euthanasia is wrong or that one should come to the aid of others in distress, should the law be used to enforce these beliefs?

John Stuart Mill (1806–1873), in his classic *On Liberty* (1859), advocated the liberal answer to that question—that society should use the coercive mechanisms of the law only to prevent actions that harm someone other than the performer or another who has consented to the performance of the action. In other words, Mill argued that the social enforcement of morality was inappropriate when only the agent or others who had consented would be harmed. In his elaboration of this position in *The Moral Limits of the Criminal Law* (1984–1988), the most important elaboration of the liberal position in the twentieth century, Joel Feinberg has argued that actions might be criminalized if they were profoundly offensive, even if not harmful, to others. Mill's followers have therefore opposed the existence of laws creating "victimless crimes," among which they have included laws against suicide and voluntary euthanasia, unless such laws are required to protect against mistake and abuse. They have also approved of court decisions that allow rational adults to refuse medical treatment on religious or on other grounds, even though the refusal would result in their dying.

A number of points must be kept in mind about the liberal position. First, it does not require legislation prohibiting all actions that harm others. Whether there should be legislation will depend upon such factors as the existence of harmful consequences and the possibility of enforcement. All that the liberal position entails is that such actions, because they harm others, are candidates for appropriate legal prohibition.

Second, actions that harm others may be prohibited legally, even when others consent, if their consent is not valid. This point is extremely important in connection with

legislation governing medical experimentation. Consider, for example, the problem of experiments on children, where the experiments are not primarily intended to aid in their therapy and where there are potential hazards. Given that the consent of the children may not count if they are young enough, and given that the relevance of parental consent is unclear, Mill's principles could allow for enforcing some socially determined moral standards in this area. In fact, the 1993 U.S. regulations on research involving children enforce a very strict moral standard; the risks must represent only a minor increase over minimal risk, and the information must be of vital importance.

Third, this liberal position is not identical either with the English common-law tradition or with American constitutional law. Both have allowed for legal prohibitions that are unacceptable in the liberal framework. For example, the consent of the person killed in an act of voluntary euthanasia has been, at least until the early 1990s, no defense against a charge of murder in either legal system. Some of the language in the U.S. Supreme Court case *Cruzan v. Missouri Department of Health* (1990) suggests that many judges are now prepared to say that the right of a competent adult to refuse life-preserving therapy is a protected constitutional right, a result that liberals would applaud. Nothing in the text of this decision, however, suggests the extension of that view to assisted suicide or voluntary active euthanasia.

Adherents of the liberal approach have in recent years expanded upon it and modified it in a number of ways. One question that has received considerable attention is determining whose consent is valid. The current understanding of mental illness makes it very difficult to accept a sharp dichotomy between those competent to consent and those incompetent, since there are many degrees of mental disturbance. Some (including Buchanan and Brock) have responded that the standard for competency must be more demanding when the decision is more momentous. Others (including Brody) insist that we must recognize that competent decisions may be overridden when the costs to the individual are great and the person's decision making is impaired, even if he or she is somewhat competent.

Another question that has received considerable attention is the extent to which society can legitimately use the law temporarily to prevent an individual from carrying out certain decisions, to see whether the individual will change his or her mind or whether the choice is truly voluntary. Within the liberal framework, could we legally require, for example, a period between a request for voluntary euthanasia and the implementation of that request? Following Joel Feinberg, many liberal authors have allowed for this form of weak or soft paternalism.

A third question that has received considerable attention is the legitimacy of legally imposing certain positive moral duties. Mill was primarily concerned with challenging the legitimacy of laws prohibiting immoral actions; it is unclear how he would have dealt with Good Samaritan laws—laws that would, for example, require trained medical personnel to come to the aid of accident victims. Would such laws that require positive actions, and not mere forbearances, be a legitimate legal enforcement of morality? A final question that has received considerable attention is whether society can pass laws designed to prevent harm to animals. If it could, this would markedly change the liberal attitude toward laws governing experimentation on animals. Peter Singer and Tom Regan are two liberal authors who have advocated the extension of the liberal tradition in this way.

From its very beginning, the liberal tradition has had its critics. Writers in the natural-law tradition objected, of course, to the liberal presupposition that the moral and legal status of rules could be separated. But even some of those who agreed with positivism have argued that there is a wider scope for legislating morality than the scope allowed by Mill.

James Fitzjames Stephen (1829–1894), in his influential *Liberty, Equality, Fraternity,* argued that one of the purposes of both the criminal and the civil law is to promote and encourage virtue while discouraging vice. Stephen conceded that certain areas of morality could not be dealt with by the law because the relevant laws could not be enforced without destroying privacy and individual rights; he claimed, however, that there are many areas of morality that should be treated by the law despite Mill's strictures. This point of view has been extended by Patrick Devlin, a distinguished English jurist. Devlin contends that the continued existence and strength of a society require a common moral code. There is, therefore, a social interest in the preservation of such a code, and it is at least sometimes appropriate to enforce part of the code through the use of the law. Devlin limits his conclusions to cases where this enforcement of morality will not violate human rights. He applied this approach to English abortion legislation in the 1960s. He argued that the severe punishment of the illegal abortionist cannot be justified on the grounds that such a person poses a threat to the health of the mother, since that threat exists primarily because the abortionist's activities are illegal. Instead, such laws can be explained and justified only as an attempt by society to protect its fundamental views on sexuality and on human life.

A number of recent authors (Bellah et al.; MacIntyre; Sandel) have emphasized, in different ways, the importance

of communities and a sense of community values, and they have seen this as standing in opposition to the liberal account. This new communitarianism no doubt has significant implications for the legislation of morality in areas related to bioethics, but those implications have not yet been studied systematically. There are, then, a number of differing systematic approaches to the question of which aspects of morality should be enforced legally. In addition to those systematic approaches, various authors and courts have suggested additional considerations that must be weighed in deciding whether legally to enforce moral standards. Among the most prominent of the considerations are the following.

1. Respect for differing views in a pluralistic society. In the 1973 discussion of abortion statutes in *Roe v. Wade,* the U.S. Supreme Court suggested that legislation enforcing a moral viewpoint is inappropriate when those who are experts in the relevant area disagree as to the legitimacy of that viewpoint. This principle is in keeping with a wider movement against legislating disputed moral positions. A number of important considerations support this mode of thought. To begin with, people seem to have a right to follow their own conscience rather than to be compelled to follow the conscience of the rest of society. Moreover, there are tremendous detrimental consequences for a society when many of its citizens feel that the law is being used to coerce them into following the moral views of others. Such considerations are even more important in societies where there are substantial moral disagreements among the citizens. One author who has particularly stressed the importance of respecting differing views in a pluralistic society is H. Tristram Engelhardt, Jr.

2. Respect for privacy. There are laws that cannot be enforced without infringing the privacy of the citizens involved. Following a long tradition that appealed to this point, the U.S. Supreme Court suggested (in *Griswold v. Connecticut,* 1965), that such laws are illegitimate because of the inability to enforce them in an acceptable fashion. For that reason, the Court declared unconstitutional a Connecticut law prohibiting the use (and not merely the production) of contraceptive devices. It has also been argued that laws regulating the patient–doctor relation are inappropriate because they can be enforced only by the state's entering into and examining a relation that must be private. Many authors have criticized the U.S. "Baby-Doe" law (P.L. 98–457, 1984), which limits on moral grounds the decision-making authority of parents and physicians with regard to severely disabled newborns, because it involves state intrusion into a private relation.

3. The consequences of passing such a law. It is sometimes argued that certain moral positions ought not to be enforced legally because the laws that codify them will be violated anyway, and their surreptitious violation will lead to many tragic results. Thus, it has been argued that laws prohibiting abortion only result in women seeking unsafe, illegal, and very dangerous abortions. Again, it has been argued that laws prohibiting voluntary euthanasia or allowing to die only result in surreptitious acts of voluntary euthanasia and in informal decisions to "let the patient die," acts and decisions that can be abused. Many studies of such abuses (by, e.g., Bedell and Delbanco; Evans and Brody) led in the 1980s to more formal policies governing such decisions.

Considerations 1–3 are reasons why certain actions should not be illegal, whether or not they are immoral. Most authors would agree that these legitimate considerations must be balanced against others that argue for the criminalization of the acts in question. These include the extent of the harmful consequences of the actions in question and the extent to which they involve infringements of the rights of others. There are, in addition, considerations for making actions illegal even if they are not immoral. Two deserve special notice:

4. The difficulty of distinguishing between fraudulent and legitimate cases. Suppose that there are no moral objections to voluntary euthanasia. Some have argued that it would be wise legally to prohibit such killings because it is difficult to distinguish cases of honest requests from cases of consent obtained by subtle fraud or duress. Again, some have argued that despite the moral permissibility of experimenting upon consenting adults, there should be laws prohibiting experiments conducted upon prison inmates, because one cannot tell when the consent of such inmates is truly voluntary.

5. Slippery-slope arguments. It is often argued that legalizing certain morally acceptable actions would later lead to irresistible pressures for legalizing immoral actions, and that the only way to avoid sliding down this slippery slope is to prohibit even the acceptable actions. Thus, it has been argued that voluntary euthanasia should be illegal, even if morally acceptable, as a way of ensuring against the later legalization of involuntary euthanasia. Naturally, both of these factors must be weighed against the possible desirable results of legalizing the morally acceptable actions.

Conclusion

It is clear, then, that there are no easy answers to questions about the relation between law and morality. There are strong considerations favoring legal positivism, but there are other considerations favoring a natural-law doctrine. And

even if one is a legal positivist, there are conflicting considerations that one has to weigh in deciding on the appropriate relation between one's moral code and society's legal code.

LIFE

• • •

Like many of the concepts foundational to the field of bioethics, life is a subject about which there is both long-standing conviction and increasing uncertainty. The beginnings and endings of life, as well as its creation, have become subject to greater technological modification, particularly through the rise of the modern biological sciences and new reproductive and genetic technologies. In the late twentieth century, increasing technological control over the management, regulation, and production of life and lifelike systems, as well as the accelerating commodification of life forms, raise questions about the limits of what can or should be done to life itself. Hence, seemingly timeless and universal human attitudes toward life, such as mourning in the wake of its loss and joy in its creation, are today accompanied by profound ambiguities concerning the meaning, value, and definition of life.

Some commentators have claimed that even a few decades ago life was more often understood as an absolute value—for example, among medical professionals, for whom the protection of life was an unquestioned moral duty (Parsons et al.). Related arguments hold that the technologization of life has produced a shift away from an understanding of life as an absolute value, and toward more relative assessments of the quality of life (Parsons et al., pp. 405–410). The appearance of an entry entitled "Life" in an encyclopedia of bioethics would support the position that life itself has become the object of increased management in the form of decision making.

In contrast to the urgent call for guidelines concerning the subject of life is the difficulty of defining this term. Neither philosophers, theologians, nor scientists can offer a clear understanding of life. This is in part due to the wide-ranging uses of the term. Not only does life have many meanings as a noun, it is a key term within a wide range of systems of thought from religion to science. In all of the many senses in which the word is used, definitions of it have varied historically in relation to changing social forces and cultural values. Contemporary moral, legal, theological, and scientific uncertainty attends the origins of life, the relative importance of human versus other forms of life, the beginnings and endings of life, the creation and destruction of life, and the nature of life. These and other concerns follow from the definitional issues, raised by the concept of life itself, that remain subject to dispute and ongoing transformation.

Historical and Cultural Variations

To be animate or vital is a condition for which cross-culturally and transhistorically there exists a range of modes of recognition. Broadly speaking, notions of life, or of a vital force, are often connected to beliefs about the supernatural, divinity, and sacredness. It is also generally the case that understandings of life are often made most explicit in relation to death (Bloch and Parry; Huntington and Metcalf). These features characterize both Judeo-Christian and classical understandings of life, the two predominant sources of its definition in the Euro-American tradition prior to the rise of modern science.

According to the Judeo-Christian tradition, life is interpreted and valued as a gift from God. The Old Testament relates that God created man (Adam) in his own likeness, with dominion over all living things. In the Garden of Eden, life was everlasting; and Adam and Eve's expulsion, through which they became mortal, was both a sign of divine displeasure and a partial rescinding of the gift of life. According to the New Testament, the gift of everlasting life was restored through the sacrifice of God's only begotten son, Jesus, and his resurrection to the kingdom of Heaven. Consequently, only those who believe in the resurrection of Christ have "life" in the Christian sense. When Jesus states "I am life" (or "I am the way, the truth, and the life"), it is the resurrection promised to believers in the life, death, and salvation of Christ that is invoked. The historian Barbara Duden notes:

> In most of the New Testament and in two thousand years of ecclesiastical usage, to "have life" means to participate as a believing Christian in the life of Christ.… Even the dead live in Christ, and only those who live in Christ can have life in this world. Of those who exist outside this relationship, the Church has consistently spoken of those who "live" under conditions of death. (p. 102)

Blood is a key symbol of life in the Christian tradition as well as in much secular culture, most notably medicine. To give the "gift of life" is more literally possible today than ever before in the context of organ donation, whereby a body part of a deceased person may "live on" in the body of another person, or a living donor may sacrifice a body part (such as a kidney) on behalf of a relative. The capacity to donate not only blood and vital organs but also egg and sperm cells, and the increasing availability of bodily tissues through a service

sector and a marketplace, complicate the understanding of life as a "gift" (Parsons et al.; Titmuss). The sacrificial importance of the body and the blood of Christ makes the exchange of body tissue a potent symbolic practice, as does the definition of kin ties in terms of "blood relations."

The association between the flow of blood and the flow of life anticipates the notion of germ plasm (the hereditary material of the germ cells) as the basis for heredity; this in turn gives rise to the modern scientific concept of the gene, which is today described as the essence of life. While the gene in some senses represents the triumph of mechanistic explanations of life itself, the most reductionist accounts of genes as "selfishly" reproducing entities defined by the attainment of their own inbuilt "ends" may seem not dissimilar from that of the most influential proponent of vitalism, Aristotle. Aristotelian definitions of life were predominant for nearly two millennia, in part because Aristotle was among the few philosophers of antiquity to pay significant attention to the problem of defining life. According to Aristotle, life is defined by the possession of a soul, or vital force, through which an entity is rendered animate and given shape. The attainment of a predetermined end point is seen as the purpose of life in Aristotelian terms, a purpose that is contained in itself, independent of any external causal agent. This view is known as *entelechy*—a *telos,* an ultimate end that is self-defined as the achievement of a final form.

Although the Aristotelian view was based on close observations of the natural world and eschewed any notion of divine creation, it is strongly criticized by modern scientists for its *teleologism* (conflation of an endpoint with a cause) and *essentialism* (predeterminism), which are dismissed as metaphysical and therefore insufficiently empirical. Cartesian accounts of animation, which defined life in terms of the organization instead of the essence of matter, succeeded Aristotelian vitalism in the seventeenth century. From the perspective of mechanism, which explained motion or aliveness purely in terms of the articulation among parts of a whole (as in the ticking of a watch), Aristotelian vitalism came to be seen as mystical, nonobservable, and therefore unscientific.

The history of the concept of life in Western science, from which many of the most authoritative contemporary definitions of it are derived, underscores the importance of change and variation in the meanings of this term (Canguilhem; Schrödinger). Eighteenth-century natural historians employed a horizontal ordering strategy to classify diverse life forms into taxonomies of kind or type. A vertical ranking of the value of these life forms (known as the great chain of being, descending from God to humanity and thence to other living entities) was based on their proximity to the divine. According to this conceptual framework, *life* comprised a diverse array of animate entities classified epistemologically and ranked theologically in terms of proximity to God. The sacred act of divine creation that brought life into being was, in this schema, paralleled by the secular production by natural philosophers, such as Carolus Linnaeus (1707–1778), of a classification system through which life forms were named, defined, and ordered according to their perceived nature, which was seen to be immutable.

The stability of these vertical ranking and horizontal classifying axes was irrevocably shaken by the gradual acceptance of the evolutionary model of life, in particular the work of Charles Darwin, which, over the latter half of the nineteenth century, gained acceptance in Europe and America. With the rise of Darwinian theories of evolution came a radical new understanding of life: as an underlying connectedness of all living things. It was the evolutionary view of life as a distinct object of study in its own right that gave rise to the modern notion of *life itself*; not until this time could such a thing have been conceived. Many of the current dilemmas in bioethics demanding our attention came to be understood as a direct result of the emergence of this particular conceptualization of life.

As the historian Michel Foucault points out, life itself did not exist before the end of the nineteenth century; it is a concept indebted to the rise of the modern biological sciences.

> Historians want to write histories of biology in the nineteenth century; but they do not realise that biology did not exist then, and that the pattern of knowledge that has been familiar to us for a hundred and fifty years is not valid for a previous period. And that if biology was unknown, there was a very simple reason for it: *that life itself did not exist.* All that existed was living beings, which were viewed through a grid of knowledge constituted by natural history. (p. 128; emphasis added)

Life, in the sense of life itself, is thus a concept linked closely to the rise of the modern life sciences, founded on notions of evolutionary change, the underlying connectedness of all living things, and a biogenetic mechanism of heredity through which life reproduces itself. As the foundational object of the modern life sciences, the concept of life itself does not exist as a thing, as something visible or tangible. Only its traces are accessible, through the forms in which life manifests itself. Like Newtonian gravity, Darwinian life is a principle or force subject to an orderliness decipherable by science, such as the process of natural selection by which evolution is understood to proceed.

Life as Defined by Modern Science

From the vantage point of the modern life sciences, life itself has come to be associated with certain qualities, including movement, the ability to reproduce and to evolve, and the capacity for growth and development. Other criteria for defining life as opposed to nonlife include the capacity to metabolize, in particular through the possession of cells. These characteristics of aliveness in turn comprise key areas in the study of life forms, and in the forms of connectedness and interrelatedness among them. Whereas the comparative anatomy or morphology of animals and plants was the definitive technique for the classification of life forms during the classical period of natural history, it is molecular biology that today provides the primary analytic perspective on the essence of life, which is seen to be DNA, or the genetic code. It is DNA, composed of nucleotide chains that guide the manufacture of essential proteins, that all living beings are said to have in common. Thus DNA is the substance and mechanism of heredity intrinsic to the neo-Darwinian notion of life itself. (For a historical account of Darwinian notions of life itself, see Jacob. For a contemporary view, see Pollack.)

The most definitive accounts of life itself today rely on evolutionary and genetic models. "The possession of a genetic program provides for an absolute difference between organisms and inorganic matter," claims the biologist Ernst Mayr, one of the great twentieth-century exponents of evolution as a unifying theme in modern biological thought (p. 55). "Life should be defined by the possession of those properties which are needed to ensure evolution by natural selection," states John Maynard Smith, one of the leading evolutionary biologists in Britain (p. 7).

In addition to offering the most definitive accounts of life, the modern life sciences provide the most detailed and substantive information on the subject. In the article "Life" written for the *Encyclopaedia Britannica,* Carl Sagan notes: "A great deal is known about life.… Anatomists and taxonomists have studied the forms and relations of more than a million separate species of plants and animals." A range of biological specialties have together compiled "an enormous fund of information" on the origin, diversity, interaction, and complexity of living organisms and the principles that order their existence (p. 985).

Yet even such definitive accounts of life from established scientific figures are often admittedly provisional. Both within and outside the scientific community there is considerable uncertainty about what is being studied when the subject is life itself. As Sagan notes perfunctorily, "There is no generally accepted definition of life" (p. 985).

Problems in Defining Life

The definition of life is not only contested from within the scientific community; it is also troubled by the proximity of lifelike systems, especially those that are computer-generated, to the requisite features of animate existence. There may well be, as Stephen Levy notes in his account of artificial life, a "particular reluctance to grant anything synthetic or man-made the exalted status of a life-form" (p. 6). Yet insofar as the biogenetic definition of life itself relies on an informational model, of DNA as a message or a code, the distinction between life and nonlife is readily challenged by complex informational systems that are to a degree self-regulating and that have the capacity both to replicate themselves and to evolve. If, as some have claimed (Oyama), information is the modern equivalent of form, then life is transformed from an absolute property into a receding horizon merging with artificial, synthetic, or virtual *life.* (see also Langton, and Levy).

Today, both the border between human and nonhuman life and the distinction between life and death are increasingly blurred. Genetic science offers the possibility of transspecies recombinations effecting a merging of human and animal body parts. Artificial-life scientists using information technology distinguish computer-generated organisms, which live, evolve, reproduce, and die, from the "wet" life forms they imitate (Levy). Health professionals distinguish degrees of death: dead (in the sense of brain-dead); double dead (respiratory failure); and triple dead (no body parts suitable for donation). Such distinctions indicate the increasing difficulties of establishing the parameters of life and death.

In sum, life itself may be charted along the course of its four-billion-year history to its estimated point of origin, and along this path may be classified and analyzed scientifically according to established principles, such as the operation of natural selection, and specific qualities, such as the possession of DNA. It is from the perspective of the modern life sciences that the most elaborate and definitive accounts of life are constructed, and from these in turn that the concept of life itself emerges. Yet the instability of these definitional parameters, like those of previous eras that they replaced, ensures their continued transformation.

Life as a Moral Issue

Despite the ubiquity and authority of biological definitions of life, they are also reductionist and materialist, relying upon mechanistic and objective terms that are ultimately most meaningful to professional specialists. Most people, when asked "What is life?" do not appeal to Darwinian principles.

Many of the more everyday definitions of life can be classed as processual or phenomenological, referring to the course of events comprising the life of an individual or other entity (including inanimate objects, as in the expression "shelf life"). Expressions such as *c'est la vie* ("that's life") invoke the fortuitous and inexplicable dimensions of life, very much in contrast to scientific accounts, which emphasize order and predictability even while admitting great uncertainty. Such expressions convey a sense of limits to the capacity for rational understanding, and especially prediction or control, in relation to the vicissitudes of life and living.

The lengthy debate in early modern science concerning *mechanism* (the presumption that animate and inanimate entities alike are composed of matter, which can be explained through inherent principles of structure and function) versus *vitalism* (the presumption of an inherently inexplicable vital force differentiating the quick from the dead) opposes the ancient association of lifelike properties with mystery and the sacred to their accessibility through instrumental reason (see Merchant). In relation to the moral questions concerning life—whether as a process, a possession, or a right—the vitalistic notion of life as something inexplicable and deserving of reverence and protection is far more prevalent than the more mechanistic and instrumental account dominant within science. In both secular and religiously derived accounts, life does not need to be fully explicated or rational to be seen as uniquely deserving of protection, especially human life.

The Protection of Life

In his discussion of abortion and euthanasia, two of the most controversial areas of debate concerning human life, philosopher Ronald Dworkin emphasizes the importance of recognizing that life is not exclusively or even primarily understood by many people in terms of scientific explanations, but rather in terms of a value more akin to sacredness. In relation to moral dilemmas, he claims, life does not present itself as a question of objective fact, but rather as a truth, or a "quasi-religious" principle held to be self-evident through "primitive conviction."

Dworkin's approach thus differs from the more utilitarian arguments about the beginnings and endings of life propounded by philosophers and other commentators who use rights or interest-based approaches to questions of the meaning and value of life. In demarcating the value of life as a "quasi-religious" one, something essentially felt rather than reasoned, Dworkin returns the question of the value of life to an older, more traditional paradigm linked to notions of divinity or a vital force.

Social scientists have shown the value of life to be a key symbolic resource in struggles of many kinds, including both ways of life (as in the preservation of ethnic traditions or indigenous cultures) and life forms (such as endangered species). Anthropologist Faye Ginsburg's study of the abortion debate in a midwestern American community, for example, demonstrates the symbolic dimensions of life as a subject of dispute extending to notions of citizenship, nationalism, and the sexual division of labor. Precisely because the preservation of human life may be seen as an absolute moral value, it proves readily amenable to the social function of grounding other beliefs and practices.

Abortion is one of the best-known arenas of controversy in which both definitions of life and the value of human life are paramount and explicitly formulated. Opponents of abortion argue that life begins at conception and therefore that the deliberate termination of a pregnancy is the taking of a human life, which is seen to be immoral or even comparable to murder. Proponents of a woman's right to control her own fertility, including the choice to terminate an unwanted pregnancy, often argue on the basis of consequentialism, that is, that the moral value of an act should be measured in reference to its outcome. Rights-based claims are used by both sides, antiabortionists stressing the right to life of the fetus, which they argue to be paramount, and pro-choice advocates stressing a woman's right to control her own reproduction, on which they, in turn, place primary importance.

Current legislation on abortion in many industrialized countries, including the United States, invokes a combination of rights-based arguments and biologically based distinctions. Hence, for example, the 1973 U.S. Supreme Court decision in *Roe v. Wade,* which currently determines abortion law in the United States, combines protection of the individual right to privacy with a biologically based definition of fetal viability as the determinant of the upper time limit for abortion. The same standard holds in Great Britain.

Both the notion of biological viability and the definition of the person to whom rights are ascribed invoke a particular construction of life. Viability, for example, is strictly biologically determined: It is measured by the ability of a fetus to survive biologically. The question of the social viability of a child's life, such as its likelihood of receiving adequate nurture, shelter, protection from disease, or sustenance is not considered part of the criteria valid in determining the morality of a decision to terminate a pregnancy. Feminists have been prominent in the challenge to the notion of the *person* often used by antiabortionists on similar grounds. It is undeniably the case that an embryo is human, that it is a being, and that it is a form of life. That it is a living

human being is therefore undeniable. Yet it is no more or less a living human being in this sense than an egg or sperm cell, or for that matter a blood cell, none of which is considered a person or seen as entitled to civil rights. Increasingly, antiabortionists have used biologically based arguments to support their position, even when it is derived from religious principles. Hence, it is the potential for an embryo—unlike an egg, a sperm, or a blood cell—to develop into a human being that is often stressed. This argument is based on an embryo's possession of a unique genetic blueprint, which some established theologians claim is evidence of ensoulment (see Ford).

Hence, arguments against abortion based on fetal viability, or those that stress the genetic potential of the fetus to develop into a person, are based on a particular model of life, according to which its sanctity may be represented in biogenetic terms. Historian Barbara Duden has called this historically recent turn toward biology as an arbiter of moral decision making the "sacralisation of life itself." Life, in this sense, is not a biological fact but a cultural value, an essentialist belief, or even a fetish.

The Geneticization of Life Itself

Similar claims have been made regarding the biogenetic definition of life as possession of a genetic blueprint. Critical biologists have argued against the genetic reductionism or genetic essentialism such definitions risk (see Hubbard). Social scientists also have warned of the dangers of eugenicism implicit in such a view (Nelkin and Lindee); other scholars have minimized such risks (Kevles).

Advocates of a "strong" genetic essentialism argue not only that genes are the essence of life but that life itself is consequently based on the selfish desire to reproduce itself. From this vantage point, humans are mere epiphenomena of a primordial genetic drive to self-replicate, and human moral or ethical systems are a complex admixture of altruism motivated by strategic sacrifice, which benefits one genetic trajectory or another (Dawkins).

The belief that life processes will one day be subject to much greater control through instrumentalized understandings of their genetic code is the basis for a major expansion in the biotechnology industry, and corresponding scientific research, since the early 1980s. International scientific projects, such as the attempt to map the human genome by sequencing all of the DNA in the twenty-three pairs of human chromosomes, reflect the increasing importance of genes and genetic processes to the understanding of life itself (for a description of the Human Genome Project, see British Medical Association, and Cook-Deegan; for an account of the ethical dimension, see Kevles and Hood; for a critical account, see Hubbard and Wald). In turn, increasing information about the role of genes in heredity will pose new choices and decisions, as well as dilemmas, for many. On the one hand, new diagnostic procedures utilizing genetic screening to detect severe, chronic, degenerative, and often terminal disorders caused by a single gene are claimed to offer greater reproductive choice and control, and the potential to alleviate human suffering and disease. On the other hand, the identification of gene "defects" poses worrisome questions, especially when linked to notions of individual predisposition, genetic selection, and the elimination of "undesirable" traits. Controversies such as that attending the putative discovery of a "gay gene" underscore the dangers of social prejudice wedded to genetic determinism in the name of greater reproductive choice and control.

Altering the genetic code of an individual entity, be it human, plant, or animal, is most controversial when the alteration has the potential to be replicated in subsequent generations, therefore resulting in irreversible and cumulative hereditary effects. Although a distinction is currently maintained between somatic cell gene therapy (genetic alteration of nonreproductive bodily tissue) and germ-line gene therapy (genetic modification of the egg or sperm cells, or the early embryo), this boundary is known to be unstable. Considerable ethical concern therefore surrounds the advent of human gene therapy, now practiced in both Great Britain and the United States (for further discussion, see British Medical Association). The release of genetically engineered organisms into the environment, largely in the form of plants and microorganisms, has also attracted controversy, in particular concerning the labeling of foodstuffs and the limits of acceptable risk.

It is the biogenetic definition of life, then, that informs many of the moral debates about the protection of life, whether human, animal, or environmental—the latter category denoting the ecosystem as a complex "living whole" (for a discussion of protecting life as "biodiversity," see Wilson; also Kellert and Wilson). Confusions about when life begins, for example, as in debates about fetal rights, derive from a biogenetic definition of life, which is continuous: each life form has its origin in the lives of those preceding it, and their connectedness underscores the interrelation of life itself. Given such a definition of life, clear demarcations concerning the beginnings and endings of life, of a life, or of life itself are understandably subject to dispute.

Artificial Life

New techniques for technologically assisting the creation of life (e.g., assisted conception) and for prolonging life or

redesigning life (genetic engineering) add to the difficulties of establishing a clear basis for decision making by health professionals, relatives, policymakers, or legislators. Technology now enables the production, extension, and even redesign of life forms, including humans, animals, plants, and microorganisms. Increasingly sophisticated medical technology has affected both the beginning and the ending of human life. Life-support technologies can artificially sustain human life in the context of severely restricted life functions both at the beginning of life (perinatal support) and toward the end of life, in cases where the individual becomes fully dependent on technology for respiration. Cases of prolonged "vegetative" human existence raise difficult questions as a result of the availability of technologically maintained biological viability. Insofar as a person is more than a biological life, difficult decisions concerning continued treatment for a person who is only minimally alive are the inevitable result of modern technology's capacity to sustain baseline survival functions indefinitely.

Technology also affects the creation of life itself. As medical scientists acquire ever greater command of genetic structure, the question of the ethical acceptability of the creation of life forms such as the Harvard "oncomouse," genetically engineered to develop cancer so it can be used in the design of new drugs for the treatment of human disease, must be addressed. The subject of a major patent dispute in the European Parliament, and removed from the market in 1993 by its manufacturer, DuPont, the oncomouse was among the first higher life forms to be defined as a technology, comparable to other forms of laboratory apparatus. As both a mammal and a scientific instrument, the oncomouse inhabits a domain subject to increasing ethical, commercial, and political controversy (Haraway).

Most significant, the oncomouse raises the question of ownership of life, which is established as an inviolable right for humans within the liberal democratic tradition and was described by humanist philosopher John Locke as "ownership of one's person." This principle, used in arguments favoring the emancipation of women and the abolition of slavery (both women and slaves being considered chattels), is more recently evident in disputes concerning body parts. In the landmark case of *John Moore v. California Regents,* conflict over the use of Moore's body tissue in the design of a drug, through production of an immortal cell line derived from his spleen cells, culminated in a U.S. Supreme Court decision prohibiting the individual ownership of bodily tissue. Ownership of human life in this case was declared not subject to extracorporeal extension.

The question is again different in the case of the "right to life" of the oncomouse, or the "geep," the transspecies hybrid of a goat and a sheep produced through genetic manipulation. Here, the question concerns the deliberate production of a life that brings great suffering to the resultant organism. Only the greater good to humans of such developments can justify their deliberate creation by scientists. But the basis for ethical decision making in such an instance remains indeterminate.

Conclusion

Many of the ethical questions addressed to life itself concern the degree of protection it requires. These questions in turn depend on how life is defined. Whether they concern the beginnings or endings of life, its creation, redesign, or sustenance under technological conditions, the underlying definition of life itself is a fundamental force shaping ethical decision making. Scientifically, life is defined according to the modern life sciences in a biogenetic idiom, which constructs it as a continuous and connected force unto itself, manifested by the self-replicating properties of DNA. In the liberal humanist tradition, human life is also seen as a possession, and the persistent association of life with sacredness is well established. The rights to life, the protection of life, and the quality of life are extended to some degree to other life forms, on the principle of avoiding cruelty and suffering. In none of these areas are definitive boundaries or limits available upon which to base ethical practice. Instead, as definitions of both life and death are subject to ongoing transformation, so are the ethical frameworks brought to bear on the creation, management, and protection of all life forms.

LIFE, QUALITY OF

I. QUALITY OF LIFE IN CLINICAL DECISIONS

Quality of life is one of the most important but controversial issues in clinical ethics. The contemporary development of the concept and its use as a normative criterion in clinical decision making date from the period after World War II, when advances in medical technology increased tremendously. Along with other ethical criteria—for example, a medical indications policy (Meilaender; Ramsey; U.S. Department of Health and Human Services); the ordinary-extraordinary means criterion (Connery; Johnstone; Reich, 1978a); or the reasonable person standard (Veatch)—quality of life is used in conflict situations to help make clinical decisions about whether or not to forgo or to withdraw medical treatment from patients.

Modern medicine has the capacity through the application of technology to save lives that until relatively recently would have been lost to acute disease or accident. As a consequence, some of these lives either are shaped by severe disabilities or chronic illness or continue to exist only at the biological level (for example, infants born with multiple congenital abnormalities; elderly patients who suffer chronic illnesses after recovery from an acute illness; and patients in a persistent vegetative state (PVS). Quality of life is frequently proposed as a criterion in making treatment decisions about these patients, whose lives might be saved only to be lived out in severely impaired conditions.

Quality-of-life considerations arise in several key areas of clinical ethics: termination or shortening of human life, including issues of abortion and euthanasia; limiting human reproduction, such as through contraception, sterilization, or abortion; interventions that alter the genetic and biological nature of humans, such as embryo cloning or eugenic engineering; and public policy areas, including economics, ecology, and cultural development (Reich, 1978a). This article will focus principally on the first issue.

Quality-of-life considerations raise a number of important questions that bear specifically on clinical ethics: (1) Given the tremendous advances in medical technology and the implicit imperative to use it, what are the goals and limits of medicine? (2) What is normatively human, and thus, what is it that we value about life? (3) Are quality-of-life judgments purely subjective, or are there objective criteria that guide them? (4) Can there be a life that is so burdened by pain or disability that it can be judged not worth living? (5) Who should decide to terminate treatment? (6) Is it morally legitimate to include considerations of the patient's prior medical condition in a decision about forgoing future medical interventions? and (7) Is it morally legitimate to include in treatment decisions the potential burdens on affected others who will have to care for a severely handicapped patient?

The following sections will provide some preliminary clarifications and conceptual frameworks for understanding quality of life; define quality of life and identify the spectrum of positions that come under the general heading of this normative criterion; articulate the evaluative status of life that is adopted in the various quality-of-life positions and compare the so-called quality-of-life ethic with the sanctity-of-life ethic; and analyze both the normative dimensions of quality-of-life judgments and the normative theories that justify these judgments.

Preliminary Clarifications

Statements or claims about a "quality" or "qualities" of life can be either evaluative or morally normative (Reich, 1978a; Walter). Evaluative claims or statements indicate that some value or worth is attached either to a characteristic of the person (for example, capacity to choose) or to a type of life that is lived (for example, free of pain and handicap). Thus, evaluative statements assess that the quality, and by implication the life that possesses the quality, is desired, appreciated, or even considered sacred. These statements, however, do not establish whether an action to support or to terminate life is morally right or wrong, nor do they specify which action would be morally obligatory. On the other hand, morally normative or prescriptive claims about a quality of life always involve a moral judgment on the valued quality and, by implication, a judgment on the life that possesses the quality. These latter statements, then, not only presume that a quality—for example, cognitive ability—is valued, but they also entail judgments about whether, and under which conditions, one must or ought to protect and preserve a life that possesses the valued quality or qualities. Thus, one could formulate a prescriptive claim that "any life that has cognitive abilities always ought to be given all medical treatment." Evaluative statements about quality of life do bear on clinical decisions, but the more important and

controversial issues are concerned with the validity and use of the normative claims about quality of life, especially with regard to patients who lack any ability to participate in the clinical decision.

Many different perspectives could be used in establishing, defending, and assessing evaluative and normative claims in the area of quality of life. A feminist perspective could be used to analyze and critique an evaluative claim that proposes the discursive quality of rationality to be superior to a rationality based on the qualities of affectivity and caring (e.g., Gilligan; Sichel). A perspective from the elderly (Kilner) or the disabled community could be used to assess the normative claim that the qualities of youth, physical beauty, independence, and athletic ability—qualities that are extolled and prized in modern Western culture—are necessary for one to live well. Sociological perspectives could be used to study the cultural patterns of commitment to quality of life (e.g., Gerson), or legal perspectives to study the jurisprudential implications of these claims on the disabled (e.g., Destro). Each of these perspectives, and more, would be important to consult in adequately assessing both evaluative and normative claims about quality of life. However, the remainder of this article will use only the philosophical and theological perspectives that have been developed in the literature on quality of life vis-à-vis treatment decisions.

Definitions of Quality of Life

There is much ambiguity about what *quality of life* means, and consequently there is little agreement about the definition of this criterion. First, there is the word *life.* It can refer to two different realities in this context: (1) vital or metabolic processes that could be called *human biological life*; or (2) *human personal life* that includes biological life but goes beyond it to include other distinctively human capacities, for example, the capacity to choose or to think. Anencephalic infants and PVS patients have biological life, but they do not possess human personal life.

Similarly, *quality* can refer to several different realities. Sometimes the word refers to the idea of excellence. So defined, its meaning is bounded only by the horizons of our imaginations and desires. It is difficult to discover any objective criteria to assess quality-of-life judgments under this definition. Consequently, one may fear that patients whose lives cannot achieve the expected level of imagined or desired excellence, such as the handicapped or the dying, will either not be offered any life-sustaining treatment or will be actively killed.

Another possible definition is to understand *quality* as an attribute or property of either biological or personal life. Most proponents of quality of life subscribe to this general definition. Some authors identify quality of life with a single valued property of life, while others identify it with a cluster of valued properties. Thus, this definition represents a spectrum of positions. At one end of the spectrum is the original position of Richard McCormick, who isolated only one quality or attribute to be considered as the minimum for personal life: the potential for human relationships (1974). For McCormick, a Down syndrome baby would possess the potential for human relationships, but an anencephalic infant would not. At the other end of the spectrum, Joseph Fletcher originally defined the indicators of "humanhood" by reference to fifteen positive qualities, among them self-awareness, concern for others, curiosity, and balance of rationality and feeling, and five negative properties, among them, that humans are not essentially parental (1972). He believed that many, if not all, severely handicapped children would not possess the attributes necessary to live a life of quality. Between these two ends a number of "median" positions exist that identify quality of life with valued properties of life. For example, Earl Shelp has proposed minimal independence as the central property in his quality-of-life position. He includes in this basic property the abilities to relate to others, to communicate, to ambulate, and to perform the basic tasks of hygiene, feeding, and dressing. From this perspective, many, but not all, Down syndrome children would possess the necessary attributes to live a life of quality.

James Walter has suggested that the word *quality* should not primarily refer to a property or attribute of either physical or personal life. Rather, the quality that is at issue is the quality of the relationship that exists between the medical condition of the patient, on the one hand, and the patient's ability to pursue human purposes, on the other. These purposes are understood as the material, social, moral, and spiritual values that transcend physical, biological life. The quality referred to is the quality of a relation and not a property or attribute of life. Thus, for patients to judge that they possess a quality of life means that the patients themselves would evaluate that, based on their medical condition, they are able to pursue values important to them at some qualitative or acceptable level.

Evaluative Status of Life

When quality of life is defined by reference to a property or attribute of physical life, then some basic questions are raised about the value of physical life itself. What is it that we value about our physical lives? Do we value biological existence in and for its own sake, or because of the presence of some property or attribute in that life, for example, cognitive

ability? What theological or philosophical justifications can be offered for one's evaluations of life?

Many who define quality of life basically by reference to a property do not attribute intrinsic value to physical life. For example, in some of his writings McCormick has suggested that physical life does not possess inherent value but is a good to be preserved precisely as the condition of other values (1981, 1984). Based on his theological convictions that physical life is a created, limited good and that the ability to relate to others is the mediation of one's love of the divine, McCormick resists attributing to physical life itself the status of an absolute value. Kevin O'Rourke and Dennis Brodeur have stated that physiological existence as such is not a value if that life lacks any potential for a mental-creative function. Other quality-of-life proponents such as David Thomasma and his colleagues have described physical life as only a conditional value. According to these positions, what is valuable or worthwhile about physical life is either the properties that inhere in life or the values that transcend biological existence but whose pursuit is conditioned on the presence of physical life.

When quality of life is not defined as a property or attribute but rather as a qualitative relation between the patient's medical condition and his or her ability to pursue human values, then a different evaluative status is accorded to physical life. Walter has argued that physical life, as a created reality, is an ontic value, that is, a true and real value that does not depend on some property to give it value. He has tried to acknowledge that physical life is objectively a value in itself, though it may not always be experienced as such by some patients. Thus, physical life is not simply a useful or negotiable good; on the other hand, neither is it an absolute value that must be preserved in every instance.

Some commentators have attempted to address questions about the evaluative status of life by contrasting the quality-of-life ethic with the sanctity-of-life ethic (e.g., Johnstone; Reich, 1978b; Weber). Most proponents of a sanctity-of-life ethic (e.g., Connery; Johnstone; Meilaender; Reich, 1978a) do not argue that physical life itself is an absolute value. In this regard, at least, they agree with all proponents of the quality-of-life ethic. However, these authors frequently claim that when quality of life is understood as a property of life, either no value or only varying degrees of value is accorded to physical life. Possessing no intrinsic worth, physical life must receive its value based on whether it possesses one or more of the valued qualities, for example, neo-cortical function.

The sanctity-of-life position argues that this view is intolerable on several counts. First, quality of life does not acknowledge the equality of physical lives and the equality of persons because it assigns only relative or unequal value to physical lives and persons when certain valued qualities are only partially present or totally absent. Second, quality of life denies that all lives are inherently valuable, and so it leaves open the possibility that some lives can be deemed "not worth living." Finally, it is charged that the quality-of-life position adopts a two-level anthropology committed to protecting physical life only as an instrumental value (Reich, 1978b). Consequently, it is argued that the sanctity-of-life position is far superior because it affirms the equality of life on the basis that physical life is truly a value or good in itself. Life is not merely a useful or negotiable value, dependent on some other intrinsically valuable property.

In conclusion, it is not always clear how useful it may be to contrast sanctity of life with quality of life, as if each position could be represented by an individual and distinct "ethic." Because there are many positions that fit under each one of these "ethics," the terms and results of the comparison really depend on which two positions are selected.

Normative Considerations of Quality of Life

The most important issues related to quality of life in clinical decisions are those concerned with the normative dimensions of the criterion. This level involves several considerations: (1) assessments about what is considered normatively human, or what reasons can be adduced to consider a certain trait or property of life decisive in making a clinical decision to treat or not to treat; (2) the normative moral theory that grounds and justifies moral obligations; and (3) the limits or exceptions to moral obligations to preserve life and the moral justifications for these limits or exceptions. The first issue is definitional in nature, although it also entails some normative features. The second issue relates to the debate over deontology, which determines the rightness of actions by reference to moral rules or the doing of one's duty, and teleology, which determines moral rightness by reference to the ends or consequences of actions. The third issue involves a discussion of the nature and degree of obligation in moral duties to preserve life.

Before turning to actual positions and their normative implications, it is important to distinguish cases where quality-of-life judgments are made by patients who possess decision-making capacity, and those cases where patients—for example, PVS patients, neonates, or severely mentally handicapped adults from birth—lack the capacity to decide. Many issues need to be faced once patients with decision-making capacity are permitted to make treatment choices based on their own assessments of quality of life. However, these problems may pale in comparison to the application of

the quality-of-life criterion to situations where a proxy or surrogate must make a decision to terminate treatment.

Some authors (e.g., Ramsey) argue that quality-of-life judgments should never be permitted in treatment decisions for patients who lack decision-making capacity. Only competent patients can make these judgments for themselves; no one may morally substitute his or her quality-of-life judgments for those of someone else. Thus, the moral criterion that applies in treatment decisions for patients who lack decision-making capacity is whatever is medically indicated. However, quality-of-life proponents argue that the medical indications policy could be devastating for these patients. If surrogates do not apply some measure of the quality-of-life criterion, these patients may be condemned to lives of pain, suffering, or burden that no person with decision-making capacity would reasonably choose (Hastings Center). Most of the following considerations will be concerned with the use of quality-of-life judgments in cases involving patients who lack decision-making capacity.

When some proponents of this criterion define quality of life as a property or attribute that gives value to physical life, they are either implicitly or explicitly defining what is normatively human, that is, how personhood ought to be defined. For example, when Fletcher originally defined the fifteen positive and five negative indicators of humanhood, he was defining the nature of personhood, and therefore, who is morally entitled to medical care. If a handicapped neonate or adult lacked a number of the indicators of humanhood but needed medical treatment to survive, in Fletcher's view (1972), the patient should not be treated.

The moral obligation to treat or not to treat patients is derived from the objective presence or absence of a valued property that gives worth and moral standing to the patient's life. When the properties that define humanhood are absent, the patient is not considered a moral subject who possesses any rights to healthcare. The moral theory that Fletcher adopts in his quality-of-life position is a form of teleology called consequentialism. In this theory, any moral claim about the value of a patient's life or any moral duty to provide medical treatment is almost entirely based on predictable qualitative consequences for the patient or for others whose interests are involved in the situation.

In a similar position on quality of life, Earl Shelp has sought to articulate the quality or property that defines the normatively human for handicapped neonates and the extent to which parents and the medical community have moral obligations to these never-competent patients. He adopts a quality-of-life position that corresponds to the main features of a property-based theory of personhood. A property-based theory, as opposed to a genetic-based theory, seeks to designate a desired quality or property that must be present before one can consider a particular human life to be an unqualified member in the moral community.

Shelp has argued that any neonate must possess the possibility of attaining a "minimal independence" before the child can be considered a person in a full sense. If the newborn will never have the capacity of minimal independence, even with the help of modern medicine, then the parents can decide on the basis of quality-of-life considerations that their child, who is in need of medical treatment, should not be treated.

The normative position that underlies Shelp's quality-of-life criterion is a type of a socially weighted calculus. Because he believes that no newborn, whether normal or impaired, is a full member of the moral community (person), he maintains that there is no compelling reason why a severely defective newborn's interests should take priority over those of the parents or siblings who are already persons in a moral sense. In fact, the interests of the ill newborn can be weighed against the independent interests of those whom the child will affect. Thus, if the burden imposed on others is unreasonable or disproportionate, then a decision to forgo or terminate all treatment for the imperiled child is morally legitimate.

What may be problematic in both Fletcher's and Shelp's versions of quality of life, and certainly what worries all opponents of quality-of-life positions, is that their views appear to define and prescribe the "good life" in terms of the quality or qualities necessary to live a minimal moral existence. Their positions then become entrapped within what William Aiken has called the "exclusionary" use of quality of life. The lack of certain valued qualities in a patient's life is a way of positively excluding potential patients from the normal standards of medical and moral treatment.

Other versions on the spectrum of quality-of-life positions do not limit the meaning of quality of life merely to a property of life and then establish moral obligations on the basis of the presence or absence of the property. In addition, these positions do not define the normatively human by reference to a valued attribute and then identify it with quality of life. For them, quality of life functions as a way to include in the clinical decision what they believe are morally relevant factors that are often excluded by other criteria. In other words, some proponents of this normative position hold that quality of life is a patient-centered way of discovering the best interests of a patient.

These authors (e.g., Sparks) argue that in the clinical situation for noncompetent patients, we should be trying to discover what is in their best interests. They recognize that other criteria, such as the ordinary-extraordinary means

criterion, have also been used to determine the patient's best interests, and that these criteria have been used to ground moral duties to patients in treatment decisions. However, they argue that these criteria often exclude some morally relevant factors needed to make an adequate and informed moral judgment, for example, the experienced burdens of the patient's prior medical condition in cases of spina bifida.

A comparison of the quality-of-life criterion with the ordinary-extraordinary means criterion might be helpful in illustrating the point that these authors are making. Those who subscribe to the ordinary-extraordinary means criterion argue that all ordinary means of preserving life are morally obligatory, but extraordinary means are morally optional. They do permit surrogates to use what could be called a limited version of the quality-of-life criterion. Surrogates can legitimately include quality-of-life considerations in their treatment decisions, but these considerations are only valid where the treatment itself would cause either excessive harm or leave the patient in a debilitated state (Connery; Reich, 1978b). For example, a surrogate could morally refuse quadruple amputation because the surgery itself would leave the patient with such an extremely low quality of life that the patient would have no duty to undergo the surgery.

All too often, however, the use of this criterion excludes all quality-of-life considerations that cannot be directly connected to the treatment itself or to its application. For example, the fact that a child who is born with Lesch-Nyhan syndrome will have a very poor quality of life is not considered relevant in the clinical decision to treat the child for a life-threatening condition. Lesch-Nyhan is an incurable genetic disease that causes its victims to suffer uncontrollable spasms and mental retardation. Once the young patients of this disease develop teeth, they gnaw their hands and shoulders, and they often bite off a finger or mutilate other parts of their bodies.

Some proponents of the quality-of-life criterion (e.g., McCormick, 1986; Sparks) identify this criterion with the category of "patient's best interests." They adopt what they believe is a patient-centered, teleological assessment of the best interests of the patient. If a patient in a life-threatening condition does possess at least a minimal ability to relate to others, then it can be presumed that the patient would want treatment; thus, treatment should be provided. This form of the quality-of-life criterion maintains that physical life itself is the ground of a prima facie duty to preserve it.

However, other factors—for example, the patient's prior medical condition, which might include permanent loss of all sentient and cognitive abilities, or the financial cost to the family and society of caring for these patients—also come to bear in determining the actual moral duty these patients have to preserve their own lives. Proponents of this version of the criterion argue that medical interventions to continue the lives of accurately diagnosed PVS patients and neonates born with anencephaly or hydranencephaly are unwarranted. These patients have reached the limits of their moral obligations to preserve their own lives, based on an assessment of their best interests. Any medical intervention to save their lives would only perpetuate a condition that most people who possess decision-making capacity would judge burdensome and intolerable. These authors do not judge that some patients' lives are not worth living; however, they do argue that the experienced burdens on patients' lives prior to treatment must be considered in determining the patient's best interests, and thus whether the patient himself or herself has a moral obligation to preserve life.

One of the more difficult questions involved in the debate over the use of quality-of-life judgments is whether one can include in the assessment of best interests of the patient any of the burdens that accrue to affected others. For example, when a family must face the tragic situation of financially and psychologically caring for a severely handicapped child, many would find such a lifelong commitment quite burdensome. Must one discount in treatment decisions the burdens experienced by the family and society in caring for these children, and focus only on the burdens imposed on the child either by the disease or by the treatments themselves? Or is it morally legitimate to include at least some of the burdens imposed on the family and society in assessing the patient's best interests? In other words, how broadly should one interpret the category of "best interests of the patient"? And finally, should the interests of others be considered in their own right? These are some of the questions that the proponents of quality of life regularly ask in clinical situations.

Richard Sparks (1988) is critical of any position that tries to understand the proportionality of benefits and burdens in a way that weighs a severely handicapped child's claims against the interests, claims, and rights of others who are affected, whether within the family or in society. He is also critical of quality-of-life proponents like McCormick, whom he sees as too narrowly defining the range of burdens in these cases. Sparks suggests the phrase "total best interests" as a way not only of including the burden experienced by the patient but also of including the broader social factors, for example, the financial cost, psychic strain, and inconvenience borne by others. He reasons that the patient's social nature must be taken into account, not only in calculating benefits (for example, the benefit to the patient derived from his or her ability to relate to others), but also in calculating burdens (for example, psychic strain to the family or financial cost to society).

Sparks's version of the quality-of-life criterion rejects a socially weighted calculus similar to the one Shelp adopts in determining the best interests of the patient. He judges that such a calculus denies the inherent worth of each individual patient, and that it weighs the benefits and burdens experienced by the patient against those of affected others. Although he argues that the burden to others should be included in assessing the total best interests of the patient, this burden is only one factor among many that must be considered. What is essential is that one not construe the burden to the patient and the burden to affected others as being in competition with one another when making decisions to terminate medical treatment.

By trying to construe the social burdens from the patient's perspective, Sparks believes one can avoid the competitive atmosphere that is part of the socially weighted position. His version of quality of life seems to imply that the child would not, and perhaps should not, want to be treated if it were an excessive social burden because the child's best interests would not be served if these burdens were placed on those who must care for him or her.

The spectrum of definitions and positions representing quality of life makes it difficult to identify any one quality-of-life ethic for analysis or critique. Though there are some shared features among the various positions, in the end it is necessary to assess the validity or invalidity of each position on its own merits.

II. QUALITY OF LIFE IN HEALTHCARE ALLOCATION

Issues concerning quality of life in healthcare allocation arise from three factors. First, there is an important project that a society wants to undertake: in this case, to provide access to healthcare for more of its citizens. Second, unlike the ordinary marketplace, in which individuals purchase what they want for their own reasons, with no need to seek anyone else's agreement about what to purchase, a society that collectively funds a community project such as healthcare must agree on what outcomes will count as fulfilling that goal. Third, resources are limited partly because taxpayers cannot be expected to forfeit an unlimited amount of their income, and partly because there are other important projects that command taxpayers' funds. Together, these three factors mean that a society needs reasonable assurance that expenditures will actually enhance health without wasting resources.

Prioritizing expenditures becomes urgent because healthcare is extraordinarily expensive, commonly consuming around 15 percent of the gross domestic product of the United States. The need is further dramatized by various cases in which families of patients with anencephaly or persistent vegetative state have insisted on unlimited medical support, regardless of the cost, on the grounds that all life is infinitely precious (*Matter of Baby K,* Miles). Many who have commented on such cases deem it wasteful to prolong the life of someone who will never be conscious while so many other social needs, from healthcare to education, are underfunded. More controversial examples point out the trade-offs between costly new technologies that benefit a few identified patients versus more routine kinds of care that benefit many more people whose identities may never be known (Eddy, 1992a, 1992b). Cases such as these raise the question of whether it is permissible, and if so in what way, to consider quality of life in healthcare resource allocation.

There are two ways to do so. Negatively, one might rule out certain kinds of expenditure on the grounds that they produce little or no benefit for the patient. This might be based on evidence that the treatment has not been shown to be effective, as when a treatment is highly experimental or when a patient is so close to death that no medical interventions can help. Positively, one might invoke quality-of-life judgments to give funding priority to health interventions that will produce the greatest overall benefit for the money spent. Since healthcare is intended to improve as well as prolong life, quality-of-life judgments could shape this quest for the greatest benefit.

It is important to identify some basic distinctions. To speak of the quality of life is not equivalent to making judgments about the value of that life. Persons suffering from a painful terminal illness might have a poor quality of life even though their value and dignity as human beings are every bit as precious as those of healthier persons. Similarly, the quality that someone's life has for himself or herself is not equivalent to the impact that the person has on another person's quality of life. A patient suffering from advanced Alzheimer's disease or other dementia, for instance, might be content and free of suffering, while posing serious burdens and sorrow for family members. Finally, judgments about the quality of an individual's life might come from the individual himself or herself, or from others. Several of the most commonly used instruments for measuring quality of life rely on views elicited from the public at large as they contemplate the life quality caused by certain illnesses or disabilities. However, these opinions may not match the views of people who actually experience these conditions.

Formulas for Measuring Health Benefits

A variety of instruments have been developed to measure the benefits of healthcare interventions. The *human capital* approach, for instance, measures the value of saving or prolonging a life by projecting that person's future earnings. This method is not widely accepted, mainly because it looks only at market valuation of economic contributions, and not at broader features of the person's experiences, relationships, and noneconomic contributions.

A more sophisticated instrument, the *willingness-to-pay* approach, hypothetically lets individuals determine what value they place on a prolongation or improvement of their lives by indicating how much they would actually be willing to pay in order to avoid a certain risk of mortality or morbidity, or to gain a chance at improving their lot. Though this approach permits individuals to make their own quality-of-life judgments, its main disadvantage is that it could represent wealth status rather than personal preferences, which may in turn reflect factors such as social injustices (Brock).

A still more sophisticated approach does not try to translate morbidity and mortality directly into cash equivalents, nor to count lives saved or the number of years saved by a particular healthcare intervention. Rather, it attempts to determine the effect that an intervention has on the quality as well as duration of life by computing Quality-Adjusted Life-Years (QALYs). Extending an extra year for a patient in a vegetative state, for instance, is presumably not as worthwhile as adding a year of vigorous, healthy function. This approach estimates the quality of life that may accompany a particular set of circumstances before and after a proposed intervention, such as a medical treatment or a course of physical therapy, and calculates how long the change is expected to last. The net value of that intervention can then be compared with the value of other healthcare interventions to determine which ones produce the greatest value.

Quality of Life Measurements: Application and Controversy

Various instruments have been used to measure quality of life. The Quality of Well-Being (QWB) Index defines twenty-four health or functional states from perfect health to death. Through questionnaires and community surveys, each QWB state is given a weight, from zero for death to one for perfect health (Kaplan, 1992, 1985; Kaplan et al.). Other scales, such as the Quality of Life Index or the Sickness Impact Profile, evaluate quality of life according to factors such as ability to perform daily activities, feelings of satisfaction with one's health status, and the like (Brock; Zeckhauser; Zeckhauser and Shepard; Wenger et al.).

The state of Oregon used the QALY approach in an effort to ensure, on the negative side, that it does not waste limited state dollars, and on the positive side, to maximize the good achieved by its Medicaid program by avoiding marginally valuable expenditures while expanding coverage to encompass numerous uninsured people. Initially, a series of town meetings and phone surveys elicited community opinions about the value of a variety of conditions, such as perfect health, feeling depressed and upset, being burned over large areas of one's body, and so on. The value system thus generated was then combined with physicians' estimates of the magnitude and duration of effects produced by various medical interventions for those assorted conditions. After combining the QALY units derived for these treatment/condition pairs with their respective costs, a priority list was developed. Taking the prevalence and cost of treatment for each condition on that list, accountants were able to tell the legislature how much money would be required to fund the program as the next lower priority item was added. The legislature then set its Medicaid budget and identified a cutoff point: Eligible recipients would receive all services prioritized above that line, but not below it (Garland; Eddy, 1991; Hadorn; Kaplan, 1992). This first attempt yielded enough unexpected and unsatisfactory results that the priority list was significantly changed before the program was finally approved (Eddy, 1991).

The problems the Oregon process encountered illustrate the ethical challenges in using quality-of-life considerations in healthcare allocation. They begin with methodological problems. Oregon's plan, and QALY approaches generally, are criticized for ignoring the wide variations of severity that can characterize any medical condition, from broken bones to lupus, and the equally varying results that any given treatment can have for a particular condition. Further, it is not clear whose values should be attached to these factual descriptions. Opinions solicited from the public at large may be based on a poor understanding of the medical condition at stake. A one-sentence summary on a questionnaire, for instance, is hardly sufficient for understanding what it is like to live as a paraplegic. The Oregon plan, in particular, was criticized for eliciting values mainly from articulate, middle-class persons rather than from the poor and disabled, who would be most affected by the resulting distribution of healthcare resources. On the other hand, it is not always possible to discover patients' views on their own quality of life. Advanced dementia, infancy, stroke, retardation, and a host of conditions can prevent the individual from expressing his or her views or even, in some cases, from conceptualizing his or her quality of life. These and other methodological criticisms (Morreim, 1986, 1992) are important, because even if one can on principle justify allocating healthcare resources according to treatments' impact on life quality, it is morally more difficult to justify using measures that may not capture what they should.

Moral issues also concern the very idea of using quality of life as a basis on which to allocate care. Vitalists who believe that all life is infinitely valuable, regardless of its quality, simply reject the idea that interventions should be graded according to how well they enhance quality of life.

Others, however, insist that it is wasteful, if not unconscionable, to spend limited resources sustaining the lives of permanently unconscious or imminently dying patients.

A corollary objection insists that the cost of treatment is no reason for restricting it. Individuals should not suffer needlessly just because their care is costly. Rather, costs should be contained in other ways, such as by eliminating wasteful expenditures. In reply, it is argued that needs are always greater than resources, rendering rationing inevitable, and that overt public decisions are preferable to covert priorities.

A further critique holds that maximizing QALYs, somehow reified as a good in themselves, ignores the justice of the distribution. In one of the classic challenges to utilitarianism, critics point out that a pure cost–benefit approach can ignore terrible suffering, simply because some other intervention may be cheaper and help larger numbers of people. The first listing of Oregon's priorities, for instance, ranked dental caps for pulp exposure higher than surgery for ectopic pregnancy, and splints for temporomandibular joints higher than appendectomies for appendicitis. Although some people might reply that only the methodology needs to be adjusted (Eddy, 1991), others would argue that this approach is inherently incapable of honoring the preciousness that attaches to the lives and well-being of individual people (Hadorn). Severely disabled persons may not be capable of enjoying as great a benefit as healthy persons snatched from the jaws of death, but their comfort and personhood are not necessarily less important.

Another controversy concerns whose values should shape estimates of life quality. If the purpose of medical interventions is to help individuals, perhaps patients should be permitted to define for themselves what constitutes a benefit. Studies indicate that persons afflicted with a particular malady often rate their quality of life higher than observers do (Evans et al.). On the other hand, a broader kind of fairness might require recognizing that sometimes individual preferences are costly and idiosyncratic, and acknowledging that the community paying for care should be permitted to use its own community values to determine monetary allocation (Morreim, 1986, 1992).

A related concern points out that the QALY approach inherently discriminates against the elderly and the disabled, whose prognoses and initial quality of life are typically lower than average. In reply, it is argued that the elderly at least have had the opportunity to complete their life's biography (Callahan), and that while methods to value the comfort and improved function of the disabled can be developed, aggressive medical interventions may not serve the most severely compromised patients well.

Conclusion

The issues cannot be resolved here, but a few comments seem pertinent. First, society is not required to fund every expenditure that each citizen might find worthwhile. Vitalists should arguably be permitted to seek life support for permanently unconscious loved ones, but this does not entail that a society that does not share this belief must pay for their quest (Morreim, 1992). Second, the moral character of a society is at least partly reflected by the ways it treats its weakest members. The fact that someone is not useful to others does not entail that his or her sensibilities are insignificant or undeserving of help. Third, those obligations are not unlimited. There is a virtually endless variety of ways in which society can arrange its resource priorities, and none of them is the single morally correct approach. What is probably most important is to implement procedures that are fair and open to wide participation, are sensitive to varying viewpoints, and embrace a respect for citizens as persons (Brock, Engelhardt).

III. QUALITY OF LIFE IN LEGAL PERSPECTIVE

Law has addressed quality-of-life issues primarily in the context of the withholding or withdrawal of life-sustaining medical intervention. The legal dilemma arose when medical technology became capable of keeping alive persons with gravely debilitating and potentially fatal afflictions long beyond the point that most people would wish to live. The questions became: Under what circumstances is the removal of life support lawful? Can decisions to remove life support be grounded on quality-of-life factors?

Many sources contend that deteriorated quality of life—in the sense of a patient's mental and physical debilitation—is a natural and inevitable element in shaping the bounds of medical intervention in the dying process. Most people, faced with a prolonged and debilitated dying process for themselves or a loved one, prefer that life support be withdrawn at some stage of deterioration. Decisions about life support for formerly vital people are therefore often grounded on factors such as extreme mental dysfunction, immobility, and helplessness.

The opponents of using quality-of-life factors in ending people's lives cite numerous concerns. The most common is that judicial or legislative sanctioning of quality-of-life considerations will undermine the traditional focus of both criminal and tort law on preserving and protecting all human life, regardless of quality. One asserted hazard is that quality of life will be measured in terms of utilitarian elements such as cost of care, social productiveness of the patient, and burdens imposed upon the people caring for the patient. Such a utilitarian calculus would place the lives of the weak and vulnerable—the very young, the developmentally disabled, and the elderly—at particular risk (Destro).

Even if quality-of-life considerations are confined to factors that, from the patient's own perspective, make existence intolerable, some observers find moral hazards. If dismal quality of life focuses on physical and mental dysfunction, a concern is that the lives of disabled persons generally might be devalued and their morale eroded. Surrogate decision makers for incompetent patients might also be insensitive to the true quality of life as a disabled person, so that vulnerable populations would be endangered by arbitrary determinations. Some sanctity-of-life proponents prefer to protect and support all human existence even in the face of fatal afflictions and severe degeneration.

This tension between sanctity of life and quality of life has surfaced in a number of legal settings. Each of the following sections discusses the resolution of that tension in a particular legal context.

Patients Competent to Make Their Own Decisions

Current law, rooted in concepts of self-determination and bodily integrity, establishes that competent patients are entitled to reject life-sustaining medical intervention. The relevant cases recognize that patients can and often do base their rejection of life-sustaining treatment on quality-of-life factors. That fact emerges most clearly in cases involving severely disabled persons who reject treatment capable of preserving their existences for many years.

The typical situation involves a quadriplegic person dependent on mechanical life support who finds the debilitated existence so painful or demeaning that he or she orders the cessation of life-sustaining measures (*McKay v. Bergstedt,* 1990; *State v. McAfee,* 1989; *Bouvia v. Superior Court,* 1986). Courts uniformly uphold the patient's decision. These courts recognize that patient self-determination encompasses personal values and preferences about whether a prospective medical state is intolerably painful or degrading—that is, constitutes an unacceptable quality of life. A California court explained:

> Since death is the natural conclusion of all life, the precise moment may be less critical than the quality of time preceding it. Especially when the prognosis for full recovery from serious illness or incapacity is dim, the relative balance of benefit and burden must lie within the patient's exclusive estimation: "That personal weighing of values is the essence of self-determination." (*Thor v. Superior Court,* 1993, p. 384)

These same courts reject any notion that judicial acceptance of debilitated patients' fatal decisions weakens respect for life generally or devalues the lives of the disabled. The judges view their decisions as upholding individual autonomy and thereby promoting a critical element of human dignity, rather than as denigrating the sanctity of life.

Incompetent Patients

Many medical patients lack the capacity to make their own decisions about life-sustaining treatment. A surrogate must then act on the patient's behalf. Some commentators oppose the use of quality of life—determining whether a patient's life is "worth" preserving—in decision making for incompetent patients (see Wicclair, pp. 56–60). Again, the concerns include use of utilitarian factors such as economic costs and social unproductivity of the patient. Beyond that, sanctity-of-life proponents fear arbitrary decisions by surrogates who are insensitive to the value of disabled persons' lives or motivated by self-interest.

In some instances, the now-incompetent patient has exercised personal autonomy by previously, when competent, issuing written or oral instructions about terminal medical care. Both courts and legislatures accept in principle this prospective autonomy (though some state legislatures have confined their endorsement of advance medical directives to situations in which the patient is in a "terminal" state). Through advance instructions, people can seek to discontinue medical intervention at a point when their existence becomes intolerable according to their own previously expressed definitions of quality of life.

The situation is more complicated when a now-incompetent patient facing a potentially fatal affliction has never clearly articulated personal values and preferences about life-sustaining medical intervention (Cantor, 2001). Courts in a few states disallow any terminal decision on behalf of an incompetent patient who has never issued advance instructions that clearly and convincingly express the patient's desire to forgo life support in the medical circumstances at hand (*In re Westchester County Medical Center,* 1988; *Cruzan v. Harmon,* 1990; *Mack v. Mack,* 1993; *DeGrella v. Elston,* 1993). A few state courts insist on clear and convincing evidence of the now-incompetent patient's prior wishes only when the patient is still conscious (*Spahn v. Eisenberg,* 1997; *In re Martin,* 1995; *Matter of Wendland,* 2001). These courts all express grave apprehension about allowing surrogates to determine that another person's life is not worth preserving. To foreclose end-of-life decisions grounded on the surrogate's values rather than the patient's, they insist either upon the patient's personal prior assessment of an intolerable quality of life or upon legislative guidance concerning what kinds of deteriorated existence are so undignified as not to be worth preserving.

Insistence upon clear-cut prior instructions as a prerequisite for withdrawal of life support from an incompetent patient disregards certain interests of people who have simply neglected to address the issue of terminal care (as well as those of people who have never been competent). The hazard is that such persons, once afflicted with debilitating medical conditions, will be indefinitely maintained in a status that the patients themselves would deem intolerably painful or demeaning, were they able to express their wishes. In the words of one judge, invariable preservation of life without regard to the incompetent patient's prospective deteriorated status "transforms human beings into unwilling prisoners of medical technology" (*In re Guardianship of L.W.,* 1992, p. 74). To avoid this unfortunate consequence, most courts that have spoken to the issue allow some surrogate decisions to reject life support even in the absence of prior instructions.

Courts subscribing to this position usually articulate a best-interests-of-the-patient standard to guide the surrogate decision maker (*In re Conroy,* 1985; *In re Grant,* 1987). This normally means that in order to justify removal of life support, the "burdens" to the patient must clearly outweigh the "benefits," with irremediable suffering being the primary burden and pleasure being the primary benefit. The relevant cases carefully exclude "social utility" or "personal worth" as factors in the best interests calculus (*Conroy,* pp. 1232–1233). However, the role of quality of life (in the sense of a severely deteriorated and undignified patient status) is uncertain. Quality of life or dignity of the patient is often mentioned as an element within the best-interests formula (*Rasmussen v. Fleming,* 1987; *Grant,* 1987). Indeed, in 1983 the President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research listed "quality as well as the extent of life sustained" as a major component within the best-interests standard. But in application in the reported cases, quality of life has been a determinative factor primarily in the context of permanently unconscious patients.

A few commentators have suggested that the concept of "medically inappropriate" or "futile" treatment ought to fix the bounds of life support for gravely debilitated patients (e.g., Jecker). Futile treatment, in the sense of medical intervention that cannot achieve a particular physiological goal, may be a meaningful and useful concept. But when medical intervention can extend life, albeit debilitated life, the futility concept is much less helpful. A determination that life-sustaining medical intervention is futile really represents a judgment that the quality of life is so dismal that life support ought to be withdrawn as inconsistent with the best interests of the incompetent patient or as contrary to the patient's likely preferences. That determination may be appropriate for surrogate decision makers (in conjunction with medical staff), but it cannot be the province of medical personnel alone (Cranford and Gostin; Veatch and Spicer, 1992).

Patients in a Permanent Vegetative State

A permanently unconscious patient cannot experience suffering or sense the bodily invasions that normally constitute "burdens" to be assessed under a best-interests-of-the-patient standard. At the same time, permanent unconsciousness represents a dehumanizing condition, with the patient indefinitely devoid of sensation, emotion, or human interaction. The vast majority of people contemplating such a status deem it so degrading that they would not want to be medically sustained in that insensate condition. (Some commentators even argue that the legal definition of death should be changed to include permanently vegetative beings, a suggestion that has not yet been adopted [Schrode].)

The clear majority of state court decisions regarding permanently unconscious patients have permitted surrogate decision makers to end life support. Still undecided is the precise legal rationale for this result and whether this line of cases represents use of quality of life as a determinative factor in surrogate decision making.

In some instances, the courts upholding removal of life support rely on prior expressions (whether written or oral) by the now unconscious patient. Those courts simply respect the patient's self-determination and accept the patient's own declaration of permanent unconsciousness as an unacceptable quality of life. These cases sometimes disclaim any surrogate's prerogative to define another person's quality of life as unacceptable (e.g., *DeGrella,* 1993).

A number of cases, however, uphold removal of life support from a permanently unconscious patient even in the absence of prior expressions. Some of these cases include never-competent patients, such as infants. None of the cases relies on the burdens placed upon society or surrounding family by having to care for the insensate patient. Rather, the judges articulate diverse rationales. Some courts use the substituted judgment rationale and accept that the patient, if competent, would have wanted removal of life support (*In re Fiori,* 1995; *Matter of Tavel,* 1995; *In re Guardianship of Jane Doe,* 1992). Other courts purport to apply a best-interests standard but rely on the patient's dismal existence without cognitive function as warranting removal of life support (*In re Guardianship of Crum,* 1992).

Most courts confronting the fate of permanently unconscious patients recognize, either explicitly or implicitly, that the patient's status is so dehumanizing that it represents what most people would regard as an unacceptable quality of life. These courts sometimes demand that the surrogate decision maker not rely on his or her personal views about the value of an unconscious person's life (*Guardianship of L.W.,* 1992). But they do allow for surrogates' reliance on the common judgment that most people wish to avoid a permanently unconscious state (because it lacks dignity and is devoid of value from the perspective of the unconscious patient), as long as the patient's ostensible preferences did not deviate from that norm (*Guardianship of Jane Doe,* 1992).

By contrast, courts in a few jurisdictions have refused to endorse removal of life support from a permanently unconscious patient in the absence of clear-cut prior expressions from that patient (*Cruzan,* 1990; *Mack,* 1993; *DeGrella,* 1993). These courts see the removal decision as a quality-of-life determination that should be made, if at all, pursuant to

legislative directions. Some judges also fear that permission to remove life-sustaining medical intervention from the permanently unconscious would ultimately endanger vulnerable populations, such as the severely retarded (*Mack,* 1993; *Guardianship of Jane Doe,* 1992, dissent).

Infants and Young Children

Some congenital anomalies entail a foreshortened lifespan, as well as neurological impairment, physical incapacity, repeated bodily invasion, and suffering so severe that the affected infant is arguably better off dead than alive. As patient autonomy cannot function in this setting, the question becomes whether parents, in conjunction with medical sources, can withhold life support on the basis that the child's life would be so burdened or devoid of personal value that death is preferable. Some commentators oppose this surrogate option, fearing that decisions would be based on prejudice or ignorance about life as a disabled person or concern for parental burdens, rather than burdens upon the child (Field).

Only a small number of cases have been litigated, and the legal picture concerning removal of infants' life support is murky. A few cases use a best-interests standard and rely on likely physical suffering to uphold parental decisions involving withholding of life-sustaining intervention (*In re C.A.,* 1993; *Newmark v. Williams,* 1991). A few cases purport to apply a substituted judgment rationale (reasoning that the child, if competent, would choose death) in order to uphold removal of life support from a permanently vegetative child (*In re L.H.R.,* 1984; *In re Guardianship of Barry,* 1984). In a 2001 case, a court declared that Texas law prohibits any parental effort to remove life support from a newborn (*Miller v. Hospital Corporation of America*).

The best-interests approach seems most plausible, allowing consideration of irremediable suffering and continuous bodily intrusions (Weir). An unresolved issue is the extent to which a dismal quality of life—in the sense of total helplessness and minimal potential for human relationships—can be used legitimately in this best-interests calculus. As a practical matter, it is hard for decision makers to exclude extreme debilitation in applying a best-interests standard. Extreme disability is commonly associated with hardship for the affected child. This element apparently emerges in decision making not only in the United States but also in Australia, Canada, and Great Britain (Charlesworth).

At the same time, stereotypes about disabled persons might prompt inappropriate terminal decisions. This happened in one case involving an infant afflicted with Down syndrome (*Baby Doe v. Hancock County Board of Health,* 1982). One possible limitation appears in U.S. federal statutes and regulations prohibiting hospital discrimination against the disabled and requiring states to protect the interests of disabled infants (see *In re Baby K,* 1993; *Johnson v. Thompson,* 1993). (Note that quality of life issues arose under the Americans with Disabilities Act in the context of state funding priorities under Medicaid.) The effect of these antidiscrimination measures is still unclear. U.S. federal regulations purport to bar quality-of-life considerations in decisions about infants' medical treatment (Clark). Those regulations are applicable to states participating in certain child abuse prevention programs and do not directly apply to individual hospitals. Moreover, decisions about medical treatment ineluctably involve consideration of the hardship and debilitation to be encountered by the patient after treatment. Where a patient's disability is intertwined with the contemplated medical service (as in spina bifida), a nontreatment decision cannot be deemed unlawful discrimination if the decision is grounded on a reasonable assessment of the suffering and hardship to be encountered by the affected individual. The disabled infant's fate is being determined by the same criteria—overall best interests—applicable to any child under treatment.

Conclusion

Diminished quality of life, in the sense of grievous bodily deterioration, is a frequent consideration in shaping the bounds of medical intervention in the dying process. The current challenge for law and medicine is to fix quality-of-life criteria for surrogate decision makers that avoid arbitrariness and abuse toward vulnerable, incapacitated patients. The key, for previously competent patients without advance instructions, should be assessment of which levels of deterioration the great majority of competent persons would consider (for their own dying processes) to be so undignified that they would prefer that life support be withdrawn (Cantor, 1996).

By using this shared vision of dignity as a guideline, decision makers will better replicate the likely wishes of now-incompetent patients, thus ultimately attaining results as consistent as possible with personal preferences. Empirical data for measuring common notions of dignity can be gleaned from public surveys as well as from scrutiny of patterns in advance medical directives. Anyone whose preferences diverge from common notions of dignity can provide individualized instructions reflecting those preferences.

LIFE, SANCTITY OF

• • •

The sanctity of life is the theological or philosophical understanding that all human life has an inherent dignity, worth and sacredness that sets it apart from all other beings within the world. This perspective does not assert that human life is sacred in the sense of being divine, but that its very essence is distinct within the biological world and of incalculable worth, thus warranting protection throughout the course of its entire existence. The sanctity of life as a doctrine has both religious and philosophical roots and is applied to a wide range of bioethical issues such as abortion, euthanasia, genetic engineering, and cadaver organ transplants. Advocates often consider this understanding of human life to be the foundation of moral civilization, and have applied it to issues outside of bioethics such as human rights, suicide, and care for the poor and weak in society.

Religious Foundations

Various religious traditions have articulated and defended a concept of human sanctity in reference to their overarching worldview conceptions. In the Hebrew tradition the doctrine is rooted in human creation in the image of God: "Then God said, 'Let us make humankind in our image, according to our likeness; and let them have dominion over the fish of the sea, and over the birds of the air, and over the cattle, and over all the wild animals of the earth, and over every creeping thing that creeps upon the earth.' So God created humankind in his image, in the image of God he created them; male and female he created them" (Genesis 1:26–27, NRSV). The creation in God's image became then for the Hebraic tradition the foundation for protecting human life and for justice when it was de-sacralized (Genesis 9:6). The duty to protect human life extended to the necessities for life, such as food and clothing (Deuteronomy 24:6,12–13), and especially to justice for the poor and disenfranchised (Leviticus 19:15, 33–34).

Within the Jewish tradition the taking or defacing of human life is morally wrong because it violates a sacredness that "inheres in life itself, and that life, by its very being calls forth an appropriate human response, whether of veneration or restraint" (Kass, p. 235). The tradition does not teach that humans are God, but rather, "To be an image is also to be different from that of which one is an image. Man is, at most a mere likeness of God" (Kass, p. 242).

Jakobovits notes that in Jewish law and moral teaching, "The value of human life is infinite and beyond measure, so that any part of life—even if only an hour or a second—is of precisely the same worth as seventy years of it" (Jakobovits, p. 380). In contrast to Roman Catholic thinking and some Protestants, this intrinsic value does not extend to the life in the womb. "An unborn fetus in Jewish law is not considered a person … until it has been born" (Rosner, p. 136). For most Jewish scholars this does not give automatic sanction to abortion, for as Rosner points out, "The destruction of the unborn fetus, although legally not considered murder, can be considered to constitute 'moral murder'. The unborn baby has a heartbeat, a brain, arms, legs, and nearly everything with which a healthy newborn baby is endowed" (Rosner, p. 146). Within the various branches of Judaism there is wide variation on the issue of abortion, though fairly uniform agreement that a person is not present until birth. At the other end of life, Jewish moral teaching repudiates active euthanasia or assisted suicide on the grounds that it cheapens life and constitutes murder.

The Christian tradition, incorporating and building from the Hebrew Scriptures, similarly articulates the sanctity of human life on the basis of creation in God's image. This has not only been a warrant for rejecting the willful taking of human life, but also for treating every human life with respect and dignity. Thus, the epistle of James calls for restraint of the human tongue on the basis of this foundation: "No one can tame the tongue—a restless evil, full of deadly poison. With it we bless the lord and Father, and with it we curse those who are made in the likeness of God" (James 3:8–9). The application of human dignity rooted in the *imago dei* is often extended more broadly to social

realities, in that it forms the foundation and the ideal of inalienable rights and intrinsic human values that have long been articulated in Western cultures.

The Christian church has also grounded the sanctity of human life in the doctrine of the incarnation, God taking on human flesh in the person of Jesus Christ. As theologian Karl Barth put it, "The respect of life which becomes a command in the recognition of the union of God with humanity in Jesus Christ has an incomparable power and width" (Barth, p. 339). Barth and other theologians argue that the very fact that God became human in Jesus of Nazareth and then died for human beings is an affirmation that human life has great worth and value.

The sanctity of life tradition stemming from Judeo-Christian sources has historically argued that the value of human life is not dependent upon its being valued by others or by the presence of certain functional capabilities such as rationality or relationality. Rather, sanctity and dignity inhere within the human person. Thus, with regard to bioethical issues of life and death the late Protestant ethicist Paul Ramsey argued against a benign neglect of infants with severe physiological handicaps on the grounds that their value is not dependent on extrinsic characteristics. He noted, for example, that a Tay-Sachs baby is born destined to die, but their dying is no different from our own dying. "For about the first six months it is like any other baby; living and growing and presumably enjoying human existence as any other infant would. In religious perspective there is no reason for saying those six months are a life span of lesser worth to God than living seventy years before the onset of irreversible degeneration" (Ramsey, p. 191).

The Roman Catholic Church has been without doubt the most consistent voice in defense of the sanctity of life. In the words of the Church's catechism, "Human life is sacred because from its beginning it involves the creative action of God and it remains forever in a special relationship with the Creator.… No one can under any circumstance claim for himself the right directly to destroy an innocent human being" (*Catechism,* p. 544). As Pellegrino and Thomasma put it, "The person is to be affirmed as a person, possessing dignity simply because he or she is a person. Man is a personal being, created and loved by a personal God and destined to be united face-to-face with the Creator" (Pellegrino and Thomasma, p. 143).

The Roman Catholic application of this doctrine extends not only to abortion and euthanasia, but also to matters such as research on human subjects. "Research or experimentation on the human being cannot legitimate acts that are in themselves contrary to the dignity of persons and to the moral law. The subjects' potential consent does not justify such acts" (*Catechism,* p. 553).

The sanctity of human life is by no means only found in the Jewish/Christian traditions, though these traditions have given the most explicit renditions of the doctrine due to their common theology of creation. Traditional and contemporary Islamic teaching does not generally use the language "sanctity of human life," but there is a conception of the sacredness of human life: "And do not kill anyone whom Allah has made sacred, except for a just cause" (Qur'an 17:33). In the contemporary setting the Islamic Code of Medical Ethics states that "Human life is sacred…and should not be willfully taken except upon the indications specified in Islamic jurisprudence, all of which are outside the domain of the medical profession" (van Bommel, p. 211). A sense of sanctity seems to be implied in the teaching that humankind is granted a vice-regency (*khalifa*) by Allah, but that role must be carried out consistent with the commandments of Islamic moral law. In the Islamic tradition ensoulment or becoming a person takes place at 120 days in the gestation period. Thus, "It can be said that although abortion in the first 120 days of gestation is morally wrong in Islamic law, it is not considered to be murder or even killing. Rather, abortion in this early period would fall into the categories of bodily injury or breaking of an oath, both of which require some type of penance" (Rogers, p. 129).

Philosophical Foundations

The sanctity of life doctrine is not limited to religious foundations. Various philosophers have attempted to articulate the unique, intrinsic value of human beings on the basis of experience and/or reason. Immanuel Kant, for example, argued that a person should be treated as an end, not as means to an end. The foundation for this assertion is that humans are rational and autonomous beings who thus possess a freedom which must be protected. Human freedom for Kant is not a license to do with life as we please, but rather a warrant for maintaining and protecting human dignity as an absolute inner worth. The problem in Kant's account, for those who today affirm the sanctity of life, is his insistence on rationality as its foundation; for if rationality is no longer present it would seem that human sanctity or personhood is no longer present, if indeed rationality is its foundation and primary indicator.

In the contemporary scene Arthur Dyck has argued for the sanctity of life on the grounds that it is a necessary prerequisite for communal life in society. As Dyck sees it, "Our lives did not and could not originate and persist

because we valued it but because someone else valued it, parents to begin with, but also a whole network of individuals and groups. Our lives depended upon and continue to depend on the persistence of the moral behavior that makes life, and the communal protection of it, possible at all" (p. 52). Killing, including oneself, is thus morally wrong because it undermines mutual moral responsibilities which are necessary for human life to exist.

Humans throughout history, says Dyck, have had a natural love of life that has been enshrined even in law as a protection of the sanctity of human life. He notes, for example, that the U.S. Supreme Court in 1997 rejected the individual's right to exercise control over one's life to the point of seeking assistance in suicide. In rejecting the right to assisted suicide the Court appealed to the American Bar Association's Model Penal Code: "The interests in the sanctity of life are represented in the criminal homicide laws" (p. 59). Dyck, therefore, concludes that there is a moral structure for life's worth and protection, which is based legally, not on religious doctrines, but on the necessary requirements for communal life in society. "If laws were permitted to embody the idea that in some circumstances life loses its worth, or that some people lack sufficient worth to have their lives protected, individuals would no longer enjoy equal protection of the law so far as their lives are concerned" (p. 60).

Challenges to the Sanctity of Life

There have been various challenges to the sanctity of life doctrine from both religious and philosophical frameworks. These challenges have invariably led to different conclusions on a host of bioethical issues.

One set of challenges has been metaphysical, arguing that the human person is not inherently different in nature from the rest of biological life. Thus, there is no warrant for a notion of exclusive human sanctity. Peter Singer, for example, argues against speciesism, the view that *Homo sapiens* life is to be valued above all others. "The wrongness of inflicting pain on a being cannot depend on the being's species, nor can the wrongness of killing it. The biological facts upon which the boundary of our species is drawn do not have moral significance" (p. 128). Thus, he contends that the sanctity of life doctrine is false, for there is no special value to a being by virtue of its species identity.

In contrast to the sanctity of life doctrine, Singer argues that the primary moral criterion for determining the protection of life is its ability to experience pain and pleasure. There are many beings that are capable of experiencing pain and pleasure who do not fit the ordinary conception of personhood (i.e., animals), and there are beings who are often considered persons that are not capable of experiencing pain and pleasure (i.e., some newborn infants and severely mentally disabled adults). Thus, says Singer, "If we value our own pleasures … then the universal aspect of ethical judgments requires us to extend our positive evaluation of our own experience of these pleasures to the similar experiences of all who can experience them" (p. 139). This leads Singer to a strong affirmation of animal rights on the one hand, and to a belief that in some cases deformed children may be euthanized.

Peter Singer utilizes a utilitarian framework for his ethical judgments, but his ethics, including his rejection of the sanctity of life doctrine, ultimately rests on metaphysical commitments about the nature of life. Sanctity of life adherents note that the root difference between Singer and themselves is distinct foundational world views.

A second challenge to the sanctity of human life commitment is theological in nature. Some have argued that the conception overstates the nature of human essence and is idolatrous in its insistence that human life is sacred, an attribute reserved only for God. Margaret Mohrmann believes that the notion of sanctity of life is intrinsically idolatrous. "Theologically speaking there can be no argument based on a purported 'sanctity of life', both because there is no 'life' as such and because we are on very shaky ground when we speak of anything or anyone but God as unqualifiedly sacred" (Mohrmann, p. 22). She notes that "Christians do not believe that God is somehow generically present in something called 'life'. We believe that God is present in individual human persons" (p. 30). And God alone is sacred.

Adherents of the sanctity of life perspective generally counter that such conceptions are caricatures of their understanding. They believe that sanctity of life in no way implies that human life is sacred in the sense of being divine, but rather is set apart by God and hence distinct within the created order.

A third challenge to sanctity of life thinking is the charge of medical vitalism, the notion that all means must be utilized to keep a human being alive in the face of death. Vitalism is the view that because human life has incalculable worth, there must be a commitment to keeping patients alive at all costs. Many critics of the sanctity of life perspective have assumed that vitalism is an inherent part of the tradition.

But advocates of human dignity and worth respond that vitalism is not implied in the commitment to human sacredness, for there is natural cycle to human life, even under divine providence, that must be accepted. Gilbert Meilaender, a strong advocate of the sanctity of human life,

notes that "we indefinitely transcend our historical location. But it is as embodied creatures that we do so, and our person cannot be divorced from the body and its natural trajectory. This is not vitalism; it is the wisdom of the body" (Meilaender, p. 22).

A fourth challenge to sanctity of life formulations is the emphasis on quality of life as an ethical criterion. In contrast to the assumption that all human life has an inherent value and dignity, a number of bioethicists have suggested that quality of life measures ought to be determinative in ethical dilemmas throughout the course of life. Joseph Fletcher a number of years ago argued that for one to be considered a person, four functional traits must be present: neocortical function, self-awareness, relational ability, and happiness (1974, pp. 4–7). There is a clear rational bias in this formulation of personhood, as he questions whether one with an IQ below 40 is a person and concludes that those below 20 are clearly not persons. As Fletcher sees it, "Mere biological life, before minimal intelligence is achieved or after it is lost irretrievably, is without personal status" (1972, p. 1).

Other bioethicists and philosophers have argued similarly for quality of life indices over against sanctity of life. Mary Anne Warren, for example, believes that we can never get away from some notion of speciesism (contra Singer), but she does believe that we must make distinctions within humans on the basis of their capacities. Warren sees two ways in which we speak of humans: humans in the genetic sense, and humans in the moral sense. Being a member of the human species does not ensure that one is human in the moral sense. Warren believes that inclusion in the moral community of humanity entails qualities such as consciousness, reason, self-motivated activity, self-awareness, and the ability to communicate (pp. 457–458).

Sanctity of life advocates counter that while quality of life may be a medical category used to determine when treatment is futile, it is not an ethical category to determine human dignity or personhood.

Applications of Sanctity of Life

The sanctity of human life is not the only ethical norm utilized by its advocates. Nonetheless, they claim, it is a foundational assumption for bioethical issues surrounding life, death, and human treatment.

One of the applications of the doctrine is in the ethics of abortion. Sanctity of human life does not automatically imply that a human or person is present from the moment of conception, but its advocates tend in that direction because human value and dignity is not dependent on functionality. Continuity in human life is usually emphasized, and thus the protection of a fetus or human embryo is just as important as protecting a healthy, mature adult. As a result, most advocates of the sanctity of human life reject abortion on demand and the use of embryonic stem cells in research and therapy.

Sanctity of life is also applied to death and dying issues. Advocates, as noted above, do not generally espouse vitalism and the necessity of futile treatment, but they do raise strong ethical objections to euthanasia or assisted suicide, contending that allowing to die and causing to die are not identical. Sanctity of human life proponents emphasize the role of palliative medicine and compassionate presence as is provided by hospice care in the face of pain and impending death.

Other applications of the sanctity of human life include organ transplants and genetic engineering. In transplantation one of the crucial issues is triage, the allocation of scare resources. Advocates of human sanctity argue that justice in this realm should not depend on merit or the way one is valued in society, but rather must entail a blind-folded egalitarian justice which gives equal opportunity to all potential candidates. With regard to genetic engineering, human sanctity usually means not transgressing one's essential humanness and not utilizing experimental measures for the sake of knowledge, at the expense of human dignity.

In summary, the doctrine of the sanctity of human life teaches that "all human beings possess equal dignity and worth regardless of the level of maturity they have achieved.… Thus, all humans—not just those who are rational or self-conscious—retain the right to life" (Hui, p. 148).

LIFESTYLES AND PUBLIC HEALTH

• • •

The people of every nation would be healthier if they adopted healthier lifestyles. Ninety percent of those who die of lung cancer would not have contracted the disease if they had not smoked. Exercise, sensible diet, and compliance with treatment for high blood pressure can, and do, prevent countless episodes of cardiovascular disease. Practicing safe sex reduces the risk of contracting AIDS. Use of seat belts and motorcycle helmets lowers the chance of injury from accidents on the road.

The prospect of improving health and reducing illness through changes in living habits rather than through curative healthcare is attractive on a number of grounds. Since it is preventive, it avoids the distress of disease; side effects and iatrogenic consequences may be fewer; cost may be lower; and the healthier ways of living may be rewarding in their own right. For these reasons, any government that failed to promote healthy lifestyles could be faulted on ethical grounds.

Nevertheless, the encouragement of healthier lifestyles has drawn moral criticism in the literatures of bioethics and health policy. The chief concern is that governmental (and even private) attempts to bring about changes in living habits will encroach on personal liberty or privacy. A second complaint is that lifestyle-change programs may have the wrong motives, and may have undesirable social and psychological effects.

Health versus Liberty

INTERVENTION: WHAT JUSTIFICATION? Nearly everything we do affects health in some way, if only because the time spent could be devoted to exercise or other health-enhancing behavior. The notion of unhealthy lifestyles, however, is typically associated with a small number of habits. Smoking, the leading killer in the United States, always takes first place, closely followed by alcohol and other drug abuse, lack of exercise, and being overweight. Other risk factors affected by individual choice veer toward the medical, including behavioral change intended to control serum cholesterol and hypertension, perhaps including compliance with doctors' orders. Construed still more broadly, a "healthy lifestyle" would include living in a region not plagued by pollution or recurring natural disasters; avoidance of unsafe jobs; and purchasing the safest cars and appliances.

Attempts to change unhealthy behavior through education and exhortation are relatively unproblematic from the moral point of view. But these measures are less likely to be effective than programs that seek to influence behavior more directly through penalties, taxes, restrictions, or prohibitions. These, however, involve or border on coercion, and in some cases, as with sexual behavior, they necessarily intrude into a person's most private domains.

The fact that good health may be valued by every person does not by itself justify these interventions, since for some people the health risks seem to be less important than

the benefits derived from the risk-taking behavior. Few would seriously assert that eating rich ice cream or smoking falls within the category of fundamental human rights, but each encroachment on individual autonomy is commonly regarded as standing in need of justification, especially in the United States, which has a cultural history marked by an ideology of individualism. Three kinds of justification have been offered for programs aiming to change lifestyles: (1) paternalist concern for the person's good; (2) protection of others from burdens involuntarily imposed by the risk-taking behavior; and (3) the public's stake in the nation's health.

PATERNALIST JUSTIFICATIONS. In the United States, paternalist justifications are rarely provided as such. Though exceptions and counterexamples abound, lip service is still paid to the tradition of John Stuart Mill's *On Liberty.* It is easier to argue for motorcycle helmet laws as a means of reducing the costs of medical care than as a means of protecting human life, despite the greater importance of the latter. When paternalism is explicitly defended, however, it is usually on the grounds that the choices the paternalistic policy prohibits are not fully voluntary ones: Bad habits, such as smoking and overeating, may be sustained by addiction or genetic predisposition. This "soft" paternalism avoids the need to argue for the "hard" paternalist view that even fully voluntary choices may be overruled if the state concludes that the individual might benefit.

For many unhealthy habits, the argument that the behavior is not fully voluntary is easy to make. The individual choice may be determined by chemical, psychological, or social causes. Once a person is addicted to nicotine, it is extremely difficult to stop smoking, as millions of unhappy smokers know; the same holds true for alcoholics and those addicted to legal or illegal drugs. The original decision to try cigarettes, alcohol, or drugs is often made during adolescence, when the individual's ability to resist peer pressure is typically weak.

Nevertheless, the soft paternalist argument faces a number of objections. Not all unhealthy choices are obviously involuntary. The decision to engage in unprotected sex, for example, may be the result of partner coercion, or inner compulsion or denial, but it may also stem from the individual's dislike of condoms or not having a condom. Moreover, even the person whose behavior is shaped by an addiction may be capable of deciding to seek professional help in breaking the addiction. The decision to forgo seeking help, a "second-order" choice about choice, is not necessarily rendered involuntary by the "first-order" addiction. In these instances, paternalistic intervention will be of the hard variety, which involves the authorities acting on the principle that their goals for the individual should be imposed on the individual's own goals.

Intervention aimed at altering lifestyle choices on paternalist grounds may overemphasize the goal of health at the expense of other goals. If the paternalist justification is strongest when the unhealthy choices are least voluntary, these may also be the occasions when the choices are most difficult to influence, and the degree of coercion required may be objectionable in itself. Smokers subjected to very high excise taxes, for example, may suffer from the taxes without giving up cigarettes. Finally, the behavior in question may be difficult to change without considerable meddling in the individual's culture and milieu, whether these champion "wine, women, and song," or risk taking and violence, or quiet (and unathletic) contemplation. The life of the fitness-loving moderate is not for everyone, even if it is most conducive to long life and good health.

FAIR DISTRIBUTION OF BURDENS. Mill's principle of liberty sought to limit intervention to the protection of others from the effects of one's own actions; "self-regarding" behavior is thus the domain of the individual, while others have a say in the regulation of "other-regarding" behavior. Critics have long noted that the boundary is indistinct; nearly everything we do has effects on others. Sexual behavior, the most private of acts, is not at all self-regarding in the era of the AIDS epidemic. And since few people pay all their healthcare bills out of pocket, any behavior that necessitates care will impose a financial burden on other parties.

If these behavioral choices are to be protected, they will have to find some shelter other than Mill's principle. In the case of AIDS, an argument might be made that intrusive regulation would violate a right of privacy, where "private" does not mean "self-regarding" (AIDS transmission is anything but that) but "intimate" or "personal." This right might not be defensible in light of the seriousness of the AIDS epidemic, however; and in any case, other unhealthy habits and choices—for example, smoking, which incurs risks to others through passive smoke inhalation—fall outside of this personal zone. Since there is no general right of liberty when our choices affect the lives of others, the individual's prerogative to maintain unhealthy practices must be decided on other grounds.

Paternalist arguments aim at justifying interventions that seek to curb unhealthy behavior. Arguments that point to the burden of unhealthy behavior for other people, however, may or may not share this aim. They may indeed

seek to justify curbs on the behavior in order to forestall the imposition of burdens. But this can also be accomplished by requiring the individual to pay his or her own way, perhaps through excise taxes, without any diminution of the unhealthy behavior. Finally, the individual whose choices result in illness may be made to pay for his or her own healthcare, or to forfeit any claim on the resources of others, or, at the least, to be placed at the end of the line when resources are scarce.

These steps represent a particular understanding of distributive justice. They seek to impose the true costs of choices on the one who chooses, so that these costs will be taken into account at the moment of choice. Those who believe that the welfare state should assist its citizens in meeting their basic needs, in this view, should not regard all needs as equal. Unhealthy lifestyles create avoidable needs, and individuals should be held responsible for these choices. Those who refuse to take care of themselves, in this view, forfeit at least some of the liberties (to individual choice) and the entitlements (to help, on an equal footing, in time of need) that others deserve.

As with the paternalist justification for intervention in lifestyle choices, this argument concerning the fair sharing of burdens faces a number of objections. One might argue that distinguishing between patients with similar healthcare needs on the basis of personal responsibility for illness introduces a concept of fault more at home in the legal world than in the system of healthcare. Treating all patients according to need, without regard to such factors as status, ability to pay, or fault, is a powerful way of affirming the importance of those aspects of people in virtue of which they are equal, relative to those that divide, distinguish, and rank us. This equality is important both to us as patients and to doctors and other healthcare providers, whose first instinct should be compassionate response to human suffering.

On more technical grounds, the burden-sharing argument rests the case for intervention into unhealthy lifestyles on the outcome of an economic calculation: that the habit in question incurs a net cost. The problem is that those who die prematurely because of unhealthy habits avoid burdening others with the cost of maintaining them in their old age. Economists have long debated whether smokers burden others or relieve others of a financial burden of care; the answer may vary by country, depending on such variables as the cost of healthcare and the cost of living. If there are places in which smokers actually save society money, the burden-sharing argument would entail penalties for those who do not smoke.

Care must be taken, moreover, in stating the burden-sharing argument. Insurance, including health insurance, protects against risk, but it also can make risk taking less unwise. Those Americans who play football, for example, can regard America's healthcare system as a partial safety net; the sport would be too dangerous for many without it. In this light, the burden-sharing argument might succeed in justifying special and higher insurance premiums for risk takers, but unless the risk takers refused to pay these fees, it would not justify curbs on the actual risk taking. Even the special fees would be unjustified if there were rough equivalence in the degree of risk taken by a large number of coinsureds, one person's motorcycle riding offsetting another's sedentary library dwelling.

PUBLIC HEALTH. The third justification for intervention on behalf of healthier lifestyles points to the collective health of the public as a common good. In material terms, a healthy population enhances economic productivity and the nation's capacity to defend itself. General health also provides some degree of protection from the spread of infectious disease. Theorists of public health have contended, moreover, that the *public health,* meaning the sum of each person's health, constitutes a further goal of public policy that can be distinguished from both the paternalist and the burden-sharing arguments.

Another feature of the public-health perspective is the "prevention paradox," the observation that many critical prevention policies affecting lifestyles produce large aggregate savings in lives but little demonstrable benefit to each individual. For example, seat-belt policies may save thousands of lives nationally but only marginally reduce the risk for each individual who drives. Similarly, changes in fat intake will strongly reduce the number who die prematurely from heart disease but affect the chances of each individual only slightly.

The prevention paradox thus arises from the fact that even small changes in the behaviors of tens of millions of individuals involved in low to moderate lifestyle risks avert thousands of deaths. The prevention paradox further underscores the emphasis in public health on rates of disease and deaths averted, and the difficulty of producing mass changes in behaviors through voluntary measures alone.

Far more important than the government's stake in a healthy work force is the centuries-old tradition of governmental responsibility to protect the health and safety of the public, construed as a public or common good. The public-health perspective is rooted in the democratic and constitutional tradition of assigning to elected officials and members of executive agencies responsibilities for protecting the common good, where this has been interpreted by courts as

involving the protection of health and safety (and morals as well, which accounts for the long entanglement of public health and moralism). The public-health or regulatory power of government has long been justified on the grounds that reasonable restrictions on liberty and property, as weighed by the legislature, to promote the common good are the very essence of the regulatory power. This tradition is rooted in theories of government and the duties of citizens that antedate the rise of concerns with paternalism and Mill's famous essay.

Motives and Effects of Intervention Programs

The preceding discussion of arguments for intervention in unhealthy lifestyles has taken the arguments at face value. Critics, however, have suggested that the real motivations for these policies are usually unannounced. The actual motivation, in this view, is moral—or, to be more precise, moralistic, proceeding from a rarely examined and rarely defended set of moral premises. Once these are made explicit, according to the critics, both the motive and the policies are rendered less attractive.

One sign that lifestyle intervention has a moralistic motive, according to critics, is the selectivity of targets. Many kinds of behavior have negative health effects that are not equally addressed. Promiscuity, lack of exercise, and being overweight are merely the medieval vices of lust, sloth, and gluttony. These habits have negative effects on health, to be sure; but so do other kinds of behavior not viewed as vices. Childbirth, for example, presents a certain level of risk to every woman and a decided risk for some; but because it is socially approved, there is no thought of penalizing, taxing, or discouraging the behavior. The burden-sharing argument presents itself as a neutral act of accounting; but, in the critics' view, it is actually concerned with the costs of behavior deemed undesirable on moral grounds while it tolerates behavior of which it approves, no matter how costly.

The moral perspective from which lifestyle intervention is urged, moreover, has been criticized as *healthism,* a parochial view that elevates health from a self-interested goal to a virtue. In this light, "personal responsibility for health" stems not from the need to avoid burdening others with the costs of one's care but from the conviction that healthy people (at least, those who choose health) are better people, morally speaking. This perspective is also said to be linked to an ideology that emphasizes the degree to which one's state of health is a function of choices one makes, rather than the whims of nature or the safety of one's environment and workplace.

One of the most frequent complaints about the lifestyle debate is that it is used to "blame the victim" and undercut the justification for collective action. Thus, those who wish to restrict in various ways the availability of alcohol or tobacco, to limit overall use of these risky products, meet counterclaims that these are not problems of regulation but of individual responsibility and education. The advocates for regulation, in effect challenging the motivation of this view, argue that their opponents do not really want to see a well-financed campaign against smoking and drinking but want no official action at all. Instead, they want wider acceptance of the view that these are problems that will be resolved only when people take more responsibility for their own health and safety.

Conclusion

Though this entry has dwelt on the difficulties in making a convincing case for intervening in unhealthy lifestyles, the collective weight of such lifestyles should not be exaggerated. Much of the bioethical literature on lifestyles indicates that the choices posing the greatest problem for public-health authorities are those which involve personal or intimate behavior, are entirely self-regarding, and represent fully voluntary behavior. Little in our behavioral repertoire falls in this narrowly defined category, however, and those who wish to pursue this promising avenue to health can enter the argument on an even footing.

LIFE-SUSTAINING TREATMENT AND EUTHANASIA

• • •

I. ETHICAL ASPECTS

Ethical and legal norms exist in virtually all societies to help protect human life and regulate when taking or not prolonging life is ethically permissible. In most Western societies, the Judeo-Christian religious tradition has given great importance to the sanctity of life. Modern medicine has also gained extraordinary new powers to prolong life. Within the last few decades, medical treatments such as kidney dialysis, cardiopulmonary resuscitation, organ transplantation, respirator support, and provision of food and water by artificial means have become common in hospitals.

While these new treatments often benefit patients, restoring them to well-functioning lives, they also can be employed in circumstances where they may be neither a benefit to nor wanted by patients. Where once pneumonia was the "old man's friend," the way in which "nature" ended a life that had become seriously debilitated, now the time and manner of death has been brought increasingly under human control. In coming to grips with sustaining, taking, or not prolonging life, medicine has drawn on both its own ethical traditions and society's broader ethical and religious traditions.

This entry will first develop an ethical framework for life-sustaining-treatment decisions around which a considerable, though hardly universal, consensus has developed, and contrast it with the distinction between ordinary and extraordinary care. It will then consider broad alternative positions on the morality of taking life and some of their implications for care of the dying. Focusing on more specific controversies, it will then address the intentional taking of life versus pain relief that hastens death, killing and allowing to die, not starting versus stopping treatment, and four prominent examples of end-of-life treatment—resuscitation, artificially administered food and water, terminal sedation and futile treatment. Finally the entry will conclude with discussions of life-sustaining treatment and suicide and of physician-assisted suicide and voluntary euthanasia.

An Ethical Framework for Life-Sustaining-Treatment Decisions

An ethical framework for life-sustaining-treatment decisions should be sufficiently general to apply to all forms of such decisions and to both competent and incompetent patients.

COMPETENT PATIENTS. In the United States in the twentieth century, healthcare-treatment decision making came increasingly under the dominion of the ethical and legal doctrine of informed consent. This doctrine requires that treatment not be administered without the informed and voluntary consent of a competent patient. From a paternalistic and authoritarian tradition, in which the physician made almost all treatment decisions and the patient's role was to follow the doctor's orders, a new ideal emerged that involves shared treatment decision making between physicians and patients. Physicians use their knowledge, experience, and training to determine the patient's diagnosis and prognosis with different possible alternative treatments, including the alternative of no treatment, and the risks and benefits of each. Patients, on the other hand, use their own aims and values to discern and decide which option is best for them. Shared decision making is based on the recognition that sound, individualized-treatment decision making requires both contributions.

The principal ethical values that underlie shared decision making involve promoting the well-being of patients while respecting their self-determination or autonomy. The term *well-being* is meant to signal that what is best for a particular patient depends not only on the "medical facts" but also on the patient's own aims and values. It is also meant to signal the extremely important point that preserving or sustaining life is not always a benefit to patients; whether it is depends on the nature of the life sustained and whether the patient values that life. Self-determination is the interest ordinary persons have in making important decisions about their lives for themselves and according to their own values or conception of a good life. The capacity for self-determination allows people to take control over and responsibility for their lives and the kind of persons they become. The fundamental importance of self-determination has consistently been the central appeal in the United States both in the long line of informed-consent legal cases going back at least as far as the 1914 case *Schloendorf v. Society of New York Hospital,* and in the more recent life-sustaining-treatment cases.

On the basis of these two values, as well as the ideal of shared decision making and the requirement of informed consent they support, competent patients have the right to weigh the benefits and burdens of alternative treatments, including the option of no treatment, and to make their own selection. While this ethical framework applies to any treatment, it provides especially strong support for patients deciding about life-sustaining treatment. When forgoing life-sustaining treatment is seriously in question, the patient is often critically or terminally ill and near death and also often in a seriously debilitated state. Whether a particular patient will want to fight to stay alive as long as possible, or will instead at some point find continued life no longer a benefit but now a burden, is highly variable and unpredictable. Self-determination on so important a decision as when and in what ways one's life comes to an end or is sustained by medical treatment is of particular importance.

INCOMPETENT PATIENTS. When forgoing life-sustaining treatment is seriously in question, patients are often—probably usually—incompetent to make the decision for themselves, and so another person must decide for them. Bioethics and the law have given much attention to who should decide about life support for incompetent patients and what standards should be used. A number of ethical grounds support the common practice, employed by physicians and sanctioned by the courts, of turning to a close family member of the patient, when one is available. Most patients would want such a person to make these decisions for them when they are unable to do so; in most cases, then, turning to a close family member respects the patient's self-determination. Moreover, a close family member will usually know the patient best and will therefore be in the best position to determine what the patient would have wanted. This person is also likely to care most about doing what is best for the patient. Turning to a close family member thus promotes both the patient's self-determination and the patient's well-being. Finally, in most societies the family is the social unit in which important social bonds and responsibilities to care for dependent members are developed; one exercise of this responsibility is to serve as surrogate for an incompetent family member. These ethical grounds usually, but do not always, apply and so can be thought of as establishing an ethical presumption that a close family member is the appropriate surrogate to make life-sustaining-treatment decisions for an incompetent patient. When these reasons do not apply—for example, when there is evidence that the patient would have wanted someone else to serve as surrogate or there is a serious conflict of interest between the family member and surrogate—then the presumption in favor of the family member as surrogate can be rebutted and another should be selected to serve instead.

How should a surrogate make life-sustaining-treatment decisions for an incompetent patient? A significant consensus has developed, both in ethics and in law, that there are three standards for a surrogate's decisions. First, if the

patient has made an advance directive (e.g., a "living will" or a "durable power of attorney for healthcare") that includes instructions about the individual's wishes as to the decision in question, then the patient's choice expressed in the advance directive should be followed, with only limited qualifications. Second, when most patients do not have an advance directive or their advance directive is too general to determine the actual treatment decision, the "substituted judgment" standard should be used. This directs a surrogate to attempt to make the decision that the patient would have made, in the circumstances that then obtain, if the patient were competent. More informally, the surrogate should use his or her knowledge of the patient and the patient's values and wishes to attempt to decide what the patient would have wanted. Third, when there is no knowledge available of the patient and the patient's values that bear on the decision at hand, the "best-interest" standard should be used. Here, the surrogate should determine what is in the patient's overall best interests by a more objective and communal conception of best interest. This often amounts to asking what most reasonable persons would want; in the absence of available evidence about how, in relevant respects, the patient is different from most people, this is justified. These three standards constitute a way to promote patient well-being and self-determination to the extent possible when the patient lacks capacity to make decisions.

These standards have not gone unchallenged (Meisel; Veatch; Dresser and Whitehead). For example, parents are given significant discretion, especially in the case of young children, in deciding what would be best for their child and are permitted to give some weight to the effects of different options on important interests of other family members. The authority of both advance directives and substituted judgment have also been challenged when following them would conflict with important interests of the now-incompetent patient or when the patient has undergone such profound mental changes that he or she appears to be a "new person" with new interests. Despite the substantial consensus on the ethical framework sketched above, it is not uncontroversial.

This ethical framework for life-sustaining-treatment decisions by competent and incompetent patients does give weight to a narrowly focused quality-of-life judgment: Is the best life possible for the patient with treatment sufficiently poor, according to the patient's evaluation of that quality, that it is worse than no further life at all? No weight is given, on the other hand, to the fact that the patient's quality of life may have diminished from what it once was or from most people's lives, or to any evaluation of the social worth or social value of the patient. The fundamental feature of this ethical framework is that it entitles the patient or surrogate to weigh the benefits and burdens of possible treatments, including the option of no treatment, according to the patient's aims and values, and to select from among available treatments or to refuse any treatment. This decision-making framework has now largely supplanted the distinction between ordinary and extraordinary treatment.

Ordinary versus Extraordinary Care

The distinction between ordinary and extraordinary care has its origins in Roman Catholic moral theology, where it is employed to distinguish between obligatory care—ordinary—and care that may be permissibly forgone—extraordinary. The two central issues about this distinction are: (1) What is the difference between ordinary and extraordinary care? and (2) Why should that difference determine whether care is morally obligatory or optional?

The distinction itself has been criticized as being unclear and resulting in confusion and controversy about how it should be applied (U.S. President's Commission). For example, it has been used to mark the difference between statistically usual and statistically unusual care (perhaps the most commonly held understanding of the terms), between noninvasive and highly invasive treatments, and between treatments that employ low- and high-technology interventions. Because the distinction has many different, natural understandings, confusion often arises about what it means. None of the possible meanings of the distinction explains why the difference itself should determine whether the treatment is morally obligatory or optional. For example, treatment that is statistically common or involves the use of low technology might be beneficial to a particular patient in particular circumstances, but not beneficial or, perhaps, even burdensome to another patient in different circumstances.

The correct understanding of the traditional distinction is the difference between treatment that is beneficial and treatment that is unduly burdensome (or without benefit) to a patient. Of course, treatment is unduly burdensome only when the benefits it provides are insufficient to warrant its burdens. Unlike the other interpretations noted above, this interpretation of the ordinary–extraordinary distinction does mark a morally significant difference. Understood in this way, however, no general list of kinds of treatments that would be consistently ordinary or consistently extraordinary is possible; any treatment may be beneficial in some circumstances but not in others. More important, when the distinction is understood in this way it ceases to be an alternative to the benefit–burden framework. The judgment that a treatment is "extraordinary" places a label on treatment already and independently determined to be without benefit or unduly burdensome to the patient. The benefit–burden

assessment does the substantive work in assessing treatments. For this reason, most commentators have given up the ordinary–extraordinary analysis in favor of the clearer and more direct appeal to the assessment of the benefits and burdens of treatment to a particular patient.

Of course, no ethical framework of the sort sketched here can be applied mechanically to make decisions to forgo life-sustaining treatment easy and unambiguous; even with the best efforts and the clearest reasoning, many decisions will remain ethically problematic and emotionally wrenching. While this is also true of many decisions about treatment that is not life sustaining, decisions concerning whether to sustain or shorten life raise several special ethical issues. In the 1960s and 1970s, it was common to distinguish between "active" and "passive" euthanasia. Passive euthanasia was understood to include forgoing life-sustaining treatment, either by stopping it or by not starting it. Active euthanasia was understood to be a deliberate intervention to end a patient's life, for example, by administering a lethal injection. Because euthanasia is often understood to be only active euthanasia, it has become common to avoid the term passive euthanasia in favor of referring to forgoing life-sustaining treatment. Most of these additional ethical issues raised about life-sustaining treatment represent special constraints or limits to be considered regarding the ethical framework just discussed for decisions where life itself is at stake.

The Morality of Taking Life

Any view about the morality of forgoing life-sustaining treatment or of euthanasia will depend in large measure on the basic moral principle presupposed concerning the taking of human life. This principle will differ depending on the general moral theory or conception of which it is a part or from which it is derived. Moral conceptions regarding taking life and killing may be divided into those that are goal-based, duty-based, and rights-based. A goal-based position, of which utilitarianism is the best-known variant, prohibits taking life when doing so fails to maximize the goals or consequences the position holds to be valuable, for example, human happiness or the satisfaction of people's desires. In this view it is a factual matter whether any particular killing produces better consequences than any other available alternative. Because this position not only permits but requires taking an innocent person's life when doing so will produce the greatest balance of benefits over harms, it is in sharp conflict with the patient-centered, ethical framework, which does not permit sacrifice of the patient for the benefit of others.

In a duty-based view, taking life is wrong because it violates a fundamental moral duty not to take innocent human life intentionally. This view looks not to the consequences produced by a particular killing but to the action itself, which is prohibited by the duty not to kill. It is often found within religions that view life as a gift from God, and therefore subject only to God's decision about when to take it. Perhaps the most serious difficulty for this view is its failure to give moral weight to the consent of the person whose life may or may not be taken. In this view, a competent patient's free request that another take her life need not morally justify doing so; instead, it is a request or temptation to do evil and should be resisted by a moral person.

In a rights-based view, taking human life is morally wrong because it violates a basic moral right not to be killed. In this view, killing harms its victims because it denies them their future, together with all that they wanted to pursue or achieve in that future. It wrongs its victims by taking from them without their consent what is rightfully theirs—their lives. In contrast with the duty-based view, however, when a competent individual freely requests that another person take his or her life because that life has become a burden and no longer a good for the individual, that request would be understood to be a waiving of the individual's right not to be killed, and acceding to it would be morally permissible.

The most important, substantive moral difference between duty-based and rights-based views is whether an individual's free and informed consent can make taking the person's life permissible. The distinction between duty-based and rights-based views is a natural way in which this moral difference is often expressed. Nevertheless, the duty not to kill could be understood to apply only to individuals who wish to live, and the right not to be killed could be understood to be unwaivable, as many in the right-to-life movement understand it. The distinction between rights-based and duty-based accounts of the morality of killing is used in this entry only to distinguish whether an individual's consent to be killed does or does not make killing that individual morally permissible.

Which of these alternative positions is correct is controversial and raises general questions of moral theory that cannot be addressed here. An ethical position that gives fundamental ethical importance to individual self-determination—as the ethical framework for life-sustaining-treatment decisions sketched above does—is most naturally formulated as a rights-based position. Whichever basic view is adopted, however, there are two important questions: (1) What actions are included under the moral prohibition of taking life, broadly construed? and (2) Is this prohibition absolute or does it have exceptions? The duty-based view is

sometimes understood to make absolute the prohibition on intentionally taking human life; but it also typically distinguishes acts that intentionally take life from acts in which death is a foreseen but unintended consequence. Both duty-based and rights-based views about the morality of taking life tend to share the position that allowing to die is a less serious wrong than taking a life by killing.

Intended versus Foreseen but Unintended Taking of Life

When caring for dying patients, health professionals sometimes take actions that may shorten the patient's life. They may, for example, provide larger and larger doses of morphine when necessary to relieve a patient's pain, and in doing so, risk bringing on respiratory depression and earlier death. When this is done with the patient's or surrogate's knowledge of the risk and consent, it is morally justified. For the rights-based moral view about taking life, consent to the risk is crucial. In many duty-based positions, however, the consent of the victim does not justify taking human life, and a distinction is drawn instead between whether the resulting death was intended and whether it was only foreseen but unintended.

This intended/foreseen distinction has a long history. Invoked in the thirteenth century by the Italian theologian and philosopher Thomas Aquinas to justify killing in self-defense, the distinction is central to the Roman Catholic doctrine of double effect. (Double effect here refers to actions that may have two effects, one that is directly intended and the other one only indirectly intended or foreseen.) In some form, it is also common in much secular thinking about the morality of taking life.

Two central questions must be answered in order to evaluate whether this distinction really can or should be used to distinguish some morally permissible from impermissible taking of life. First, what precisely is the nature of the difference between "intended" and "foreseen"? Second, why is this difference morally important? In treating a dying cancer patient's pain, it may seem clear that the physician's primary or direct intention is to treat the pain; the earlier death from respiratory depression caused by the morphine the physician prescribes to treat the pain is, at most, a secondary or indirect intention, or more accurately, a foreseen but unintended consequence. (It is also clinically rare, especially for patients who have been receiving morphine for a considerable period of time.) Many physicians would not give this same patient a lethal injection if all other means of pain relief had failed, because then the death would be intended. Yet the physician's primary intention in the case of killing by lethal injection might also be to relieve the patient's pain, though then the means of doing so is to kill the patient. This distinction between what is intended as a means and what is a foreseen but unintended consequence, however, is not always clear. Killings that seem plainly wrong because they are an impermissible means to a good end can be redescribed as only a foreseen but unintended consequence of achieving the good end, and as, therefore, morally permissible. An extreme example will illustrate the point. Suppose a renowned transplant surgeon removes the heart and liver from a healthy person without the person's consent in order to transplant them in two patients who otherwise will die from heart and liver failure. Such killing is wrong even though it is a means of saving a greater number of persons. But suppose the surgeon denies that the killing is the means of saving other patients: The means of saving the other patients, he claims, was by removing the healthy person's organs and transplanting them, whereas the death of the healthy person was merely foreseen but not intended. Proponents of this distinction have not clarified it in a way that prevents such unwelcome misuse of it.

In many cases, such as giving morphine as opposed to a lethal injection, there is agreement about how to apply the intended-versus-foreseen-but-unintended distinction. The question then arises, what is its moral significance? Critics of the distinction note that in each case the physician's end is to relieve suffering, and that to gain such relief, both physician and patient are prepared to accept the risk of the patient's earlier death. Whether by morphine or a lethal injection, relieving the patient's suffering will bring about an earlier death. These similarities cast doubt on the moral importance of this difference. In the case of morphine, there may be only a risk of death, whereas in the case of a lethal injection the death is certain. But sometimes the amount of morphine necessary makes the likelihood of earlier death extremely high, and then this small difference in probabilities is too slim a foundation for the very great moral difference between permissible and impermissible killings. In any event, this is a difference in the certainty or risk of the outcome of death, not in whether it is intended or unintended.

Critics of the distinction between intended and foreseen deaths argue that physicians are morally responsible for all foreseen or reasonably foreseeable consequences of their actions, whether intended or foreseen but unintended, because foreseeability brings these consequences under the control of physicians and so makes physicians responsible for them. This disagreement in medical contexts about the moral importance of whether death is intended is often a particular instance of a broader disagreement between goal-based or utilitarian theorists who are concerned only with

good results and duty- or rights-based theorists who place moral restrictions on how good results may be brought about.

Killing and Allowing to Die

Many moral theorists distinguish between duties not to kill, called negative duties, and duties to save or not to allow to die, called positive duties (Steinbock and Norcross). They argue that, unless this distinction is used to set reasonable moral limits, moral responsibilities will extend far beyond what they are usually thought to be and will deeply limit people's pursuit of their various life plans. Persons can usually satisfy the duty not to kill simply by pursuing their particular aims and purposes, although these goals may have to be altered if necessary to avoid killing. But if there is an equally stringent duty not to allow to die, it might seem that people must likewise set aside nearly all their usual aims and activities and devote their lives to saving those whose lives are in peril, such as victims of famines or extreme poverty. The implications of whether killing is morally worse than allowing to die are far-reaching both within and outside of medicine.

There are again two distinct issues. First, what makes one particular "doing," understood to include both acts and omissions, a "killing," and another, an "allowing to die"? Once the difference is clear, the second issue is whether and why this difference between killing and allowing to die is morally important. Killing is usually distinguished from allowing to die by establishing whether something was done, or not done, that resulted in death. A person who kills performs an action that causes a person to die in a way and at a time that the person would not otherwise have died. For example, two people are in a boat; Person 1 cannot swim. Knowing this, Person 2 pushes Person 1 out of the boat; Person 1 drowns.

A person who allows another to die knows that there is an action she could perform that would prevent another's death, but she does not take this action, and the person dies. For example, Person 1 accidentally falls out of the boat. Person 2 does not throw out an available life preserver, and Person 1 drowns. Some philosophers have argued that if the difference between killing and allowing to die is predicated on acting or not acting, killing is not morally worse than allowing to die.

The meaning of this claim has often been misunderstood. The claim is that the mere fact that one doing is a killing, while the other is an allowing to die, does not make one morally better or worse than the other, or make one morally justified or permissible when the other is not. This is compatible with saying that a particular killing, all things considered, is morally worse than, or not as bad as, a particular allowing to die because of other differences between the two, such as the motives of the agents or the presence or absence of the consent of the victim. This is also compatible with holding that most killing, all things considered, is morally worse than most allowing to die, but once again, that must be because of other morally important differences between them.

The usual argument for the position that killing is not in itself morally worse than allowing to die has consisted of comparing two cases that differ in no other morally relevant respect except that one is a killing, the other an allowing to die. Such a comparison helps focus on whether this difference by itself is morally important. James Rachels provided the following well-known example:

> In the first [instance], Smith stands to gain a large inheritance if anything should happen to his six-year-old cousin. One evening, while the child is taking his bath, Smith sneaks into the bathroom and drowns the child, and then arranges things so that it will look like an accident.
>
> In the second, Jones also stands to gain if anything should happen to his six-year-old cousin. Like Smith, Jones sneaks in planning to drown the child in his bath. However, just as he enters the bathroom Jones sees the child slip and hit his head, and fall face down in the water, Jones is delighted; he stands by, ready to push the child's head back under if it is necessary, but it is not necessary. With only a little thrashing about, the child drowns all by himself, "accidentally," as Jones watches and does nothing. (1975, p. 79)

Whereas Smith killed, Jones allowed to die. Rachels argued that there seems to be no basis for saying that what Smith did was any worse than what Jones did; there must be other factors in real cases that account for any moral differences. The conclusion that killing is not, in itself, morally worse than allowing to die remains controversial. Those who hold that there is a significant moral difference between the two argue that it is important to establish which of the two types of forgoing of life support, if either, comes under the stronger moral prohibition against killing. Because forgoing life support includes both not starting treatment and stopping treatment, the issue of whether either is equivalent to killing can be pursued by asking whether or not starting life support and stopping life support are morally different.

Not Starting Treatment and Stopping Treatment

When a decision is made not to initiate some form of life-sustaining treatment, such as kidney dialysis or respirator

support, and the patient dies as a result, this is commonly understood to be an omission and so an allowing to die. Even if active killing is wrong, its prohibition does not apply to not initiating life support. But what of stopping life support—for example, stopping respirator support at the persistent, voluntary request of a clearly competent and respirator-dependent patient who is terminally ill and undergoing suffering that cannot be adequately relieved? If such action is taken by the physician with the intent of respecting the patient's right to decide about his or her treatment, most people would consider it a morally justified instance of allowing the patient to die. If only killing, but not allowing to die, is prohibited, then stopping life support and not starting it are both allowing to die and morally permitted.

But some philosophers have argued that stopping this patient's respirator is killing, not allowing to die (Brock). Suppose, for example, the patient has a greedy son who mistakenly believes that his mother will never decide to stop treatment and that even if she did, her physicians would not comply with her wishes. Afraid that his inheritance will be exhausted by a long hospitalization, he enters his mother's room while she is deeply sedated and removes her from the respirator, and she dies. If upon being found out, the son protested, "I didn't kill her; I merely allowed her to die; it was her disease that caused her death," this claim would be rejected. The son went into his mother's room and deliberately killed her.

Does the physician who did the same thing, performed the same physical action, kill the patient as well? Even if the physician in such a case does kill, other moral differences make the physician's killing morally justified, whereas the son's is morally wrong. The physician acts with a good motive, to respect the patient's wishes, with the patient's consent, and in a professional role in which the physician is socially and legally authorized to so act; the son acts with a bad motive, without consent, and with no social or legal authorization to do so. But these do not appear to be differences in whether either kills or allows to die: One can kill or allow to die with a good or bad motive, with or without consent, and in or not in a role that authorizes the action.

Those who reject this analysis and hold that stopping and not starting life support are both allowing to die usually have a different account of the kill/allow-to-die difference than the act/omission account offered in the last section. They hold that when a patient has a lethal illness such as lung disease, whose usual fatal outcome is being held off by a life-sustaining treatment such as a respirator, removing this artificial intervention amounts to allowing the patient to die by letting the disease process proceed unimpeded to death. But this account is problematic, not least because it requires one to accept that the greedy son also allows to die, but does not kill.

Whether stopping life support is killing or allowing to die, some physicians and others have contended that it is an ethically graver matter to stop a life-sustaining treatment than not to start it, or that it is permissible not to start it in circumstances in which it would not be justified to stop it. But consideration of cases such as the following has led most persons to reject the argument that stopping life support is different from or more serious morally from not starting it:

> A gravely ill patient, Mr. S, arrives at the hospital in respiratory distress and is sent to the intensive care unit (ICU) to be intubated and placed on a respirator. Before he is intubated, his family and physician arrive at the ICU and inform the staff that while clearly competent Mr. S, after extensive consideration and because of his debilitated and terminal condition, had firmly rejected being put on a respirator under any circumstances. The ICU staff respect his wishes, keep him comfortable, and he dies of respiratory failure. Now suppose instead that heavy traffic had delayed the family and the physician and they arrive at the ICU just after Mr. S is put on the respirator. His treatment now must be stopped instead of not started as before. (Brock, p. 209)

It is hard to see why the same factors that morally justified not starting his treatment do not, equally, morally justify stopping it.

Those who hold that stopping life support is not different ethically from not starting it usually stress two bad effects of a greater reluctance to stop life support. First, it will result in continuing treatment beyond the point at which it is a benefit to or still wanted by the patient. Second, and less obvious but at least as important, the belief that it will be harder to stop life support once it is begun can make physicians, patients, and family members all reluctant to try treatment when the benefits are uncertain or unlikely, for fear that if the treatment proves not to be beneficial they will not be able to stop it and the patient will end up "stuck on machines." The result is to deny patients possibly beneficial life-sustaining treatment.

In fact, there is often better reason to stop a life-sustaining treatment than not to start it. Often, before a life-sustaining treatment is started, it is uncertain whether it will bring the hoped-for benefits to the patient. Once it has been tried, and it is clear that it does not produce the benefits sought, a reason exists for stopping it that did not exist for not starting it. This supports the use of time-limited trials of

life-sustaining treatment, with the understanding that if the treatment does not prove to be beneficial it will be stopped.

Four Kinds of End-of-Life Treatment

Four forms of treatment of patients near death that have received special attention are resuscitation, artificial nutrition and hydration, terminal sedation, and so-called futile treatment.

RESUSCITATION. Life-sustaining-treatment debates in the United States during the 1970s and 1980s often focused on the use of cardiopulmonary resuscitation (CPR) for persons who suffer cardiac or pulmonary arrest. Because CPR, to be effective, must be administered immediately after a patient suffers an arrest, hospitals have developed policies generally requiring that CPR be administered to any such patient, unless there is a "do not resuscitate" (DNR) order already in effect for the patient. The presumption of these policies—that anyone in medical need of resuscitation should receive CPR unless there was a prior order not to use it—made CPR different from many other life-sustaining treatments, which required a physician's explicit order to start them.

CPR is the most prominent example of a class of emergency procedures for which consent is presumed unless the patient or the patient's surrogate has explicitly refused it beforehand. Because CPR in the hospital is usually not successful, is associated with significant morbidity for the patient even when it is successful, and often would, at best, extend the lives of dying patients only briefly, there is widespread consensus that forgoing it is often ethically justified so long as patients or their surrogates agree and explicitly withdraw the presumption of consent for it. As a result, resuscitation, or "code status," is probably the most frequently raised life-sustaining-treatment decision.

ARTIFICIAL NUTRITION AND HYDRATION. Those who seek to limit the life-sustaining treatments which it is ethically permissible for patients or their surrogates to decide to forgo have usually focused on the provision of nutrition and hydration by artificial means, such as intravenous, nasogastric, and other forms of tube feeding. Some people have argued that food and water are not medical treatment but are instead the most basic form of caring for dependent persons; all people, not just medical patients, need food and water. Others argue that when the patient's medical condition necessitates the artificial provision of food and water, and when this is done by medical personnel using medical means, there is not much difference between this situation and the provision of oxygen by respirators to patients with lung disease.

Other opponents of forgoing food and water focus not on the issue of whether it is medical treatment, but on the strong symbolic meaning and importance of feeding those in need. The usual symbolism of food and water, however, may be misleading in the circumstances in which the question arises in medicine. There the cultural and social symbolism and meaning associated with eating and feeding are largely absent, as is the suffering typically associated with starvation. Applying the benefits-and-burdens analysis, food and water should be forgone only if doing so would not cause significant suffering to the patient. The benefits-and-burdens analysis will support forgoing nutrition and hydration either when continued life itself is burdensome or not a benefit to the patient, or when providing nutrition and hydration increases, rather than decreases, the patient's suffering. For example, many patients in a persistent vegetative state—that is, those who have permanently and completely lost the capacity for any conscious experience—would not want nor consider it a benefit to have their lives continued. Consequently, treatment that sustains life is not beneficial, and its withdrawal cannot impose any burden on such a patient. In other cases, providing normal levels of nutrition and hydration may increase the awareness and suffering of some dying patients; for these patients, feelings of thirst can be assuaged, for example, with ice chips, without providing a level of hydration that would make their dying less peaceful and comfortable (Lynn). In still other cases, the benefits of continued life for seriously demented patients must be weighed against the burdens of physical restraints necessary to keep them from removing feeding tubes.

A different form of forgoing food and water can occur when a competent patient refuses them because the patient wishes to die. Some have argued that because competent patents always have not only the right to refuse artificially provided nutrition and hydration but also the right to refuse to eat or drink by ordinary means, physician-assisted suicide is an unnecessary option. Refusing to eat or drink will always result in the patient's death, and so a competent patient who wishes to die but who does not have any life-sustaining treatment to be forgone does not need access to physician-assisted suicide to do so. Stopping eating and drinking, however, can take considerable resolve on the patient's part and may not meet many patients' views of a humane and dignified death. Proponents argue that it still may be a better policy option than physician-assisted suicide if the latter has substantial risks that stopping eating and drinking does not have.

TERMINAL SEDATION. Related to stopping nutrition and hydration as an alternative to physician-assisted suicide is the use of terminal sedation (Quill, Lo, and Brock). This

typically involves sedating a patient with otherwise intractable pain to the point of unconsciousness and then withdrawing nutrition and hydration, with the inevitable result of the patient's death. Terminal sedation is used by some hospices and is defended as an acceptable practice because treating patients' pain is an uncontroversial responsibility of physicians and withdrawing nutrition and hydration is within patients' general right to refuse any treatment. The practice remains controversial, however, both because it raises the previously discussed problems with the distinction between intended and foreseen but unintended consequences, and because it is subject to abuse, especially if employed with incompetent patients. Others argue that because it may take up to a week or more for the patient to die, physician-assisted suicide would usually provide the patient with a preferable death.

FUTILE TREATMENT. A final recent controversy concerns futile care. As physicians have come to accept patients' rights to refuse treatment, they have increasingly encountered patients, or more commonly the families of incompetent patients, demanding treatment that the physicians judge to be futile. The debate began with CPR but has expanded to other forms of life-sustaining care. When physicians are asked to actively provide a treatment, it has seemed to many that the treatment should be acceptable both to the patient and to the physician; typically, in any joint enterprise, such as that between patient and treating physician, what is done must be acceptable to both participants. This may help account for the asymmetry many support between patients' right to refuse any treatment but to choose only from among medically acceptable alternative treatments.

A central issue in the futility debate has been how to define futility. Some have tried to narrowly restrict it to only those treatments known with certainty not to achieve their goal. The attempt is to eliminate value judgments from futility determinations and to make them only an empirical matter about which the physician should be expert. But others have pointed out that it is not possible to eliminate all value judgments. How certain is certain enough, and what are the legitimate goals of the treatment? Others have more broadly characterized futility to include cases in which the probability of benefit is considered too low, or the size of benefit too small, to warrant the burdens of the treatment. Here, the value judgment in determining futility is whether the treatment's benefits are likely enough, or large enough, to warrant its burdens. This value judgment seems in most cases appropriately left to the patient or surrogate, not the physician. The courts that have addressed futility cases have largely sided with patients or surrogates seeking treatment rather than with physicians who wish not to provide it.

Life-Sustaining Treatment and Suicide

Suicide is difficult to define precisely but is usually understood as the intentional taking of one's own life. In some religious traditions, suicide has long been and continues to be prohibited and considered a sin, and some important moral philosophers such as Immanuel Kant (1724–1804) have held that suicide is morally wrong (Battin). Historically, the law often reflected these views, although in the United States no states now criminalize suicide or attempted suicide, but a majority prohibit assisting in suicide.

The different, basic moral positions discussed earlier on the morality of taking human life have different implications for the morality of suicide. Despite these differences, most people agree that a public policy of seeking to prevent most suicide attempts is morally justified. Even strong defenders of individual self-determination generally agree that most suicide attempts are dramatic pleas for help and occur when a person's decision-making capacity is seriously disordered by such conditions as depression. These features justify intervention to prevent the suicide, so as to determine if the patient is competent and not subject to impaired decision making, in which case, some believe, others should cease coercive interference.

Because a patient's decision to forgo treatment correctly believed to be life-sustaining will result in the patient's death, the question arises whether this is suicide. In some cases, the patient may not intend her own death, or seek death, but only be unwilling to undergo the burdens of a particular life-sustaining treatment. In other cases, however, the patient's decision may also be made in the interest of seeking an end to an excessively burdensome existence; in such cases, therefore, there is an intent to cause one's own death, making it hard to differentiate the decision from suicide. Many legal decisions about life-sustaining treatment, and most Western religious traditions, have sought to distinguish forgoing life support from suicide, often by characterizing the former as an exercise of self-determination about one's medical treatment, not intentional self-destruction. (The courts may have sought to distinguish forgoing life support from suicide to protect participating physicians and others from potential prosecution under legal statutes prohibiting assisting in suicide.) Yet the normative judgment a competent person makes justifying each act is often essentially the same: The best future life possible for me (with life-sustaining treatment, in the case of a decision to forgo treatment) is so bad that it is worse than no further life at all. The principal difference between some cases of forgoing life-sustaining treatment and suicide appears to be only a difference in the means a person uses to bring about her death. Nevertheless, even if some or all forgoing of life support is essentially suicide, it need not, for

that reason, be morally wrong, but might instead be considered a justified exercise of self-determination.

Physician-Assisted Suicide

In nearly all countries, neither professional practice nor the law permits physicians to grant patients' requests for physician-assisted suicide or voluntary euthanasia. An example of physician-assisted suicide is when a patient ingests a lethal substance provided by a physician for that purpose; voluntary euthanasia, by contrast, involves the physician administering the lethal substance. In both cases, the choice rests fully with the patient, and the patient can change his mind up until the moment the lethal process becomes irreversible. The only difference need be who performs the last physical action of administering the lethal dose, for example, placing potassium chloride in the patient's intravenous line. This small difference in the part played by the physician in the causal process leading to death does not seem to support a substantial moral difference between physician-assisted suicide and voluntary euthanasia.

Those who nevertheless believe that it is morally worse for physicians to perform voluntary euthanasia than physician-assisted suicide can argue that in the former, the physician kills the patient, whereas in the latter, the patient kills herself. But it may be more accurate to say that in physician-assisted suicide, the physician and the patient together kill the patient—a case of joint action for which both together bear responsibility. This suggests that physician-assisted suicide and voluntary euthanasia may not be substantially different morally.

Voluntary, Active Euthanasia

Considerable public and professional attention, spurred by publicity about the practice in the Netherlands (Van Der Maas, Van Delden, and Pijnenborg) and several notorious cases in the United States, such as those of Dr. Jack Kevorkian, has focused on voluntary, active euthanasia. In significant part, the public interest in euthanasia reflects fear of loss of control and dignity while dying. It also reflects recognition that the same values of patient self-determination and well-being that have been accepted as guiding treatment decision making in general, and decisions about life-sustaining treatment in particular, can in some cases support voluntary, active euthanasia as well. If this positive support for voluntary euthanasia is granted, opponents have in general offered two kinds of arguments against it.

The first argument is that any individual instance of euthanasia is morally wrong because it violates the duty not to kill innocent human beings. As noted earlier, in some duty-based accounts of the wrongness of killing, the consent of the one killed does not make the killing permissible. Nevertheless, given the centrality of the patient's consent in ethical accounts of the permissibility of forgoing life-sustaining treatment, some special argument is needed for why consent has no relevance for euthanasia. Moreover, if the argument in the earlier section on killing and allowing to die is correct—that some stopping of life support is justified killing—then euthanasia cannot be morally condemned simply because it is killing. Many duty-based moral accounts of the wrongness of killing either implicitly or explicitly depend on theological premises that give God sole dominion over life and death. However, in pluralistic societies that respect religious freedom, public policy should not be based on religious beliefs that many members of that society do not share. The rights-based account of the wrongness of killing, however, gives decisive weight to the consent and self-determination of the patient who seeks it.

The other general kind of argument against euthanasia is that although it may be morally permissible in some individual cases, it would nonetheless be bad public policy to permit voluntary, active euthanasia. This argument depends on an assessment of the likely good and bad consequences of permitting euthanasia, only a few of which can be noted here. Among the potential good consequences that proponents cite are: respecting the self-determination of those who request euthanasia but have not been able to get it; assuring the much larger number of people who believe it should be permitted so that should they request it, it would be available; ending the pain and suffering of dying patients that cannot be relieved by any other means; and providing for some patients a more humane and peaceful death than they would otherwise have.

Among the potential bad consequences opponents cite are: its apparent incompatibility with the aim of medicine of protecting life in all its frailty; the erosion of the trust of patients in their physicians as caregivers; the erosion of the social commitment to provide appropriate care to the dying if euthanasia, in an era of cost containment, is seen as an acceptable and cheaper alternative; and fear that permitting voluntary euthanasia would, over time, lead to involuntary euthanasia, or at least to nonvoluntary euthanasia of incompetent patients. Evaluating the likelihood and relative seriousness of these and other possible good and bad consequences of permitting either physician-assisted suicide or voluntary euthanasia is difficult and controversial. In 2003 in the United States, physician-assisted suicide is legal in the state of Oregon, and that state's accumulating experience with the practice is the basis for considerable debate (Sullivan, Hedberg, and Hopkins; Nuland). Whether either

practice should be permitted remains one of the most deeply controversial issues in medical ethics.

Conclusion

Since the 1960s, the capacity of medicine to prolong patients' lives has steadily increased, making the time and circumstances of a person's death increasingly a matter of human choice and control. The debates considered and the ethical framework for life-sustaining-treatment decisions sketched in this entry have been responses to this new control over how and when humans die. Perhaps the central feature and accomplishment of the great public and professional attention to death and dying in recent decades has been securing the rights of patients or their surrogates to decide about care near the end of life together with focusing the medical profession's attention on improving care at the end of life. However, the deeply personal, emotionally complex, and ethically controversial nature of decisions about care at the end of life ensures that they will continue to be a prominent part of bioethics.

II. HISTORICAL ASPECTS

The history sustaining and ending of human life in the West has three facets: a chronology of the meanings of euthanasia, the major cultural heritages that have influenced the beliefs and actions of physicians, and changing modes of medical practice. This entry explores this multifaceted history from its ancient Hebrew origins to the rise of the "right to die" and "death and dying" movements after the1960s.

The Meanings of Euthanasia

All the meanings of the term *euthanasia* can be related to the etymology of the Greek term *euthanatos*: *eu* meaning "good" and *thanatos* meaning "death." At the present time the word is used to denote a doctor's painlessly terminating the life of a suffering, terminally ill patient who wishes to die: physician produced or physician induced death (*Oxford English Dictionary*). Advocates for euthanasia often call it mercy killing.

The current meaning is actually the *second* way the term was used in Western history. The term's *first* and most long-standing use denoted a gentle and natural or noninduced death. The Roman historian Suetonius (c. 69–135 C.E.) described how Augustus Caesar was "blessed with an easy death" when he expired peacefully at age seventy-five: "For almost always on hearing that anyone had died swiftly and painlessly, [Augustus] prayed that he and his might have a like 'euthanasia'" [here *euthanatos* is inserted in the Latin text] (Suetonius, p. 281).

Francis Bacon (1561–1626) appears to have been the first scholar to maintain that the practice of medicine should include knowledge and skill that enable doctors to help patients to die easily and naturally. Bacon entitled this dimension of medicine *euthanasia exteriori* ("outward euthanasia") to distinguish it from "that euthanasia, or sweet calm dying, procured by a due preparation of the soul" in religious literature on consoling the dying (Bacon, pp. 124–125; Beaty). By saying that doctors should help patients "make a fair and easy passage out of life" Bacon meant that they should enable patients to die as Augustus Caesar had or like the aged Antoninus Pius, who died calmly "as though he were falling asleep" (Bacon; Bryant). This analysis of what Bacon proposed corrects the claim that he advocated doctor-induced death (Fletcher; Wilson; Emanuel).

For the next two centuries the term denoted physician-aided natural dying. The replacement of this meaning by the current understanding of euthanasia occurred between 1870 and the 1920s. A defense of doctor-induced peaceful death was made by Samuel D. Williams in 1870, after which heated debate ensued in Great Britain and the United States (Williams, 1872; Vanderpool, 1997). The fact that the debate has continued accounts for the current use of the term.

The meaning of euthanasia in its original sense continued into the 1920s, but its equation with mercy killing was so common by the turn of the century that some suggested that the original term should be replaced with the term *euphoria* ("Euphoria vs. Euthanasia"; Rosenberg and Aronstam). Later proponents of the duty of doctors to help patients die peacefully and naturally dropped such terminology in favor of phrases such as *caring for the dying* (Worcester; Alvarez).

Third, during the first four decades of the twentieth century the practice of extinguishing the lives of unwanted persons also was called euthanasia. Newspapers, films, books, physicians, professors such as Harvard's Charles Eliot Norton, clergy, scientists such as the Nobel laureate Alexis Carrel, and other eugenicists in the West called for euthanasia, that is, a painless extermination of various groups: "lunatics," "degenerates," "cripples," and others ("Dr. Norton on Euthanasia"; "The Right to Kill"; Pernick). That eugenics euthanasia movement played a complex role in Nazi ideology and the legitimization of Nazi genocide (Pernick).

Fourth, at times euthanasia was identified with the use of sedatives to "secure easy deaths" to the point of shortening life (South Carolina Medical Association, p. xvii). *Fifth,* the term occasionally was associated with what is now called assisted or physician-assisted suicide (Sperry, 1948), in part because some of the legislative bills sponsored by the Euthanasia Society of America were essentially assisted-suicide bills (Sperry, 1950).

Sixth, euthanasia became attached to the practice of withdrawing terminally ill persons from life-prolonging medical measures. After 1970 that practice commonly was termed *passive* or *indirect* euthanasia to distinguish it from *active* or *voluntary* euthanasia: doctor-produced death (Vanderpool, 1997). Although some authors disassociated the right to refuse life-sustaining measures from the term *euthanasia* (Pope Pius XII; Rynearson), the distinction between active and passive euthanasia made as early as 1884 ("Editorial: Permissive Euthanasia") had significant staying power.

An understanding of the major cultural heritages that informed and still inform the beliefs and actions of physicians sets the stage for the history of euthanasia and the sustaining of life in medical practice.

Hebraic and Jewish Perspectives

The Hebrew Scriptures proclaim an understanding of human life that has been immensely influential in Western history. Humans are created by God (Genesis 2:2–27), life and consciousness are gifts of God, and as Lord of life, God alone should determine when and how humans die (Job 1:21). As God's property, no individual has the right to destroy his or her life as if it were self-owned. It also is not lawful wantonly to take the life of another person (Exodus 20:13, Genesis 9:5–6).

On the basis of this legacy, Jewish tradition requires that when life is threatened by illness or injury, it must be sustained if possible. Because Jews were and are obligated to prolong their lives, they must not settle in communities where no physician is available. Obligations to save and extend life are drawn from Scripture: "You shall not stand idly by the blood of your neighbor" (Leviticus 19:16). Advanced medical interventions are urged for critically ill persons as long as it seems probable that those treatments will save or prolong life (Bleich). Rabbinic debate continues over situations in which life can be prolonged for a while, but at the expense of great pain and no hope for a real cure. Past and present, Jewish authorities have held that active pain relief can be undertaken at the risk of a patient's dying sooner (Jakobovits; Brody).

Doctors who induce death to spare patients from pain are considered murderers (Exodus 20:13, Carmi). Destroying those who are socially unwanted is absolutely prohibited. This includes neglecting or killing severely deformed newborns (Bleich).

Although it forbids mercy killing, Judaism defends the morality of letting fatally ill persons die naturally. The meaning of *honorable death* (*Mita Yafa*) in the Talmud centers on merciful dying, not mercy killing (Carmi). Each dying person should be comforted by relatives, friends, and physicians. Prayers for life to end are permissible. Once a patient is near death, treatments that interrupt dying should be discontinued (Bleich).

Greco-Roman Antiquity

By the fifth century B.C.E. Greek physicians and elite citizens were praising health as one of the greatest human goods. The goals of the physician's art were "to bring health in all cases of sickness [and] preservation of health to those who are well" (Hippocratic Corpus, "Regimen in Acute Diseases," p. 71). Greek physicians recognized the limitations of their art. Modestly conceived, their goals were "to do away with the sufferings of the sick, to lessen the violence of their diseases, and to refuse to treat those who are overmastered by their diseases" (Hippocratic Corpus, "The Art," p. 193). Physicians would abuse their art and ruin their reputations if they attempted to prolong the lives of the severely sick and injured. A terminally-ill patient's death would be blamed on the physician's lack of skill, so it behooved the physician to refuse even to try to treat at all. Galen (131–201 C.E.) and other Roman physicians adapted those values and goals to Roman life and its institutions.

Although the Greek heritage is unambiguous about the limits of life prolongation, it includes two traditions related to physician-aided death. Vastly influential in Western medicine, the Hippocratic Oath has physicians swear that they will not "give a deadly drug to anybody if asked for it" or even "make a suggestion" to that effect (Edelstein, p. 6). Debate continues over whether that oath reflects a Pythagorean origin or some other origin (Edelstein, Carrick, Anagnastopoulos). Insofar as it reflects opinions of the Pythagorean sect, it would oppose physician-assisted euthanasia in an almost Hebraic sense. With the gods as keepers and humans as their possessions, people sin against the gods if they seek to escape from their posts in life. Insofar as it is non-Pythagorean, the oath could reflect the philosophical logic of Plato (c. 427–348 B.C.E.) and Aristotle (384–322 B.C.E.): Because health is one of the greatest human goods and restoration of heath is the ultimate end of medicine, the termination of life is contrary to medical practice (Anagnastopoulos).

In contrast to the prohibition of physician-assisted death in the oath, Plato, Aristotle, and Stoic philosophers from Zeno (c. 336–264 B.C.E., Greece) to Seneca (4 B.C.E.–65 C.E., Rome) argued that incurably sick adults who consume vital resources of the city—the polis—should die from neglect or be put to death involuntarily (Carrick; Anagnastopoulos). Similarly, deformed and sickly infants should be exposed or drowned for the good of the community, the highest and greatest human end according to Plato and Aristotle. Exposure included taking newborns to rock caverns or casting them into the sea. By law in Sparta and Rome newborns were examined by nonparents for anatomic flawlessness and vigor to determine which ones should be exposed (Amundsen, 1987).

Seneca praised the ability of humans to choose when to end their lives. People should quit life nobly rather than await the cruel endings "either of disease or of man" (Seneca, quoted in Carrick, p. 145). Certain elite citizens, virgins, married women, slaves, common persons, and soldiers ended their lives when they were faced with humiliation, a fearful future, illness, or old age (Van Hooff).

Opposed to suicide in those instances, Aristotle held that death is "the most terrible of all things" (quoted in

Carrick, p. 51). Suicide also conflicted with Aristotle's theory of human virtue: the nobility of facing death bravely versus the cowardly quitting of life when one is faced with misfortune.

Christianity

Christianity emerged from Judaism and flourished in the Roman world. The early churches regarded Hebrew Scripture as the authoritative word of God even as they reinterpreted it as forecasting the life, death, and resurrection of Jesus. Christians thus inherited Hebraic and Jewish teachings about life and death.

EARLY CHRISTIANITY. Christians regarded God as the creator and sustainer of human life and opposed suicide in response to suffering or despair. Contrary to the myth that Christians were inclined to commit suicide to escape from life and be with God, Christ, and their departed loved ones, early Christians ardently opposed self-induced death (Amundsen, 1998).

With Jesus as their model, Christians added new themes to Jewish opposition to suicide and mercy killing. They accented the redemptive dimensions of suffering (2 Corinthians 12:7–10, Hebrews 12:5–11). Faced with pain and death, they too should exclaim, "Not my will, but thine be done" (Luke 22:42). Beginning with the early church (James. 5:10), Christians praised Job, who endured grave suffering steadfastly. Patience and steadfastness were valued all the more because of frequent persecutions (1 Peter 4:12–5:1).

Based on Jesus's teaching that all humans are the children of a loving Father (Luke 15), Christians also displayed mercy and offered care for sick, infirm, and dying persons (Luke 4:16–21, 6:36, 8:26–56, 10:29–37). Believing that no human group should be despised or considered unworthy of life, they condemned cruel executions, abortion, infanticide, and suicide by the second century (Amundsen, 1987).

AUGUSTINE. Augustine (354–430 C.E.) developed systematic criticisms of suicide. Like Aristotle, he argued that self-inflicted death was cowardly. He also viewed it as contrary to the Sixth Commandment, "Thou shall not kill." He regarded suicide as a mortal sin because it excluded the possibility of repentance (Amundsen, 1989). With the establishment of Christianity as the official religion of the Roman Empire after 325, self-killing was equated with homicide. In central and northern Europe the properties of suicides were confiscated, their corpses were desecrated, and they were excluded from Christian burial grounds.

THOMAS AQUINAS AND MODERN ROMAN CATHOLICISM. Thomas Aquinas (1225–1274) expanded on Augustine's arguments against suicide in ways that have shaped Catholic perspectives to the present time. Suicide and by extension induced euthanasia for sufferers were and are viewed as contrary to Christian tradition, natural law, the well-being of society, Christian compassion, and, most important, the dominion of God over human life (O'Malley; Sacred Congregation for the Doctrine of the Faith).

Through the centuries Catholics condemned physician-induced euthanasia as well as ending the lives of mentally or physically handicapped persons. At the same time, decades before the right to die movement began, Catholic authorities distinguished between "ordinary" and "extraordinary" medical treatments and argued that incurably ill persons in most circumstances had the right to refuse advanced medical interventions (Kelley; Pope Pius XII).

PROTESTANTISM. On issues involving life and death the Protestant reformers of the sixteenth century differed little from their early Christian and Roman Catholic predecessors. By the seventeenth century, however, certain Lutheran and Calvinist theologians were arguing that some self-inflicted deaths stemmed from mental imbalance. Holding that traditional arguments that cosigned the souls of suicides to eternal damnation were subject to human hubris, they also argued that the soul's eternal destiny was for God alone to decide (Ferngren). Directly countering the inclusive condemnation of Catholic heritage, the English poet and Anglican prelate John Donne (1572–1631) reasoned that some suicides did not violate natural law, human reason, Scripture, or the dominion of God over human life.

The lack of unanimity within seventeenth-century Protestantism increased in the ensuing centuries (Numbers and Amundsen 1998 [1986]). In the 1930s and afterward Anglican, Episcopalian, and Unitarian clergy played active roles in euthanasia societies in Great Britain and the United States. Beginning in the 1950s, a Protestant Episcopalian priest, Joseph Fletcher, became the most influential advocate of mercy killing in the United States (Fletcher;Vanderpool, 1997). Fletcher opposed the declaration against legalized mercy killing by his own denomination in 1952, by the Presbyterian General Assembly in 1951, and by the assertion of Willard L. Sperry, dean of the Harvard Divinity School, that legalized euthanasia cuts "against the whole basis and practice of medicine" (Sperry, 1948, p. 988).

Nevertheless, Jews, Catholics, and Protestants remained united about the virtue of helping persons die peacefully and naturally not by inducing death but by alleviating suffering and isolation through attentive care. The literature on

consoling the dying that first flourished in Catholicism in the fifteenth century was adopted readily by Calvinists (Reformed Protestants) and Anglicans and transformed by Methodists and those in other denominations (Beaty; Vanderpool, 1998 [1986]). Francis Bacon rightly forecast how this literature harmonized with medical euthanasia in its original sense: special care of the dying.

The Law

Continental and Anglo-American law during the centuries following the advent of Christianity included a mixture of Roman law, the customs of various ethnic groups and communities, and canon laws developed and systematized by Roman Catholic jurists. Having inherited the Hebraic-Jewish conviction that God is the ultimate law-giver and judge and holding to the view that universal truths can be rationally discerned from the laws of nature, Catholic canonists sought systematically to adapt Roman law to Christian teaching (Plucknett). The cohesiveness, power, and geographical expansion of the Church enabled canon law to exert a profound influence on national laws, including the tradition of common law in England and its colonies.

Canon law was first adopted in England at the Council of Hereford in 673 C.E. Rooted in centuries of custom, canon law influenced the development of the common law from the time of the reforms of William the Conqueror (1027–1087 C.E.), to the vastly influential interpretations of the common law by Sir Edward Coke (1552–1654), to the present time (Plucknett; Williams, 1957). The canon laws adopted at the Council of Hereford included prohibition of suicide (*Washington et al. v. Glucksberg et al.*).

Savage penalties for suicide—bodily desecration, property forfeiture, and exclusion from Christian burial grounds—were set forth in common law by the thirteenth century and were rigorously enforced between 1500 and 1700. Coke wrote in 1644 that suicide is a category of murder and the property of suicides should be forfeited. In the middle of the sixteenth century, the Court at Common Bench—one of the pivotal councils of English sovereigns that developed and defined the common law—observed, as if it were taking a page from Thomas Aquinas, that suicide "is an Offence against Nature, against God, and against the King … To destroy one's self is contrary to Nature, and a Thing most horrible" (quoted in *Washington et al. v. Glucksberg et al.*)

Penalties against suicide were removed in England in 1823, followed by abolishment of suicide as a crime in 1961 (Markson). Beginning with Pennsylvania in 1701, the harsh common law penalties enacted in several American colonies were also abolished (*Washington et al. v. Glucksberg et al.*).

Nevertheless, laws in England, the majority of American states, and most western democracies associated assisted suicide with homicide and with suicide as a grievous wrong (MacDonald; Markson; *Washington et al v. Glucksberg et al.*). Considered a criminal offense ranging from second degree murder to manslaughter, laws against assisted suicide never contained exceptions for those who helped to end the lives of persons who were terminally ill, fatally wounded, or condemned to death (*Washington et al v. Glucksberg et al.*). American statutes that explicitly outlawed assisted suicide were first enacted in New York in 1828, then most other American jurisdictions. The Model Penal Code of the twentieth century, including its official 1980 draft, opposes anyone's "willingness to participate in taking the life of another, even though the act may be accomplished with the consent, or at the request, of the suicide victim" (quoted from *Washington et al v. Glucksberg et al.*).

Criminalization of assisted suicide was and is based on States' interests to protect and preserve human life, prevent suicides by persons who are young, elderly, or suffering from mental disorders, and protect the ethical integrity and healing roles of the medical profession (*Washington et al v. Glucksberg et al.*; Kamisar). The relatively high incidences of acquittals, suspended sentences, and reprieves of citizen- and doctor-induced euthanasia proves that, "The Law in Action is as malleable as the Law On the Books is [in almost every State] uncompromising" (Kamisar, p. 408).

Secular Legacies

As minority opinions in the dominant Christian culture, various humanists from the sixteenth through the eighteenth centuries spoke of the permissibility of suicide for seriously sick and injured persons. Enamored with Greco-Roman culture, Michel de Montaigne (1533–1592) voiced the unorthodox views that the "most voluntary death is the finest" and that "God gives us permission" to take our lives "when he reduces us to such a condition that living is worse than dying" (Montaigne, 1946 [1580], p. 338).

Skepticism, secular interests, and an emphasis on personal pleasure became more pervasive during the seventeenth and eighteenth centuries. English playwrights such as John Dryden (1631–1700) and Deists such as Charles Blount (1654–1693) defended certain suicides motivated by honor, suffering, lost love, or self-willed destiny (Ferngren). These themes informed the thought of one of the Enlightenment's most influential representatives, David Hume (1711–1776).

HUME. Hume began his essay "On Suicide" (1963 [1783]) with an attack on "superstition and false religion," which

compel a person to prolong "a miserable existence … lest he offend his Maker" (pp. 252–253). He held that overwhelming suffering and wishes to die should be regarded as calling persons from life "in the clearest and most express terms" (p. 259). Like Socrates and Plato, Hume argued that persons plagued with suffering that negates social usefulness are not obligated to prolong their lives. He also held that each person's "native liberty" consists of carrying out an autonomous course of action in keeping with one's "chance for happiness" (p. 261).

Hume's critics included Immanuel Kant (1724–1824), who censured self-killing because it cannot be willed as a universal action without undermining the possibility of morality, that is, the existence of rational beings. Kant also viewed suicide as a violation of one's duty to God, the sovereign of all life. Unlike Kant, nineteenth-century thinkers such as Friedrich Nietzsche (1844–1900) adopted Hume's view that autonomous persons have the right to end their lives when disease extinguishes pleasure and social usefulness.

DARWINISM. Charles Darwin's (1809–1892) theory of evolution played a pivotal role in reshaping Western religion, science, literature, and political philosophy and policy (Vanderpool, 1973). The secular understanding of the world advanced by Darwin and Darwinians directly affected views of euthanasia. The Darwinian theme that human progress depends on the survival of the fittest through natural selection engendered a Westernwide eugenics movement that promoted active interventions to rid the world of the "unfit" (Vanderpool, 1973; Pernick). Other Darwinians argued that euthanasia in the form of doctor-induced painless death was permissible because "nature certainly knows nothing" of the sacredness of life ("Euthanasia," p. 91) and "the doctrine of evolution" justifies shortening the lives of sufferers in the face of outmoded religious opposition (South Carolina Medical Association, p. xv).

EXPERIMENTAL MEDICAL SCIENCE. Well before the Darwinian revolution physician scientists performed extensive laboratory experiments on the physiology of death and resuscitation from which they developed a mechanistic understanding of life and death. After describing his experiments on "the laws of the vital functions," the British doctor A. P. W. Philip concluded that human life is not "a subject of peculiar mystery" (p. 211).

That mechanistic understanding led to the dominant twentieth-century view that the human body is a physical-chemical and mechanical entity that can and should be salvaged with sufficient repair. Ivan Pavlov's (1849–1936) vivisection experiments with dogs proved how severe and sequential injuries could be repaired one after the other to the point where a dog's death could be seen to represent a failure in technical mastery. This was the backdrop to ever greater attempts to sustain human life and to the neglect of care for dying patients after 1945.

Modes of Medical Practice to 1870

In keeping with the cultural heritages of Judaism, Christianity, and experimental medical science, physicians from the seventeenth century to 1870 focused on mitigating the effects of disease and the ultimate goals of saving and sustaining human life. In the eighteenth century the goal of saving life engendered a Western-wide movement to establish humane societies to rescue persons who appeared to be dead from drowning and other causes. Imbued with a sense of progress, physicians, human society members, and others discovered many means by which life could be restored and extended: manual breathing methods, ammonia, strychnine, bloodletting, tongue stretching, and electric shocks (Liss).

Nevertheless, in keeping with the admonition of Francis Bacon in the seventeenth century, a number of notable physicians lectured and wrote about the duty "to soothe the last moments of existence" (Ferriar, p. 392). Addressing his German faculty of medicine colleagues, Carl F. H. Marx termed the physician's "skilful alleviation of suffering" as "that science, called euthanasia, which checks oppressing features of illness, relieves pain, and renders the … inescapable hour a most peaceful one" (p. 405). Marx and others stressed shared themes: the painlessness of dying versus myths about "death agonies," the necessity of not disturbing dying patients, the comforting presence of physicians, expertise in symptom relief, the skilled use of opiates, the immorality of purposefully shortening life, and steadfast opposition to "dangerous and dubious treatment measures" to prolong life (p. 407).

These advocates of euthanasia in its original sense of helping patients to die naturally and peacefully appealed to moral, philosophical, and spiritual values: how close attention to the process of dying causes "the physical process of death [to lose] much of its horror" for patients and physicians alike (Ferriar, p. 392), the virtue of alleviating "the supreme anguish of the patient's mind" (Marx, p. 411), the humanity of caring for "a powerless and suffering creature" when "the scene of life is closing" (Dendy, p. 121), and the assurance that humane and steadfast care "will ever prove consolation to the hearts of attached friends" (Dendy, p. 124). Predicated on these values, end-of-life care was deemed

"not unworthy of the attention of the most scientific physician" (Dendy, p. 124).

All these physicians strongly opposed futile life-prolonging measures utilized by inexperienced and uninformed practitioners. Physicians ought to be able to know "when any hope [of cure] has departed" (Marx, p. 405) and they should honor the moral principle of refraining from harm. John Ferriar criticized "ignorant practitioners" who "torment" dying patients with "liquors of different kinds" (pp. 393, 397). W. C. Dendy spoke of the cruelty of using stimulants such as brandy or ammonia "when hope is gone" (p. 122). Marx decried the use of caustics, "external irritants," "and other tortures" (p. 409).

In the first half of the nineteenth century when educated physicians were closing ranks against poorly trained and unorthodox practitioners, this tradition of terminal care was set forth as a profession. Thomas Percival's (1740–1804) widely published code of medical ethics shaped the codes of several U.S. medical societies and became the primary moral foundation for membership in the new American Medical Association (AMA). The AMA's Code of Ethics was unanimously adopted in 1847, and its sections on the care for dying patients were lifted verbatim from Percival's Medical Ethics. When doctors find that they cannot "revive expiring life," they should "soothe the bed of death" and not "abandon a patient because the case is deemed incurable, for [their] attendance may continue to be highly useful … by alleviating pain … and by soothing mental anguish" (Code of Medical Ethics of the American Medical Association p. 221).

Medical Practice and Turmoil: 1870–1945

SUSTAINING LIFE AND CARING FOR THE DYING. The ability to cure diseases and repair injuries increased exponentially between 1870 and 1945. The sophisticated advances in surgery and curative medicine during this time were symbiotic with the creation and explosive growth of modern hospitals. Increasing from 200 in 1873 to 4,438 in 1928, these hospitals were monuments to scientific medicine. They became and remain the central places in which an ever increasing number of medical specialists treate countless patients from all walks of life. Within these hospitals, new techniques for resuscitation and life prolongation were readily developed and adopted: "the struggle to reactivate the whole organism" with blistering benzine compresses (Jellinek, p. 216), injections of epinephrine via long hypodermic needles directly into the failing heart in the 1900s, open-chest message during cardiac surgery in the 1930s, and positive- and negative-pressure ventilation apparatuses and masks in the 1930s (Liss; Hermreck).

The resulting institutionalization of curative medicine and life-sustaining techniques detracted from care for dying patients. The increasing lack of concern is mirrored in revisions of the AMA Code of Ethics. The two paragraphs on care for the dying in the 1847 code were reduced to four lines in 1903, then to this part of a sentence in 1912: "a physician should not abandon or neglect the patient because the disease is deemed incurable" (Vanderpool, 1997, p. 40).

Only a few increasingly isolated physicians continued to explore and write about "the medical art" of "euthanasia" as "aid of an easy, gentle, and placid death" (Munk, pp. 4–5). By the late 1920s doctors were beginning to leave dying patients in care of nurses, clergy and sorrowing relatives. Alfred Worcester considered "this shifting of responsibility" to be "unpardonable" (p. 33). Worcester also lamented the lack of teaching about terminal care in medical schools and decried the increasing use of "modern methods of resuscitation" such as cardiac stimulation for dying patients. Worcester exclaimed that his peers "ought to know better" (p. 47). Beyond his criticisms, Worcester published a lengthy book chapter that outlined what medical students should be taught about care of the dying. Years later Walter C. Alvarez praised Worcester's "excellent little book" as one "every physician in the land should read and re-read" (Alvarez, p. 87).

DOCTOR-INDUCED DEATH FOR THE DESPERATELY ILL. Many factors contributed to the post-1870 turmoil over the morality of doctors' inducing the deaths of suffering and incurable patients. Several of these preceded the development of modern hospitals by a few decades, but included factors—such as the discovery of anesthesia—that made modern surgery in these hospitals possible. The factors underlying the debate included the resurgence of secular challenges to traditional Jewish and Christian understandings of human life and death in the second half of the nineteenth century, the discovery and refinements of anesthesia after 1846, the development the hypodermic syringe (introduced in the United States in 1856) by which morphine could be injected by physicians with quick and powerful results, paternalistic physician supervision of patients with dread disease in modern hospitals, and the public's increasing reliance on physicians to relieve their aches and pains (Vanderpool, 1997, p. 37).

Turmoil over the painlessly putting to death of incurable sufferers began after the speech by Samuel D. Williams before the Birmingham Speculative Club in 1870 was

turned into a pamphlet and seized upon as newsworthy. Williams defended the proposition that in "all cases of hopeless and painful illness it should be the recognized duty of the medical attendant, whenever desired by the patient to administer chloroform … or … other anesthetic … so as to destroy consciousness at once, and put the sufferer at once to a quick and painless death" ("Euthanasia," p. 90).

Williams's speech became newsworthy for several reasons. It directly challenged doctors who regularly used chloroform and hypodermic morphine and were responsible for dealing with catastrophic illness and determining when patients' conditions were incurable. It challenged lawyers because Williams's proposition was illegal. It alarmed the clergy because of the clergy's historical opposition to induced death. It engaged the American public because opiates were unregulated before 1920 and because dying persons often were cared for at home.

Through the years journals and newspapers perpetuated the debate and reported about euthanasia societies, attempts to legalize euthanasia, and individuals who admitted to ending the lives of desperately sick persons or were brought to trial for doing so ("Euthanasia"; Rosenberg and Aronstam; "Shakers Justify Killing Sister"; "Physician Admits to 'Mercy' Killings"). The arguments set forth in the early years of the debate became fixtures in the years to come (Vanderpool, 1997).

Proponents argued that euthanasia is merciful and that refusal to perform it is cruel. Doctors have the duty to alleviate pain as well as prolong life. Life racked with pain is hardly sacred, and evolution undermines the value of individual life ("Euthanasia"). The fact that some physicians were already practicing it surreptitiously attests to its moral acceptability. People deserve "at least as much kindness and sympathy" as animals that readily are put out of their misery (Wolbarst, p. 354).

Medical societies and most physicians found "insuperable objections" to the practice (Victor Robinson, 1913, p. 145). Intentionally ending the lives of suffering patients repeatedly was declared to be antithetical to the traditions of medicine. That "ghastly" practice would undermine the physician's premier goal of saving life and turn doctors into executioners ("The Moral Side of Euthanasia"). Euthanasia was a crime, and legalized euthanasia would be abused by devious physicians and nonphysicians. It would display cruelty to dying patients who would question their worth and fear for their lives rather than receive the care they deserved. It would devalue suffering, cheapen life, and undermine the dominion of God. Between 1906 and 1969 opponents of physician-caused death in Great Britain and the United States united to defeat the many attempts to legalize euthanasia.

KILLING UNWANTED HUMAN BEINGS. Advocacy to end the lives of unwanted human beings—euthanasia in the *third* sense—emerged in Europe and the United States toward the end of the nineteenth century. Those who promoted euthanasia for "defectives" often claimed that civilized sentimentality "nullified nature's methods of eliminating the unfit" ("Foreign Letters," p. 1617). Others spoke of the "benevolent extermination of degenerates," (Smith, p. 50) the "inhumanity" of not relieving a "gibbering driveling idiot" from his or her misery (William Robinson, p. 88), and the need to "liberate" retarded and insane persons from "tortured mentalities" (Wolbarst, 1935, p. 332). Those despised groups were thought to be interfering with the progressive evolution of the human race (Smith).

Devotees of eugenic euthanasia differed over which groups should be eliminated and how their lives should be ended: denying treatment to newborn "monstrosities" and/or actively ending the lives of insane persons and/or others. After Dr. J. J. Haiselden created a storm of controversy between 1915 and 1919 over his refusal to save the lives of several severely defective newborns and young children, eugenic euthanasia rhetoric continued, but its practice remained hidden and rare in the United States (Pernick).

In Germany proposals for exterminating unwanted persons became political policy. In 1868 Ernst Haeckel (1834–1919), a disciple of Darwin, argued that Germany's physical and mental incurables should be put to death painlessly. Haeckel praised the Spartans for killing their deformed and weak children, in contrast to the "antiselection" of Christian compassion for the infirm and sickly (Lifton).

Germany was considered the new polis. Each doctor should become a "physician to the Volk" for the "perfection of the health" of the people (Lifton, p. 30). The "biological body of the German people" should be invigorated through programs of physical fitness and the science of "race hygiene" (Ernst, p. 574). Preceded by the recommendation of a child-welfare pioneer Sigmund Engle that "cripples, high-grade cretins, idiots, and children with gross deformities" should be destroyed painlessly (quoted in Pernick, p. 23), a jurist Karl Binding and academic psychiatrist Alfred Hoche called for the elimination of mentally ill and retarded persons in their influencial book titled *Release and Destruction of Lives Not Worth Living,* 1920.

Eugenic beliefs infused the thinking of mainstream physicians, academicians, and scientists in Germany well before their adoption by Adolf Hitler (1889–1945) as National Socialist (Nazi) policy (Shevell). Physicians played

a critical role in creating the concept of racial hygiene, supporting the Nazi rise to power, and administering sterilization and extermination programs (Ernst; White).

Shortly before Germany's invasion of Poland in September 1939 Hitler directed that children with severe mongolism, hydrocephaly, paralysis, and deformities be registered. In thirty pediatric departments across Germany doctors supervised the registering, sorting out, and killing of 5,000 children (Lauter and Meyer). Within months Hitler issued a decree that mentally incurable adolescents and adults should "be granted a mercy death." That decree created an agency that orchestrated physician-directed killing of over 70,000 persons in gas chambers disguised as showers (Shevell).

When they were stereotyped as destructive to the health of the body politic, Jews, Gypsies, and others were consigned to a massive, bureaucratic doctor-run extermination program that was modeled on its medical predecessors. Those programs lasted only six years, but their horror is unforgettable. After World War II the World Medical Association (WMA) and several national medical associations condemned the Nazi extermination programs.

Medical Practice and Debate: 1945–1960s

MERCY KILLING. The revulsion against Nazi practices did not curtail campaigns to legalize mercy killing (Vanderpool, 1997). At the end of the war a new campaign to legalize euthanasia backed by 1,776 physicians and 54 eminent clergypersons began in New York, and from 1945 through 1969 petitions were signed and legislative attempts were made in the United States and Great Britain (Wilson). In spite of those efforts and the passionate defense of euthanasia by Joseph Fletcher, bills to legalize mercy killing were not introduced for a vote or were voted down. At its meeting in 1950 the World Medical Association resolved that national medical associations should "condemn the practice of euthanasia in any circumstances" ("Official Notes").

THE PREEMINENCE OF PROLONGATION. Effective and sophisticated ways to save life were developed during and after World War II, including penicillin and other antibiotics and methods to overcome cardiac arrests through the use of open-chest heart massage in the 1950s and closed chest defibrillators in the 1960s. The reversal of cardiac arrest was called "the restoration of life after death" in the media (Bains, p. 1346). The use of nasogastric feeding tubes and blood transfusions became widespread, and mechanical ventilators as a "complete substitution of the spontaneous ventilation of the patient" were refined (Petty, p. 2).

Along with these technological advancements, the physician's duty to sustain life achieved a preeminent status in hospitals from the 1940s through the 1960s. Lest they betray their training, many doctors felt that they should do everything possible to sustain life rather than "just let the patient die" (Glaser and Strauss, p. 196). Even in the face of dire prognoses heroic treatments often were continued until a patient's organ systems deteriorated, extensive pain was experienced, the patient's family reached "an advanced stage of grieving," or a doctor's colleagues intervened (Glaser and Strauss, p. 199).

Graphic accounts of attempts to prolong life became news in the 1950s. No story was more influential than that of a widow's anguish over her husband's treatment in a metropolitan hospital in 1957. "If you are very ill," the widow said, "modern medicine can save you. If you are going to die it can prevent you from so doing for a very long time." She lamented the use of "all the latest wonder drugs, the tricks and artificial wizardry" that "deprived death of its dignity." Upon begging a doctor to "cease this torture," she was told that "they had to maintain life" ("A Way of Dying," pp. 53–54). The reasons for the priority of prolongation included the equation of medical practice with mastery of the new technologies, death as the ultimate evil, the equation of death with defeat and medical failure, and lost concern with care for the dying. "Who causes these extraordinary measures to be continued indefinitely?" one doctor asked. "In most cases, it is the physician himself" (Rynearson, p. 86).

CARE FOR THE DYING. The few physicians who perpetuated the tradition of natural dying displayed despair. Describing how he was "bringing comfort to the slowly dying" in their homes, Walter C. Alvarez wrote that dying persons "should never be cast off and neglected simply because they cannot be 'cured'" (pp. 89–90). Alvarez observed that "rarely does anyone ever discuss the subject in medical schools, at medical meetings, or in the journals." Like his predecessors, he decried the abuses of prolongation:

> When I myself lie dying, I hope that I will have by me some wise and kindly physician who will keep interns from … puncturing my veins, or putting a tube down my nose, or giving me enemas and drastic medicines (p. 91).

Depicting his medical training between 1957 and 1960, Roger Bulger described how students were taught "the intricacies of every method or technique that might possibly bring someone back from *extremis* but no one has ever suggested that we ought to attempt to care" for the person beneath "the multiplicity of tubes that are entering him from

every direction" (Bulger, pp. 23–24). In hospitals doctors probe and test, nurses are indifferent, and the dying "'crock' is a second class citizen" (Kohn, p. 1180).

SHORTENING LIFE AND ASSISTING IN SUICIDE. In the context of the preeminence of prolongation, instances of euthanasia in the *fourth* sense—painless death to the point of shortening life—were designated "invisible acts" by hospital personnel in the late 1950s (Glaser and Strauss, p. 198). At times, however, a patient's right to receive pain relief at the cost of abbreviating life was advocated openly (Fletcher; Ayd).

Euthanasia in the *fifth* sense—assisting patients to end their lives—was practiced even more surreptitiously. Suffering patients who begged to die at times were relegated to a "dying room" where overdoses of pills were left at the bedside and patients were unwatched for long periods so that they could "manage" their own deaths (Glaser and Strauss). Stories of doctors giving overdoses of opiates for patients to take at home were told to clergypersons and known by physicians (Sperry, 1948). The extent of the practice of shortening life and assisting suicide in medical practice remains unknown.

TWO IMPENDING REFORMS. Descriptions of dreadful and often futile attempts to prolong life increased in medical and popular journals in the 1950s and 1960s. Those descriptions identified two problems: how to curtail life-prolonging attempts so that patients could die naturally (passive euthanasia) and how to care for sick persons and aged individuals at the end of life.

Father Gerald Kelly wrote a sophisticated analysis of the first problem in 1950, and a way to resolve it was announced by Pope Pius XII seven years later: "The doctor … has no separate or independent right where the patient is concerned … he can take action only if the patient … gives him permission" (p. 285). Despite opposition, several physicians, including non-Catholics, citing the widow's story and the pronouncement of the Pope, agreed that "the decision concerning further treatment should be in terms of the patient's own interests" (Rynearson, p. 86). In their articles those doctors occasionally outlined "components of the care of the dying patient": death with "dignity, respect and humanity," minimal pain, and familiar surroundings that promote sharing with family and friends (Rynearson, p. 87).

In 1966 Charles Hofling observed that the problem of determining when to terminate life by withholding various medical interventions had "thus far received little thoughtful, and very little authoritative, attention" from his fellow practitioners. In fact, "the typical approach has been to arrive at a course of action with a minimum of discussion." Convinced that this approach "will force the whole matter on the public's attention," he called for "multidisciplinary consultations" on the part of physicians, lawyers, clergy, sociologists, and "quite possibly" philosophers (pp. 43–46).

Those authors were the prophets of two impending reforms: the "right to die" movement and the "death and dying" movement.

Conclusions

An untutored glance at the title of this entry could give the impression that it would be far more conceptually balanced—though less provocative—if it were entitled "Ending and Sustaining Life, Historical Aspects." In fact, due to the multiple meanings of euthanasia in medical history, this entry does balance the many ways doctors have dealt with ending human life on the one hand and sustaining and extending life on the other.

This history is filled with an intriguing combination of continuities and tensions. The continuities surface in the first cultural legacy explored in this entry—Hebraic and Jewish perspectives. Its major motifs forecast enduring themes for the ensuing three thousand years: a commitment to saving and extending life whenever possible, a mandate to display concern and care for dying persons, and, based on the sacredness and ultimate value of human life, an opposition to mercy killing of incurably sick persons, disabled children and others.

Christianity inherited these motifs from Judaism and embedded them within Western culture to the extent that they became moral givens. The cultural transformation that occurred over the centuries included the way canon law infused common law and the way those motifs shaped codes of conduct, common commitments, and the increasing power of the medical profession.

Historical tensions were both exterior to and inherent within these continuities. Exterior to them, Nazi programs of extinguishing unwanted and despised persons appealed to Greco-Roman precedent, but due to the depth of Western cultural transformation that had occurred, became equated with unspeakable moral deviance. The Nazi programs secured the loyalty of a number of German physicians enamored by Aryan supremacy and eugenic-based notions of evolutionary progress. These programs were condemned as betrayals of professional ethics that continued to uphold the moral mandates transmitted to Western culture through Judaism and Christianity. Euthanasia in its current meaning—a doctor's terminating the life of a terminally ill patient—began and remained contentious because it drew upon

factors that were both inherent within and external to the reigning motifs of Western medicine. Advocates of mercy killing appealed to the themes of mercy for sufferers of fatal illnesses and the cruelty of not relieving persons from pain. At the same time, against the strictures of common law and in the name of naturalistic evolution and/or secular notions of self-ownership and autonomy, these advocates countenanced circumscribed forms of homicide and assisted suicide.

Within the historic continuities, tensions developed between the primacy of prolonging human life and humanitarian care for the bodily, emotional, and spiritual needs of persons who could not be cured. By the eighteenth century physicians devoted to this humanitarian ideal began opposing the sustaining of life by every available means for persons at the end of life. The last decades of history covered by this essay end when experimental science provided means by which to extend life in hitherto fore unimagined ways. Devoted to the prolongation of life, scientific medicine became entrenched in modern hospitals and the preoccupation of medical training.

The agonizing stories of patients, the troubled concerns voiced by a handful of physicians, and the voices of historical continuity from the Pope and physicians with similar concerns declared that modern medicine was losing its moral moorings. The seeds for the impending reforms regarding the rights to refuse advanced life-prolonging treatment and to receive attentive humane end-of-life care were sown in the late 1950s and 1960s. Their germinating power lay in the fact that they were gleaned from dominant cultural motifs that had shaped the practice of medicine through centuries of Western history.

LITERATURE AND HEALTHCARE

• • •

If dialogue—sophisticated, passionate, often angry dialogue—is the mark of a lively field of inquiry, then the study of creative literature is thriving. Central to the dialogue has been the question of the relation, if any, of literature to the world outside itself—that is, to the so-called real world of culture, politics, and ethics. Some of the most influential philosophers of literature (e.g., Derrida; see also Belsey) have been warning readers that they can no longer go to the classics of literature to mine gold nuggets of knowledge about life. Ironically, all this has been happening at the same time that certain prominent ethicists have been rediscovering the moral value of literature while speaking of "virtue" (MacIntyre) and—most prominently—"narrative ethics" (Hauerwas and Burrell; Nelson, 1997; Chambers; Charon and Montello). Have literature and ethics passed each other in the night? This much is clear: Before anyone can speak responsibly of the relationship of bioethics to literature, it is necessary to understand the general terms of the literary professionals' fight about meaning.

Theoretical Contexts

Of course, the agitation is far more complicated than it will appear here in a nontechnical summary. But the commentators can fairly be divided into two loose groups called values-oriented and language-oriented theorists. This distinction is related to the ethics/aesthetics, art for life's sake/art for art's sake, and content/form divisions of the past in that the first term of each pair (values, ethics, life, content) encourages the use of literature as a tool for living a good life, and the second term (language, aesthetics, art, form) points to a view of literature as an important end in itself. But today's values/language debate, particularly the language side, is by no means strictly congruent with past positions. Values-oriented people can be taken to include those who believe that the relationship between literature and ethics can be richly productive of change in individuals and society; the language-oriented group includes those who believe that, given contemporary understandings of language, such a relationship is

an illusion. Thus far, the language theorists have prevailed—if not in the classroom, then certainly in the scholarly conferences and journals as well as in the commercial reviews.

VALUES-ORIENTED THEORIES. The values side has nevertheless been accorded intelligent attention, too, and their side is showing strong signs of renewal (Booth, 2001). Using various technical terms for values in literature (e.g., *classic realism, hermeneutics, ethical criticism,* and *moral imagination*), literary commentators have: (1) suggested that, in the words of Mark Twain, the reports of their death have been greatly exaggerated and would, in any case, be disastrous for both literature and society (Graff); and (2) proclaimed that moralists may very well have died but should be resurrected and readmitted, within certain limits, to the practice of criticism (Booth, 1988). Influential endorsement for the values-oriented position has also come from outside literature. Most notably, the philosopher Martha C. Nussbaum has insisted in a string of influential books that literary narratives of ideas and emotions constitute an essentially—and, for her, sometimes the solely—adequate depiction of ethical dilemmas. Another philosopher, Geoffrey Galt Harpham, agrees. And psychiatrist Robert Coles has championed the traditional view of literature as balm for the human spirit.

The complete history of values-oriented critics must make space for the two towering figures who, in the first half of the twentieth century, took up the mantle of the English poet and critic Matthew Arnold (1822–1888) to proclaim that a commitment to individual and social morality was the mark of supreme writers. In 1967 F. R. Leavis wrote in *The Great Tradition* that the finest novelists "are all distinguished by a vital capacity for experience, a kind of reverent openness before life, and a marked moral intensity" (p. 9). And Lionel Trilling, whose influence in the United States was once as widespread as Leavis's in England, said in *The Liberal Imagination:* "For our time the most effective agent of the moral imagination has been the novel of the last two hundred years" (p. 209).

Today, the two men are ignored or reviled by many of the most famous critics of literature. To some of them, Leavis's and Trilling's classics-minded disciples share part of the blame for enthroning the traditional academic canon—largely produced, in the now infamous phrase, by "dead, white, male writers"—as opposed to a more flexible list that is open to writers of both sexes and those of multicultural origins. The followers of Leavis and Trilling are among those who have been tagged as "liberals" and "humanists" by self-proclaimed "radicals" of the Marxist, African-American, and feminist schools of literary criticism. But, if examined closely from the perspective of this entry, these arguments are all in the family—the family of literary critics whose guidelines promote discussions of values. So are the arguments of the so-called reader-response critics, such as Wolfgang Iser, who locate the meaning of literature in the interaction between the text and the reader, and, probably, even the "formalists" of various stripes (e.g., Mikhail Bakhtin), who emphasize form over—and occasionally at the expense of—content.

LANGUAGE-ORIENTED THEORIES. The true opposition to the values-oriented approach comes from the theorists who, under several different banners (most often "semiotics," "deconstruction," and, according to some definitions, "postmodernism"), deny that literary texts have an objective relationship to the world outside themselves. The founding father of these language-oriented thinkers is often said to be Ferdinand de Saussure, whose revolutionary book, *Course in General Linguistics,* was published in 1916 and is still being analyzed for its contributions to literary studies. Paul de Man, Roland Barthes, and Jacques Derrida are other influential writers whose theories undermine literature's direct contribution to ethics.

The basis of their position, which is introduced by Catherine Belsey, is roughly this: Contrary to the empiricist-idealistic tradition that language, and therefore literature, is a reflection of the real world of facts, objects, and transcendent states of being, language is arbitrary and constructed solely by cultural convention. Language does not name things that are already in existence, but is, instead, responsible for a person's recognition of distinctions in what would otherwise be a blurred continuum. If, for instance, our language recognizes a difference between the color blue and the color green, we will see a line on the horizon over land. If there is no such distinction, the sky will melt into the earth. In other words, the language-oriented literary critics say, we cannot experience the world except through language; there is no reality except for language. In effect, we are prisoners of the languages we understand, for language structures our world.

None of these ideas is remotely startling anymore. But trouble arises when they are logically extended, because, with these ideas in place, it is foolish to speak of a literary text as possessing any "truth" about ethical matters or about an empirical world in which ethical matters must be considered. Language is not related directly to the world, but only to other language, texts only to other texts. Does this post-Saussurean conclusion leave any room for ethicists seeking help from literature? For the most extreme of the language theorists, the answer is "very little." They would grant that literature might portray people making moral decisions or, at most, shame readers into feeling "a little ethical flutter, a little frisson" (Bly, p. xix). But they would add that because

language by itself has no agency—that is, no power to bring anything about in the real world—then neither has literature.

For bioethicists, what is finally important about the maelstrom of contemporary literary/linguistic theory is that, first, whether they acknowledge it or not, people who think about bioethics and literature (e.g., Brody, 1987, 1992; Jones; Brock and Ratzan; Clouser and Hawkins) generally derive their theoretical justification from the values-oriented thinkers, and, second, these ethicists are thereby ignoring the dominant literary epistemology of recent decades.

The Ethics of Literary Form

To be sure, there have always been routes through literature to ethics that circumvent the entire values/language debate. A number of these routes are a matter of form as opposed to content.

THE STUDY OF NARRATIVE FORM. Chief among these routes is the form called "narrative" or "story." Narrative is not exclusively literary: Writers from nearly every academic discipline have asserted that human beings tend to perceive life not as isolated ideas, facts, or problems, but as stories—series of plotted events involving characters and told from certain perspectives. In literature, the study of narrative form has become highly sophisticated (Martin; Newton), and literature-and-medicine scholars have participated in its development (Hunter, 1991). Narrative ethicists use the narrative paradigm to counter, or at least to supplement, an ethics based solely on abstract principles (Reich; Clouser and Hawkins; Nelson, 1997; Charon and Montello). In other words, narrative ethics is an attempt to return ethical dilemmas to the messy, complicated lives from which they arose and to plumb those narrated dilemmas with other stories that are coherent and meaningful.

Narrative ethics usually stops there, and it should not. No one looking to literature for moral anecdotes should think that the task is complete when they are found, for the narrative form itself may present—or, more commonly, mask—ethical problems. Most ethical problems derive from questions about the adequacy and authority of what is called the "narrative point of view." Whether a story is oral or written, whether it is from life or art, the audience needs to know the narrator's angle of perspective. That is, who is telling a particular story, and what constitutes his or her authority for doing so? Did the narrator witness the events related or is the report secondhand? Is the narrator deeply involved with the events, distant from them, or perhaps not able to understand them? T. Hugh Crawford points out that one needs to determine the narrator's social privilege, which, in the case of physicians, may be so great that the truth of their stories will go unchallenged. An ethicist should also realize that the narrator always functions as an editor and therefore inevitably omits some elements of the imaginary "complete story" that may have a substantial moral impact. A second set of questions should concern the audience to whom the narrator directs the story, for the tale will be adjusted accordingly.

The questions become more complicated when a story is written, more complicated still when it is part of literary art. For instance, the narrator must not be unthinkingly identified with the real man or woman who composed the story, especially when the story is written in the first person, or even when authors use their own names for the narrators. The doctor who narrates the William Carlos Williams stories about patients in Rutherford, New Jersey, where the author practiced medicine, is not the same person as the Dr. Williams who made house calls or the Bill Williams who was Floss's husband; for the simple truth is that the author is never precisely the same as the narrator. Medical ethicists, writing about paternalism in Williams's famous short story "The Use of Force" (1933), do not always make this distinction, and their conclusions are thereby less precise.

Nevertheless, most literary narratives are written in the third person (e.g., "Sid was thinking that the surgeon seemed unresponsive"). It is an ethical, as well as an aesthetic, question to ask whether the narrator is positioned inside Sid's head, as it were, and therefore knows authoritatively only what Sidney knows, or whether the narrator also knows that "the surgeon was thinking about Sid's gall bladder," that outside "the wind was pushing the fall leaves around the parking lot," and that in the world at large "it was the worst of times." The first kind of narrator is technically a "concealed narrator" or "center of consciousness," the second an "omniscient narrator." Fashion in the twentieth and early twenty-first centuries has favored the first kind for its epistemological and ethical qualities because the omniscient narrator's sweeping knowledge is suspect. In the United States, especially, people tend to balk at according anyone—a president, a spouse, a doctor, a narrator—that kind of power.

These sticky questions about narrators lie in wait for medical ethicists when they are using their favorite narrative form, the case history. When "participant–observer" David Barnard published an extended case history, his intentions were to broaden the social and temporal bases from which ethical decisions are made and to show that a given illness affects the caregivers as well as the patient. He achieved these goals, but literary critic Eric Rabkin challenged the form of the case, asserting that Barnard-as-narrator and the physician, Valerie Walsh, had unconsciously produced "a story in which each could be the hero" (Banks, et al., p. 52). The

resultant furor, summarized by Barnard (1992), who later (2000) accepted the criticism as valid, has helped to clarify the ethics of narrative form, but some aspects are still underexplored.

THE IMPORTANCE OF GENRE. The study of narrative is only one of the important ways to understand how literary form affects ethics. In fact, an awareness of what genre a given work falls into—is it a story or a play, a comedy or a tragedy?—is almost always important for the ethicist. Because drama, for instance, is distinguished from other literary forms by virtue of its dialogue and conflict, perhaps ethical conflicts should be presented in dramatic form rather than in narrative case histories. Not only would the various positions on a problem be fully embodied in the individual language of each "character," the format would also encourage the greater objectivity for which drama has a reputation. An argument can also be made that great plays and their first cousins, films, ought to be studied by ethicists to sharpen their awareness of not only dialogue and conflict but also such matters as role, costume, setting, set speeches, and audience reaction, because all of these factors change the moral climate of any scene from life. It would not matter whether the play chosen was specifically about bioethics or not. Any good play would serve the ethical goals (Banks, 1990).

Genre also affects more pervasively and subtly, because genres are, finally, forms that cultures select to convey their deepest values. Granted, for language-oriented theorists, the traditional distinctions among the genres have blurred—even disintegrated. Texts are texts, no matter what the form. They refer solely to other linguistic productions in an endless line of what literary critics call "intertextuality" and "subjectivities." These are important concepts. Nevertheless, traditional genres yield valuable information for ethicists. For example, the form of Greek tragedy inevitably introduced certain ethical values. One of the most troublesome for modern individualists is the widespread attitude toward fate (often personified as the vengeful Erinyes, or, in Rome, the Furies), whereby the Greeks believed that once a sequence of events had been set into motion, human beings had no ability to prevent its outcome. Once Oedipus had unknowingly killed his father, he was destined to marry his mother. Furthermore, he had to be punished for these acts even though he had no evil intention. That is, in order for the good to triumph in the ultimate balance of the universe, all those who had done wrong, whether consciously or not, had to pay. Like all great artists, Sophocles (c. 496–406 B.C.E.) lived in creative tension with what conventional form forced upon him: His Oedipus sees himself as free enough to be blamed and to inflict his own punishment by blinding himself. Nevertheless, a belief in what might be called the "Greek tragic plot" not only affected ethical decisions—in a sense, it precluded them. Though less confining, certain ethical perspectives are already inherent in modern authors' affinity for mixing the traditional genres, as in "tragicomedy" and "docudrama." We may be too sophisticated to separate the serious from the funny, the real from the make-believe; or—and here is the ethical issue—we may be too confused to understand the difference.

AN EXAMPLE FROM SHAW. If literary form may thus limit ethics, form may also free it. The British playwright George Bernard Shaw's *The Doctor's Dilemma* can serve as an efficient illustration of both capabilities. Next to Williams's "The Use of Force," Shaw's play is probably the most oft-cited example of medical ethics in literature (see, e.g., Brody, 1991, on teaching Shaw in an ethics class). Shaw, of course, was a first-rate comic writer: The pompous, ignorant, and fee-grabbing physicians in this play are squarely in the tradition of the hilariously unethical doctors created by the seventeenth-century French playwright Molireè. But Shaw was also a playwright of great moral passion, an unabashed didact who mounted theatrical soapboxes to preach his ideas about social reform. The play form simply did not give this second Shaw enough room. Therefore, to most plays he published, he attached an essay of polemical prose that allowed him to go over much of the same material in a different literary form. In the case of *The Doctor's Dilemma,* this material was medical ethics.

The two forms, preface and play, dictate two startlingly different takes on the same ideas. Whereas the preface requires precision, the play requires ambiguity, or, more accurately, encourages it. In the play, Sir Colenso Ridgeon, who has recently discovered a successful treatment for tuberculosis, is forced by limited resources into deciding whom to treat and whom to allow to die. Specifically, he must choose between a poor, worthy—and dull—doctor, and a poor, reprehensible—and uniquely brilliant—artist. The situation is complicated by Sir Colenso's amorous feelings for the artist's wife, whom he imagines as an available widow. That is the dilemma of the title. Sir Colenso resolves it by treating the doctor. His justification for this action is that because the artist has no moral integrity, he, Sir Colenso, is saving the wife from discovering her husband's deceit and killing herself, as she has threatened. When he reveals his reasoning to the wife, now the widow, she accuses him of murder. In reply, he justifies his actions by citing Arthur Hugh Clough's satiric poem, *The Latest Decalogue:* "Thou shalt not kill, but needst not strive / Officiously to keep alive."

Shaw's play raises more questions than it answers. When he writes polemical prose, Shaw argues easily, logically, and from an unshakable moral perspective. But when he takes ethics into the personal realm of drama, he cannot manage equally clear conclusions. So the play, as distinct from the preface, reverberates with moral ambiguity. Sir Colenso and an older, sensible physician soundly debate the central dilemma—but no conclusion is drawn by Shaw. Similarly, Sir Colenso's decision is padded with ethical red herrings. When, with no apology, he recommends as a physician for the artist a man of eminent reputation but shameful ignorance, Sir Colenso is behaving in a superficially licit manner that serves to distract him from the ethical problem. What the playwright does face directly is that ethical decisions in medicine are difficult to sort out logically; that no physician alone, or even in consultation with other professionals, can make them on objective grounds; that the results, when allocating limited medical resources, will be a type of murder; and that these burdens are too much for one person to bear.

For Shaw the playwright, then, the dilemma of who shall live and who shall die cannot be answered without dishonor and tragedy. (He calls this play, and this play only, a tragedy.) For Shaw the political philosopher, the same question is answered in terms that, by contrast to the subtleties of the play, are chillingly clear. He asserts in the preface that "invalids, meaning persons who cannot, beyond reason, expect to be kept alive by the activity of others," must be allowed for social reasons to die. "The theory," Shaw concludes firmly, "that every individual alive is of infinite value is legislatively impracticable … the man who costs more than he is worth is doomed by sound hygiene as inexorably as by sound economics" (pp. 86–87). And that's that.

Abortion and AIDS, among Others

Shaw, Williams, Molireè: These names are the beginning of a long, long list of first-rate creative writers who have narrated, dramatized, and, in general, illuminated specific topics of bioethics. Hundreds of other names and their works could be added. A partial roll call of the most useful would include Tobias Smollett's *The Adventures of Roderick Random* (1748), Herman Melville's *White-Jacket* (1850), Anthony Trollope's *Doctor Thorne* (1858), George Eliot's *Middlemarch* (1871–1872), Georg Büchner's *Woyzeck* (1836), Henrik Ibsen's *An Enemy of the People* (1882), Sinclair Lewis's *Arrowsmith* (1925), Albert Camus's *The Plague* (1948), Peter Nichols's *A Day in the Death of Joe Egg* (1967), Joyce Carol Oates's *Wonderland* (1971), and Peter Shaffer's *Equus* (1973).

In the first bibliography of literature and medicine (Trautmann and Pollard), which annotated about 1,400 literary works from classical to contemporary times under thirty-nine categories, ethicists can check for information not only under "medical ethics" but also under "abortion," "euthanasia," and "evil doctors." The years since the bibliography's publication have, of course, added more authors, and many more works, to the inventory of resources. It is intriguing that the years have also changed the categories. Among the bibliography's topics, "age," "handicaps," "mental retardation," "plague," "suicide," "venereal disease," and "women as patients" have taken on extensive political, and therefore ethical, implications. New categories have emerged too. "Cross-cultural," for instance, must be clearly distinguished from the old "poverty and health"; "AIDS" deserves its own category, having grown beyond "plague" and "venereal disease" (which itself has developed into "sexually transmitted diseases").

Bibliographic assembly for literature and healthcare has, since 1993, been under the direction of Felice Aull at the New York University (NYU) School of Medicine. Aull and a large board of editors and annotators have brought their subjective, interactive, and regularly revised bibliographic work where it needs to be—to the Internet. The NYU group has tripled the number of Trautmann and Pollard's subjects and mirrored the movement in literary criticism toward cultural studies, thereby broadening the definitions of text and literature to include, for example, film and the visual arts. Following the trend in ethics, medicine has also been broadened to include not only nursing but also all the newer healthcare professions.

Along with the expansion of creative work about bioethics, the field of literature and healthcare has seen an enormous growth of books *about* these works. The studies are generally about topics and people at some distance from U.S. culture's centers of power: the feminist body (Grosz); disabilities (Thomson); aging (Wyatt-Brown and Rossen); pain (Scarry; Morris); and caregivers (Poirier and Ayres).

To demonstrate precisely how literature illuminates bioethics, it might be helpful to analyze, first, a traditional work on an established ethics topic—in this case, abortion—and, second, a group of fiery works about a newer topic, AIDS.

ABORTION AND *THE CIDER HOUSE RULES*. One of the most important novels on U.S. medical ethics is John Irving's *The Cider House Rules*, which was made into an influential film that was released in 1999. Morality—the metaphorical "rules" of the title—is its central concern, specifically the morality of abortion before *Roe v. Wade,* the 1973 U.S. Supreme Court case that established abortion's constitutionality. One of the book's two main characters is

Dr. Wilbur Larch, who performs illegal abortions at the orphanage he has established in a remote area of Maine. He offers women a choice—an orphan or an abortion. The other character is Homer Wells, one of those orphans, who, as a young man, is an ardent antiabortionist, able to articulate arguments in opposition to Larch. But, in the end, breaking his own and society's rules, Homer assumes a medical identity that allows him to take over Dr. Larch's practice.

As is so often the case in life, Homer's position begins with an image rather than an idea. At the age of thirteen, Homer sees a dead, nearly nine-month-old entity, whom Dr. Larch wants to call a "fetus," but Homer feels compelled to call a "child." After that, Homer immediately links any argument from Larch about "the products of conception" before the quickening to the image of the dead baby. Now the pictures of even the eight-week-old fetuses in Gray's *Anatomy* strike Homer as having an "expression," or, the narrator tells us, what other people call a "soul."

Nor is Dr. Larch initially won over to abortion by arguments. As a medical student, Larch sees for himself the damage inflicted on women by the alleyway butchers and poisonous aborticides. He stares into the dead face of a woman to whom he had refused an abortion. He witnesses the deprivations of orphans. Later, Dr. Larch adds reason to his emotions. He has a large array of arguments at his command, including, for instance, his disgust at someone "who cares more for the misgivings suffered in his own frail soul than for the actual suffering of countless unwanted and mistreated children" (Irving, p. 260). He presents another argument that finally convinces Homer. Written in a letter, it reads: "If abortions were legal, you could refuse—in fact, given your beliefs, you *should* refuse. But … how can you feel free to choose not to help people who are not free to get other help?" (p. 488).

These characters, these events, and these ethical concepts are all embedded in a form that must be described and its intimate connection to the ethical content made plain. Basically, the form is adapted from the nineteenth-century, realistic, English novel because it suits Irving's traditionalism—his sense that fiction has as its chief mission the examination of values. In that regard, his model is surely Charles Dickens. *The Cider House Rules* has Dickensian size. Like a Dickens novel, it is openly concerned with individual and social ethics. Every night, Homer reads Dickens's *David Copperfield* or *Great Expectations* to the boy orphans, who unquestioningly accept the novels as portals to morality.

To the girls, by the way, Homer reads Charlotte Brontë's *Jane Eyre,* whose orphan heroine is blatantly offered as a role model—and is sometimes blatantly rejected. Jane's sweet optimism is too much for one angry, world-weary orphan. In a vividly comic instance of what scholars such as Wayne C. Booth and Nussbaum would be forced to call "ethical criticism," the hulking, teenaged orphan demonstrates the power of literature:

> "Even for me [chirped little Jane Eyre], life had its gleam of sunshine."
>
> "'Gleams of sunshine'!" Melony shouted in violent disbelief. "Let her come here! Let her show me the gleams of sunshine!" (Irving, p. 84).

From the nineteenth century, too, comes the novel's narrative voice. It is omniscience, moving freely in and out of any character's mind and making such general observations as: "Society is so complex that even [the little town of] Heart's Haven had a wrong part to it" (Irving, p. 125). The narrator knows everything in this created world. If he (let us say) can build an aesthetically convincing world, readers may believe he knows a great deal about the real world, too. Irving has tried to buttress the authority of his novel's narrator by appending the scholarly apparatus of endnotes. Tied to certain pages and narrative "facts," these notes assert that Irving has researched his material. He has read medical texts, both old and modern. He has consulted with physicians, including one of the canonical authors in literature and medicine, Richard Selzer. All the evidence points to this author being very serious about the real world, a values-oriented thinker as described earlier, rather than one for whom language is a closed system.

Irving writes tragicomedy. One distinguishing mark of an Irving novel (the most successful was *The World According to Garp* [1978]) is that, after much humor, someone innocent dies. This is Dickensian too: Think of Little Nell in *The Old Curiosity Shop.* As noted earlier, the mixed genre of tragicomedy is a favorite twentieth-century form, and cultural critics are still sorting out its implications. More and more, tragicomedy seems appropriate to the creative literature of medical ethics because the genre deals simultaneously with patients' tragic losses and caregivers' need to continue in spite of them. Tragedy ends something, but comedy always implies continuation, and the two are interdependent. Here is a literary lesson that bioethicists, whose "quandary ethics" proceeds from an exclusively tragic premise, have yet to learn. As that wily moralist, Shaw, has Dr. Ridgeon say in *The Doctor's Dilemma,* "Life does not cease to be funny when people die any more than it ceases to be serious when people laugh" (p. 185).

SEVERAL WORKS ABOUT AIDS. Literary writers have responded to AIDS faster and more often than to abortion. They have also tended to leap more aggressively from art to

ethics. Taken as a group, the narratives, plays, poems, films, and critical essays about AIDS (see Nelson, 1992, for a bibliography) are fervently contesting the ethical boundaries of language itself. For a start, some of the creative writers and critics who write about AIDS are activists. Larry Kramer, author of *The Normal Heart,* was an early and loud voice. These activists insist that the first goal of AIDS literature must be to change the critical circumstances of the disease and its sufferers. They call for "stridently interventionist cultural practice" (Nelson, 1992, p. 8, citing Douglas Crimp). They say that to write about AIDS at all is automatically to be a moralist, for, in this battle, no sidelines exist. Demurrers about art for art's sake are irrelevant and themselves immoral. So one question about activist AIDS literature is: Does such work fit into the artistic genre called "social realism" or is it not art at all, but, instead, blatant propaganda whose first and last goal is social change? To the first category, literary historians have assigned, for instance, Ibsen's *An Enemy of the People,* which is an ardent piece about an idealistic doctor's crusade to warn tourists about his town's polluted public baths in the face of community pressure, as represented by his brother the mayor, to keep his mouth shut. The play is comparable to Kramer's *The Normal Heart,* in which another doctor battles to get money for AIDS research in a New York whose mayor seeks to prevent would-be tourists from knowing about the epidemic. But where do we draw the line between taking a stand and propaganda, wherein the end shapes, even justifies, the means?

What might any writer, activist or not, be excused for saying in order to bring about a desired end? What language—which images, which metaphors—may validly be used to inflame audiences with a just passion? One of the most common metaphors for the AIDS epidemic in the homosexual community is the Holocaust (e.g., Nelson, 1992), which was said in the early days of activism to be recurring through the establishment's lack of a plan to prevent the genocide of gay men. Is this horrifying image apt? Is it logical? Alternatively, are these questions themselves out of place in view of the absolute primacy, for some people, of subjective data about illness?—that is, "I have AIDS, and it feels as though I am living through another Holocaust. What do you know about it?"

The morality of metaphor is the territory famously covered by Susan Sontag in *Illness as Metaphor* (1978). There she argues that to substitute metaphors, especially negative metaphors, for the reality of bodily suffering is to impose a spurious meaning on illness and a sense of guilt on the patient. If cancer, in the common military metaphor, is a battleground, then the patient can be blamed for not winning. Sontag comes back to her point in *AIDS and Its Metaphors* (1989), where she contends that "plague," the most common metaphor for AIDS, implies judgment on a corrupt society. In her own story about AIDS, "The Way We Live Now" (1987), there are no metaphors for the illness. Moreover, in what would seem to be a further attempt to free AIDS from contaminating linguistic associations, she does not even name it.

Sontag's reasoned approach to this crisis is similar to the theories of the German playwright Bertolt Brecht (1898–1956). Unlike the AIDS plays, most of which are designed to be deeply cathartic, Brecht's plays aimed for the "alienation effect" in order to limit his audience's emotional involvement in the work. He used various devices to remind audiences that they were watching illusion, not reality—a play, not life. This distancing, he hoped, would free their minds to reason clearly that humanitarian action was needed in the world outside the theater. A former medical student, Brecht wanted to achieve the theatrical equivalent of clinical objectivity. His goal, like that of AIDS activists, was to change society, but, unlike some of them, he thought it unethical to reach minds by manipulating emotions.

In arguing against metaphor, Sontag seeks to chip away at the use of language as a shield to protect people from difficult experience. Given the symbol-making nature of the human mind, she has chosen a position that finally may be impossible to defend. She seems to know that, and yet she thinks it eminently worthwhile to fight for the "thereness" of the human body, for the indisputable fact of its physical presence. So does literary and film critic James Morrison, who is worried that postmodernism (read: "language-oriented thinking") has infected criticism about AIDS literature. Defining allegory as "a series of metaphors arranged in sequence" (Nelson, 1992, p. 169), Morrison complains that the postmodern attraction to allegory—that is, to expressing experience as an abstract text that refers only to other language and not to the real world—has moved readers further away from the actual experience of AIDS. In his eyes, allegories dictate that both AIDS and the person with AIDS be classified as "other"—something, at any rate, that cannot be approached without the intervention of elaborate figures of speech. The allegory to which he objects most vehemently is the series of metaphors that describe the body as text. When logically extended, he says, such an allegory would allow someone to "read," as it were, "the lesions of Kaposi's sarcoma as indexical signs" of the body-book (Nelson, 1992, p. 171). This he thinks a ludicrously unsympathetic way to approach the body in pain.

Morrison may not realize it, but his challenge implicitly goes out to the scholars in the interdisciplinary field of literature and medicine for whom the patient-as-text is both metaphor and method. He might just as well challenge every

one of us, because the process of abstracting that he condemns in the case of literary criticism and AIDS seems to be a universal human phenomenon. The combined evidence of the writers examined here suggests that all of us are trapped between our suffering bodies and our symbolizing minds—that is, between a world whose existence we can prove simply by stubbing a toe and the engrossing stories that we are constantly creating about that world. It would appear to be nearly useless to ask which level of experience, the physical or the imaginative, is more real; or to look to one, at the exclusion of the other, for ethical insight.

In a sense, this brings us back to the values/language split with which this entry began. In calling for a clear-sighted view of every specific person with AIDS, Morrison aligns himself with the values-oriented camp. He wants not only creative writers but also commentators on literature to write justly. So does Sontag. But, as she demonstrates in her own fictional works, language is a powerful and playful human trait that tends to seek its own ends, regardless of its possible relationship to the real world of ethical problems. Language, in fact, creates new worlds all the time. Consider only Tony Kushner's *Angels in America,* so magnificent an achievement that it transcends the category of AIDS play. In short, the values/language dichotomy is more properly seen not as a true division but as a perpetual ethical tension.

LONG-TERM CARE

• • •

I. CONCEPT AND POLICIES

Long-term care (LTC) is an individualized mix of personal care, healthcare, and social services for persons whose functional impairments dictate that they need help with tasks of everyday living (Kane and Kane). Consumers of LTC may live in congregate residential settings such as nursing homes, assisted living settings, adult foster homes, or board-and-care homes, but most live in their own homes and are candidates for community-based LTC programs including home care, adult day care, home-delivered meals, emergency assistance, and home renovation. LTC may be provided by paid workers, but most often it is provided voluntarily by family and friends. The need for LTC is assessed by evaluating the person's ability to perform activities of daily living (ADL), such as bathing, dressing, using the toilet, getting in and out of bed, eating, and performing household and other practical tasks including cleaning, cooking, shopping, managing money, and transporting oneself. LTC services correspond directly to measured impairments in ADL performance and to other functional impairments. People may choose to purchase similar services for convenience alone, but a service is defined as LTC only if a measurable disability prevents the RAK (people receiving care) person from performing the given task.

Most LTC consumers are elderly and, indeed, well over age seventy-five. But many younger people also need and receive LTC. These include physically disabled adults with conditions such as multiple sclerosis, spinal-cord injuries, head injuries, and late-stage cancer; persons with late-stage acquired immunodeficiency syndrome (AIDS); technology-dependent, severely disabled children; and persons of all ages with developmental disabilities such as cerebral palsy. Anyone who needs and receives help with everyday functioning because of a disability may be considered to be receiving LTC. They may, of course, also receive preventive and curative acute medical care from time to time. Some disability activists prefer to replace the term LTC with a substitute such as "long-term services," both because LTC is often equated with nursing homes in the popular mind and because they prefer to distinguish the emotional and nurturing aspects of "care" from the concept of services.

The goals of LTC may be multiple and often are ambiguous. Sometimes the goal appropriately includes rehabilitation or improvement of the consumer's functional abilities, but frequently the most reasonable goal is to enable consumers to live as meaningfully as possible given their impairments, abilities, interests, and life-cycle stage and roles. Sometimes LTC providers treat the LTC services (e.g., bathing assistance and cooking, or any particular mix of services in the plan) as the actual goal of LTC. Other LTC programs promulgate ambitious goals, for example, that LTC consumers should be well satisfied with life and score well on absolute indicators of well-being or social adjustment. In either case, practitioners and policymakers struggle to attend to rehabilitation possibilities while avoiding grandiose or intrusive goals. For service providers to assume responsibility for global outcomes of someone's life along with their provision of routine services requires some hubris, and LTC professionals are perplexed about how comprehensively to cast their goals.

A number of other factors make LTC unique. LTC is an enterprise in which the services are diverse though often ordinary, the providers are diverse (including professionals, paraprofessionals, and family members), the clientele is diverse, and the goals are often unclear. Furthermore, much LTC, and most publicly subsidized LTC, takes place in nursing homes, where the functionally impaired consumer may have been involuntarily relocated, and the high cost of LTC in residential settings and in the community is of concern to private and public payers. Finally, LTC is a women's issue because the consumers, the family caregivers who are pressed into service, and the paid caregivers are predominantly female. Of course, husbands give care to their wives as needed, but the typical LTC consumer is a widow, and the typical family caregiver is a wife, a daughter, or a daughter-in-law.

Trends in the 1990s and Early 2000s

Several trends in the United States during and following the 1990s have also helped shape the key ethical issues involving LTC. In the United States, publicly funded LTC is usually offered on a means-tested basis and is a matter of state rather than federal policy (although the Medicaid program matches state funds and sets some broad program parameters). State governments expend most of their funds on care in nursing homes, although consumers prefer to live anywhere else. The magnitude of this disproportionate spending has receded somewhat since 1990, and a concomitant growth has occurred in what is called the home- and community-based services (HCBS) sector. Three elements are highlighted: the growth of assisted living, the promotion of consumer-centered approaches to care, and the pursuit of LTC as a civil right for persons with disabilities.

Assisted living is an umbrella term for a variety of residential settings that provide or arrange care and are not licensed as nursing homes. They have proliferated, partly because of consumer interest in alternatives to nursing homes. At their best, assisted living settings combine a high level of privacy and autonomy-enhancing architectural features with a capacity to provide substantial care to residents in their own assisted living apartments. At their worse, they fail to offer high privacy or high service or both, they are costly, and they evict residents when they have real care needs. The presence of almost a million assisted living units by 2002, and the coverage of the services provided or arranged by assisted living programs in most states (Mollica), has given rise to concerns about quality, punctuated by highly publicized scandals in the print media and a 1999 U.S. General Accounting Office study showing that consumers had poor and incomplete information prior to purchase. The extent to which the federal government should regulate assisted living programs and how they should be regulated is now a matter of spirited debate.

Consumer-directed care and consumer-centered care are slogans that reflect a growing sentiment that the users of services should as much as possible direct the nature of those services and that their views should be solicited for quality reviews and program development. At the extreme end of this view, advocates suggest that funds for services be provided directly to consumers or their agents, who would then hire, train, supervise, and dismiss care workers. Advocates of this view prefer the use of personal attendants or personal assistants to home care from agencies. In some European countries, notably Germany, cash is offered in lieu

of services in LTC insurance programs, and the United States launched in the late 1990s a randomized trial of the effectiveness of cash with the cash amount established as somewhat less than the average cost of service plans versus services for HCBS under Medicaid. Care patterns that emphasize the authority of the consumer, however, raise problems about the rights of paid care workers, who themselves have been making strides toward collective bargaining.

Finally, the Americans with Disabilities Act (ADA) of 1990 provided leverage for social action related to LTC in a different vein than advocacy for better health and human service programs. In the closely watched *Olmstead v. L.C.* case, the U.S. Supreme Court in 1999 enunciated a right to care in the most integrated setting based on the ADA (although the right was circumscribed by vaguely stated requirements for "appropriateness"). This brought the Office of Civil Rights into the business of enforcing decisions related to quality of care (Rosenbaum; Rosenbaum, Teitelbaum, and Stewart). Younger persons with disabilities, even people with developmental disabilities and mental retardation, have made greater progress toward care outside of institutions than have older people. Comparisons between HCBS received by seniors and younger people with disabilities reveal sharp discrepancies; for example, the former often must be homebound to get publicly funded help at home, whereas the latter can use publicly funded personal attendants to help them leave their homes. Some argue that older people prefer the more secure; institutionally based services, but others suggest ageism is at work in the discrepancies. Also, older LTC consumers tend not to perceive themselves as being disabled and having rights under the ADA. Possibly the options and services would be better for seniors if pursued as a rights issue rather than as a healthcare quality issue.

Ethical Themes in LTC

Nine interrelated themes can be identified that give rise to ethical dilemmas for those who provide, administer, plan, or finance LTC.

INTIMACY OF LTC. Whether it is provided in consumers' own homes or in group residential settings, LTC is inextricably tied to daily routines. The way it is provided literally affects how LTC consumers live, where they live, whom they see, and how they spend their time. Ethical issues arise concerning the extent to which personal preferences and wishes should be honored, especially when they conflict with operating procedures of a caregiving organization or when they entail public costs. For example, should a person receiving home care be permitted to establish the timing for getting up and going to bed, even if this requires an attendant to visit late in the evening? Because LTC plans can be so comprehensive and intrusive, many believe that the consumer should be given as much choice and control as possible. Further, George J. Agich suggested in his 1993 book, *Autonomy and Long Term Care,* that a legalistic ethic based narrowly on the right to noninterference ignores the existential reality of LTC. He argued that respect for autonomy must include provision of meaningful choices and maintenance of personal identity. Writing largely about nursing homes, Bart Collopy, Philip Boyle, and Bruce Jennings also argued for a view of autonomy that takes into account "the moral ecology" of LTC settings. A large ethnographic and anthropological literature offers insights into the complexity of this moral ecology, that is, the settings and arrangements of care (Henderson and Vesperi).

With its focus on intimate, repetitive tasks and assistance with bodily functions that adults usually handle independently and privately, LTC can profoundly affect the dignity of the consumers and alter their sense of personal identity and worth. Cognitively intact LTC consumers may retain a keen sense of privacy concerning their bodies, their possessions, and even information about themselves. Assembly-line approaches to dressing, toileting, and bathing may be perceived as demeaning. Questions arise about how much energy LTC providers should be obliged to expend protecting the dignity of consumers and helping them preserve their sense of identity. Even if consumers are cognitively incapacitated and completely helpless physically, many believe it is wrong to subject them to procedures that are inherently undignified.

DEPENDENCY OF LTC CONSUMERS. Functionally impaired people are, by definition, dependent to some degree. Some people receiving care, though they may have the ability to conceive, plan, and choose actions, are virtually helpless to initiate or carry out actions. This creates a paradox: The more physically dependent the LTC consumers, the more they must depend on the help of others to exercise autonomy. Although providers taking a rehabilitation stance may strive to have consumers do things for themselves, respect for the consumer's autonomy dictate that great care be taken in fulfilling requests. Striking the right balance between encouraging independence and providing help is an ethical issue for LTC providers.

GROUP-LIVING SETTINGS. When LTC is provided in a collective, residential setting, the needs and interests of residents can collide. Residents in group settings are always expected to modify their individual wishes and behaviors to adjust to collective situations, and such expectations are

usually well understood by all who enter such a setting. But it is unclear what rules of conduct and mutual expectations should govern a nursing home, an entity that is neither a hospital nor a housing unit. To some degree, the facility's search for efficient routines defines permissible behavior and opportunities for nursing-home residents.

Typically, nursing homes accommodate, in multiple-occupancy rooms and close quarters, residents who are markedly varied in physical ability, cognitive ability, prognosis, age, social class, interests, and personal taste. Some now question, however, whether continuing to house residents in shared quarters is ethically justifiable. One reason why assisted living is attractive in the private market is the greater availability of singly-occupied quarters; as states begin covering assisted living services under Medicaid, they face a decision about whether to fund privacy as a minimum expectation or to encourage a two-class system of assisted living with publicly subsidized clientele living in boarding home situations. The advent of assisted living also challenges the very nature of congregate LTC and obfuscates the boundaries between home care and institutional care. If assisted living consumers are viewed as tenants of their own apartments, where they receive services as well, then laws pertaining to fair housing may prevent providers from moving them to a reputedly higher care setting such as a nursing home.

Nursing homes themselves are in considerable ferment about how to adapt to the current LTC world. A social movement, originally called the Nursing Home Pioneers, gained momentum in the 1990s. Dedicated to culture change in nursing homes, those identified with the Pioneers recommend a variety of remedies, including empowering the line staff, flattening nursing-home hierarchical structures, and refashioning the physical settings into smaller neighborhoods and households (Lustbader). Within this group are proponents of specific changes such as the Eden Alternative (Thomas), an approach to combat boredom, loneliness, and lack of meaning in nursing homes; and the Wellspring model, a version of continuous quality improvement directed at empowering nurse's aides (Stone et al.). Many of these developments are antithetical to more traditional approaches to nursing-home reform proposals such as establishing higher nursing-staff–to–resident ratios and vigorously enforcing quality of care standards.

FAMILY ROLES. LTC is inevitably a family affair. Family members provide most of the care given to people at home. Indeed, much paid home care is organized explicitly to give relief, assistance, or training to family members, who in turn are expected to do most of the work. Questions arise about what is right to expect of various family members, and even whether older persons should be forced to accept, against their will, help from a family member. One also wonders whether family anxiety for a relative's safety should lead to the placement of that relative in a nursing home. On the personal level, LTC evokes questions about the duties and rights of spouses, parents, adult children, and other relatives.

In practice, LTC providers, and especially case managers who coordinate and allocate care, sometimes view the whole family constellation as the client, especially if all the family members are elderly or if they live in the same household as the person getting care. But family members' interests are not always identical to those of the consumers, nor are their intentions always benign. For example, nursing-home staff often find that family members disagree with each other about the resident's care. They also sometimes note that the decisions of family members are motivated by an interest in minimizing the costs of care. Nursing-home personnel, who may themselves have a conflict of interest involving payment and money management, for example, when their recommendations entail more payment to the nursing home, often turn to the state's nursing-home ombudsperson to resolve such disputes. Home-care providers and state-designated case managers who purchase publicly subsidized home care also often disagree with family members about the type and amount of care needed and about whether a nursing-home admission is in the LTC consumer's best interest.

END-OF-LIFE ISSUES. Death typically occurs during a period of LTC, either at the end of decades of care or after a relatively short episode. For this reason, many of the issues about death that confront acute-care providers also arise in long-term contexts, including the use of cardiopulmonary resuscitation, starting or stopping a respirator, or starting or stopping tube placement for nutrition and fluid intake. Issues of active or passive euthanasia also arise, which in turn evoke basic questions about the extent of the obligation of the healthcare professional to preserve life on the one hand and to avert suffering on the other. It is a challenge to give proper, systematic attention to end-of-life issues in LTC, while also giving weight to the everyday ethical matters that shape the quality of LTC consumers' lives (Kane and Caplan, 1990).

RISKS, RISK AVERSION, AND LIABILITY. Functionally disabled people are frequently unable to protect themselves against outside dangers such as fending off an intruder or escaping from a fire. Increased risks are associated with the simplest activities—walking to the bathroom, getting out of bed, or boiling a pot of water. People with precarious

physical health may be at increased risk of a fall or of a sudden health incident, such as a stroke or heart attack, that needs immediate attention. If the LTC consumer suffers memory loss, the risks to safety because of forgetfulness or bad judgment increase. At the same time, supervision and surveillance exact a high price in both dollars and personal freedom.

In every type of LTC, questions arise about when it is right to leave a vulnerable person unprotected and subject to risk. The corollary question, asked less often, is when is it right to force a functionally impaired person to accept protection and eliminate risks, even risks the person prefers to take. The extreme example of restricting people for their own protection is the use of physical restraints, which were formerly ubiquitous in nursing homes but have been curbed by regulatory changes following a highly publicized Institute of Medicine study, published in 1986, on the quality of LTC settings. Sedatives and psychoactive medications also have been used as a form of restraint and behavior control, presumably for safety reasons. On a less dramatic level, numerous organizational routines and professional practices and decisions designed to keep a consumer safe also restrict personal freedom and may conflict with consumer preferences. Although attorneys point out that LTC providers have rarely been sued successfully for injuries sustained by a consumer while the consumer was pursuing an expressed preference or choice, the fear of liability is pervasive in LTC industries (Kapp).

A concept variously called negotiated risk agreement, negotiated risk contracting, or managed risk agreement has gained prominence since the early 1990s as a mechanism for LTC consumers or their agents to take conscious risks and behave in a way that professionals fear endangers their health. Based on contractual principles, the notion is that the consumer who had been informed of risks related to certain behavior should be able to take those risks unless the well-being of others is clearly threatened. This is an emerging area of practice that has advocates and many detractors; it raises the potential for adjusting the power balance somewhat in favor of the consumer, but raises the specter of provider negligence masquerading as respect for autonomy. The effort to put negotiated risk agreements into place sharply reveals the flimsy information base for many of the risks that are guarded against in LTC (Kane and Levin; Kapp and Wilson).

PROFESSIONAL STANDARDS AND PARAPROFESSIONAL ROLES. It is a truism that ethical care must be competent care. The codes of ethics that govern health professionals generally require that health professionals act within the framework of correct and up-to-date scientific knowledge and that they comply with the standards of adequate professional practice. Such judgments are easier to make about specific medical and nursing procedures than about the more amorphous and less specialized services of LTC, even when professionals are delivering the services. Without clear criteria for an adequate assessment of LTC needs or a competent care plan for a person with particular characteristics, it is difficult to promulgate standards or hold any one individual accountable.

One might argue that standards for care be set high and held to rigidly, to ensure safety. The more particular educational and other standards (e.g., caseload size) are mandated, however, the higher the cost of services. Professionals may unwittingly deny services to some older persons by advocating standards that inflate prices. Because professional self-interest usually accompanies concern for consumers in advocacy for professional standards, this subject has ethical import. Also, the more rigid the standards, the less flexibility there is for consumers to work out plans that suit their individual preferences.

The mainstays of LTC are the nursing assistants, home-health aides, homemakers, chore workers, and personal-care attendants who do the bulk of the difficult, labor-intensive, sometimes unpleasant work. Little consensus has been reached about either the responsibilities of the paraprofessional LTC worker or the extent to which the worker should be expected to do independent problem solving. Historically, little attention has been paid to the rights of the paraprofessional worker, who is typically paid a poor wage and sometimes faces substandard working conditions in people's homes. The worker may also suffer verbal or physical abuse from consumers or their family members. The care providers are often members of ethnic or racial minority groups serving a largely white, middle-class clientele. With the movement toward consumer-directed care that began in the early 1990s, however, the rights and needs of workers have been raised as a major obstacle to such consumer control.

RESOURCE LIMITATION. Decisions about what ought to be done must take costs into account, particularly when governments pay or subsidize payment of the bills. For each element of LTC services and programs, one can ask whether it is worth the money, compared to other good uses for the resources. Limited resources result in fewer caregiving staff in residential facilities, poorly paid home-care attendants or limited hours of home care for each person, less space, less privacy, and less personal attention overall.

A scarce resource might be a single room in a nursing home or an extra half hour of attention at home. Without

explicitly translating cost-consciousness into human terms—such as the numbers of baths or assisted trips to the toilet an LTC consumer is entitled to or the number of minutes an LTC consumer should have to wait after pushing a call button—authorities tacitly accept that the resources available are limited and that resource constraints will compromise the best care for functionally impaired persons.

INTERGENERATIONAL ISSUES. Finally, LTC forces consideration of what an ethical society should offer to older people. Older people—people over seventy-five—are by far the most numerous group needing LTC, but the lifetime costs of LTC may be greater for a younger person. Some LTC planners ask whether the claims on society for care of a younger person with a disability and an older one are different in kind, degree, or justification.

Although justifications are often made for caring for older people based on reciprocity across the generations, the elderly are given resources and encouraged to manage their own care less often than are younger persons with disabilities. Indeed, political action among younger persons with disabilities has led to changes for older people receiving community LTC. In the 1980s and early 1990s, several states restructured their LTC programs under Medicaid and state financing to include adults of all ages with disabilities. As a result, these administrators now need to determine how to allocate resources fairly among consumers of widely different ages and circumstances. Advocacy groups representing younger persons with disabilities argue for a model of LTC that gives more power to the LTC consumer or his or her agent (Litvak, Zukas, and Heumann). Such groups prefer a social rather than a medical model of care that would, as much as possible, relegate to the consumer the prerogative of selecting, training, supervising, and firing those who provide personal care. A personal-care assistant who accompanies the consumer as needed is perceived as liberating, whereas home care was seen as restricting. Authorities disagree about whether the personal-assistant model is desirable or feasible for the much larger group of elderly LTC consumers.

Policy Issues

As with acute care, LTC poses interrelated problems in access, quality, and cost. Access to care is uneven because of geographic variation in supply and price. Care is most available in the least-preferred nursing-home form, because that is the form that is publicly subsidized. Quality concerns are present for both nursing-home care and home care. Public and private costs are high. Reimbursement methods and levels for LTC often create perverse incentives. Flat-rate systems discriminate against those who need the most care. At the same time, "case-mix-adjusted" systems, which increase payment for persons with greater disabilities, provide clear incentives against rehabilitation (Kane and Kane).

BENEFITS AND COVERAGE. The 1.9 million U.S. nursing-home residents represent about 5 percent of the country's elderly population. It is estimated, however, that an additional 10 percent of the elderly population have comparable functional impairments requiring LTC (Wiener, Illston, and Hanley). In contrast to many other industrialized countries, publicly funded LTC in the United States is available only to persons of low income, and, moreover, the vast bulk of public LTC expenditures are for nursing-home care. Despite expectations that LTC costs be met first by the consumers themselves, at least 50 percent of nursing-home costs in the United States are borne publicly (largely through Medicaid), because private resources are quickly exhausted. The public share of the costs also increases because some older people, to qualify for Medicaid, divest their resources in the years before they expect a nursing-home admission. The extent to which divestment increases public costs has been sharply debated. Publicly financed home-care benefits, though they became more widely available in the 1980s and 1990s, accounted for a relatively small outlay and were used by relatively few consumers. Further, almost all publicly funded home care has been capped at a rate less than the rate of public reimbursement for nursing-home care for the same consumer in the same state.

Nursing homes are perceived negatively. People do not want to live in them, send their family members to them, or expend their life savings and deplete their estates to pay for them. If the LTC-service setting were less aversive in terms of unappealing settings, rigid routines, and high costs, presumably some who now depend on volunteered family help would use paid LTC. This consideration dampens the enthusiasm of officials for expanding home-care benefits; they fear that home care, rather than substituting for nursing-home care, would be received by people formerly receiving uncompensated care from families.

Private LTC insurance is financially viable for only a fraction of the group at risk (Rivlin and Wiener). Both private insurers and public policymakers worry that if benefits were more desirable, they would be heavily used. After all, some LTC services (e.g., cooking, housekeeping, laundry) are intrinsically desirable even for people without LTC needs. Moreover, despite earlier beliefs, research has conclusively shown that at certain disability levels home care is more expensive than nursing-home care (Carcagno and Kemper). Economies of scale are achieved when brief,

intermittent services and protective oversight are offered in centralized locations.

When community-based LTC is financed through Medicaid or state appropriations, case managers, usually social workers or nurses, typically perform initial assessments, authorize payments for home care, and monitor the quality of care and its continuing appropriateness. The case-management role promotes equity and efficiency in the use of benefits across a population but also creates a powerful agent, involved in the allocation of benefits, who may have no clear professional ethic, training, or authority. Home health agencies often complain that interposing a case manager between them and their clientele is wasteful and interferes with consumer choice; state officials argue that case managers who are separate from service delivery provide a disinterested advocate for the consumer. Juggling the roles of advocate and gatekeeper creates ethical tension for the case manager (Kane and Caplan, 1993). Case managers often have difficulty reconciling these roles but, at a minimum, should disclose to consumers the assumptions under which they work. In the early 1990s and before, informed-consent processes for case management were rudimentary.

Reimbursement issues are confounded by confusion about the extent to which LTC is a health program. In the United States, healthcare is considered a public responsibility (at least in part), whereas housing and social services are typically considered private responsibilities to be purchased with private income and with government subsidies for the poor. LTC includes social services and, when provided in nursing homes, housing. Policymakers have not determined whether they should extricate these components for financing purposes, or how to do so. Assisted living programs, such as those developed in Oregon in the early 1990s (Kane and Wilson), combine housing and board with service to functionally disabled, nursing-home-certifiable tenants in private apartments with kitchenettes, full baths, and doors that lock from the inside. Such programs may use outside home-care agencies to deliver the care, and in many states Medicaid reimburses the service component. This blurs the distinction between institutional care and home care. It also permits separating the financing of the room and lodging from that of the personal-care and nursing services, so the latter can be funded publicly and the former privately.

LTC costs and payment are also complicated by unclear boundaries between LTC and primary healthcare, acute hospital care, and post-acute care. Medicare, the universal health insurance program for persons over sixty-five, covers rehabilitation, skilled nursing-home care, and skilled home care in the immediate aftermath of an acute illness. These types of services, known as "post-acute" or "sub-acute" care, fall in an ill-defined area between acute care and LTC. Efforts to save money in acute care and post-acute care—for example, through earlier hospital discharge or denial of Medicare claims for post-acute care—can result in higher LTC costs. Demonstration projects have paid a per capita rate to care providers who are then responsible for both acute care and LTC costs; the projects are meant to determine whether better or more efficient use can be made of the total dollars when acute care and LTC are integrated into a single program. The social health maintenance organization is one such model, and another is the Program of All-Inclusive Care for the Elderly, which was modeled on an innovative program in San Francisco's Chinatown that uses a day healthcare center as a key feature.

STANDARDS, REGULATION, AND QUALITY. The more professional standards are exacted for LTC services and the more providers are regulated, the more expensive LTC becomes. Because family members provide much LTC, some state policymakers suggest that professional-practice acts in most states are unduly restrictive in their requiring licensed nurses for many procedures routinely done by family caregivers. Others believe that vulnerable LTC consumers need protection by high standards for professional practice and managed professional supervision of nonprofessionals. This issue is salient because many LTC consumers would like to purchase cost-effective services. The break-even point, at which the price of community services exceeds that of home-based services, can be reached rather quickly and is influenced not only by the disability levels of the consumer but also by the price of the services. These, in turn, are influenced by regulations governing professional practices and agency licensure.

Regulation of care providers such as nursing homes and home-care agencies through state licensure, quality inspection, and federal certification programs also drives up costs, stifling innovation and consumer choice. Protection of vulnerable adults and avoidance of politically damaging incidents fuel these efforts. The supply of nursing homes is also regulated to stimulate community care and to save money (on the theory that a licensed bed will be used). This form of regulation has been criticized by those who believe that if market forces prevail, quality will improve.

Regulation of care settings, especially residential settings with great potential to affect quality of life, is hampered by disagreement about what should be included in the definition of quality and how various components of quality should be weighted. Although quality of life can be measured through direct interview with residents, including those with substantial cognitive disability (Kane et al.), the

usual methods of accountability give greatest credence to low rates of negative health outcomes such as bedsores, infections, and weight loss. An Institute of Medicine committee charged to study the quality of LTC reported in 2001 that the field is characterized by profound disagreements about the very nature of quality; indeed, these very disagreements led to the inclusion of a minority report by committee members that placed higher emphasis on quality of life and consumer control as elements of quality (Wunderlich and Kohler).

FAMILY POLICY. Case managers make implicit and explicit decisions about the ability of family members to provide help before allocating publicly funded services to LTC consumers. LTC policymakers do not want to replace family care with public programs but want to protect families from undue burden. Respite programs have been developed specifically to provide episodic or emergency assistance to family caregivers. Various forms of compensation for family members have been suggested, ranging from tax credits to direct payment. In some states, LTC consumers have received cash payments, which they, in turn, can and often do use to pay relatives. Supporting these strategies, Nathan L. Linsk and his colleagues, in their 1992 book, *Wages for Caring,* noted the irony of paying strangers but not relatives. Direct payments to family caregivers are also seen as an income transfer to poor families. Opponents of family payment cite the cost implications. A midway position argues for family payments only when the caregiver has left the labor force to provide care—disqualifying most retirement-age spouses—and only for low-income families.

LTC LABOR FORCE. Paraprofessional workers in nursing homes and, more particularly, in home care, may receive minimum wages and no benefits. The cost implications of paying the workers an adequate wage are enormous. Although advocates of greater LTC benefits for senior citizens historically ignored the situation for workers, in the 1990s groups such as the Older Women's League formally recognized the condition of care workers as an issue. The very persons who perform the hands-on LTC tasks—typically, persons with low wages and nonexistent benefits—will become at risk for needing LTC themselves, without any personal financial reservoir from which to draw.

Conclusion

With the aging of the population and the chronicity of disease, long-term-care policies may be expected to continue to receive great attention. Many specific policies are in flux, and thematic and policy changes may be expected in response to current debates. The nagging questions about how a society can meet the ordinary needs of people with functional impairments competently, efficiently, and fairly—without compromising the autonomy and quality of life of the clientele—are likely to endure.

II. NURSING HOMES

The decision to enter a nursing home is the most wrenching outcome of long-term-care decision making. It changes almost every aspect of the life of an elder, who moves to new surroundings, may acquire a perfect stranger as a roommate, and must adhere to the nursing-home schedule. The either/or nature of the decision and the move to what has been described as a "total institution" (Lidz, Fischer, and Arnold) marks the decision about nursing-home admission as a "nodal" decision (Agich, 1993, 1995).

A nursing home is an institution in which persons, usually elderly (sixty-five years of age and older), live and receive nursing care and supervision. The provision of nursing care and supervision differentiates nursing homes from other senior residences; the lack of advanced medical and surgical services, and the fact that a nursing home is also a residence, differentiate it from a hospital. At any time, about 5 percent of those in the United States over sixty-five years of age are in nursing homes, many more than in acute-care hospitals. Over 40 percent of those over sixty-five will spend at least some time in a nursing home (Kemper and Murtaugh). Residents of nursing homes tend to be old, poor, and sick; younger patients, often with mental disorders, chronic conditions such as HIV-related disease, or post-traumatic conditions, account for a relatively small number. Nursing-home residents are disproportionately female and white.

Most nursing-home residents have trouble performing normal daily activities, such as bathing and dressing. They often have multiple long-term problems, such as confusion or walking difficulties; these changes frequently precipitate nursing home admission, when they overwhelm informal support systems. Nursing homes are increasingly used to provide further care after hospital discharge (Densen).

Ethical problems in nursing homes differ in several ways from those seen in other settings. Decision making often involves multiple related decisions made over time. There are multiple participants, and family members are often intimately involved. Many nursing-home residents are unable to make or communicate decisions, resulting in reliance on proxy decision makers. Institutional policies and practices act as powerful constraints on the autonomy of decision makers (Lidz et al.; Kane and Caplan, 1990).

Demographic changes in developed countries that have led to an increased need for nursing homes include an increase in the aging population in both absolute numbers and percentage of the population, nuclear rather than extended families, and more women in the work force. The emphasis on autonomy and the fear of lawsuits on the part of healthcare providers and institutions may be unique to the United States, but basic ethical conflicts between respecting personal autonomy and ensuring personal safety occur in nursing homes everywhere in the world.

Reimbursement

In the United States, nursing-home care is paid for almost entirely by Medicaid and "self-pay," with Medicare and long-term care insurance accounting for only a small percentage. Over two-thirds of those in nursing homes for more than six months are covered by Medicaid. Medicaid reimbursement is usually low, and nursing homes may react by raising the rates for other payers to subsidize the Medicaid population, maximizing the number of self-payers, or minimizing the amenities offered.

Asset management, in which assets are shielded or transferred while the elder becomes eligible for Medicaid, raises several questions. Is it ethically justified for relatively well-off elders to use programs meant for the poor? Alternatively, should those elders have to spend all their resources in the last few months or years of life? Several state programs have been developed in response to these questions, in which elders who purchase long-term care insurance are covered by Medicaid when their insurance runs out (Mahoney and Wetle).

Major questions regarding reimbursement remain. Who should bear the responsibility for the long-term care of elders? What are the ethically justified means of financing nursing-home care? What mix of long-term care settings should be offered as a matter of public policy? What incentives to improve care ought to be provided to those who care for nursing-home residents? In the United States, changes in healthcare policy in the future may affect reimbursement for long-term care, including nursing-home care.

The Admissions Process

A sustained effort by families to keep elders at home or in other community settings usually precedes nursing-home admission. Problems leading to admission may include increasing confusion, decreasing ability to care for oneself, and collapse of social supports.

Pertinent questions concerning nursing-home admission include "Who is making the decision?" and "Who ought to participate in making the decision?" The circumstances in which decisions are made exert powerful influence. Thus, a hospital may put pressure on the physician and family to have the patient discharged to a nursing home after acute problems are resolved. Involved parties may have conflicting interests and obligations. For example, family members may be involved as overburdened caregivers, concerned relatives, and proxy decision makers. These factors should be identified to prevent ethical conflict in the decision-making process.

Many conflicts arise between respecting the elder's autonomy and protecting his or her safety (Collopy). Participants may disagree about whether the elder's safety is actually threatened (elder: "I'm all right, I've just tripped once or twice"; versus family: "She falls all the time. I'm terrified she's going to break her hip"). This has been called the problem of "competing realities" in long-term care decision making (McCullough, et al.). Participants may also disagree about the relative safety of the nursing home. Healthcare professionals and family members may perceive the nursing home as a safer environment than it is. Confusion, falls, and increased dependency are common sequelae of nursing-home admissions. However, those admitted to nursing homes are often very frail, and it is usually not clear whether they would have fared better at home.

The nursing home itself challenges the elder's autonomy. Lack of privacy, regimented schedules, and uniform treatment of residents without regard for their wishes or interests are common. Autonomy is also constrained by other factors, including mental and physical disorders that limit the ability to make and carry out decisions, the elder's obligations to respect the legitimate interests of caregivers and family members, and the lack of a stable public policy establishing the obligations of society to elders and of elders and their families to society (Jecker, 1991, 1995). The ethical complexity of long-term-care decision making throws into question the relevance of the acute-care model of decision making, with its emphasis on patient autonomy (Agich, 1993, 1995; Hofland, 1990; McCullough et al.). A distinctive ethic may be required for long-term care, perhaps based on mediation and negotiation of opposing views (Collopy, Boyle, and Jennings; Moody).

Decision Making in Treatment

After admission to a nursing home, everyday issues such as phone access, roommate selection, and opportunity for spiritual growth must be addressed, requiring mediation among several concerns: respect for the elder's autonomy, the obligations of residents to each other, the institution's legitimate interests, and the family's role in decision making (Agich, 1993; Kane and Caplan, 1990, 1993). The task for nursing homes is to identify meaningful possibilities for the elder's exercise of everyday autonomy in the context of these legitimate constraints on autonomy.

Under the Patient Self-Determination Act (PSDA), implemented in 1991 in response to the case of Nancy Cruzan in Missouri, advance directives must be explained to the patient upon admission. The impact of the PSDA on the low rates of advance directives for nursing-home patients in

the 1990s (Gamble, McDonald, and Lichstein) is not yet apparent. Issues requiring decision making that often arise in nursing homes include hospital transfers, artificial feeding, antibiotic use, amputation, and the use of restraints (Besdine; Volicer et al.).

Discussions of treatment choices should involve the resident, if he or she is able to participate, and family members or designated proxy decision makers, if the elder is unable to participate or desires their involvement. Although family members may not make the same choice the elder would make, many elders would still rather have family members make decisions for them (Menikoff, Sachs, and Siegler). Demented patients may be able to make some decisions about their healthcare. Decision-making capacity should be assessed by the physician relative to the particular decision that must be made. For example, a patient with moderate dementia might be able to decide not to have a leg amputated, and yet be unable to remember to take her medications without being reminded.

Competent patients or surrogate decision makers have the well-established right to refuse any treatment, though there is debate about whether they have the right to demand any treatment (Brett and McCullough). Trying a therapy for a time to evaluate its effectiveness may be a better choice than simply using or not using a treatment. However, institutions and caregivers, who have traditionally been reluctant to stop a treatment once begun, must be flexible if this approach is to succeed. Before such a trial of therapy, specific goals (such as expected improvements in status) should be agreed upon.

Conflict between family members and staff is often exacerbated by serious illness. For example, a family member who has not previously been involved in the patient's care may demand inappropriately aggressive care (Molloy et al.). When family members or staff members cannot reach a decision without significant disagreement, they may refer the matter to a nursing home ombudsman, an ethics committee or consultant, or, if there are issues of neglect or abuse, initiate a state inspection. Clerics may be helpful in addressing conflicts arising out of religious beliefs held by various participants. Legal proceedings are usually a last resort.

Many nursing-home residents with severe dementia who are not able to eat are kept alive with feeding tubes; many of these persons might not have wished to be kept alive under these circumstances. Legal decisions in U.S. courts in the 1980s and 1990s treated the provision of nutrition and hydration as medical decisions and recognized that artificial feeding is not always obligatory. However, withholding of nutrition poses special problems for some because of the special standing of "food and water" in human life. Many nursing-home policies require the use of artificial feeding if the resident's weight or oral intake falls below specified guidelines, even if this is against the patient's or family's wishes. This default position of artificial feeding is problematic in light of recent studies showing that feeding tube placement for administration of nutrition is associated with very low survival rates, and that it does not improve survival in patients with advanced dementia (Finucane, Christmas, and Travis; Mitchell and Tetroe; Rudberg et al.). Policies requiring artificial feeding may be questioned on both ethical and legal grounds. When nursing-home residents develop serious illness requiring treatment not available in the nursing home, transfer to the hospital becomes an issue. If a decision to limit medical intervention has been made, transfer may be unnecessary. Such decisions are best made well in advance of a crisis (Volicer et al.). When patients are transferred, advance directives written in the nursing home may not be sent to or considered valid by the hospital, and emergency services and other treatment unwanted by the elder or family may be given. Nursing-home administrators and physicians need to address this problem of the "portability" of advance directives.

Restraints

Restraints are commonly used in nursing homes to prevent falls and injuries to the patient and others, to prevent wandering, and for behavioral problems. Restraints can be physical (e.g., vests or wrist restraints) or chemical (e.g., drugs that alter behavior). Restraints may be used to protect the patient or for the convenience of the staff and can cause adverse physical and psychological outcomes, including death. Less use of restraints enhances the autonomy of nursing-home residents and several studies show either no change or a decrease in the risk of falls and injuries. However, restraint-free environments are often opposed due to inadequate staffing levels, fear of litigation, and the weight of traditional practice in the United States. The informed-consent process should address the benefits and risks of a restraint-free environment versus restraint use.

Research

Research in nursing homes (for example, into the treatment of urinary incontinence) may contribute to the quality of life of nursing-home residents. However, nursing-home research is complicated by problems of obtaining permission from nursing-home administrators to do such research, obtaining adequate informed consent or proxy consent in

this vulnerable population, and ensuring privacy and confidentiality (High; Sachs and Cassel). Professionals should balance the protection of this vulnerable population with an accurate assessment of each elder's ability to give consent, and should allow those who are able to consent to participate. Proxy decision makers should consider what is known about an elder's preferences as well as the benefits, risks, and need for the research.

Staff Concerns

Nursing-home staff perform difficult, frustrating tasks, are usually poorly paid and poorly trained, and are often criticized by clients, family members, or better-paid staff members who do other jobs. Staff turnover is high in most nursing homes, affecting continuity of care and staff-elder relationships. Staff members are also often people of color, in contrast to nursing-home residents, which can lead to a mutual lack of understanding and, on occasion, to racist remarks and abuse from elderly residents or their families.

Staff members who provide regular personal care often develop strong emotional ties to residents; they are exposed daily to the outcomes of treatment choices and may disagree with patients, family members, or healthcare professionals about treatment choices. Information from staff members about the patient's wishes should be considered by those responsible for the patient's care.

Local, state, federal, and accrediting requirements and regulations pose ethical challenges to administrators in allocating the scarce resource of staff time. Complying with these regulations absorbs significant staff time and resources, diminishing the time and energy staff can devote to the care of residents. The worst institutions are unlikely to be caught, and the best are likely to spend substantial amounts of time on paperwork that does not clearly contribute to care. In addition, regulatory overemphasis on the safety of residents may restrict the autonomy of elders (Lidz et al.).

Death and Dying

A common cause of death in nursing homes is an infection or another acute illness superimposed on a chronic or progressive illness. Often, patients or family members, together with physicians and nursing home staff, have decided not to treat such illnesses aggressively. Many terminally ill patients in nursing homes are eligible for the Medicare hospice benefit. Hospice care may ensure that these patients receive improved treatment of pain and other symptoms; it may also make it easier for the family and staff to accept care focused on maintaining patient comfort rather than on treating disease. Hospice units have been developed in nursing homes; some have been designed specifically for the care of severely demented patients (Volicer et al.; Keay and Schonwetter).

Cardiopulmonary resuscitation (CPR) initiated in nursing homes or in seriously ill patients is rarely successful (Applebaum, King, and Finucane). Nursing homes may be justified in not offering CPR because of the very low probability of success. In any case, patients and family members should understand that CPR is only an attempt at resuscitation with little likelihood of success. "Do not resuscitate" (DNR) orders should not be equated with "do not treat" orders. Decisions about specific treatments should be discussed and well documented in advance.

When death is imminent, many nursing homes transfer the resident to a hospital or contact emergency medical services so that death can occur elsewhere. This may be contrary to the elder's and the family's wishes. Most emergency medical service protocols require cardiopulmonary resuscitation to be attempted, which may be traumatic to the staff and family.

Conclusion

The bioethics literature tends to typify ethical conflicts among people as involving a clash between beneficence and respect for an individual's autonomy. Nursing-home ethics is far more complex and subtle, both intellectually and practically; it includes the obligations of elders to family members, other residents, staff, and institutions; the management of scarce resources, especially in response to external constraints; the limits of caregiving obligations on the part of family members and nursing-home staff; and the anticipation and prevention of the ethical problems discussed in this article.

III. HOME CARE

Home care is an almost limitless array of preventive, therapeutic, restorative, and supportive services delivered to persons living in their own homes or the home of another in the community. In the long-term care context, home care comprises home-based services delivered to chronically ill or impaired persons. Although this care may, and increasingly does, involve high-technology medical services, the majority of care is directed at functional support (Koff). Home-care services can be divided into those services considered "skilled," such as skilled nursing, rehabilitation, speech therapy, occupational therapy, and physician home visits; and those considered "unskilled," such as personal assistance with activities of daily living (like bathing or dressing), household maintenance, monitoring, supervision, and instrumental assistance (for example, shopping or financial management).

Until the twentieth century, virtually all medical care was provided in the home. As modern medicine developed more effective and technically sophisticated interventions, medical care shifted to hospitals and physicians' offices. However, by World War I, the steadily growing numbers of persons with chronic illness reignited interest in formal home-care services. During the 1940s, limitations in the ability of hospitals to meet the increased demand for inpatient services contributed to the development of hospital-based home-care services. The 1965 amendments to the U.S. Social Security Act that created Medicaid and Medicare were intended, in part, to expand the supply of home care. Further amendments in 1967 made home care a mandatory benefit, and others in 1972 streamlined the terms of Medicare program participation for home-care agencies (Benjamin). By the mid-1980s, home care was described as the fastest-growing service under Medicare (Reilly et al.).

Growth in the home-care industry has been attributed to several factors, including the preference of patients for care at home rather than in institutions such as nursing homes, the availability of informal caregivers, the increased number of users, the intensity of utilization, and the increase in public reimbursement of services. As of 1987, home-care services were provided to about 7.7 million persons of all ages in the United States, but almost three-fourths of these persons were over the age of sixty-five (Wieland et al.). The elderly (over sixty-five) population in the United States is projected to increase by 40 percent by 2020, and the use of home care is expected to increase by 60 percent during that time (Rivlin and Wiener). Among the non-aged (under sixty-five) population, use of home-care services has been profoundly affected by the growth, in certain major cities, of the population of persons with acquired immunodeficiency syndrome (AIDS)—a 600 percent increase between 1984 and 1990 (Burbridge). The increasing use of formal home-care services—those paid for directly or by third-party reimbursement, such as Medicare, Medicaid, or private insurance—has triggered concerns regarding the cost, quality, and availability of home care. The home-care "industry" has experienced increased competition, oversight, and regulation as well as growth of the for-profit sector. There has also been a steady "medicalization" of home-care services, driven to a great degree by third-party reimbursement (Estes and Binney).

About 85 percent of home care is provided by informal caregivers, usually unpaid family members, friends, or acquaintances, and a majority of both formal and informal caregivers are women (Stone et al.). Care is provided in the most personal and intimate aspects of daily life to persons who may be vulnerable because of physical frailty and/or cognitive impairment. Several aspects of home care other than the location in which it is provided differentiate it from institutionally based long-term care. Because care is provided in the home of the client or of another individual, the client may have a stronger sense of autonomy and control, may be more comfortable, and may have the protection and security of others in the home. However, care at home raises concerns of quality assurance in unsupervised settings and the protection of the client from unscrupulous or abusive providers of formal and informal care.

Several concerns are shared in institutional and home-based long-term care. For example, problems arise in addressing autonomous decision making for persons with diminished cognitive function. There are also stresses involved in receiving intimate care from strangers. Many persons needing long-term care encounter serious limitations in the availability of services and in the funds to pay for them. Clear methods to ensure quality in both settings are lacking. And families experience stress whether care is provided at home or in institutions. There are, however, important differences. Autonomy is more strongly asserted by many home-care patients, but home-care patients may be more isolated and thus dependent on family caregivers

(Young et al.). The remainder of this article considers ethical issues that pertain to the individual receiving home care, to families, to paid workers, and to the system of care more generally.

The Home-Care Patient/Client

Chronically impaired patients, particularly elderly patients, may be at "ethical risk" of being excluded from decisions regarding their care, of having their preferences disregarded, and of having no voice in social policy decisions that affect them. This risk may result from several factors, including ageism, negative stereotypes regarding disability, misinformation, well-meaning but misguided paternalism, or reactions to spiraling healthcare costs driven in part by public spending for the old and disabled. The home setting itself may influence the nature and degree of ethical risk (Collopy et al.).

Home care may enhance the opportunity to make autonomous decisions, but it may also constrain and influence decision making. The traditional view of autonomy assumes that action is intentional, self-initiated, and not influenced by others; in reality, however, we live in a complex web of influences, including those of family members, loved ones, acquaintances, and professional caregivers. Nowhere is this web more evident than in care provided at home. Family, friends, and neighbors, as well as formal care providers, may all have an interest in the decision-making process regarding the nature and scheduling of care, the selection of workers to provide the services, and even whether or not the client can be maintained safely at home.

Safety and the assessment of risk are major considerations in the provision of home care and contribute to some of the most perplexing ethical dilemmas for providers of care. Most people of any age prefer living at home, no matter how humble or risky, to entering an institution. This preference, combined with an overestimation by some clients of their own abilities and an underestimation of the risk of living at home, frequently results in an insistence to be at home despite substantial safety concerns on the part of family and professionals.

Determination of risk is an inexact science, and it is not unusual for family and professionals to underestimate or disregard the comparable risks of institutional life. Caregivers feel strong obligation to act in the best interests of clients or loved ones by protecting them from harm, and these feelings are compounded by fear of liability should harm come to the client. While some commentators argue that fears of lawsuit have been exaggerated, they remain a powerful force in evaluating the safety of a home-based-care plan (Detzel and Kapp). An emerging model for addressing the question of risk involves "negotiating" what is an acceptable risk with the client and family by being clear about the nature of the risk and about their willingness to accept both the risk and the outcomes of negative events.

The level and nature of autonomy afforded the home-care client depends in part on the characteristics of the clients, such as their age or their cognitive or physical impairments. There are significant differences in the philosophy and organization of services for the elderly as compared to younger disabled persons (Simon-Rusinowitz and Hofland). Home healthcare for older persons tends to emphasize the avoidance of nursing home placement, to employ case management to coordinate services, and to use public regulation of providers to ensure quality of care (Eustis and Fisher). What is termed *personal assistance* in the support of the non-elderly disabled, however, evolved from the independent-living movement among working-age disabled persons who maintain that they are handicapped primarily by environmental barriers rather than by individual impairments or disabilities (DeJong et al.). Personal assistance encompasses a broader array of services than is usually found in medically oriented programs; it aims to maintain the client's well-being, personal appearance, comfort, safety, and interaction beyond the home. To the extent possible, these services to the disabled non-elderly are user-directed, with consumers supervising their personal care when possible. By comparison, for older clients, despite an emphasis on client autonomy, decisions such as scheduling services and selecting caregivers are made primarily by agency personnel without significant attention to consumer preferences (Hofland and David).

Clients may be motivated in several ways to control formal and informal caregivers. Clients are, after all, living in their own homes, and they are accustomed to having tasks accomplished in specific ways. They have habits and routines, and they may be supported by family members who share their preferences. Caregivers, for their part, are prompted to provide care and perform tasks not just by the wishes of the client but by their own values, preferences, work styles, and competing demands—and for formal caregivers, by the rules and regulations of their agencies and payors. Harry Moody argues that a model of decision making that focuses on accommodating and reciprocating autonomies is most appropriate in addressing these multiple interests. By this, he refers to a negotiation among competing needs and preferences. For example, a home-care client may not be able to refuse all formal care and remain at home and engage in behavior that is dangerous and disturbing to other persons in

the building. He or she may, instead, negotiate staying at home with unwanted services.

Family Issues

Families are intimately involved in home care in several ways: They may be direct providers of informal services, may be involved in care decisions, or may live in the same home as the client and thus have their lives directly affected by formal care providers. While clients and their families might be expected to share values, preferences, and living styles, they often do not; sometimes, in fact, interests and values clash. For example, a family member may value safety and cleanliness more than the client does; the client may be more interested in preserving privacy and avoiding having a stranger "messing with my things." The relationship between formal and informal caregivers is poorly understood, raising concerns that the increased support of formal services may "erode" family caregiving (Hanley et al.). Ethical concerns arise when "needs assessment" for formal services includes consideration of the availability of family caregivers, as is required by law in some U.S. states. This raises the question of whether clients with family members who might provide services should be considered less eligible for home care than those with no such family members.

Conflicts may also arise about what can reasonably be expected from informal caregivers. Most families do not "dump" disabled family members into institutions but rather struggle to maintain elders at home for as long as possible. Surveys of family caregivers document a variety of stress-related illnesses, such as heart disease, stomach ulcers, and sleep disturbance, as well as alcohol or drug problems and marital difficulties (Brody). Because women are more likely to be caregivers, they carry a disproportionate share of the burden. Many women find themselves "sandwiched" between the care needs of an older parent or grandparent and the needs of a spouse, child, or grandchild. Because the extent of filial obligations is unclear, family caregivers may feel guilt and shame for not "doing enough," and persons needing care may feel either that they have been abandoned or that they are asking too much. Stephen Post argues that there are limits to familial obligations, and that social policy should do more to support the family in meeting its obligations.

Although we speak of the moral obligations of "the family," it is usually an individual family member, either explicitly or implicitly designated, who bears most of the burden of caregiving. These caregivers are usually women, most of whom have been providing care for more than five years; 35 percent of them are over the age of sixty-five, and 80 percent provide assistance every day of the week (Stone et al.). Women who provide home care to a parent, spouse, or other family member may do so at substantial personal cost, including personal health, lost professional and work opportunities, other personal interests, and other relationships. The interests of and burdens on caregivers should be considered when care plans are developed. If the care plan places heavy demands on an informal caregiver, it may justify constraints on client autonomy. Although "caregiver burden" is a well-recognized concept, Jaber Gubrium argues that we should hesitate to identify caregivers as "victims," noting that there are important factors that mitigate caregiver stress, including social supports, attitude toward caregiving prior to caregiving crises, personal well-being, a sense of mutuality between the caregiver and persons receiving care, and how prepared caregivers feel for the caregiving role (Archbold et al.; Zarit et al.).

Families differ in many ways that directly influence informal care and use of the formal system. While high levels of diversity exist within ethnic groups, differences among ethnic groups have been noted. Blacks and Native Americans have more widowed and divorced persons of both sexes than do whites, and they are somewhat more likely to live in extended family structures. There is also substantial home care provided by minority family members, attributable both to preference and to other factors, such as poverty, racial bias in the service system, and willingness to tend to young children in return for care (Brown; Cueller).

In healthcare, we tend to focus on the individual client; for most persons, however, there is a family context in which decisions are carried out. This context may constrain choices, but it also provides the individual with support and assistance that would otherwise be unavailable. Moreover, for clients whose capacity to make decisions is impaired, the family usually provides guidance in decision making (Nelson). This practice is supported in common law, and many states have enacted "family decision" laws that formalize this custom. The priority list is similar in most states: court-appointed guardians, spouse, adult children, parents, adult siblings, close friends, and extended family (Capron).

Although the family is usually viewed as a resource and source of support for the client, there are circumstances in which the family may perpetrate abuse and neglect. Protection of clients from abuse is difficult for several reasons. Abuse in the home may go undetected: The client may be unable or reluctant to report abuse due to extreme disability, fear of the caregiver, or shame. The client may be unwilling to act, preferring to stay in an abusive setting because alternatives are unknown, unavailable, or unattractive. Many states require that professional caregivers report suspected

abuse of elderly persons via "elder abuse reporting laws," but responding to family failure in care is strategically difficult and ethically complex (Collopy et al.).

The Work Force

The paid work force for long-term home services consists of both skilled professionals and "unskilled" aides and personal assistants. Workers may enjoy the relationships that develop with patients and families, the opportunity to help others, and some flexibility in hours. However, workers may also face difficult working situations, travel to unsafe or dangerous neighborhoods, homes that are unclean and sometimes hazardous, and close contact with clients and/or family members who may be unpleasant, noncompliant, and even abusive. For unskilled workers such as aides and assistants, these difficulties are compounded by fluctuating schedules and hours, limited benefits, minimal training in necessary skills, and limited opportunities for promotion. The majority of home-care workers, both paid and informal, are women.

The quality of care and the reliability of workers are heavily influenced by the nature of the work, which may be monotonous and unpleasant, and by difficulties in attracting quality workers for minimum wage. In some cities, workers are drawn heavily from immigrant and/or minority populations, sometimes resulting in cultural conflicts and language difficulties between workers and clients. Clients may be uncomfortable having unfamiliar persons in their house, and workers may be treated with suspicion or hostility and confronted with racist comments. Work-force difficulties are increasingly exacerbated by the entry of women (who would otherwise provide informal care) into the paid labor force. Increased competition for workers from other service industries has reduced the availability of home-care workers in some areas. The affordability of some home-care services has been based, in part, on the low wages and benefits paid to unskilled workers, who are mostly women; this fact raises concerns regarding the exploitation of persons unable to find employment elsewhere.

The Healthcare System

Despite legislation intended to increase home-care services, restrictive eligibility requirements, perverse reimbursement incentives, and gaps in the continuum of care impede the home-care system. Not-for-profit agencies, such as the Visiting Nurse Association, face increasing competition for "attractive" clients, that is, those who are eligible for sufficient reimbursement. Hospitals, responding to reimbursement incentives, discharge patients who require heavier and more complex care. Third-party care "managers" regularly review clients' needs and have expanded paperwork and administrative reporting.

Case management, which has become an integral component of the home-care system, involves assessment of clients, determination of eligibility for public funding or insurance benefits, development of a care plan, and monitoring the quality of services (Quinn). While case management is viewed by many policymakers as fulfilling necessary gatekeeping and quality assurance functions, many home-care agencies view case management as yet another layer of bureaucracy and an additional expense in the system. Most case management agencies seek to empower clients by assisting them in implementing decisions. In their role as client advocates, case managers may find themselves in conflict with home-care agencies or family members who do not agree that the plan of care is safe, or who argue for more services than the agency can "afford" to provide under spending limits for individual clients or budget caps for groups of clients. The ethical conflicts case managers face as they balance the roles of gate keeping, quality assurance, and client advocacy are just beginning to be explored (Kane; Wetle).

Conclusion

Home care involves a complex and growing industry that is intricately intertwined with family caregiving. Most persons would prefer to remain at home, even when their need for assistance is substantial. Many persons would also prefer to give and receive care within a family context. However, the demand for home-care services can overwhelm the ability of family members to provide care in the face of other, competing family and work demands. Emerging changes in the healthcare system, including long-term-care insurance and public-healthcare reform, may encourage increased reliance on home care for persons with chronic conditions and illnesses. While additional resources for home care would be welcomed, we must be vigilant to the ethical concerns and values, not only of the home-care client but also of family caregivers and the paid work force, particularly women and disadvantaged persons. Efforts should also be made to develop formal services that are culturally appropriate and that meet the special needs of persons from diverse cultures and racial minorities.

M

MALPRACTICE, MEDICAL

• • •

Medical malpractice is a legal system that permits victims of certain medical errors to sue for their injuries. It is a branch of tort law and, like tort law generally, is intended to achieve several policy objectives. (The discussion below focuses on medical errors committed by physicians, but the medical malpractice system may hold accountable other types of healthcare professionals as well as institutions such as hospitals and managed-care organizations.)

Objectives of the System

The first objective of the medical malpractice system is to compensate the victims (or in some cases their families) for the losses they sustained as a result of the malpractice. Although some of these losses, such as pain and suffering, are non-economic in nature, the malpractice system awards only money damages. The idea is to use money to restore the victim as much as possible to the condition the victim would have been in if the malpractice had not occurred. Along with pain and suffering, a successful plaintiff can recover the additional medical expenses necessitated by the malpractice episode, lost earnings (including both lost wages from having missed work and reduced earnings in the future as a result of diminished earnings capacity), and monetary compensation for other types of emotional deprivations, such as loss of enjoyment from being unable to engage in certain activities like sex or sports. It follows from these measures of damages that the same act of medical misfeasance—for example, the failure to correctly diagnose a treatable illness in a timely manner—can yield dramatically different damage awards for different victims. Someone who is old, for example, will have fewer years of work left than someone who is young, and therefore will receive less for diminished future earnings capacity.

A second objective of the malpractice system is to deter physicians from making medical errors that injure patients. The premise is that medical mistakes can be prevented by taking greater care, such as by spending more time with patients, employing more sophisticated diagnostic tools, and so forth. Taking greater care, however, consumes greater resources. The malpractice system gives physicians an incentive to invest these additional resources in order to avoid being liable for damages.

The third objective of the malpractice system is retributive justice—to punish wrongdoers and to enable victims to exact revenge. Along with sanctions imposed by criminal law, tort liability reduces the risk that victims will take the law, so to speak, into their own hands.

Functioning of the System

A plaintiff in a malpractice case must prove certain propositions in order to recover damages, including that the physician actually caused harm to the plaintiff and that the defendant was negligent, meaning that the defendant's behavior deviated from the applicable standard of care—that of a reasonable physician under the same circumstances. Typically, the plaintiff must prove through the testimony of expert physician witnesses how a reasonable physician would have behaved. At one time, before courts adopted more flexible approaches, only a physician from the same locality could testify about the standard of care, which made it difficult or impossible for plaintiffs in small towns to find suitable expert witnesses. The expert testimony, including testimony from opposing experts for the defendant, is

supposed to describe how physicians *should* behave. In practice, however, experts may testify about how physicians *do* in fact behave, and judges and juries typically accept this evidence of professional custom as the standard of care. A notable exception is the case of *Helling v. Carey,* in which the Supreme Court of Washington State held that the entire profession of ophthalmology was failing to meet the standard of care by not routinely testing younger patients for glaucoma.

In theory, establishing whether or not someone is negligent involves a cost–benefit analysis; actors are negligent if the cost of preventing the injury is less than the risk of the injury, measured in terms of its probability and severity. In order to avoid being negligent, physicians therefore should expend enough resources to reduce patient risk to the point that any further expenditure on prevention would exceed the value of the risk being prevented, and therefore be inefficient. But because the value of a risk can be expected to vary from one patient to another, how is it to be calculated?

Here is where the doctrine of informed consent enters into malpractice law. In addition to promoting patient autonomy, informed consent assists patients and physicians in making accurate calculations about how much to spend to reduce the risk of error. By assigning a high cost to a particular injury, for example, risk-averse patients will demand greater risk-reduction expenditures. This raises a difficult question concerning how far the law will allow patient preferences to control the standard of care. Suppose a patient opts for a treatment approach that is contrary to mainstream medical practice. Does the patient's choice relieve the physician of malpractice liability? Traditionally, the law has recognized the need to permit physicians to deviate from customary practice in appropriate circumstances, such as when the mainstream approach has failed to provide a benefit to a specific patient; physicians who deviate from the mainstream approach are not negligent if, in addition to obtaining the patient's informed consent, they can prove through expert testimony that their approach would have been followed by a "respectable minority" of other physicians.

But why should a fully competent and informed patient not be permitted to agree to an alternative and complementary treatment that no other physician would employ? To what extent should malpractice law protect patients from their own folly? A related question is whether a patient ought to be permitted to waive the physician's malpractice accountability, in return, say, for a discount in the price of care. The law traditionally has frowned upon such releases from liability, fearing perhaps that patients who made such agreements must not be able to afford to pay for needed services, and therefore they should not be deemed to be acting voluntarily. But from the physicians' perspective, this traditional view may no longer be feasible in the era of managed care, where patients may be covered by low-cost plans that do not pay for some services that the medical profession considers to be customary.

Physicians are covered by malpractice insurance, which pays the damage award, up to the policy limits, if plaintiffs are successful, and also covers the costs of the physicians' defense attorneys, who typically are hired and controlled by the insurance companies. Insurance covers only a portion of the physician's malpractice costs, however; physicians also incur uninsurable costs in the form of time lost from practice while defending cases, emotional costs, and possible loss of membership on hospital medical staffs and in managed-care networks. Malpractice insurance premiums are based principally on the physician's geographic location and area of medical specialty, rather than on the physician's past malpractice history ("experience rating"). Increasing premiums for physicians who are repeatedly and successfully sued for malpractice would seem to be an obvious means of helping to deter future misfeasance, but insurers contend that they cannot experience-rate physicians because the number of claims is too small.

Evaluation of the System

How well does the malpractice system perform its intended functions? According to the Harvard Malpractice Study, which examined hospital records in New York State from 1984, only about one out of eight patients whose records revealed that they had suffered a malpractice injury filed a claim, and only about half of these claims resulted in compensation. Other empirical data, however, have shown that the more severe the injury, the more likely the victims are to be compensated, and the greater the amount of recovery. Critics of the current system assert that the awards recovered are excessive, but others disagree. The system is clearly time consuming; claims take an average of twenty-five to thirty months to be resolved after they are filed with the insurer, which can create severe economic problems for victims who lack healthcare or disability insurance. In the United States, plaintiffs' lawyers take cases on a contingent fee basis, receiving an average of approximately 33 percent of the plaintiff's recovery if the case is successful. If the case is not successful, the attorney not only recovers nothing, but typically must pay out-of-pocket for court costs and expert fees. Attorneys therefore can be expected to refrain from taking cases that are marginal on their merits or that do not involve a substantial amount of damages. Because, as noted earlier, the amount of damages is contingent on such factors

as the victim's age, some victims accordingly have difficulty finding lawyers to represent them. On the other hand, there are anecdotal reports that some plaintiff's attorneys file frivolous lawsuits in the hopes that the defendants will settle in order to avoid litigation costs. Unlike in Great Britain, where a plaintiff who loses a malpractice suit must pay the defendant's attorneys' fees and court costs, defendants in the United States must bear those costs themselves, and defense attorneys, unlike attorneys for plaintiffs, get paid regardless of whether they win or lose.

There is little empirical information on why so few malpractice victims assert claims. Clearly one reason is that they do not realize that they have been the victims of malpractice. Studies also have shown that patients who have positive interactions with physicians are less likely to file claims despite becoming aware of malpractice, and that patients are less likely to sue after physicians have apologized for mistakes. The latter practice is discouraged, however, by the fact that, in all but a handful of states, the physician's apology is admissible in a lawsuit as an admission of liability.

There are no good data on how well the malpractice system performs its deterrence or retributive functions. Some critics point out that medical errors persist despite the malpractice system and that the number of claims is growing. Others argue in effect that the system is overdeterring physicians by causing them to practice defensive medicine.

Malpractice insurance premiums comprise a substantial portion of the overhead of the practice of medicine. Premiums have tended to increase over time, due at least in part to significant increases in the number of suits filed (known as *frequency*) and the size of damage awards (known as *severity*). Premiums also reflect the cost of defending suits, including the costs of attorneys and expert witnesses. It is estimated that for every dollar of malpractice insurance premium, only 30 cents actually goes to victims.

Malpractice premiums also have gone through periods of rapid increase, especially around 1975, 1985, and beginning again in 2001, leading these periods to be characterized as *malpractice crises.* In addition to large premium increases, these crises are marked by insurance companies exiting certain markets, and anecdotal evidence suggests that some physicians switch from higher to lower risk specialties, move to geographic locations with lower premiums, or retire from practice prematurely. The malpractice crisis of 1985, for example, has been blamed for physicians leaving rural practices and abandoning obstetrics. The semicyclical nature of these crises, and their proximity to economic downturns, suggest that at least a partial explanation for why they occur can be found in the behavior of the malpractice insurance industry itself, which creates what are termed *insurance cycles.* These begin when insurance companies reduce premiums to attract more business. As claims frequency and severity continue to increase, the amount of premium funds becomes too small to pay claims, and a weak economy decreases the return on the insurance companies' investment portfolios, which they had counted upon to make up the shortfall. This leads to sudden, rapid increases in premiums, insurer insolvencies, and withdrawal of companies from less profitable markets. Eventually the market stabilizes, and insurers once more decrease premiums, beginning another cycle.

These crises have led to two main types of legislative responses. In reaction to the malpractice crisis of the mid-1970s, state legislators took steps to help ensure that healthcare providers had access to medical malpractice insurance. They provided for the creation of physician-owned mutual insurance associations, joint underwriting associations and similar entities called reinsurance exchanges, and state-run reserve funds, intended to augment the coverage provided by the market. The second major legislative response was that a number of state legislatures changed the rules governing the malpractice system to make it more difficult and less remunerative for victims to sue. These so-called reforms include *caps,* or statutory limits on the amount of damages or the amount of non-economic damages that a successful plaintiff can collect; reductions in the maximum length of time (set by statutes of limitation) that victims have in which to file suits; prerequisites to filing suits (such as first having the claim reviewed by a panel of physicians); and repeal of the collateral source rule, which allows plaintiffs to recover medical and other expenses from defendants even though these had been paid by third parties, such as health insurers. (The collateral source rule typically does not result in a windfall for successful plaintiffs, because insurers usually are "subrogated" to the plaintiffs' claims, meaning that the plaintiffs have to reimburse the insurers from the proceeds of their recovery. The effect of repealing the collateral source rule is that healthcare costs that once were shifted from health insurers to malpractice insurers must now be borne by the health insurers.) One of the broadest sets of reforms was enacted in California by the Medical Injury Compensation Reform Act (MICRA), which limits damages for pain and suffering to $250,000, places restrictions on attorney contingent fees, repeals the collateral source rule, allows health plans to require enrollees to submit malpractice claims to binding arbitration, and requires large damage awards to be paid in installments rather than in a lump sum.

Of all of the changes in the traditional malpractice system, only caps on damages and repeal of the collateral

source rule appear to have reduced malpractice cost indicators, such as premiums. Many of the caps have been overturned by state courts as unconstitutional violations of equal protection laws or deprivations of the constitutional right to a jury trial. Courts have questioned, for example, why it should be more difficult or less remunerative for victims of medical malpractice to receive compensation than for persons who have suffered other types of injuries covered by tort law.

Another malpractice crisis is taking place in the early 2000s. Renewed calls are being made for state legislative action. One recurrent proposal is some form of "no-fault" system, whereby the current tort approach would be replaced with an administrative scheme similar to workers' compensation. Victims no longer would have to prove that a physician was negligent in order to recover damages; instead, an administrative body would promulgate a list of compensable events and a schedule of associated compensation amounts. Proponents argue that more victims would receive compensation, and do so more quickly and with lower administrative costs, than under the current system. Opponents point out that, in order to be affordable, no-fault proposals would have to reduce the maximum amount of damages that victims could recover, with some proposals eliminating compensation for pain and suffering altogether. Critics question the fairness of depriving those who are most seriously injured of the large recoveries they are entitled to under the current system.

So far, the no-fault program has been adopted only in a limited fashion, in Florida and Virginia. In both states, one set of malpractice claims—those that stem from birth-related injuries—has been withdrawn from the traditional tort system, and victims are compensated under an administrative system similar to workers' compensation. Neither state program provides compensation for pain and suffering. Florida provides no award for lost future earnings. Nevertheless, some studies suggest that if attorneys' fees are subtracted and if the portion of the no-fault award that is placed in reserve for future expenses is included, the Florida program provides the same amount of compensation to victims as comparable cases do under the tort system. It remains to be seen, however, whether a no-fault program extending to a wider set of malpractice claims would be economically feasible without more significantly reducing the size of recoveries.

One legislative development that has affected the medical malpractice system is the National Practitioner Data Bank. Mandated by federal law, the data bank receives reports of all payments made by insurers in response to malpractice claims, including settlements, as well as adverse actions by state medical boards, hospitals, and managed-care plans. Hospitals are required to check the database in the course of making privileging and credentialing decisions, and state medical boards are permitted to access the data bank when considering applications for medical licenses. The purpose of the data bank is to prevent physicians (and other healthcare professionals) who have had their licenses or hospital medical staff privileges revoked, suspended, or limited, or who have been involved in a number of malpractice actions, from concealing these facts when they seek licensure, hospital privileges, or membership in a managed-care physician network. One result is that physicians may be reluctant to settle malpractice cases, preferring instead to go to trial and hope to be vindicated, in which case no report will be filed with the data bank. This in turn may place physicians in conflict with their malpractice insurers, who may prefer settlement as a means of keeping down their litigation costs.

MANAGED CARE

• • •

With the growth of employer-based medical insurance following World War II, fee-for-service indemnity insurance became the prevailing mode of financing healthcare delivery. Even prior to the rise of indemnity insurance, care was provided—for those who could afford it—in exchange for a fee or as part of a barter arrangement. Thus, a physician's order for care and the resultant delivery of care essentially commanded a payment from a payer source (for example, from a health insurance company, a self-insured employer, the government, or an individual patient) to a provider. For those who were insured and who could afford paying their co-pays and deductibles, there were few, if any, financial constraints on the delivery of healthcare in the fee-for-service era. Both healthcare costs and provider wealth soared under fee-for-service insurance; and there is compelling evidence of over-utilization of services, variable quality of services, and an increasing percentage of uninsured Americans in this period. If three cardinal measures of a well-functioning health system are quality, cost control, and access, fee-for-service financing was an across-the-board failure.

In this era, a mentality of entitlement arose among both physicians and insured patients. The insured patient was entitled to any care deemed beneficial by their physician; and the physician (by virtue of professional prestige and the resulting presumption that practice would be ethically balanced by the duties to both benefit and do no unnecessary harm to patients) was entitled to order any treatment he or she deemed to be consistent with that ethic. While physicians have, at the beginning of the twenty-first century, lost the political and economic power to practice in such an unfettered way, insured patients carry the mentality of entitlement forward, and Americans generally exhibit little understanding of the cost problems in healthcare. This is not to blame the general public as patients or consumers, but instead to assert the need for a more educated citizenry, as part of a next effort to seek a solution to the healthcare crisis of balancing quality, cost, and access.

The Rise of Managed Care

Between the end of World War II and the early 1980s, there were a few health maintenance organization (HMO)-precursor and healthcare cooperative arrangements in the United States in which individuals pooled their resources to assure themselves and their families access to medical care. In these arrangements, physicians usually settled for salaries for managing the care of their enrolled patients and population within a budget. The 1973 HMO Act created economic incentives for the creation of *federally qualified* HMOs. In essence, the act allowed for competition on cost and quality between HMO and fee-for-service arrangements. In the early 1980s, a major shift in the financing of healthcare began occurring in the United States. As a result, the financing and delivery of healthcare came to be integrated in a new way known as *managed care.* This shift also represented a significant change in the balance of power between the providers (physicians, hospitals, and delivery systems) and the financiers of healthcare private and public insurers.

In 1983, with the imposition of Medicare diagnosis-related groups (DRGs) the federal government took a major step to institute financial constraints on healthcare delivery. DRGs, which then applied only to hospitals, required hospitals to manage the care of a patient with a particular diagnosis for a set dollar or reimbursement amount. Hospitals, of course, began facing new economic threats under this arrangement. A critical unmanaged element in the healthcare delivery equation remained the physicians' accustomed approaches to ordering patient care. A hospital's failure to manage care within the Medicare reimbursement amount meant incurring a financial loss that needed to be recovered elsewhere. It also meant that surplus funds that used to be available through overpayments by Medicare could no longer be *cost-shifted* and used to support education, medical research, and charity care. Initially, this led to raising the costs for services to the privately insured, which translated into higher insurance premiums for employers and individuals. When employers or individuals could no longer afford premiums, the number of uninsured rose.

For physicians, as it had for hospitals, managed care arrangements represented a decisive change in the relationship between dollars and decisions to order healthcare services for patients. Physicians had historically been the directors of care, unconstrained by the payers in fee-for-service arrangements. Now the payers had achieved sufficient power to financially constrain physicians' ways of practicing medicine. Cost ceilings were created for the

provision of specific services; physician utilization patterns became targets of payer scrutiny and additional financial controls; physicians were required to enter into risk-sharing arrangements in exchange for access to patients in insured networks; financial incentives like bonuses and withholds were instituted to control physicians' utilization of services; and physicians were encouraged to follow practice guidelines developed from a population perspective and focused on cost-effectiveness to manage patient care. In many ways medical practice had been absorbed into the insurance side of healthcare. Thus arose managed care: a way of integrating the financing and delivery of healthcare so that the former drives, rather than is driven by, the latter. Managed care includes various organizational arrangements, approaches, tools, and strategies. It is not a single definable practice. Common threads are fiscal incentives concerning healthcare service delivery.

At the same time that the economic struggle was going in progress who would control the price tag and reap the profits of healthcare, important efforts were underway to raise the quality of healthcare by encouraging a transition to medicine as an evidence-based practice, not simply an individually-practiced art. One way to manage healthcare dollars is to restrict payment to what we know works, that is, to pay only for healthcare that has been proven to generate valued patient outcomes. Managed care reasonably declared itself to be focused on payment for medically necessary, cost-effective care.

The Managed Care Backlash

Managed care ran into significant public opposition in the imposition of policies such as twenty-four hour hospital stays for new mothers and the refusal to pay for unproven interventions for patients with life-limiting diagnoses. (Interestingly, though it is managed care organizations that have been assailed for excluding coverage for experimental treatments, this exclusion is a carry-over from fee-for-service days. Traditionally fee-for-service insurers also refused to cover unproven interventions.) What was rational to a managed care mind was fundamentally irrational or uncaring to the public's mind. Disconnected from the growing cost crisis in healthcare, the public was deeply at odds with the ethic inherent in the workings of managed care. This sentiment should have led the managed care industry to assess the ethical difference and adjust its coverage and pricing accordingly, or engage the American citizenry in a deeper discussion of these important issues in the interest of managing healthcare costs. A few managed care organizations chose to acknowledge the difference between their ethic as the manager of healthcare for a population within a defined budget and the ethic of their individual constituents and to work toward a resolution. Many if not most others ignored the fundamental tensions between individual and population good and the even larger tensions associated with for-profit healthcare payers displacing providers in the healthcare driver's seat. To date none of the significant health system stakeholders has prioritized an effective, rational public conversation around the polarizing goals of improving access, improving quality, controlling spiraling healthcare inflation, and enhancing patient and physician autonomy.

Managed care grew out of a serious need and effort to reduce healthcare spending. There were also serious concerns about quality in healthcare that were being pursued in tandem with and as part of the move toward managed care. If fee-for-service encouraged a culture of over-utilization, it also promoted harm through over-treatment; unbridled access to specialists undermined primary care and the coordination of care; and patients were subject to care recommendations that reflected the experience of the individual physician rather than systematic empirical information about patient outcomes. If the quality improvement movement rather than the struggle over wealth between providers and payers had led the managed care evolution, and communication with the public had been deliberate, things might have gone very differently.

And yet, who could take seriously discussions on such issues instigated by huge for-profit healthcare organizations that have come to dominate the healthcare marketplace? The public was never a real player in considering the big issues and has yet to be educated to understand the deeper questions that face the American healthcare system. The next evolution of our system will see a new group—or groups—in control. The options are: providers (who do not organize well); healthcare financing companies (the payers that have amassed incredible economic and political power along with potentially insurmountable public relations crises); medical manufacturing industries (the pharmaceutical and technology companies that are currently able to pass largely unregulated costs onto payers); group purchasers of insurance (employers, unions, and government that increasingly search for ways to cap their own financial risk and empower individual decision making and choice); individual purchasers of insurance (who have no market clout whatsoever and poor options for affordable insurance); patients (who are divided up into a myriad of insurance arrangements in ways that undermine their ability to organize and who feel entitled to all beneficial care); and the uninsured (40 million residents of the United States and growing).

The public backlash has been too significant to ignore: The public is now called upon to spend more for healthcare, while still facing threats to their felt entitlement to all beneficial care. Managed care organizations are assailed for failing to control costs, even as legislatures, courts and the court of public opinion prohibit them from implementing many of the tools that constrain costs. For-profit healthcare conglomerates now dominate the health system as a whole, and are among the only good bets on the stock market in 2003. Clearly, there is money there, but patients are not happy, providers are not happy, purchasers are not happy, and costs continue to rise exponentially.

In principle, managed care offers the major purchasers of healthcare (employers, unions, and government) competitively priced insurance, institutes quality-control measures to determine and encourage cost-effective care, and provides enrollees (the insured) fair access to quality healthcare from credentialed providers within a finite budget. If one assumes that effective cost control will promote a lower percentage of uninsured, managed care has the potential to serve the goals of quality, cost control, and access in a manner far superior to fee-for-service.

Yet between the principle of managed care and its implementation have fallen the shadows of public discontent and the ongoing struggle among stakeholders for economic ascendancy. The assumption has been that the market-guided evolution of managed care would issue in cost-contained, accessible, high quality healthcare for a larger share of Americans. That assumption has not been true at the beginning of the twenty-first century.

Many analysts believe that managed care is here to stay, although in forms rather markedly different from the classic HMO model of the 1980s. It is now best thought of as multiple arrangements that use selected elements of a managed care toolkit, the defining elements of which include definitions of medical necessity, practice guidelines, risk-sharing arrangements, financial incentives, and coverage policies.

Ethical Issues Raised by Managed Care Arrangements, Strategies, and Tools

From an ethical perspective, the most serious concern with managed care is that it threatens the fiduciary or trust relationship between physician and patient. Many have argued that the special *covenantal* relationship between the physician and patient necessitates a nearly absolute freedom from financial constraints on the part of the physician. While the physician–patient relationship has never been free from financial conflicts of interest, it has been argued that conflicts that induce under-treatment rather than overtreatment more seriously threaten the fiduciary quality of the relationship. In either case, however, the fiduciary character of the relationship appears sorely threatened. Despite this, the public seems to fear the withholding of necessary care more than overtreatment, and sees the physician's integrity to be more easily undermined by risk-sharing arrangements with insurers than by a more traditional for-profit practice arrangement. Ultimately, those who pursue the fiduciary profession of medicine are the last, best strongholds of the values we all hold concerning this vital human relationship. Both forms of financial conflict threaten the fiduciary role, and it falls to the moral character of the physician and other clinicians to hold the line against the compromising of that role.

Perhaps the truth is that it is easier to summon the moral courage and fortitude this requires under fee-for-service than under managed care. After all, if risk-sharing and financial incentives/disincentives and other threats are too onerous and direct, physicians will be hard-pressed to avoid the influence of the dollar on their decisions to order services. It seems clear that in the interest of maintaining the fiduciary quality of this professional role, some managed care *tools* for constraining physician utilization are themselves unethical and must be regulated.

It also seems clear that in addition to the responsibilities physicians have to their individual patients, physicians have obligations to the population of patients they serve—not only the patients in the same enrolled population, but all of the patients they might be called upon to serve (including patients requiring pro bono services due to being uninsured). The ethical tension in this role is unavoidable: Physicians must, at the same time that they seek to provide for their patients' needs, assume a resource management attitude. Physicians do not have the option of arguing that they should be able to practice without concern for cost. Somehow, in their everyday practice, they must manage this tension with an ethic of proportionality: The most serious of patient needs must be met with an appropriate outpouring of human and financial resources, while lesser needs are addressed proportionately.

This raises another issue as well: Some patients and groups of patients are much more expensive to treat than others. In short, there is a financial disincentive that automatically attaches to treating the neediest patients, unless risk-adjustment enters into the picture to protect providers. The very fact that an epidemic of service line closures is affecting the most vulnerable and costly patients (e.g., behavioral healthcare) suggests that very different solutions to the provision of certain healthcare services are needed where the market-based effort to control healthcare costs has collapsed.

The fact that resources are to be managed to deliver quality care to individuals based on their medical needs and to fairly distribute healthcare resources throughout a covered population represents a series of ethical quandaries. Managed care tools designed to manage the extreme ethical tension created by this dual goal include definitions of medical necessity, practice guidelines, and coverage policies. In managed care arrangements, evidence gathered about what works (i.e., improves the level of health from a population perspective) is captured in practice guidelines and coverage policies, that are then applied to coverage determinations for individuals.

One of the reasons medicine has always been considered an art is that it requires a depth of attention to the patient as a physical body and also as a person. While there may be algorithms to assist in determining care options when diagnoses are clear, when they are not clear, or the patient is outside clear diagnostic parameters, population-based formulas may well be off the mark. If medicine is both science and art, and contributes to healing and/or comforting through both intellectual and personal power, then clinical autonomy remains an essential feature of the practice of medicine that must somehow be blended with the power of population-based practice guidelines and coverage policies.

Further, one of the great fears must be for patients with conditions for which there are little or no practice guidelines and for which medical research has yet to find good options—and may even have few incentives to seek options. Vulnerable populations have been historically neglected in research. Mental and physical rehabilitation, crucial to quality of life, in some cases lack good evidentiary bases. Coverage for such interventions should not be denied when they may well represent a best chance for a functional life.

This leads to the issue of managed care's assumption that coverage be determined by a standard or set of criteria of medical necessity. What constitutes medically necessary care? Care that *may* restore function? That is *known* to restore function? Care that will *enhance* function beyond the normal range? Here again, the managed care disconnect from public sensibilities has been extreme. For the public, if something stands a chance of improving function or extending life, however small that chance, it is medically necessary care. For managed care organizations, there must be evidence that an intervention will improve function, as expressed in coverage policies and practice guidelines.

An Ethical Framework for Managed Care

The cornerstone of the traditional clinical ethics framework was, of course, patient autonomy or self-determination. The additional principles were beneficence, nonmaleficence, and justice. Can this framework be exported from clinical settings to organizational situations in which financing constrains patient care decisions and arrangements, or is a new ethical framework needed?

A novel framework seems to be required. One *could* say that the justice principle of the clinical ethics framework could be extended to guide the resource management responsibilities of managed care arrangements for their covered populations. But the principle of justice of the clinical ethics framework was always more individually than communally focused. It concerned the primacy of individual claims to benefits and individual rights not to be unfairly burdened for the sake of others, not communally beneficial distributions. Because managed care arrangements manage healthcare access and serve *both* populations and individuals, they have duties of *stewardship* and of protection of the fiduciary quality of clinical relationships. Because the personal good of healthcare is now available to individual patients through complex insurance businesses, *advocacy* supporting patient *autonomy* in clinical decisions and rights as an insured member of an enrolled population becomes an additional ethical imperative. Neither the patient-population tension nor the dependent relationship of care to coverage can be eliminated. The ethical tensions inherent in managed care must be named in a new healthcare organizational ethical framework, just as the tensions in clinical care were named in its ethical framework. If stewardship, autonomy, and advocacy should be included in the new framework, so must be principles of *truth telling* (both about clinical options and coverage), and *confidentiality.* Additional ethical principles, carryovers from the clinical ethics framework, are *beneficence* and *nonmaleficence.* Each of these principles must be interpreted for the financing and delivery arrangement that currently dominates the U.S. healthcare system: namely one in which financing constrains delivery.

Because managed care arrangements and tools provide the context for clinical relationships, a broader ethical framework for the analysis of ethically problematic situations is required. In addition, guidelines for the protection of essential features of clinical relationships are required. In the absence of these ethical principles and guidelines, there is no disciplined way to identify and remove unjustifiable threats to individual patients, or for that matter, to the population.

The ethical responsibilities of managed care organizations arguably extend to the broader community and society. They control distribution of healthcare resources, and as explained above, have compromised the capacity of provider organizations to cost-shift to support education, research, and charity care commitments. Society has yet to come to terms with the obligations of managed care organizations to support community needs such as these. This issue is even

more problematic when one draws the distinction between nonprofit and for-profit health systems. Due to their tax-exempt status, the former are required to provide community benefit. Due to the fact that they pay taxes, the latter have no parallel requirement; they may operate like any business, supporting community interests as they deem conducive to their own interests, despite that they exert substantial control over the healthcare resources available to their community. It is essential to determine, from an ethical perspective, the stewardship responsibilities that exist for these organizations to support the health of the broader community.

MATERNAL-FETAL RELATIONSHIP

• • •

I. MEDICAL ASPECTS

During the last decades of the twentieth century, perinatal medicine made tremendous advances in scientific knowledge and in the successful application of this knowledge toward improving pregnancy outcomes. These advances have also brought a dramatic change in medicine's conceptualization of the fetus. No longer is the fetus defined predominantly as a part of the pregnant woman, but rather as a distinct entity that can be the independent focus of diagnostic tests and individual therapies: "A second patient with many rights and privileges comparable to those previously achieved only after birth." It is the widely shared view of obstetricians that the fetus is a patient to whom they owe ethical duties. The purpose of this entry is to delineate the medical advances that have brought about this change in fetal identity and to discuss the impact of these changes on pregnant women and the obstetrical decision-making process.

Pregnancy and Maternal Health

Maternal morality in pregnancy fell dramatically in the United States from more than one in 200 in 1935 to 7.7 per 100,000 in 1999. Most of this reduction was accomplished earlier in this century through improved surgical techniques and increased access to safe blood products, antibiotics, intravenous fluids, and improved prenatal care.

Despite these improvements, pregnancy still poses the risk of serious illness and, in rare cases, death. It has been calculated that the risk of mortality in pregnant women is 179 times that of the risk of death among women using the safest method of birth control. The major causes of maternal death are hypertensive disorders of pregnancy, pulmonary embolism, uterine hemorrhage, and sepsis. The risks of pregnancy are proportional to the age of the pregnant woman and to her underlying state of health. Women with medical illness may note worsening of their disease during pregnancy, sometimes with serious long-term consequences. But even women who begin a pregnancy in excellent health may find themselves suddenly confronting the morbidity and mortality risks associated with cesarean section (nearly 25% of all U.S. deliveries in 2000), postpartum hemorrhage (4–8% of all deliveries), or pre-eclampsia (a pregnancy-related condition that can lead to seizures, strokes or death in the pregnant woman) (5% of all pregnancies).

Pregnant women may experience preterm labor (U.S. incidence was 11.9% in 2001), the development of premature contractions that if not stopped can result in delivery of the fetus before adequate development has occurred. Preterm delivery poses significant risk of disability and death for the fetus. While preterm labor itself does not pose a health risk to the pregnant woman, many of the treatments recommended for its treatment have significant maternal side effects. The three drugs commonly used to treat (attempt to stop) preterm labor have serious side effects ranging from nausea, vomiting, dizziness, flushing, tremor, and jitteriness

to life-threatening risks of pulmonary edema (fluid in the lungs), alterations in blood chemistries (hypokalemia, hyperglycemia), heart rate abnormalities (tachycardia, arrhythmias), hypotension, respiratory depression, and cardiac arrest.

For all women, pregnancy is a complex physiologic process; almost every organ system undergoes adaptation to support the maternal-fetal unit. It is important to appreciate the range of symptoms experienced by many pregnant women due to these physiologic changes. These include nausea, vomiting, fatigue, syncope (fainting), round ligament pelvic pain, backache, heartburn, hemorrhoids, constipation, urinary frequency, carpal tunnel syndrome (numbness and tingling of the hands), pedal edema, and sciatica (hip and leg nerve pain). Thus, while pregnancy is described as a normal physiologic process, it is not without common discomforts and the potential for serious illness. Most pregnant women willingly assume these sacrifices for their developing fetus.

Pregnancy and Fetal Therapies

Perinatal technologies have benefited the fetus by increasing the understanding of normal fetal development as well as improving prenatal diagnostic capabilities and therapeutic interventions. The fetus can be visualized with ultrasound, its well-being assessed with fetal heart-rate monitoring, and its diseases diagnosed with chorionic villus sampling, amniocentesis, and fetal blood sampling. Increases in diagnostic capabilities have been accompanied by the development of techniques to treat the fetus directly in utero. Our increasing ability to act on behalf of the fetus has made its claims to our care more compelling.

Prenatal technologies designed to benefit the fetus range from the simple to the complex, with differing risks and benefits for both the pregnant woman and her fetus. The most commonly used technology with the intention of improving fetal outcome is electronic fetal monitoring (EFM). EFM was introduced in the United States in the early 1970s with the promise that it would enable early detection of fetal hypoxia in labor and alert the physician to perform an immediate delivery, preventing the serious consequences of oxygen deprivation, including brain damage and stillbirth. Its use rapidly expanded from high-risk pregnancies to all pregnancies; in 1996, it was estimated that three-fourths of all U.S. pregnancies were monitored. Unfortunately, the wide acceptance of this technology occurred before adequate studies had been done to assess its efficacy and safety. There have been numerous randomized and controlled trials of EFM that have been unable to demonstrate a decrease in intrapartum fetal death or better newborn health in low-risk pregnancies. However, the use of EFM was shown to double the C-section (cesarean section) rate for the indication of fetal distress, thus exposing more women to the increased morbidity and mortality risks of C-section without the promised fetal benefit.

Other technologies include internal monitoring, used almost exclusively in high-risk situations, and telemetry monitoring, which uses radio waves and is non-invasive. Internal monitoring can cause fetal injury and infection to both the mother and baby.

A C-section entails a greater risk of maternal morbidity and mortality than does a vaginal delivery. The mortality rate associated with C-section is between two and four times that associated with a vaginal delivery. Maternal morbidity is also more frequent and usually more severe with a C-section. The common causes of morbidity associated with C-sections are infection, injury to the urinary tract, risk of placenta accreta (where the placenta attaches to the incision in a subsequent pregnancy) and hemorrhage with the possible risk of transfusion. Even an uncomplicated C-section requires a much longer recovery period for the mother at a time when she is experiencing increased physical and emotional demands.

The simplest fetal therapies are medications given to a pregnant woman for the benefit of her fetus. A well-accepted treatment of a woman who develops mild diabetes during pregnancy is to give her insulin until delivery. This practice benefits the fetus by preventing its excessive growth and associated birth trauma and by avoiding the potential neonatal difficulties of an infant of a diabetic mother. While insulin is not essential for the pregnant woman's health, it may be beneficial by reducing her risk of C-section delivery and the potential harms of a mildly elevated glucose to her own organ systems. Digoxin is a medication administered to pregnant women for the benefit of a fetus with cardiac arrhythmia. Unlike insulin, digoxin offers no benefit to the health of the pregnant woman. The risks to the pregnant woman of ingesting insulin or digoxin are minimal if administered appropriately. In summary, these pharmacologic fetal therapies confer benefit upon the fetus and are minimally invasive; one offers some benefit for the pregnant woman; the other solely benefits the fetus.

An accepted but more invasive therapy of sole benefit to the fetus is a fetal blood transfusion for isoimmunization from Rh disease (a condition in which the immune system of the pregnant woman destroys the blood cells of the fetus resulting in fetal death if severe and untreated). The most common technique is cordocentesis, in which a needle is placed through the maternal abdominal and uterine wall

into the umbilical blood vessel for the purpose of transfusing blood into the fetus. This technique is not without its risks for both the fetus and the pregnant woman. This procedure poses a 2 percent chance of fetal death. It also increases the risk of fetal bradycardia (a dangerous lowering of the heart rate), a condition that mandates an emergency C-section for the safety of the fetus. All the maternal risks of C-section delineated above are increased in an emergency C-section, with the addition of the increased risk of death from general anesthesia. Cordocentesis is an example of an accepted fetal therapy that is potentially beneficial for the fetus and invasive for the pregnant woman, with significant risks to her in complicated cases.

The most invasive fetal therapy is in utero fetal surgery. While these procedures are still uncommon, some successes have occurred. One example is the surgical removal of a lung mass in the fetus. The rationale for the surgery is that without prenatal removal, the fetal lungs will be unable to grow sufficiently to support survival after birth. Intrautrine shunt therapy for hydrocephalus (abnormal amounts of brain fluid causing brain damage and enlargement of the head) is an experimental surgical procedure. Another, more controversial surgery involves fetal surgery to fuse the spinal hole caused by myelomeningocele (spina bifida). Because spina bifida is not a life-threatening disease, some ethicists and physicians have called the procedure into question. In 2003 the National Institute of Child Health and Human Development began a study of prenatal and postnamtal closure of myelomeningocele to determine the long-term benefits.

In all maternal-fetal surgeries, the pregnant woman must undergo a major abdominal operation and take medications to prevent the preterm labor that might be caused by the surgery. The surgery entails the usual risks associated with a C-section but at a higher rate because of the type of uterine incision, the thickness of the uterine wall, and the need for general anesthesia. Because of the type of uterine incision necessary for this fetal surgery, the woman must have a C-section in this pregnancy, even if her fetus is stillborn, as well as in all future pregnancies.

Neonatal Advances and Obstetrical Decision Making

Simultaneous advances in neonatology have had a significant impact on obstetrical knowledge and care. The gestational age at which survival is possible in the modern intensive care nursery has been pushed back continuously over the past few decades to the age of twenty-four to twenty-five weeks (fifteen to sixteen weeks premature). Many fetuses/babies who in the past would have been considered nonviable now survive and develop normally. However, the cost of this success is measured in hundreds of thousands of dollars per premature infant and in the potential for severe lifelong impairments.

This improved neonatal survival has had two significant influences on the perspective of obstetrical providers. Most have seen or participated in the care of very premature babies; thus fetuses in utero from twenty-four weeks on possess a very concrete human image for those who care for them. In addition, the possibility of survival beginning at twenty-four gestational weeks creates an argument for aggressive obstetrical management at earlier and earlier stages of pregnancy. The lower the gestational age at birth and the lower the birth weight, the lower the chance of survival and the higher the risk of severe physical and mental impairment. Between twenty-four to twenty-eight weeks the likelihood of survival increases from 20 percent to 90 percent, with a 20 percent incidence of severe neonatal impairment in the survivors. Complicating this situation is the inaccuracy of techniques to estimate gestational age and fetal weight. The inability to predict with certainty before birth either the survival or the likelihood of impairment creates legitimate divergent perspectives on what to do in individual pregnancies and ensures difficult decision making for obstetricians and pregnant women.

Formerly, a woman who developed preterm labor at twenty-five weeks would have been allowed to deliver vaginally and comforted regarding the certain death of her baby. Today, that pregnant woman will be faced with the option and probable recommendation that the fetus be monitored in labor and delivered by C-section if needed for fetal benefit. A C-section at this gestational age is riskier for her than one at term and because the type of uterine incision required commits her to C-section delivery of future pregnancies. The chance of the infant's survival is between 30 and 50 percent depending on its weight (which is difficult to predict prior to delivery). If the infant does survive, there will be a significant chance of neurologic or physical impairment. Some women will choose to take any risk for a slim possibility of fetal benefit, and accept aggressive obstetrical management. Other women decide that the risk of C-section in this and future pregnancies combined with the potential suffering for their premature infant is not worth the slight chance of being able to take home a normal or mildly impaired child. They choose to let "nature take its course," and hope that their next pregnancy will be free of complications. For the obstetrician faced with this clinical dilemma, the uncertainty of prognosis (this fetus might do well), the availability of technologic intervention (C-section),

the desire to do something, and the legal fear of doing nothing may prompt him or her to advocate intervention as the baby's only hope. This is a persuasive argument for most pregnant women, especially if alternatives are not presented as legitimate.

The beneficial effects of fetal therapies and neonatal advances are impressive when successful: Babies previously at high risk of stillbirth, birth trauma, hypoxia, and neonatal death now have a greater chance of being born safely and having a near normal development. However, some babies who would have died now survive but with significant handicaps and at a significant cost to the physical, emotional, and financial well-being of the mother, her child, and her family. Some therapies are recommended with hope of fetal benefit but without good scientific evidence and with known maternal risks of death and morbidity. Pregnant women must be able to choose the best medical option based upon accurate scientific knowledge and an honest appraisal of the uncertainties involved in medical science.

Pregnancy and Fetal Development

Increased understanding of fetal development has allowed identification of environmental factors that can promote or impair the development of a healthy fetus. The placenta was once felt to operate as a barrier allowing only those substances beneficial to the fetus to pass. Now it is known that the placenta is an efficient transporter of many substances to the fetus, regardless of their toxicity, including both therapeutic and recreational drugs. Media coverage has focused on the rising incidence of crack cocaine use by pregnant women. It has been estimated that 11 percent of pregnant women use an illegal drug during their pregnancies and that 75 percent of these women use cocaine. While there are methodologic shortcomings in the studies of cocaine's effect on pregnancy, many serious sequelae of using this drug have been suggested, including an increased spontaneous abortion rate; suspected cardiac, genitourinary, facial, and limb abnormalities (though these may be alcohol-related); growth retardation; and in utero strokes. Obstetrical complications include preterm delivery, abruption (placental separation), and fetal distress. Newborns who have been exposed to cocaine in utero experience withdrawal symptoms, making them more irritable and less able to bond with caregivers. Many believe that cocaine-exposed babies will be more likely to experience learning disabilities, though some research has shown that there is no difference in learning scores between cocaine-exposed children and other children at age 4.

Alcohol is a well-known danger to the developing fetus. Fetal alcohol syndrome has been identified in the offspring of women who consumed excessive alcohol during their pregnancy; it is defined by a triad of symptoms: gross physical retardation; central nervous system dysfunction, including mental retardation; and characteristic facial abnormalities. Fetal alcohol effects are more common; they include cardiac, genitourinary, skeletal, and muscular anomalies; hypoxia; irritability; and hyperactivity. While excessive alcohol use during pregnancy has clearly been documented to cause significant fetal harm, no minimum safe level of consumption has been established. Many experts have recommended total abstinence from alcohol during pregnancy as the only way to avoid all possible harm.

Smoking has significant effects on pregnancy outcome. Approximately 30 percent of U.S. women of childbearing age smoke. Cigarette smoking results in reductions in birthweight, length, and head circumference. It has been estimated that between 20 and 40 percent of all low birthweight births in the United States can be attributed directly to smoking. Smoking has also been associated with higher rates of spontaneous abortion, preterm birth, perinatal mortality, and deficits in later physical, intellectual, and emotional development. A comparison of the known perinatal dangers of alcohol, smoking, and cocaine consumption illustrates that the legal substances a pregnant women may ingest are no less medically harmful than the illegal ones.

Public policy aimed at improving perinatal outcomes by reducing the use of fetotoxic substances by pregnant women must be grounded in medical knowledge. Recreational drug use by most pregnant women is an addiction; they do not consume the drug to harm the fetus but to satisfy an acute physical or psychological need. To address the problem of addiction, comprehensive and supportive programs designed to enlist the individual in her own recovery are necessary. There have been documented successes in programs that emphasize early identification of women at risk for substance abuse and that utilize comprehensive education, prenatal care, psychological intervention, and social services. However, there are very few substance abuse programs available to pregnant women. In one notable case of criminal prosecution of a woman for drug use during her pregnancy, the accused woman had sought drug treatment during her pregnancy without success.

Punitive approaches to addictive disease are generally ineffective. They have the potential to drive the addicted individual away from the very care that could be beneficial. Because the developing fetus is so vulnerable to uterine exposure to toxins, it is critical that pregnant women not be deterred from care. Prenatal care alone, in the presence of continuing drug use, can improve perinatal outcome for the drug-exposed fetus.

Obstetrical Decision Making

While a pregnant woman and her fetus may be conceptualized as two independent patients, they are in fact intimately interdependent, and actions taken to benefit one may pose a risk to the other. A pregnant woman may suffer from a serious illness that requires a treatment that will itself pose risk to her fetus; premature delivery to improve maternal health and chemotherapy for maternal cancer are two examples. Alternatively, treatment for the benefit of the fetus (C-section delivery, treatment of preterm labor, fetal surgery) may pose a risk to the pregnant woman. In addition, a medical treatment for presumed fetal benefit may interfere with the nonmedical needs of the pregnant woman.

These situations have been described by many as maternal-fetal conflict when they more accurately might be described as maternal-physician conflict. When an obstetrician agrees with the pregnant woman's choice and underlying values, no conflict ensues, even in the presence of potential fetal risk. The disagreement that does occur often is based on differing views of what is beneficial for the pregnant woman and her fetus and what are acceptable maternal risks to achieve obstetrical goals.

Obstetricians have a predominant focus on the current pregnancy. Appropriately, they emphasize the medical health of their patient and the fetus, give expert advice to improve pregnancy outcome, and urge women to follow this advice as a priority in their lives. However, medical recommendations are at times influenced by the fear of malpractice, research interests, a reluctance to give up, and a provider's own personal values.

A pregnant woman's values may differ from those of her providers and she may place a different value on the physician's medically based goals. Like other adults, a pregnant woman must and does make decisions about her prenatal activity within the broader context of her life. Her obligation to her fetus is sometimes weighed against her obligations to her other children, her parents, her partner, or others with whom she has a special relationship. Her decision may be influenced by religious or other strongly held personal beliefs.

Some have argued that pregnant women should be forced to undergo certain treatments if the benefit to the fetus would be substantial and the risk to the woman would be minimal or low. Medical uncertainty and medical practice make this a difficult policy to administer rationally or fairly. As delineated above, perinatal medicine is limited by diagnostic and prognostic uncertainty. This is best illustrated by a legal case in which a judge ordered a woman to undergo a forced C-section. In seeking the court order, the obstetrician testified that without delivery by C-section, the fetus had a 99 percent chance of dying and the pregnant woman had a 50 percent chance of mortality. However, the pregnant woman fled the court's jurisdiction and had an uneventful vaginal delivery. The ability to predict fetal distress in labor is frequently inaccurate. Because of this uncertainty, a policy of enforcing obstetrical recommendations would allow obstetricians to make the wrong decisions sometimes but would never allow a pregnant woman to be wrong or right about decisions that profoundly affect her life.

The problem of precisely defining fetal risk is matched by the complex task of delineating what constitutes an acceptable risk of harm for the mother. Risks, no matter how small in the medical context, may take on a different meaning within the context of an individual's life. The small risk of maternal death from a C-section may be very significant to a single woman who is the sole supporter of her children. Bed rest for the prevention of preterm labor may mean the loss of work and health insurance for her whole family. A Jehovah's Witness who is forced to receive blood may believe she is condemned to eternal damnation and may undergo significant stress or rejection within her religious community.

If obstetricians are given the authority to force pregnant women to follow their recommendations, this force may be used in a very arbitrary way. Not only is there variation in obstetrical diagnostic and prognostic accuracy, there are obstetrical debates about the appropriate management of various conditions. The medical justifications in the reported cases of requests for court-ordered C-sections have included breech presentation, prior C-section, and rupture of membranes for twenty-four hours without signs of febrile morbidity. Many obstetricians would disagree with each of these indications for C-section. Furthermore, the women who have been subjected to court orders have been shown to be more likely subjects of other forms of discrimination. In one study of forced C-sections, 81 percent of the women belonged to a minority group and 24 percent did not use English as their first language, and all requests for the court orders involved women who received care at a teaching hospital or who were receiving public assistance.

If the use of force by doctors against pregnant women were to be legitimized, it would have negative implications for their therapeutic relationship. The relationship would become less cooperative and supportive and more adversarial; compromise in situations of disagreement would become less and less possible. Under these circumstances of care, some women might lie about their behaviors or symptoms, fearing that their obstetrician would use this information to force upon them unacceptable treatment. Others might avoid prenatal care completely. The adversarial climate

created by the use of force would decrease the effectiveness of obstetricians in improving maternal and fetal health.

Conclusion

Perinatal advances have dramatically improved the perinatal survival and well-being of fetuses/babies, fulfilling the obstetrical goals of prenatal providers and the personal goals of pregnant women. Increased understanding of the developing fetus and improved technologies have given the fetus an enhanced human identity and status as a direct patient of the obstetrician. The new therapeutic options with their maternal risks have created difficult ethical decisions for the pregnant woman and her obstetrician. A discussion regarding the legitimate use of force against pregnant women for fetal benefit has begun. The resolution of this debate must take into account the implications of the uncertainty inherent in medicine, the maternal risks associated with fetal therapies, the inevitable influence of an obstetrician's personal values upon his or her medical recommendations, the harmful influence of force in any therapeutic relationship, and the ethical and constitutional rights of all parties, including pregnant women.

II. ETHICAL ISSUES

Only since the 1960s has it been recognized that the fetus in utero can be harmed by a range of maternal behaviors. Now that it is known that drinking, smoking, and using drugs during pregnancy can harm the unborn child, the question of what moral obligations a pregnant woman has to the fetus she carries has become a significant issue in biomedical ethics. When conflicts arise between what a pregnant woman wants to do or believes is right to do, on the one hand, and what may be best for the fetus, on the other, how and on what basis should those conflicts be resolved? And who should be involved in resolving them?

This article attempts to provide a conceptual framework for thinking about maternal–fetal conflicts. Whether one believes that women have moral obligations to their fetuses in utero depends largely on one's view of the moral status of the fetus—possibly the central issue in the abortion debate. The debate over whether (and at what developmental stage) fetuses can be harmed is a heated one. Pro-lifers think that fetuses can be harmed, and base their opposition to abortion on the ground that being killed is the ultimate harm. They also oppose behavior on the part of pregnant women that is likely to have less severe effects on the fetus. By contrast, many pro-choicers deny that fetuses (or at least early gestation fetuses) can be harmed. However, even if the pro-choice view of the fetus is the correct one, it does not follow that pregnant women are free to drink, smoke, or use drugs during pregnancy, if they are planning to have the baby. For if the pregnant woman does not abort but goes to term, her behavior during pregnancy can have lasting, destructive effects on the born child. Concern for the born child is a common ground that unites all people, regardless of their stance on abortion. This distinction between the fetus per se and the fetus-who-will-be-born differentiates maternal–fetal conflicts from the issue of abortion. Yet these conflicts are not entirely unrelated to the problem of abortion, because both issues concern justifications for restricting or controlling women's behavior during pregnancy.

The Moral Status of the Unborn

One of the thorniest issues in bioethics is the moral status of the fetus. (Here, the term *fetus* is used to refer to the unborn during all stages of pregnancy.) One view is that fetuses are merely potential children who do not have full-fledged moral rights, or perhaps any rights at all. According to this view, attempts to limit reproductive choices or coerce behavior during pregnancy violate very basic moral rights to bodily self-determination.

A different view is that fetuses are *pre-born children,* with all the rights of born children. Someone who regards the fetus in this way will think that a pregnant woman has the same moral obligations to protect her fetus from harm as she has to protect her born children. In keeping with this view of the fetus, some states have adopted *fetal rights* legislation, for example, making behavior during pregnancy that puts the fetus at risk of damage or death a form of child abuse.

Those who differentiate morally between fetuses and children tend vigorously to oppose fetal rights legislation, often seeing it as part of a larger political agenda to make abortion illegal. Even apart from the abortion question, many people are concerned that any attempts to control women's behavior during pregnancy violate their rights to privacy and self-determination. At the extreme, the position taken by some feminists and civil libertarians is that whatever a woman does during her pregnancy is her own business. They have opposed even noncoercive measures, such as a bill requiring the posting of signs warning pregnant women of the dangers of alcohol consumption (Sack).

However, if a woman decides not to abort, but to carry to term, then her behavior during pregnancy may have an adverse effect not only on the fetus but also on the child who is born. Whatever one's position on the moral standing of fetuses, born children clearly have moral status and rights.

The right not to be injured is one of the most basic moral and legal rights. To extend this right to prenatal injury requires only the recognition that a person can be injured by events that occurred before his or her birth—indeed, even before conception. Here is an example of preconception injury: In the 1940s, diethylstilbestrol (DES) was sometimes prescribed to prevent miscarriage. Not only was the drug ineffective, it sometimes resulted in damaged reproductive systems in the female children of women who used it. When these girls grew up, their reproductive abnormalities sometimes led to miscarriages and premature births. Prematurity can cause cerebral palsy. Thus, a child might be born with cerebral palsy due to a premature birth ultimately caused by her grandmother's ingestion of DES years before her own conception (*Enright by Enright v. Eli Lilly & Co.*, 568 N.Y.S.2d [Ct.App. 1991]). The legal right to recover for injuries negligently inflicted during pregnancy has been widely recognized in the United States since the landmark case of *Bonbrest v. Kotz* (65 F. Supp. 138 [D.D.C. 1946]). Courts have been much more reluctant to accept a right to recover for preconception injuries, primarily out of a concern to confine liability within manageable limits. The important point for bioethics is that recognition of a moral right to be free from injuries inflicted before birth is not based on recognition of the fetus as having the moral status of a person. The concern is not primarily for the fetus but for the surviving child. At the same time, attempts to protect children from prenatal injury can be accomplished only through the body of the pregnant woman. As a result, some women have been subjected to forced cesareans (Annas, 1982; Rhoden, 1986, 1987; Nelson and Milliken). With the development of new fetal therapies and surgery, women could be asked, or even required, to undergo possibly painful and risky procedures for the sake of the not-yet-born child (Robertson). Thus, if the focus is exclusively on the prevention of harm to the future child, there is a risk of forgetting that the pregnant woman is a person in her own right, not

merely a "fetal container" (Annas, 1986). The moral question, then, is how to balance the interests and rights of the pregnant woman against those of her not-yet-born child.

Most women who are expecting a child voluntarily adapt at least some of their behavior to protect their babies. But what if the woman is an alcoholic or a crack addict? What if, for religious or other reasons, she refuses a cesarean section her doctor thinks is necessary to prevent serious damage to her nearly born baby? Such cases "pit a woman's right to privacy and bodily integrity … against the possibility of a lifetime of devastating disability to a being who is within days or even hours of independent existence" (Rhoden, 1987, p. 118). How should such conflicts be resolved? What moral obligations do women have to prevent harm to the children they intend to bear?

Conceptualizing Maternal-Fetal Conflict

People have moral obligations to other people, both those existing today and those who will exist in the future. The mere fact that people do not now exist is no reason to discount the interests they will have when they come into existence. If people today do nothing about the national debt, if they allow the ozone layer to be depleted, if they pollute the air and water, then actual (as opposed to possible or potential) individuals, living in the future, will be harmed by what is done, or is not done, today. There is a responsibility to these actual, though future, people not to destroy the world they will live in. That they do not now exist does not obviate present obligations to them. Similarly, women have moral obligations to their future children, that is, the ones they will bring into the world.

In the United States, as in most societies, the primary responsibility for protecting the interests of children belongs to their parents. Although parents have a great deal of discretion in deciding how to care for and raise their children, they do not have absolute freedom. In industrialized nations, at least, it is widely accepted that parents are not only morally but also legally obligated not to inflict injury on their children, to feed and clothe them, to provide them with necessary medical care. It would seem, then, that pregnant women who intend to complete their pregnancies have comparable moral obligations to avoid harming their not-yet-born children. However, preventing prenatal harm is not the only morally relevant consideration. The woman's own interests count, too. How are conflicts between the interests of the future child and the interests of the pregnant woman to be resolved?

Some object to the very notion of *maternal–fetal conflict*. They regard this as being misleadingly adversarial, pitting pregnant women against the children they will bear, when in most cases their interests are inseparably intertwined. A less adversarial framework stresses that what is good for pregnant women, such as better prenatal care, is also good for fetuses. While this is undeniable, some women want to do things, such as smoking or using drugs or alcohol, that risk harming their unborn children. Admittedly, behavior that endangers the fetus often endangers the health of the pregnant woman, but this does not necessarily make their interests identical. What if the woman is willing to risk her own health for the enjoyment the tobacco or alcohol or cocaine brings? She may decide—perhaps irrationally, perhaps not—that use of the substance is in her own interest, all things considered. That does not mean it is in the interest of her as-yet-unborn baby. It is wishful thinking to pretend that the possible harmful effect on the pregnant woman prevents the possibility of conflict.

Others object to characterizing the conflict as one between mother and fetus. In the so-called obstetrical cases (e.g., forced cesareans), the conflict may not be between mother and fetus. Rather, it is between mother and doctor, who disagree about what is best for both mother and child. In one case, doctors sought a court order because the fetus's umbilical cord was wrapped around its neck, a clear indication for an emergency cesarean. The woman, who had nine children, refused surgery out of concern for her own health, a belief in "natural childbirth," and an intuition that the delivery would turn out fine, despite the doctors' dire predictions. She delivered vaginally, and the child was fine (Rhoden, 1986).

Attempts to prevent prenatal harm often impose risks or burdens on pregnant women, particularly when an intervention, such as a cesarean section or blood transfusion, is deemed necessary to protect the unborn child. The moral question then becomes how much risk, burden, or sacrifice a woman must undergo for the sake of her future child.

Moral Obligations to the Not-Yet-Born

It is important to distinguish the question of moral obligation and responsibility from legal obligation. Only the most extreme legal moralist would advocate compelling people to do whatever they morally ought to do. Claims that women have moral obligations to their future children should not be construed as advocating legal coercion. Thinking about moral obligations to future children in the context of general parental obligations to children prevents sentimentalizing pregnancy and the imposing of especially stringent obligations on pregnant women, or thinking that pregnant women are morally required to subordinate all their interests to their fetuses. After all, parents are not morally required to avoid

any and all risks to their children's health. The obligation is, rather, to avoid unreasonable risks of substantial harm.

With a few notable exceptions (King; Robertson; Shaw), most commentators have argued that a pregnant woman should not be forced to undergo medical treatment even when this is judged necessary to preserve the life or health or her fetus (Annas, 1982; Gallagher; Johnsen; Nelson and Milliken; Rhoden, 1986, 1987). Cesarean sections are major surgery and, while generally very safe, are associated with higher rates of maternal mortality, morbidity, and increased pain than occur with vaginal delivery. Requiring a woman to undergo a cesarean requires her to risk her own life and health for the sake of her not-yet-born child. This is contrary to our legal tradition, which forbids the forced use of the body of one person to save another. In one widely cited case, *Shimp v. McFall* (10 Pa. D. & C.3d 90 [1978]), a court refused to order David Shimp to donate bone marrow to his cousin, Robert McFall, who was dying of aplastic anemia. The court emphasized that there is no legal duty to rescue others. It would seem to follow that compelling a pregnant woman to undergo medical treatment for the sake of the fetus, when this is not required of other potential rescuers, violates equal protection.

There are compelling arguments against the government's using coercive and punitive measures to regulate women's actions in order to promote healthy births. Most people do not want to live in a society in which they can be compelled to undergo surgery or to sacrifice body parts, even if it would be morally incumbent on them to do so. Placing limits on what can be demanded of citizens, especially where bodily integrity is involved, is essential to a free society. This helps to justify the conviction that people are not legally obligated to donate parts of their bodies, even if others need them for life itself.

The situation is different when we consider people's moral obligations. While an absolute ban on forced donation seems the correct legal response, a balancing approach seems more appropriate from a moral perspective. Whether one has a moral obligation to donate a body part, or undergo invasive surgery, depends on the degree of risk and sacrifice incurred, balanced against the need of the endangered individual. Perhaps people are morally required to donate replenishable body parts, such as blood, to others who need it. Blood donation takes only an hour, has no lasting effects, and causes only slight discomfort to most donors. Where a special relationship exists between the potential donor and the needy person, there may be a moral obligation to incur greater risks and sacrifices. Parents may be thought to have a moral obligation to donate blood and bone marrow, and perhaps even nonreplenishable body parts, such as kidneys, to their children, because of their duty to protect and care for their children, and because parents are supposed to love their children. Certainly a parent who refused to give a kidney to a dying child, saying, "It's my body, and I do not feel like donating," would be rightly regarded as morally deficient.

What are the implications for women whose doctors advise a cesarean section for fetal indications? Most women, faced with the possibility of a stillbirth or having a baby born with cerebral palsy, readily consent to the treatment their doctors recommend. Occasionally, however, a woman rejects a physician's recommendation. The moral justifiability of her refusal depends largely on her reasons for refusing. Typically, women who refuse cesareans do so out of religious objections, concern for their own health, or belief that a vaginal birth is best for the baby, and they disagree with the doctors' assessment of the risk. These are not selfish or unimportant reasons. Refusing a cesarean for such reasons is not obviously immoral. By contrast, it would be immoral for a woman to refuse a cesarean, and risk having her nearly born child die or suffer permanent disability, for a trivial reason, such as wanting to avoid a scar in order to be able to wear a bikini. One can morally condemn such a refusal, even if one thinks that she should not be compelled to submit to a cesarean.

"Lifestyle cases," where the risk to the child comes from nonessential behavior, such as drinking alcohol, smoking tobacco, or using drugs, present a different situation. In lifestyle cases, the welfare of the future child appears paramount. If the woman forgoes these substances, the only harm done to her is loss of pleasure and choice—in fact, abstention is likely to benefit her physically—while the potential harm to the child is serious. On the other hand, when the risk to the fetus is slight, the obligation of the pregnant woman is less clear.

Consider, for example, drinking during pregnancy. Heavy drinking during pregnancy can cause fetal alcohol syndrome (FAS), which is typically marked by severe facial deformities and mental retardation. One study showed that even moderate drinking—defined as one to three drinks daily—during early pregnancy can result in a lowering of IQ by as much as five points (Streissguth et al.). Perhaps most important, there is no established "safe" level of alcohol consumption. While there is no evidence that a rare single drink during pregnancy does damage, there is no guarantee that it does not. The safest course is therefore total abstention. But is the safest course the morally obligatory one? We do not require this standard of parents regarding their already born children. Having a single drink occasionally in pregnancy is arguably morally permissible, primarily because the risk of causing harm is very low (perhaps nonexistent), but also because the nature of the harm (loss of a few IQ points) is not so serious as to justify moral condemnation.

For a child of normal intelligence, the loss of five IQ points is not devastating. (At the same time, five IQ points can mean the difference between a mildly and a severely retarded child.)

If the occasional drink should be considered a matter of individual discretion, binge drinking, which has a 35 percent chance of subjecting a baby to full-blown FAS, clearly qualifies as an unreasonable risk to the health of a baby. So does smoking crack cocaine. Whether women have a moral obligation not to drink heavily or smoke crack during pregnancy is profoundly complicated by the fact that these behaviors are often the product of addictions. They are less than fully voluntary—some would say they are not voluntary at all. If a woman cannot modify her behavior, then she cannot have a moral obligation to do so.

But is it true that someone who is addicted cannot modify his or her behavior? The distinction should be drawn between being able to stop doing something at will, and not being able to stop at all. Although it is difficult to get over addictions, many smokers, alcoholics, and drug users do manage to change their behaviors. We can recognize that it may be very difficult for some women to fulfill their moral obligations to the babies they intend to bear, and acknowledge that they will need help to do so, without denying that they have such obligations.

Should drug or alcohol treatment be imposed on addicted pregnant women? Perhaps—if it could be shown that coerced treatment works, and therefore protects babies from prenatal harm. However, discussion of the justifiability of coerced treatment seems premature when there are not enough treatment programs for pregnant addicts who want to get over their addictions. Many in-patient alcohol rehabilitation programs exclude pregnant women, largely due to a fear of liability. The situation is even worse for pregnant drug addicts (Chavkin); sudden withdrawal of drugs can be as damaging to the fetus as continued exposure. As a result, a few treatment programs are able or willing to treat pregnant addicts. Even in areas where there are such treatment programs, there are not nearly enough spaces for all who want help. The absence of treatment programs makes it virtually impossible for substance abusers to fulfill their moral obligations to the children they intend to bear, even with the best will in the world.

To summarize, all women who intend to bear children have moral obligations to protect those children from the serious risk of substantial harm. Heavy smoking, binge drinking, and use of drugs such as crack cocaine and heroin constitute such risks. However, the moral wrongness of engaging in such behaviors during pregnancy is affected by the woman's ability to stop. A woman who is not addicted to cocaine, but who goes on using it during her pregnancy (perhaps on the weekends, because she enjoys it), fully aware of the risks she imposes on her future child, acts very wrongly indeed, and is properly blamed. It would be inappropriate similarly to condemn the pregnant woman who wants what's best for her baby and tries to get help with her addiction, only to be turned away because of the dearth of drug programs. Such a woman is trying to do the right thing; blame properly belongs with society for failing to help her. Nevertheless, if her baby is born damaged due to her drug use, she will—and should—feel moral regret at the harm caused by her drug habit, even if she should not be blamed.

The Intention to Bear a Child

Some people object to making the future child, rather than the fetus, the locus of moral obligation, on the grounds that the existence of the future child depends entirely on the pregnant woman's decision. These critics find it unacceptable that a woman can avoid her obligations to her not-yet-born child by ensuring that it not be born (that is, by aborting it). Moreover, a woman may decide to abort, but later change her mind and continue the pregnancy. During the period when she thought she would have an abortion, she may have continued to smoke and drink. As long as she did not intend to bring a child into the world, there was no one for whose sake she should abstain; continuing to smoke or drink seems morally acceptable in this light. Yet if she changes her mind and continues the pregnancy, she may have harmed the child she bears. Is she now morally blameworthy for the harm she causes?

Two responses can be made. The first is to recognize that moral responsibility for outcomes can extend beyond harms knowingly risked, to harms unintentionally caused. The fact that a woman did not intend to continue a pregnancy at the time she engaged in heavy drinking or used drugs does not entirely absolve her from blame. Even though she does not intend to have a baby at the time of the risky behavior, the failure to consider the possibility that she might change her mind may be negligent, and thus blameworthy. The second response concerns the futility of crying over spilt milk. It says that there is nothing a woman can do about her past behavior, and that if she changes her mind and decides to carry the pregnancy to term, she should focus on what she can do to ensure her baby's health. For example, giving up smoking in the second or third trimester gives the not-yet-born child a better chance than continuing to smoke throughout the pregnancy. If, despite her efforts, the baby is born damaged (a fairly unlikely result), the woman does not completely escape responsibility, but her blameworthiness is

mitigated by the fact that she acted rightly once she decided to continue the pregnancy.

Another objection to making "the child she intends to bear" rather than the fetus the object of the pregnant woman's moral obligation is that often women do not "intend" to bear children. Drug addicts, in particular, may regard pregnancy as something that "happens" to them, often as a result of bartering their bodies for drugs, rather than something they intend. Nor do they necessarily choose to give birth: They may not be able to afford an abortion, or it may not be available in a particular geographical area. For some women, abortion is not a morally or culturally acceptable option. Do restrictions on the choice of whether to bear a child affect the woman's moral obligations to the child she bears? It can be argued that these restrictions do not affect how the woman ought to act, but they may affect how much she is to be blamed if she acts wrongly.

Consider a woman who deliberately gets pregnant, intending to have a baby. If she goes on drinking and smoking and using recreational drugs, knowing of the possible effects on her baby's health and making no effort to stop, she acts very wrongly indeed. By contrast, consider a woman who has no responsibility for becoming pregnant (she was raped), in a jurisdiction that prohibits abortion. She is the victim of two grave injustices, first in being raped and second in being denied an abortion. Still, that would not justify behavior likely to inflict severe damage on the child she will perforce bear. Ideally, she should behave as if the pregnancy were chosen, since she is prevented from terminating the pregnancy. That is, she should stop smoking, drink moderately or not at all, and so on. However, her failure to do so is certainly less blameworthy than the failure of a woman who has chosen to conceive and bear a child. Most cases will fall somewhere in between the extremes of deliberate conception and forced childbirth. In general, the fewer options a woman has regarding pregnancy and childbirth, the less she deserves blame for failing to fulfill her obligations to her future child. However, women are not relieved of moral responsibility simply because they do not see pregnancy as a choice.

Conclusion

Deciding to have a baby carries with it certain moral responsibilities. Children have a moral right to be protected from harm, whether inflicted post- or prenatally. This right to be free from harm imposes obligations on those in a position to protect children, including their mothers during pregnancy. Yet a single-minded focus on the risk of harm to the future child ignores the impact on the pregnant woman. She is not a "fetal container" but an individual in her own right, one whose interests must be considered in determining morally permissible options.

Another factor in determining the moral obligations of pregnant women to their future children is the degree of risk and the nature of the harm. Just as parents are not morally required to avoid any and all risks to their born children, neither are pregnant women morally obligated to curtail their own interests to avoid even the slightest risk of harm.

Distinct from the question of the obligations women have to their future children is the issue of their blameworthiness for failing to fulfill those obligations. In general, blameworthiness is mitigated by the inability to have done otherwise. Such factors as addiction and the degree of control over reproductive ability must be considered in assessing morally the conduct of pregnant women.

III. LEGAL AND REGULATORY ISSUES

The intimate relationship between a woman and a fetus developing within her body has long given rise to vital questions of morality, religion, science, medicine, law, and public policy. The abortion controversy in the United States is perhaps the most easily recognized context for this debate over the extent of a pregnant woman's right to autonomy. But over the course of recent decades, this issue has extended far beyond the abortion debate to encompass numerous legal and public policy issues concerning the maternal–fetal relationship when women continue pregnancy and give birth. Courts, legislatures, state prosecutors and doctors have sought to compel women to behave in ways deemed likely to promote the birth of healthy babies. Women have faced

pregnancy-related restrictions and penalties, including civil suit, criminal prosecution, and court-ordered surgery, aimed at a wide range of conduct: driving an automobile, failing to follow a doctor's advice, drinking alcohol, taking prescription and illegal drugs, among others. This entry describes the status of such efforts and explores the implications for children's well-being and women's liberty.

Biological Aspects of the Maternal-Fetal Relationship

Beliefs about the independent moral and religious status of the fetus vary widely among Americans. The physical status of a fetus, however, is clear: A fetus cannot exist apart from a particular woman prior to *viability,* which occurs at approximately twenty-four to twenty-eight weeks's gestational age. That a fetus does not and cannot exist wholly apart from the pregnant woman makes the maternal–fetal relationship unique.

A fetus makes unparalleled physical and psychological demands on a woman, subjecting her body to tremendous physical adjustments and creating significant risks for even the healthiest woman. Concomitantly, with the fetus completely dependent upon and entirely within a particular woman's body, her actions, experiences, and physical health during and even prior to pregnancy substantially affect fetal development and the health of her child at birth. Throughout their reproductive lives, women inevitably confront innumerable decisions, large and small, that create varying probabilities of harm or benefit to fetal development.

The biological realities of the maternal–fetal relationship may not dictate any particular social response, but they highlight the need to scrutinize the impact on women of any law or policy aimed at fetuses. If not formulated with care, governmental policies adopted to promote healthy births can substantially and unnecessarily intrude upon women's fundamental liberties, limiting their ability to decide how to live their lives, and creating tension between women and their healthcare providers.

Law Versus Morality

In general, women have a strong interest in giving birth to healthy children and go to great lengths to increase the likelihood that they will do so. Widespread consensus exists that a woman who chooses to bear a child has a moral obligation to consider the effects her actions will have on her future child. Current public policy recognizes a role for the government in supporting women's ability to have the healthy pregnancies they desire. Existing programs seek to help women overcome obstacles such as poverty and dangerous addictions by providing prenatal care, food, housing, and drug and alcohol treatment, though the adequacy and appropriate scope of such programs is hotly debated.

Far more controversial are the rare instances when governmental action coerces rather than supports, and seeks to compel women to change their behavior. Should the government use punitive measures to regulate women's actions in an effort to promote healthy births? Should the government thereby transform women's moral obligations into legally required standards of conduct?

In spite of the moral complexity of these issues, U.S. law is quite consistent in granting pregnant women the right to make virtually all decisions affecting their bodily integrity and the well-being of their fetuses during pregnancy. For the most part, U.S. law does not recognize, let alone privilege competing fetal rights. Women retain the freedom to make their own judgments and to balance their obligations to their future children against other responsibilities, such as to family, religion and work. This approach is consistent with women's constitutional rights to liberty, privacy, and equal protection, guaranteed by the U.S. Constitution as well as by state constitutions.

Over the course of the past several decades, this legal consensus has been tested in a variety of contexts. These *tests* arise out of conflicts between pregnant women and their doctors—conflicts that look to the law for resolution. (Oberman, 2000). Often termed *maternal–fetal* conflicts, these issues have generated a veritable cottage industry for scholars in legal, medical, ethical, religious and philosophical circles (Kolder et al.; Markens; Nelson; Reid; Roberts, 1997; Steinbock). Legal and academic debates over the clashing rights of mothers and fetuses have emerged in various contexts, including substance abuse by pregnant women, home births, mandatory HIV screening in prenatal care, and a pregnant woman's rights to utilize a living will (Balisy; Dyke; Hafner-Eaton et al.; Oberman, 1996). As before, the center of the maternal–fetal conflict debate is the question of when and whether it is appropriate for the law to dictate a pregnant woman's behavior in an effort to benefit her unborn fetus. The medical, ethical and legal literature on maternal–fetal conflict is rich in analysis of the competing rights of mother and fetus. Yet, for all their depth and diversity, the overwhelming majority of articles reach an identical conclusion: In all but the most extreme circumstances, it is impermissible to infringe upon the pregnant woman's autonomy rights (But see Finer; Parness; Robertson).

The remainder of this entry examines some forms of pregnancy-related restrictions aimed at women, including

exclusionary employment policies, civil suits for prenatal injuries, criminal prosecution, loss of child custody, court-ordered surgery and HIV screening.

Civil Suits for Prenatal Injuries

Some commentators have suggested that women should be subjected to civil liability for breaching *prenatal duties* (Shaw), such as the "duty to bring the child into the world as healthy as is reasonably possible" (Robertson, p. 438). The only appellate court to adopt such a standard, which was in Michigan, ruled in *Grodin v. Grodin* (1980) that a child could sue his mother for prenatal injuries if she failed to comply with the standard of a *reasonable* pregnant woman.

More recently, courts have refused to impose such duties, claiming that they are inherently subjective and that they would carry with them a host of unacceptable policy ramifications. The only state supreme court to consider the issue, the Supreme Court of Illinois, ruled in 1988 that a child could not sue her mother for prenatal injuries allegedly caused when the woman was in an automobile accident while she was pregnant. In rejecting the girl's request to recognize a legal right to begin life with a sound mind and body, the Illinois court noted the serious ramifications that would result for women: "[M]other and child would be legal adversaries from the moment of conception until birth" (*Stallman v. Youngquist*, p. 359).

A 2002 decision of the Superior Court of Massachusetts cited *Stallman* and similar decisions when ruling in favor of a mother's motion for summary judgment in an action brought on her child's behalf (*Remy v. MacDonald*). The child, through her father and appointed guardian, alleged that her mother's negligence in operating a vehicle resulted in numerous medical complications. The Court ruled that holding a pregnant woman legally accountable to her unborn child, "would present a court with problematic and impossible tasks of determining when the duty arises and how the nature of the duty is to be defined." (*Remy*, p. 7–8). Moreover, the court stated that civil liability, "rather than discouraging conduct so difficult to define in terms of duty, may unwittingly have the opposite negative effect of women fearing civil liability so that they may not reveal critical facts about their condition to their physicians resulting in less than adequate prenatal care." (*Remy*, p. 9).

Criminal Prosecutions for Actions During Pregnancy

The most common form of adversarial governmental action against women for engaging in behavior viewed as harmful to fetal development has been criminal prosecution. State prosecutors have relied on laws that clearly were not intended to create special restrictions on women's actions during pregnancy, including laws prohibiting child abuse, distributing drugs to a minor, and murder.

Several prosecutions have been based on women's otherwise lawful actions. One of the first occurred in 1986, when a California woman was prosecuted for allegedly causing her infant son to be born severely brain damaged, and ultimately to die, as a result of her own excessive loss of blood during delivery (*People v. Stewart*). The prosecution claimed that, by waiting a number of hours before obtaining medical care when she went into labor and began bleeding vaginally, the woman had violated a statute that required parents to provide their children with clothing, food, shelter, and medical care.

Other prosecutions have involved alcohol use during pregnancy. A Massachusetts woman who suffered serious injuries in a car accident, including a miscarriage, was prosecuted for involuntary manslaughter of the fetus because she allegedly caused the accident by driving while intoxicated (Loth). In another reported case, a pregnant woman in Wyoming who notified the police that her husband had physically assaulted her was arrested for child abuse when they detected she had been drinking. The charges ultimately were dismissed in all three of these cases.

By far the most common reason for prosecuting pregnant women involves the use of illicit drugs during pregnancy. Of course, a woman's pregnancy does not immunize her from prosecution under generally applicable laws prohibiting the use or possession of drugs. In many cases, however, women have been subjected to special prosecutions and more severe penalties for the express reason that they were pregnant at the time they used drugs.

Although some women charged in these cases have pled guilty in return for reduced sentences, those who have gone to trial have prevailed in the overwhelming majority of cases. This is largely due to the fact that courts find the statutes under which the women are charged were not intended to apply to prenatal behavior (Brody and McMillin). The first three high state courts that reviewed the legality of prosecution for prenatal drug use all found that the statutes had been misapplied. In 1992, the Supreme Court of Ohio dismissed an indictment for child endangerment against a woman who allegedly used cocaine while pregnant (*Ohio v. Gray*). Also in 1992, the Supreme Court of Florida reversed a woman's conviction under a statute prohibiting the distribution of a controlled substance to a minor and imposing a penalty of up to thirty years imprisonment. In holding that the statute

was not intended to apply to prenatal behavior, the court rejected the "State's invitation to walk down a path that the law, public policy, reason and common sense forbid it to tread." (*Johnson v. State,* p. 1297). In 1997, the Supreme Court of Wisconsin held that the state could not initiate proceedings to remove a child from his or her mother's custody, due to the mother's use of illegal drugs, because the term *child* in the statute does not include a viable fetus (*Wisconsin v. Kruzicki*). The court reasoned that the statute would be rendered absurd if the word child included a viable fetus, because a fetus cannot be, as worded in the statute, "removed from his or her present custody" (*Wisconsin v. Kruzicki,* p. 736).

However, in another 1997 decision, the Supreme Court of South Carolina upheld the trial court's conviction of a mother for child abuse following the mother's use of crack cocaine during her pregnancy (*Whitner v. South Carolina*). The court concluded that the word child in the state's child abuse and endangerment statute includes viable fetuses. In reaching its conclusion, the court reviewed earlier South Carolina decisions recognizing a fetus's legal rights and decisions, and distinguished other states's decisions holding that maternal conduct before the birth of a child does not give rise to criminal prosecution. It concluded that those other states's decisions were distinguishable because those states had "entirely different bodies of case law from South Carolina." (*Whitner,* p. 782).

The *Whitner* court also concluded that a woman's constitutional right to privacy is not violated when she is prosecuted for using illegal drugs during a pregnancy. It stated that the state's interest in protecting the life and health of viable fetuses is compelling, and that no fundamental rights are implicated in such prosecutions. The court reasoned that the use of crack cocaine is illegal by anyone, not just by pregnant women, and the additional penalty on pregnant women "simply recognized that a third party (the viable fetus or newborn child) is harmed by the behavior" (*Whitner,* p. 786).

The issue of prosecuting pregnant women for drug use reached the U.S. Supreme Court, albeit indirectly, in the case of *Ferguson v. City of Charleston* (2001). The case involved a hospital that routinely tested pregnant women for drugs, without obtaining informed consent. The hospital then used the results of these drug screens in order to facilitate criminal prosecutions. The Court held that, as a state-operated facility, hospital staff members were actors subject to the Fourth Amendment's strictures. As such, the drug testing of pregnant women without their informed consent amounted to *searches,* and violated the women's constitutional rights.

Loss of Child Custody for Actions During Pregnancy

States have attempted to deprive women of custody of their children based solely on women's actions during pregnancy, rather than on the customary determination of the current ability of the woman and other family members to care for the child. While most cases involved a woman's use of illegal drugs during pregnancy, several courts have based custody decisions on activity that was lawful but seen as detrimental to fetal development. For example, in 1987 a Michigan woman temporarily lost custody of her infant and was charged with child abuse because while pregnant she had taken Valium without a prescription to relieve pain from injuries she suffered in a car accident (*In re J. Jeffrey*).

The first high state court to consider this issue, the Supreme Court of Connecticut, ruled in 1992 that state law did not allow the termination of parental rights based on a woman's use of cocaine during pregnancy. The court cited the legislature's determination that the threat of losing custody of their children would cause women to avoid prenatal care and substance abuse treatment, and "would lead to more, rather than fewer, babies being born either without adequate prenatal care or damaged by prenatal drug abuse…." (*In re Valerie D.,* p. 764). However, the Supreme Court of Ohio, in *In re Baby Boy Blackshear* (2000), affirmed a Court of Appeals decision, holding that it is appropriate to remove a child from his or her mother's custody when drug testing proves, after the child's birth, that the child has cocaine in his or her system due to the mother's consumption of such drug. The court reasoned that, for purposes of the state's child abuse statute, R.C. 2151.031, a child born with cocaine in his or her system is an *abused child.*

Although the use of illegal drugs during pregnancy may at first glance seem to be the strongest justification for punitive governmental action such as the imposition of enhanced criminal penalties or deprivation of child custody, these approaches have been widely repudiated. The government clearly has a strong interest in preventing pregnant women from using dangerous drugs. With remarkable consistency, experts agree that this interest is best pursued through programs that help women overcome drug and alcohol dependencies and obtain prenatal care. Entities such as the U.S. General Accounting Office (GAO) and the American Medical Association (AMA) have argued that fear of prosecution and loss of custody of their children will discourage women from seeking care and increase the number of unhealthy births. As the Florida Supreme Court noted, "Rather than face the possibility of prosecution, pregnant women who are substance abusers may simply avoid prenatal care or medical care for fear of being detected. Yet the newborns of these women are, as a group, the most

fragile and sick, and most in need of hospital neonatal care" (*Johnson v. State,* p. 1295–1296).

Court-Ordered Cesarean Sections

Courts in at least eleven states have ordered women, against their wishes, to give birth by cesarean section rather than vaginal delivery (Kolder et al.). The severe bodily intrusion of this court-ordered surgery contrasts sharply with our legal system's general refusal to order invasive medical procedures or to force one person to assume any personal risk to save the life of another. Although judicial opinions are rare in these time-pressured cases, three published appellate court decisions illustrate both the motivations behind and the harm caused by such court orders.

In the first published appellate court decision, the Supreme Court of Georgia in 1981 declined to lift a court order authorizing the performance of a cesarean section against a woman's religious objections where the examining physician found a "ninety-nine percent certainty" that the child would not survive a vaginal delivery and a 50 percent chance the woman would die (*Jefferson v. Griffin Spalding County Hospital Authority,* p. 459). With no analysis of the constitutional and policy implications, the court granted *temporary custody* of the fetus to the state and gave it full authority to make all surgical decisions concerning the birth. In the end, a court-ordered cesarean section was not performed; despite the physician's predictions, the woman gave birth by vaginal delivery to a healthy baby without adverse effects.

More recent appellate court decisions have ruled that compelling a pregnant woman to undergo a cesarean section against her will violates the woman's fundamental constitutional rights. (*In re A.C.*; *Baby Boy Doe v. Mother Doe*). In the most widely cited case, in re A.C., a three-judge panel of the District of Columbia Court of Appeals ordered a woman who was twenty-six weeks pregnant and terminally ill with cancer to undergo the surgery. The woman did not consent to the cesarean and her husband, parents, and attending physicians all opposed it on the ground that the woman's health and comfort should be the first priority. The cesarean section was performed nonetheless. The fetus was not viable and did not survive. The woman died two days after the cesarean section.

Following her death, the full Court of Appeals reversed the panel's decision, ruling that "in virtually all cases the question of what is to be done is to be decided by the patient—the pregnant woman—on behalf of herself and the fetus" (*In re A.C.,* p. 1237). The court found that a court order compelling a woman to have a cesarean section violates her rights to bodily integrity and to refuse medical treatment, which are protected under both common law and the U.S. Constitution. The court graphically described the violent bodily intrusion that would be required to enforce an order against a woman who resisted: "[She] would have to be fastened with restraints to the operating table, or perhaps involuntarily rendered unconscious by forcibly injecting her with an anesthetic, and then subjected to unwanted major surgery. Such actions would surely give one pause in a civilized society…" (*In re A.C.,* p. 1244, n. 8). Indeed, in another case a court-ordered cesarean section was performed by tying the woman to the operating table and forcibly removing her husband from the room (Kolder et al.).

An Illinois appellate court similarly ruled in 1994 that ordering a woman to give birth by cesarean section would violate her constitutional rights. Citing *In re A.C.,* the court held that "a woman's competent choice in refusing medical treatment as invasive as a cesarean section during her pregnancy must be honored, even in circumstances where the choice may be harmful to her fetus" (*Baby Boy Doe v. Mother Doe,* p. 330).

At least one federal court has disagreed with the state decisions holding that court-ordered cesarean sections violate women's constitutional rights. In *Pemberton v. Tallahassee Memorial Regional Medical Center, Inc.* (1999), a federal district court held that a court-ordered cesarean section did not violate the mother's substantive constitutional rights. Pemberton was advised by a number of doctors that a vaginal delivery would likely harm the newborn. However, Pemberton opposed having a cesarean section. She returned to the hospital following a full day of labor and requested an IV because she had become dehydrated. Pemberton was denied an IV, and then returned home against the wishes of doctors at the hospital. Following a hearing conducted at the hospital, Pemberton was returned to the hospital, against her will, where her child was delivered via cesarean section.

Pemberton sued, claiming that numerous substantive constitutional rights were violated by the court-order. However, the court stated, "Whatever the scope of Ms. Pemberton's personal constitutional rights in this situation, they clearly did not outweigh the interests of the State of Florida in preserving the life of the unborn child" (*Pemberton v. Tallahassee Memorial Regional Medical Center, Inc.,* p. 1251).

A number of medical and public-health organizations have opposed court orders overriding a pregnant woman's decision concerning medical treatment. The AMA is among the organizations that has endorsed respect for women's constitutional right to bodily integrity: "[D]ecisions that would result in health risks are properly made only by the individual who must bear the risk. Considerable uncertainty

can surround medical evaluations of the risks and benefits of obstetrical interventions. Through a court-ordered intervention, a physician deprives a pregnant woman of her right to reject personal risk and replaces it with the physician's evaluation of the amount of risk that is properly acceptable" (AMA, p. 2665). The practice of seeking court orders not only violates women's right to evaluate the risks and uncertainties involved in their medical care, it is counterproductive to the goal of promoting healthy pregnancies and births because it causes women to distrust physicians. Citing a case in which a woman left the hospital to avoid a court-ordered cesarean section, the AMA expressed concern that "women may withhold information from the physician.… Or they may reject medical or prenatal care altogether…" (AMA, p. 2665–2666). Furthermore, AMA Policy H-420.969 states as follows, "Judicial intervention is inappropriate when a woman has made an informed refusal of a medical treatment designed to benefit her fetus." Paragraphs 2 and 3 of H-420.969 further provide, "The physician's duty is to provide appropriate information, such that the pregnant woman may make an informed and thoughtful decision, not to dictate the woman's decision. A physician should not be liable for honoring a pregnant woman's informed refusal of medical treatment designed to benefit the fetus."

Exclusionary Employment Policies

In an effort to reduce perceived liability risks, some employers have sought to restrict the access of pregnant, or even fertile, women to jobs that might expose them, and consequently, their fetuses, to potentially hazardous conditions. In a unanimous decision, the U.S. Supreme Court ruled that such policies violate federal anti-discrimination law. The policy at issue in the case prohibited fertile women from working with lead in the production of batteries. The Supreme Court acknowledged that holding such jobs "late in pregnancy often imposes risks on the unborn child," but found that "Congress made clear that the decision to become pregnant or to work while being either pregnant or capable of becoming pregnant was reserved for each individual woman to make for herself." (*International Union, United Auto Workers v. Johnson Controls, Inc.,* p. 205–206).

Mandatory HIV-Testing and Treatment of Pregnant Women

Approximately 4 million women give birth each year in the United States. Of these, approximately 7,600 women are HIV-infected, and run the risk of passing on the fatal virus to their fetuses. (Eden, p. 661).

In 1994, a study known as Protocol 076, administered by the Pediatric AIDS Clinical Trials Group (PACTG), demonstrated a two-thirds reduction in perinatal transmission of HIV by administering Zidovudine (AZT) to pregnant women and newborns, reducing rates from approximately 25 percent to 8.3 percent. (Connor). Later studies demonstrated that the perinatal transmission rate may be as low as 3 percent when mothers are treated with AZT. (Eden, p. 661).

Most states reacted to this news by enacting statutes delineating procedures for doctors to counsel and test pregnant mothers for HIV. Some called for the mandatory HIV testing of all pregnant women, but a broad coalition of physicians, policy-makers, lawyers and public health specialists warned that such a move would discourage *at-risk* women from seeking prenatal care. As a result, no state mandates HIV testing for pregnant women.

Interestingly, at least two states mandate HIV testing of all newborns. (See N.Y. Public Health Law § 2500-f, for New York; and C.G.S.A. § 19a-55, for Connecticut). Because a newborn will not test positive for HIV unless his or her mother is infected with the virus, the HIV testing of newborns is effectively a test of the mother, as well. The ostensible purpose of such laws would be to notify the new mother of her HIV status, so that she might avoid transmitting the virus to her newborn via breast-feeding, and so that the infant might begin antiviral medications.

As implemented, there are several problems with these laws, stemming largely from the lack of appropriate training and funding for those who implement them. First, many women who have been indirectly *tested* for HIV via the testing of their newborns never receive appropriate counseling. Years of work with HIV patients demonstrates that pre- and post-test counseling is vitally important in assuring that infected individuals will obtain the information and treatment necessary to protect themselves and others (McGovern). Second, no mechanisms exist for monitoring the medical privacy of mothers of newborns who test positive for HIV. In virtually all other contexts, the law recognizes this loss of privacy as a grave risk, and vigorously protects the confidentiality of an individual's HIV status (McGovern). Finally, as late as 2003, the efficacy of these laws has been hampered by slow response times, such that mothers do not learn of the HIV status for several weeks after giving birth (McGovern).

Mandatory testing policies, whether directed toward pregnant women or newborns, are predicated upon the belief that the benefits of testing and treating the children outweigh the risks to their mothers. This reasoning rests on somewhat shaky scientific knowledge, as the long-term side effects of AZT on both the mother and child are not clear. In

2003, however, it seems that AZT does not inhibit cognitive function, growth, cause cancer, or impair immune function (Culnane et al., p. 152). Nonetheless, this risk-benefit calculus treats pregnant women (or new mothers) differently from the rest of the population, according them fewer rights, simply by virtue of the fact that they have given birth. As in other contexts, this treatment suggests that pregnant women are uniquely incapable of making morally trustworthy healthcare decisions, and that the state is therefore entitled to intervene. If the knowledge of one's HIV status were indeed so vitally important, one would expect to see widespread calls for mandatory testing of the entire population. Well into the third decade of HIV-related policy making (in even the first years of the twenty-first century), there has been no real effort in that direction.

Racial Disparities

In addition to the concerns about gender discrimination raised by pregnancy-related restrictions and penalties, virtually all of these pregnancy-related legal interventions have a disproportionately negative impact upon women of color. A 1987 survey of court-ordered cesarean sections published in the *New England Journal of Medicine* found that 80 percent of the women against whom orders were sought were African American or Asian (Kolder et al.). A 1990 study, also published in the New England Journal of Medicine, found that African-American women were ten times more likely than white women to be reported to health authorities when they tested positive for illegal drug use during pregnancy (Chasnoff et al.). Another 1990 survey of forty-seven women prosecuted for behavior during pregnancy found that 80 percent of the prosecutions were against women of color (Paltrow). As Dorothy Roberts effectively demonstrates in her book, *Killing the Black Body: Race, Reproduction, and the Meaning of Liberty,* these policies not only are problematic in terms of law, ethics and policy, but also they reflect a sentiment that the women of color are somehow *public property.* In a sense, these fetal-protection policies may be viewed as the contemporary legacy of slavery.

Conclusion

Attempts to impose special pregnancy-related restrictions or penalties on women have been relatively rare and typically have been invalidated by courts and opposed by interested organizations and most commentators. The threat of criminal prosecution, loss of custody of children, and court-ordered medical interventions risk deterring those women who are most at risk of poor birth outcomes from seeking prenatal care and drug and alcohol treatment.

The government can, however, do a great deal to improve the health of children by helping women to have healthy pregnancies. For example, experts agree that the high rate of infant mortality in the United States can be drastically cut by providing prenatal care to the approximately one-third of American women who receive inadequate or no prenatal care. Drug treatment programs routinely turn away pregnant women, and the few that will treat women during pregnancy have long waiting lists. Government studies have shown that expending the funds necessary to provide these services would actually save taxpayers three to four times as much in reduced infant healthcare costs.

While creating legal conflicts between a woman and the fetus within her is ineffective and even counterproductive, laws and policies that respect women's rights can effectively promote the healthy pregnancies and births that are in the interests of all.

MEDICAID

• • •

Medicare and Medicaid were created in 1965, and together they revolutionized public health insurance in the United States. Before Medicaid, healthcare insurance for the poor was not perceived as a societal or governmental responsibility.

Initial Goals and Early Challenges

Medicare and Medicaid could not be more different in their underlying philosophies and structures. Medicare was designed to be a universal entitlement program like Social Security. It was established to provide basic hospital and physician-care insurance for all elderly Americans and is financed through a special trust fund. Its benefits are controlled by the federal government and do not vary by state.

In contrast, Medicaid was designed to be a means-tested program funded by general revenue from the federal government and the states. Within federal guidelines and options states determine who will be covered, what services will be paid for, how much providers will be paid, and how the program will be administered. It was not designed to provide social insurance to the full poverty population but to cover particular recipients of public aid, mainly those receiving Aid to Families with Dependent Children (AFDC) and Supplemental Security Income (SSI). Soon after its inception Medicare was thought to be a model for the next step toward universal health insurance, whereas Medicaid was seen as a stigmatized program for the poor.

The history of the two programs, however, has shown that Medicaid has been the more important and effective vehicle for increasing access to healthcare services. Medicare has remained largely constant and rigid in its covered population and its structure. By contrast, the Medicaid program has been the structure to which policymakers have turned to repeatedly over the years to make incremental additions to the population covered by health insurance.

Growth in the Medicaid Safety Net

Medicaid began small. In 1966, there were four million enrollees and the annual cost was $400 million. Those numbers increased as persons in need of long-term care were added to the program after 1972. Although the number of recipients grew slowly between 1975 and 1990 (22 million to 26 million), total government costs for Medicaid increased dramatically, rising from $12 billion to $72 billion. By 2002 the number of enrollees had reached 47 million, making Medicaid slightly larger than Medicare, and total costs had reached $257 billion. However, not everyone who is eligible for Medicaid enrolls. Seventy-two percent of eligible children and 51 percent of eligible nonelderly adults are estimated to be enrolled. In 1999 Medicaid covered 5 percent of nonelderly adults and 15 percent of those with incomes below 200 percent of the poverty level.

The Medicaid program has grown in several important ways. Although originally it was limited to those who received cash benefits under AFDC (poor women and children) and SSI (the permanently disabled), more than half the persons Medicaid covered in the early years of the twenty-first century did not receive cash benefits from other programs. Indeed, Medicaid at that time was the principal source of funding for a vast infrastructure that served the poor and disabled, including safety-net hospitals, community and migrant health centers, mental health clinics, and school-based health programs.

Long-term care was added to the mandated benefits in 1972. Without private insurance, middle-class Americans may become impoverished because of out-of-pocket nursing home costs and "spenddown" to qualify for Medicaid. Institutional coverage also is provided for inpatient mental health services and intermediate-care facilities for the mentally retarded. Medicaid is also the largest payer for medical services for persons with AIDS.

The largest and most important expansions of the scope of Medicaid have been in the areas of prenatal care for poor women and healthcare for children. In 1989 poor women began to receive coverage for prenatal care. In 1997 the State Children's Health Insurance Program (SCHIP) was enacted to cover low-income children who did not qualify for Medicaid under the previous criteria. Together Medicaid and SCHIP account for 16 percent of the nation's healthcare spending, nearly as much as Medicare's share (18%).

Impact on the Nation's Health

Medicaid has achieved significant advances in the healthcare of the poor and previously middle-class persons who require mental health services or long-term care. With Medicaid, poor persons use health services at the same rate as nonpoor persons with a similar health status. Medicaid also provides access to a broader service package that supplements physician care, such as dental care and prescription coverage.

Medicaid has proved to be a better vehicle for incremental reform than Medicare because it is more flexible and

does not have the high level of national political visibility and volatility that Medicare has. Additions to the Medicaid program typically have had three effects; they have (1) increased access to care, (2) shifted at least part of the cost to the federal government, and (3) increased the uncompensated care burden on healthcare providers. Overall, the health of the poor has improved significantly in the post-Medicaid era, with substantial declines in infant mortality, maternal mortality, and death rates for major diseases for which medical intervention is effective.

Major Criticisms of the Program

Medicaid is not a "user-friendly" program. Many persons who are eligible for the program are not enrolled. Once a person is enrolled, eligibility status is evaluated periodically, as frequently as every month in some programs. When income eligibility standards are no longer met, Medicaid coverage is suspended. This results in poor continuity of care and personal hardship.

The state-based nature of the program has resulted in variations in coverage and benefits across the states. Federal requirements ensure relatively uniform coverage for children, pregnant women, the elderly, and the disabled across the states. Childless adults are not covered by Medicaid regardless of their income level. Adults who are parents are the group for whom Medicaid eligibility varies the most widely from state to state. Half the states set eligibility below 40 percent of the federal poverty line; those whose incomes put them at the poverty level ($15,020 for a family of three in 2002) make too much to qualify for Medicaid in all but eighteen states.

Throughout its history there have been repeated cycles of cutbacks and expansions in response to fiscal pressure in the states. From the 1970s until the mid-1980s cutbacks eroded Medicaid coverage of the poor and began to reverse the progress that had been made in closing gaps in access to care across income groups. Since the mid-1980s, however, the trend has been to expand Medicaid eligibility and services. This has not been due to the increased political leverage of the poor but has occurred because from both the federal and the state point of view the cost-sharing arrangement makes it attractive to add to the program. Only in the early 2000s did the nation begin to reenter a period of fiscal crisis at the state level. As a result of a general economic downturn, state revenues declined while Medicaid costs expanded to account for a very significant portion of state governmental budgets.

The prospects for the future of Medicaid are unclear. Some states want the authority to cap enrollment levels and create waiting lists so that even those who qualify with incomes at 40 percent of less of poverty may not be enrolled. About half the Medicaid enrollees in the country are in managed-care plans, but that has not stemmed the tide of rising costs.

Issues for the Future of Medicaid

Medicaid reform is charged with moral issues that frame the fundamental policy decisions. Can public health insurance be equitable when it is targeted only to the poor, or is the inevitable outcome a lesser program? Can an equitable package of minimum benefits be determined? Will the trend toward using Medicaid to expand access to health insurance incrementally be reversed by a weakening of federal requirements and the fiscal crisis of state governments that began at the turn of the twenty-first century? How should society share the costs that a decent healthcare safety net will incur?
